There seems to be a high correlation between lacuna as well as sickness as well as dysfunction in humans. Having a greater in-depth understanding of the characteristics of those cranes, the insight could become even more widespread. Because description lacks full functioning data, forecast models could be effective in rejoining the split threads in the next years, which would be useful in a greater understanding of illness aetiology. Unanswered questions such as the significant role of lacunas in symptoms can range from neurodegenerative disorders to melanoma, different legislation transcribed in disease-specific circumstances, as well as molecular orbital, chemical imbalances, as well as genetic variation of lacunas in various metabolic processes, could indeed aid us here in a system that determines lacunas as well as connected biological markers for diagnosis of diseases, therapeutic interventions, as well as prognosis. A recently developed elevated classification technique could emphasize fundamental principles in lacuna biology that have yet to be highlighted to build a solid foundation for lacuna heredity. Thereby, the ultimate focus of lacuna prognostication, as well as marginalization from programming RNA, would be to see if these lacunas could be used as substantiation in clinical diagnosis, painkiller object tracking, or perhaps even identified critical biological molecules that have been previously labelled as "hypothetical" caused by a lack of well-established proof. The illustration shows could aid in a better analysis of the different processes that underpin the involvement of lacunas in common diseases.

***Abstract*—Now a days the life of people without wireless devices are unimaginable. People use wireless mobile phones not only for communication purposes but also for all their personal needs such as internet banking, health monitoring, online shopping, educational purposes and much more. This makes the researchers to work over the continuous improvement towards wireless communication in order to satisfy the needs of people. In order to support all the technical needs of future wireless communication, various research has been developed. In this paper, a brief study on equalization technique, coding technique and diversity technique has been made. From this it is noted that diversity can be provided by using Orthogonal Time Frequency Space modulation technique.**

Keywords*—*Equalization technique, Coding technique, Diversity technique, Orthogonal Time Frequency Space (OTFS) modulation.

I. Introduction

General structure of a wireless communication system has been depicted in "Fig. 1". The performance of the wireless communication system can be deteriorated by both inter-symbol interference & fading. Frequency selective fading results in Inter-Symbol Interference (ISI) [1]. Inter-symbol interference occurs when one symbol intrudes with other ensuing symbols due to channel distortion. This makes the communication uncomfortable to the user. These results in loss of signal power by degrading signal to noise power ratio and even sometimes implies to temporary failure of the communication systems when there is severe drop in signal to noise ratio. This makes the system more liable to the errors due to synchronization.

When the transmitted signal gets affected by means of time, frequency or position, the variation in the signal is called fading. Fading in wireless communication is considered as major problem while considering a wireless link [2]. The communication channel which suffers from fading is known as fading channel.

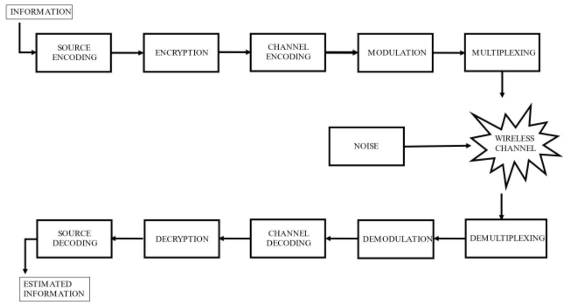

Fig. 1. General Structure of a wireless communication system

The fading can be caused due to multipath propagation or wave propagation i.e., due to atmospheric changes (such as rainfall, thunder, lightning) and obstacles present in the environment depicted in the "Fig. 2". There are two different types of fading which have been listed in the "Fig. 3", according to [1]. Hence there arises research to work towards these fading environment and certain mitigation techniques have been noticed to combat these fading environments and that have been denoted in "Fig. 4".

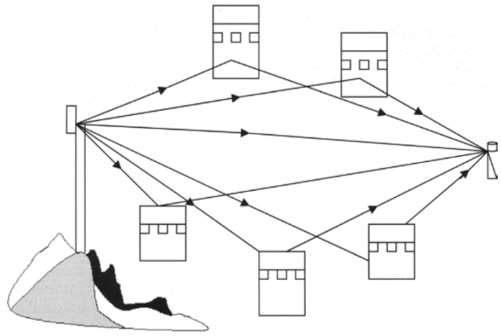

Fig. 2. Multipath Propagation

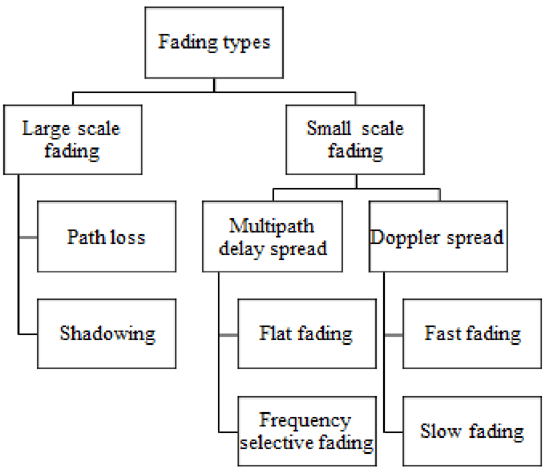

Fig. 3.Types of Fading

II. Equalization technique

Equalization is the signal processing technique that is usually implemented to combat the problem of inter-symbol interferences. In order to achieve perfect data transmission through a wireless channel, it is necessary to design an equalizer at the receiver side.

The different classifications of equalizers have been listed in the "Fig. 5". The device used to function the above process is called an Equalizer. The main objective of the equalizer is to force the Inter-symbol Interference to zero.In general,

DOI: rp-9788770040723.081

Equalizers were usually designed to compensate the channel effect, which deteriorates the system performance.

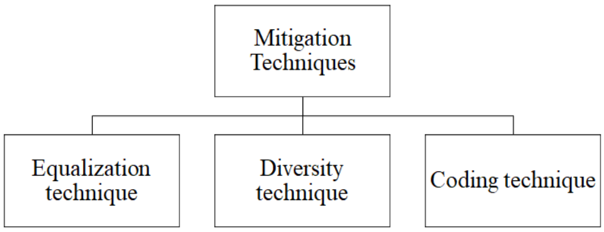

Fig. 4. Mitigation Techniques

Zero forcing Equalizers eliminates the inter-symbol interference at the slicer input whereas the Minimum mean square error equalizers trade-off between minimizing the inter-symbol interference and minimizing noise at the slicer input. The Zero forcing Equalizers found to achieve maximum diversity with minimum complexity [3].The Decision feedback equalizers (DFE) outperforms the zero forcing equalizer when the channel has severe amplitude distortion. Also, a non-linear DFE achieves higher data rate rather than conventional DFE [4]. In Minimum mean square error equalizers, the mean square error has been reduced by incorporating prediction filter.Fractionally spaced equalizers are based on Nyquist-rate sampling, usually 2 x symbol-rate sampling, avoids synchronization problems associated with matched filter front end.All the above equalizers perform with known channel state information. When the channel state information is unknown at the receiver an adaptive equalizer is opted.

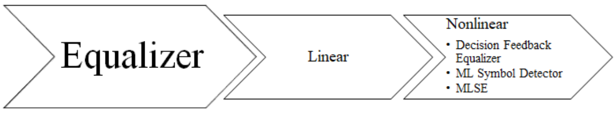

Fig. 5. Types of Equalizers

The adaptive equalizer tracks the time varying characteristics of the channel and thus known as adaptive equalizers. This equalizer significantly improves the system performance in presence of fading channel with raise in SNR value [5]. Adaptive Equalizers works on two operating modes, decision directed mode and training mode. Among the two operating modes, the training mode is mostly preferred. In the training mode, the transmitter can generate data symbol which is known to the receiver. So that, the receiver uses the known training signal at the slicer output. Once a certain time has been elapsed, then the slicer output is utilized and the corresponding data transmission begins. In Blind equalizer the transmitted signal is equalized based on the information of transmitted signal alone. It employs using Interleaving/Deinterleaving, advanced coding and ML criterion.

III. Diversity Technique

The effective technique to mitigate fast fading problem in wireless communication is the diversity technique [6]. Different types of diversity schemes have been listed in the "Fig. 6". Diversity can be achieved by transmitting multiple copies of information signal via N number of different channels. The main objective of diversity technique is that if some of the signal may undergoes fading and others may not. The various types of diversity include Temporal diversity, Frequency diversity, Spatial diversity and Polarization diversity.

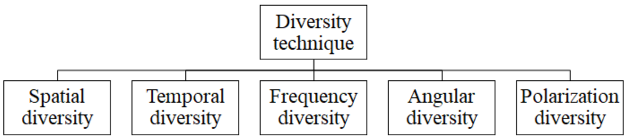

Fig. 6. Classification of Diversity technique

TABLE 1. Different Methodology of Diversity

S.No	Diversity	Methodology
1	Spatial	M number of transmit antennas & N number of receive antennas
2	Temporal	Different time slots
3	Frequency	Different frequency slots
4	Polarization	Receiver antenna with different polarization

A. *Space Time Block Codes*

The technique in which multiple copies of information source is transmitted through M number of transmitting antennas and received by N number of receiving antennas in order to enhance the performance of communication systems in table 1. The several copies of information source were generated by a space time encoder, which encodes the single information source. Then it sends the several copies of information source in the form of blocks using all M number of transmitting antennas at different time slots. Hence named as Space Time Block Codes [7]. A sample space diversity model has been depicted in the "Fig. 7". When the information regarding the channel is known to the receiver, then the system can able to achieve full diversity. However, it is little difficult that all the information about channel is known to the receiver. The channel state information can be predicted by sending some training signals to the transmitter and by this making the receiver to estimate the channel state information. In the communication system with two transmit antennas and M receive antennas were constructed. At the receiver a combiner combines all the received signal and pass through the Maximum Likelihood Detector. Here the transmit diversity technique with Maximum Likelihood Detector outperforms the Maximal Ratio Receiver Combining.

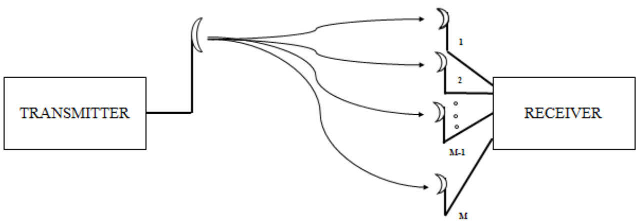

Fig. 7. Space Diversity

The comparison made between MIMO - Space Time Block Codes (STBC - MIMO) and MIMO - Spatial Multiplexing (SM - MIMO) schemes has been tabulated in

DOI: rp-9788770040723.081

the table 2. Both the STBC-MIMO and SM-MIMO were used to improve the performance of the wireless communication systems by means of coding gain and diversity gain by supporting multiple number of users at the same time. Sometimes, the SM-MIMO outperforms the STBC-MIMO system in table 2.

TABLE 2.COMPARISON OF STBC-MIMO AND SPATIAL MULTIPLEXING-MIMO (SM-MIMO)

Parameter	STBC-MIMO	SM-MIMO
Input	Single stream (single information split into many).	Multiple streams (different information source).
Receive antenna	Single or many.	Same as or more than the number of transmitting antenna but not less than that.
Channel estimation	Least square method is used.	Least square method is used.
Channel equalization	Maximum Likelihood decoding or Maximal Ratio Combining is used.	Zero forcing or Minimum Mean Square Error Equalizer or Maximum Likelihood decoding is used.

IV. LOW DENSITY PARITY CHECK CODES

The error correcting codes along with diversity technique will enhance the performance of a communication systems [8]. Here we discuss the linear error correcting code called Low Density Parity Check Codes (LDPC), which is best opted for error correction of information with high block size. It is also named as linear block code with sparse parity check matrix. In which sparse means there are many more zeros than ones. As it has very low ones, it is named as low-density parity check codes. Robert Gallager invented the LDPC codes in 1963. In 1981, R.M Tanner gave the pictorial representation of the parity check matrix called the Tanner graph.For example, consider a parity check matrix equation(1),

$$H = \begin{bmatrix} 1 & 0 & 11 & 0 & 10 \\ 0 & 1 & 01 & 1 & 01 \\ 1 & 1 & 00 & 1 & 10 \end{bmatrix} \qquad (1)$$

"Fig. 8" depicts every column is denoted as bit node in circle representation and every row is denoted as check node in square representation. The edges correspond to 1's in the parity check matrix (H).Check node 2 denotes the row 2 of the parity check matrix(H). for LDPC $HC^T=0$. For the above matrix,

$$H = \begin{bmatrix} 1 & 0 & 11 & 0 & 10 \\ 0 & 1 & 01 & 1 & 01 \\ 1 & 1 & 00 & 1 & 10 \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \\ c_5 \\ c_6 \\ c_7 \end{bmatrix} \qquad (2)$$

$$C_2 + C_4 + C_5 + C_7 = 0 \qquad (3)$$

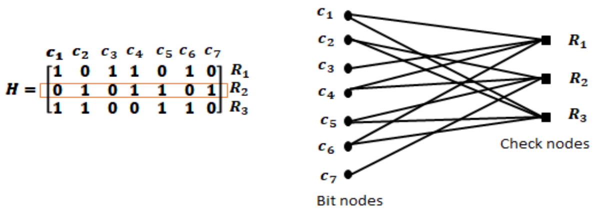

Fig. 8. Tanner Graph

In this equation (2) & equation (3) denotes that C_2, C_4, C_5, C_7 belongs to single parity check code (SPC). Every check node in the tanner graph enforces a SPC. Each SPC is named as local constraints. By using this we can easily decode.Tanner graph is a proper solution for decoding the LDPC codes. By simple decoding of each single parity check codes, we easily decode any large size matrix and thus it is well opted for 5G wireless communication systems as error correction codes.

"Fig. 9" is noted that the MIMO system with LDPC codes will provide excellent performance improvement in terms of BER [9]. On comparing turbo codes and other higher order codes, the non-binary LDPC provides improvement in the system performance by means of Bit Error Rate (BER) corresponding to Signal to Noise Ratio (SNR) [10].Error correcting codes can be combined with diversity technique to further improve the fading channel impairments, also a non-linear detector outperforms other linear combiners [11]. LDPC along with optimum combiner results in very good BER performance [12].

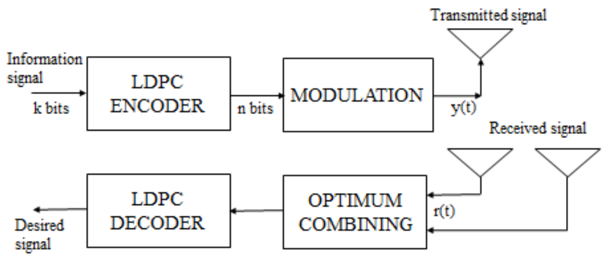

Fig. 9. LDPC System Model

V. ORTHOGONAL FREQUENCY DIVISION MULTIPLEXING (OFDM)

In the emerging development in the wireless communication, a very high data-rate is craving in many applications. But we know that along with the raise in data rate there arises a big issue in case of symbol duration [13]. Here arises the problem called Inter-Symbol Interference (ISI), which needs complex equalization technique. An OFDM system splits the entire channel into more numbers of subchannels through which high-bit-rate data can be transmitted parallelly, so that the OFDM system does not suffer from the problem of ISI. In [14-16], full space and frequency diversity can be achieved by Combining Bit Interleaved coded modulation (BCIM) along with Space time block codes (STBC) and orthogonal frequency division multiplexing (OFDM).

However, OFDM technique suffers from synchronization error and it is found difficult to equalize multiple dopplers [17-18]. It results in unequal subchannel

DOI: rp-9788770040723.081

gain, which degrades the system performance. A new modulation technique has been found to outperform the OFDM technique named as Orthogonal Time Frequency Space (OTFS) Modulation [19].

VI. ORTHOGONAL TIME FREQUENCY SPACE MODULATION (OTFS)

From [22], OTFS modulation takes place by use of two transforms at both the transmitter and receiver shown in “Fig. 10”. The importance of OTFS has been known from the literature survey summarized in Table 3. The two-dimensional information symbols from the QAM modulator in delay doppler domain is converted into a two-dimensional complex number sequence which is in Time-Frequency (TF) domain [20-22]. This can be made happened by using Inverse Symplectic Finite Fourier Transform (ISFFT) and Heisenberg Transform (HT).

HT converts the TF modulated symbols to time domain signal and makes it suitable for transmission via channel. On the receiver section the vice versa of the transmitter has been processed by using Symplectic Finite Fourier Transform (SFFT) and Wigner Transform (WT). This scheme provides promising solution for high-speed vehicular communication.

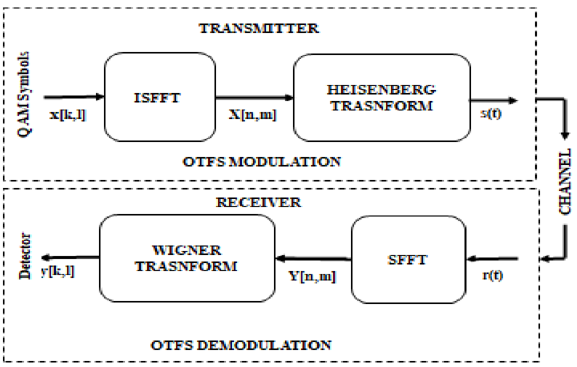

Fig. 10. OTFS Modulation and Demodulation

TABLE 3. LITERATURE SURVEY

Author	Year of Publication	Findings
Xiang Wang [14]	2020	Frequency Division Complementary Coded Code Division Multiple Access (FD-CC-CDMA) provides High diversity gain compared to OFDM-DS-CDMA.
Tadashi Ebihara [17]	2020	Doppler-resilient orthogonal signal division multiplexing (D-OSDM) along with MIMO achieves reliable error rate compared with normal OFDM system.
Zuwei Chen [19]	2020	A Discrete-Cosine-Spreading (DCS) aided M-ary DCSK scheme provides high data rate with minimum BER under multipath fading channel.
Huan Ma [21]	2022	TD-DCSK is compared with STBC-DCSK, OMC-MIMO-DCSK, and conventional DCSK system and proven that TD-DCSK provides high data rate.
Farah Arabian [15]	2022	Diversity alone cannot provide reliable communication link. There is also some error control coding is required.
Qi-Yue Yu [20]	2022	Space time domain parity check transmit diversity provides better BER performance compared to classical space time block codes in case of both the frequency selective and frequency non selective fading channels.
Jaewha Kim [18]	2022	A new method of Gamma Evolution has been used to derive upper bound on BER, to analyse the performance of LDPC for higher data rate
HuiyangQu [16]	2022	An Enhanced Data Detection scheme has been developed in order to cancel the interference and also to provide spatial and multipath diversities.
S.M. Alamouti [6]	1998	Error control codes can provide better diversity by incorporating of time diversity.
M. Kalaivani [7]	2014	Using STBC-OFDM, Full diversity can be achieved in case of known channel state information.
DAN FENG [10]	2018	Compared to turbo codes and other higher order codes LDPC can provide better improvement in system performance in terms of BER.
Zhen Mei [11]	2017	Error control coding technique along with diversity technique can further improve the system performance.
Beng Soon Tan [9]	2011	MIMO system along with LDPC support improving the efficiency in terms of BER.
EnisAkay [13]	2006	When the Bit Interleaved coded modulation technique combined with STBC-OFDM system, then frequency as well as space diversity can be achieved.
Sharma [12]	2009	An optimum combiner has been developed to support LDPC to improve the system performance.

VII. RESULTS & DISCUSSIONS

In order to support all the technical needs of future wireless communication, various research has been developed. It is clear that full diversity can be achieved by employing Parity check transmit diversity scheme [20]. Also, by employing enhanced data detection along with proper equalization technique, BER performance can be improved in consideration with higher order modulation technique for MIMO OTFS systems [16]. From this article, it is clear that the performance of a communication system can be improved by using the new modulation technique OTFS, along with suitable equalization technique.

VIII. CONCLUSION & FUTURE WORK

From the study, it is noted that the new 2D modulation technique, Orthogonal Time Frequency Space (OTFS) modulation provide improved latency when compared with Orthogonal Frequency Division Multiplexing (OFDM) technique for an high speed vehicular communication. Also, the future work can be proceeded by combining low density parity check codes along with STBC-OTFS in order to support future mobile communication with high mobility.

***Abstract*—The topic of self-driving cars has recently gained popularity. This paper presents an overview of several algorithms often employed in autonomous vehicle sensing and path planning. We have compiled a list of different algorithms used for these two purposes and provided a description of the same. A brief description of different sensors typically used in autonomous vehicles has also been provided. Sensor algorithms have been divided into 'Locational and Positioning' and 'Environmental modeling'. Location and Positioning Algorithms require the use of GPS, IMU, and Encoders to estimate accurate distance and use some variant of the Kalman Filter. Environmental modeling algorithms mainly rely on Cameras and use deep-learning object detection models like YOLO. There are also methods that require the use of Cameras with LiDAR and RADAR. For path planning, a description of the two most popular methods A* and Dijkstra has been provided along with their comparison.**

***Index Terms*—Autonomous Vehicles, Positioning, Environment, Heuristics**

I. Introduction

The term autonomous vehicle refers to any vehicle that does not require human interaction to perform its task. Lately, with the increase in technology, especially advancements in the field of deep-learning, capabilities of autonomous vehicles have increased tremendously. A typical autonomous vehicle consists of standard locomotive machinery, sensors in order to gain insight into the environment, a central dedicated CPU that gives signals to the locomotive machinery based on user input (such as target destination, etc.) and a map database. Autonomous vehicles equipped with such technology can most possibly improve energy efficiency, reduce the risk of collisions and reduce pollution [1]-[2] since most autonomous vehicle are electric in nature. These are various algorithms available that coordinate the working of an autonomous vehicle(used by the CPU) that we have categorized. The paper focuses on different algorithms involved in different parts of the system. We start with the sensors. Sensors themselves can be categorized into various parts[3]. They include sensors like LiDAR[4], RADAR[5]-[6], Camera[7]-[8], Ultrasonic Sensors[9], GPS (Global Positioning System)[10] and IMU (Inertial Measurement Unit)[11]. Focusing on the routing algorithm or the main algorithm, there are many, however, they can be broadly classified into heuristic[12]-[14] and nonheuristicalgorithms[15]. These algorithms are also dynamic, they have an inbuilt obstacle avoidance system. The main input for these algorithms is the sensor values and the map database.

Heuristic algorithms may also take into account information like traffic density which would probably require an internet connection. Heuristic functions are mostly dependent on the heuristic function provided[16]. In path-finding algorithms, modern heuristic algorithms perform better than non-heuristic algorithms[17]-[18]. For our paper, we shall only consider one heuristic algorithm[19]-[20] (A*) and one non-heuristic algorithm[21](Dijkstra).

II. Sensor Overview

A. LiDAR

LiDAR, which stands for light detection and ranging, is most commonly used to determine object ranges. It works by directing a beam of laser at an object and calculates the distance from the beam source by calculating the time it takes for the reflected laser beam to return. Using algorithms like SLAM(Simultaneous Location and Mapping), it is even possible to generate visual 3-D representations of the environment and as such, this sensor is extensively used in autonomous vehicles for environment detection to determine object ranges.

B. RADAR

RADAR(radio detection and ranging) is an algorithm very similar to LiDAR except for the fact that it requires the use of radio waves rather than laser beams. It is mostly used for the detection of objects and has been used in defense for detecting enemy vehicles. For use in autonomous vehicles, RADAR is generally used with radio waves having a frequency of 24,74, 77, and 79 GHz. Generally, two types of RADAR exist that have been used in autonomous vehicles namely Impulse RADAR and (FMCW) Frequency Modulated Continuous Wave Radar. Impulse RADAR emits only one pulse, the frequency of which remains constant. FMCW RADAR, on the other hand, emits pulses continually at different frequencies. FMCW is widely used owing to its high-depth perception[22].

C. Camera

A Camera is a form of sensor that records images of objects. It is comprised of a lens and a shutter used for projecting the lens image on a surface(typically a photosensitive film or an electronic sensor) or directly translated into electronic signals. In autonomous vehicles, a Camera is typically used with an object detection algorithm which detects surroundings and objects of interest. Using Photogrammetry methods,estimation of the ranges of objects is also possible. Most popular object detection methods for use with camera in Autonomous vehicles are YOLo(You Only Look Once) and SSD(Single shot detection) as they are faster than most object detection algorithms. Camera is the most widely used sensor for autonomous vehicles and in most scenarios has replaced LiDAR, RADAR and ultrasonic sensors.

Ultrasonic Sensors

DOI: rp-9788770040723.082

This sensor is used in fusion with other sensors in environ- mental modelling for error correction and to get an accurate reading of the ranges, It works similar to a LiDAR and a RADAR by using Ultrasonic Waves to determine the distance of objects. It works at a very high frequency and as such is limited to close range detection only. Ultrasonic sensor can be found in almost every modern car these days. They assist in parking.

D. GPS

It is a satellite based radio-navigation system. Most autonomous cars contain a GPS receiver which receives data from satellites continuously. For accurate measurement, the GPS typically receives data from 4 or more satellites. Satellites used for transmission of GPS signals use an atomic clock which provides the broadcast time to be encoded in the signal. The reciever uses the broadcast time, satellite location and the time that the data was received to calculate current location.

E. IMU

It is a fusion of a gyroscope and an accelerometer. Gyro- scope is used for the measurement of rotation and accelerometer is used for measuring odometry. In scenarios where GPS signals are not available, IMUs are used for location and positioning of autonomous vehicles. IMU's are typically used in co-ordination with encoders.

F. Encoders

An encoder is a sensor attached to a wheel or a rotation de- vice to measure rotation. It works similar to an accelerometerby measuring odometry of a vehicle given wheel radius. BothIMUs and Encoders are used to measure relative position of an autonomous vehicle. There are 4 main types of encoders namely optical, mechanical, magnetic and electromagnetic. The specific type of encoder typically used in autonomous vehicles is an incremental rotary encoder which can be of any type. Incremental rotary encoders are used widely because of their accuracy and ability to provide real time data with efficiency.

III. SENSOR ALGORITHMS

A. Location and Positioning

Autonomous cars have a map database kept inside them or obtain it through a server connection; nonetheless, for route planning, the current position with regard to the map must be estimated. A GPS system is used to determine the current approximate position however this is prone to errorand GPS outages. [23] provides a way for combining GPS, IMU sensors, and encoders. It is an odometry model that is based on Ackerman steering geometry and is computed using encoder data from the rear two wheels and steering. Because there is sensor fusion, it employs the Unscented Kalman Filter (UKF).

B. Environment modelling

There are various algorithms used for this purpose. For autonomous vehicles, the representation of environment should be dynamic i.e. it should take into consideration changes in the environment as well. [24] proposes a very simple solution based on Camera. It uses and object detection deep learning algorithm YOLO v2 trained on a set of vehicle images which is then used for identification of vehicles. They pass the information from YOLO v2 to a ROS node which then estimates the approximate distance of the vehicle. [25] proposes a similar method which uses Tiny YOLO and estimating neighbouring vehicle speed by tracking their taillights. [26] presents an approach to this problem for indoor environments by using a 2D LiDAR and a low cost camera.

IV. MAIN/ROUTE PLANNING ALGORITHMS

A. A* algorithm

A* is a well-known heuristic-based technique that is commonly employed in graph search issues. In 1968, Stanford Research Institute's Peter Hart, Nils Nilsson, and Bertram Raphael suggested it. By transforming the map to a graph and using heuristics as information supplied by sensor values, the route planning issue might be described in A*. The A* algorithm takes a greedy approach. It is a development of Dijkstra's Algorithm. The A* algorithm's evaluation function is provided by

$$f(n) = g(n) + h(n) \tag{1}$$

where$g(n)$ is the cost of getting to the current place and $h(n)$ is the expected cost of getting to the destination. The euclidean distance function or any other distance function may readily determine $h(n)$.

$$h(n) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

where (x_1, x_2) and (y_1, y_2) represent the co-ordinates of the current location and destination respectively. We can find their values using their latitudes and longitudes of the two points. We can also include heuristics like traffic and sensor information for more efficient path planning. The time complexity of this algorithm dependent on the heuristic function. [20] proposes an improved A* algorithm for path planning which focuses on obstacles and path proposals using circle equations. The algorithm proposed is more effective and faster by about 200%.

B. Dijkstra's algorithm

EdsgerWybeDijkstra, a computer scientist, devised this technique in 1956. It's a well-known non-heuristic path planning algorithm. This algorithm determines the shortest pathbetween two points on a graph. Given the current position and destination, this method returns the shortest distance or the shortest cost path. [27] describes how to apply this method on a network of interconnected roadways. Although Dijkstra always finds the shortest path, it does not ensure time efficiency. Because we must consider traffic, the shortest road is not always the quickest option. This approach has a temporal or time complexity of $O(V^2)$ when utilising an adjacency list representation of a graph, where V is the number of vertices in the graph.

Algorithm 1 A* Algorithm

1: **function** A*(*start, goal*)
2:*openSet* ← *{start}*

DOI: rp-9788770040723.082

```
closedSet ← {}
cameFrom ← {}
gScore[start]   0 ← {}
f Score[start]   ← heuristic(start, goal)
while openSetis not empty do
  current   ← the node in openSetwith the lowest
    f Score
  if current is goal then
    return   reconstructPath(cameFrom, current)
  end if
  remove current from openSet
  add current to closedSet
  for all neighbors neighbor of current do
    tentativeGScore ← gScore[current] +
      dist(current, neighbor)
    if   neighbor is in closedSet and
      tentativeGScore   ≥gScore[neighbor] then
      continue
    end if
    if   neighbor is not in openSet or
      tentativeGScoregScore[neighbor] then
      cameFrom[neighbor] ← current
      gScore[neighbor]   ← tentativeGScore
      f Score[neighbor]   ← gScore[neighbor] + heuristic(neighbor,
        goal)
      if neighbor is not in openSetthen
        add neighbor to openSet
      end if
    end if
  end for
end while
return failure
end function
```

C. Comparison between A* and Dijkstra

However, because A* is primarily dependent on its heuristic function, its optimality can only be established by the effectiveness of its heuristic function. Dijkstra has consistently outperformed in circumstances with little to no traffic. However, while dealing with traffic and having to include sensor data, A* performs better if these data are incorporated

Algorithm 2 Dijkstra's Algorithm

```
function DIJKSTRA(start, goal)
openSet   ← {start}
closedSet ← {}
cameFrom ← {}
gScore[start]   ← 0
while openSetis not empty do
  current   ← the node in openSetwith the lowest
    gScore
  if current is goal then
    return   reconstructPath(cameFrom, current)
  end if
  remove current from openSet
  add current to closedSet
  for all neighbors neighbor of current do
    tentativeGScore ← gScore[current] +
      dist(current, neighbor)
    if   neighbor is in closedSet and
      tentativeGScore   ≥gScore[neighbor] then
      continue
    end if
    if   neighbor is not in openSet or
      tentativeGScoregScore[neighbor] then
      cameFrom[neighbor] ←current
      gScore[neighbor]   ←tentativeGScore
      if neighbor is not in openSetthen
        add neighbor to openSet
      end if
    end if
  end for
end while
return failure
end function
```

TABLE I COMPARISON OF DIJKSTRA AND A*

	Dijkstra	A*
Advantages	Guaranteedtofindshortestpath Canuseheuristictoguidesearch Noneedforadmissibleheuristic	FasterthanDijkstra Canusedifferentheuristics Consistentlyfindsoptimalpath
Disadvantages	CanbeslowerthanA* Doesnotconsiderdistancetogoal Nowaytoguidesearchtowardsgoal	Requiresadmissibleheuristic NotguaranteedtobefasterthanDijkstra

into its heuristic function. This is owing to the fact that A* might easily incorporate dynamicity in it's approach.[28] also suggests that A* is more efficient than Dijkstra in terms of destination finding if provided appropriate heuristic. [29] compares computational efficiency of both the algorithms in a static scenario whereas [30] compares both the algorithm in different applications on the field. The results of which are summarized in the table below.

A* relies heavily on it's heuristic function and therefore it may or may not be faster than Dijkstra. We can see that Dijkstra outperforms A* in long distance path planning algorithms however in terms of time and memory A* is moreefficient. In dynamic environments, A* always outperforms Dijkstra.

TABLE II IMPLEMENTATION RESULTS FOR A* AND DIJKSTRA ALGORITHMS

		Metric Type	Result
A*	Static short distance Dynamic	Time Time	Faster than Dijkstra Faster than Dijkstra
Dijkstra	Staticlongdistanc Stati c	Time	Faster than Dijkstra

V. CONCLUSION

An overview of different popular algorithms have been provided and a comparison of two path planning algorithms has also been provided. Most of the sensor methods require the use of camera only owing to developments in distance estimation methods and the low cost of using only one Camera sensor however, a few methods still use a fusion of Camera and Lidar. In path planning algorithms, Dijkstra provides the shortest path, however A* may also consider information from sensors and traffic information. A* is shown to more efficient than Dijkstra.

***Abstract*—Online Social Networks (OSN) have grown in popularity as a result, for the previous few years of the quick development of mobile applications and the explosive expansion of online engagement. As technology and the Internet become more accessible, so has the ease with which users can upload and share photos on Social Networking Sites (SNS). Therefore, it is necessary to safeguard the confidentiality of the same. On the other hand, those methods lose their utility as soon as someone posts the images on other platforms, this unauthorised disclosure of the user's private information causes negative effects and endangers the user's safety. In order to present effective spreading control for cross-social network picture sharing, Photo Chain, a blockchain-based framework, has been created with the goal of protected photo sharing. Combining blockchain, Gaussian Blur for face masking, Pre-Hash Algorithm for photo integrity verification, and Access Control, sharing, and access without having to worry about potential harm to user's interests. To maximize the adaptability of re- posters without jeopardizing the privacy of the former, a vivid privacy policy generating algorithm has been created. The concept also incorporates robust photo ownership identification technologies to stop illicit reprinting. The project culminates with the execution of a prototype and setup in a nearby simulated social setting. The extensive tests and safety measures investigation demonstrate the suggested framework's competence, security, and efficiency.**

Keywords—Block Chain, Cross Social Network, Photo Sharing, Security, Pre-Hashing Algorithm, Gaussian Blur Algorithm, Privacy Preserving.

I. INTRODUCTION

A digital communication tool is social media. Users may participate in conversations, share information, andproduce material for the internet via social medias. Some of the examples for social media can take include social networking sites, photo and video sharing websites, blogs, instant messaging, podcasts, widgets, virtual reality, and other platforms.

Fig. 1.1. Social Media

Most of us today use social media sites like Instagram, Twitter, Snapchat, You Tube, and Meta to communicate with potential virtual mates. These devices leverage online social media networks to alert users of news about their friends, favourite celebrities, and significant global events. Social media is now widely used by many people as part of their daily lives. Numerous billions of people use social media to communicate and share information. Social networking offers you the freedom to connect with loved ones, learn new things, pursue new interests, and seek entertainment.

Frequently used social media platforms and tools: Blogs: A forum for casual conversations and talks about a specific topic or point of view.

Meta: The primary social network in the world, with regularly active users creating private accounts, adding other users as friends, and exchanging communications like status updates to communicate current information. The brand-generated pages can be liked by meta users.

Twitter: A social networking or microblogging platform that enables quick status updates to be exchanged between users and organizations (140- character limit).

YouTube/Video: Uploading videos and browsing websites.

Instagram: An app that allows users to add digital filters, frames, and other creative effects to photos they want to post on social media.

LinkedIn: A topic where a group of professionals with comparable interests can share data and participate in discussions.

II. RELATED WORKS

- KambizGhazinour, John Ponchak [1] This study aims to reduce the security risk for common users by developing a GUI-based metadata reader and editor. The underlying risk, which is concealed in all shared media, can be brought out in the open and reduced by bringing the capacity to examine and modify metadata to various platforms.R. Regin, B. Sneha [2] It displays an adaptive concealing policy indication mechanism that, when shared with several clients, offers a policy to the client. Based on their level of trust in the recipient, this policy aids the client in deciding whether or not to share an image.

DOI: rp-9788770040723.083

- PrashantAbhang, S.B.Rathod [3] The main concept was to create a participant-free tagging technique that would enable the automatic association of a user's account with a specific person's face. In this instance, adversaries were unable to use malicious tagging assaults to share photographs on social media.

- Lei Xu, Ting Bao [4] It is implemented a fine-grained confidentiality managing of photo sharing by means of image processing algorithms. A notion for access controlling in photo sharing in which a image is broken up as several layers that are containing single blurred face. A viewer's final image is created by superimposing specific layers in accordance with their privacy settings. For photo sharing in OSNs, Edwin et al. developed a multi-party admittance architecture that enables access control granularity to be gradually tweaked from photo-level to face-level.

- Mary Jean Amon, RakibulHasan [5] I-Pic and COIN are privacy-preserving sharing systems that let users publish privacy options so that nearby photographers can learn about and respect their preferences. They alert registered users whenever another person nearby takes a picture and tell them whenever another user does so. So, in the current study, we also investigate how often, infrequently, or never people exchange photographs.

- PooryaAghdaie, BaariaChaudhary [6] Genuine facial pictures from two separate people are used to create a morphing image. The final morphed image may be compared to both genuine persons because it has traits from each, allowing for verification. Two methods are used to create morphed photos. In the first method, a morphing image is produced by alpha blending two real facial photographs.

- HarshaliChandel ,Dr. A. M. Bagade [7] Social networking sites (SNSs) are a limitless form of communication that allow people to stay in touch across borders. SNSs are more than just a web application; they are a component of human civilization. SNS use has outpaced conventional forms of communication in practically every industry, including that of news organizations, large and small businesses, governments, and well-known individuals. The abundance of technology and services has made it easier to share information with friends and family, including news, photographs, personal preferences, and information.

- VatsavaiSrija& T SaiDurga [8] Utilizing the K- Nearest Neighbours technique, we are studying the face matching notion. In our project, we are employing the Ball-Tree technique, one of the many sub-methods in the KNN algorithms. Binary Tree Method is another name for the Ball-Tree algorithm. Each node in this technique generates a D-dimensional hypersphere that contains a subset of the searchable points. The prediction parameters are saved in a CLF file when the B-Tree is constructed.

III. PROPOSED METHODOLOGY

With the help of fairness and without any potential risk to the user's safety, Photo Chain, a combined block- chain, Gaussian Blur for face masking, Pre-Hash Algorithm for photo integrity verification, and Access Control, Mechanism realises secured data sharing, retrieval, and access.

Algorithms and Techniques used

- Smart Contract
- Gaussian Blur
- Pre-Hash Algorithm
- Access Control Mechanisms
- Hash-Key to verify the integrity in photo shared

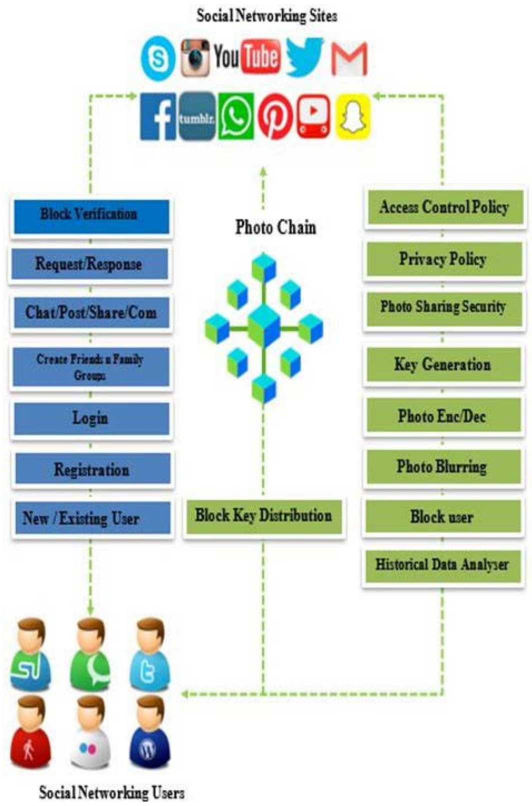

Fig. 3.1. Proposed Architecture

1. SN Web App

The development of SNS as a platform that people may use to connect with others who share their interest, abilities, environments, and real-life connections is taking place. SNS come with a range of formats and facets

2. End user C-panel

2.1. Register

Users of the App must first register their data in order to access and share pictures on the website. In order to access the current and contact information shared by friends, one must first log into the application. They can upload the image as either private or public. Wherein others have the ability to make friend requests, accept them, and intend to reveal secret representations of the medium.

2.2. Login

The user will exhibit many social network functions, including editing his profile and performing the actions of

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.083

viewing and adding friends, searching for other users, and seeing user profiles.

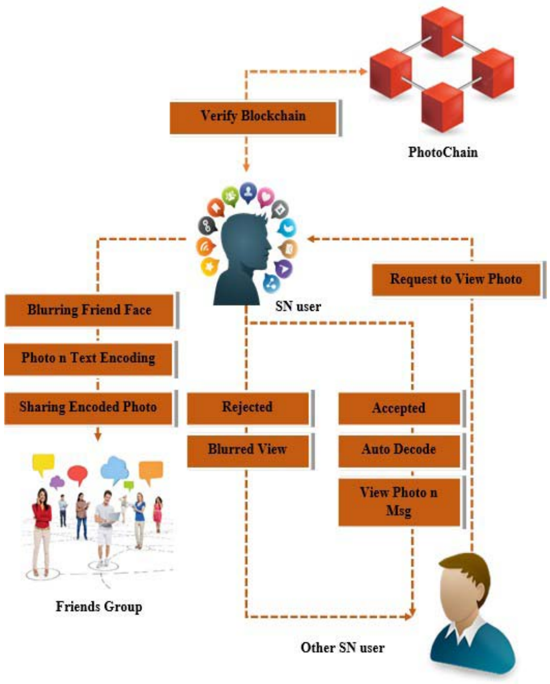

Fig. 3.2. System Flow

2.3. Add Friends /Family Groups

The log-in/log-out button for the social platform is called Friend Request. A greeting and the profile picture are made public after logging in. The proposed prototype has three operating modes: setting up, sleeping, and functioning.

In order to organize the area by selecting the "Pick-Friends" button, a user must physically locate the group of "close friends" from the list on the social networking platform.

2.4. Share/Post/Comment/Chat

Users that post photos can limit their sharing to their friend's in-lists. The projected plan complies with the co-owner's disclosure guiding principle and the list of communications of owner's privacy process.

2.5. Policy mining

Users can choose whether to make an uploaded image public or private; only eligible users who have permission to see public photographs can then access these images; otherwise, they will be hidden. The owner of the content should make available the key forthat image if people wish to see private content. Since representations in the same class are also anticipated in a comparable level of confidentiality fortification, policy mining is conducted inside the same class.

2.6. Policy prediction

This process generates a vast number of application policies while returning to the user the most promising applicants. In terms of offering the anticipated guiding principle of a recently uploaded photo for personal reference, this represents a step towards selecting the best candidate method.

2.7. Request/Response

There are two ways to react to a friend's request: either click the buttons labelled "confirm" or "not now" to decline the invitation.

3. Photo Privacy

3.1. Key Generation

During this process, the personal information of the photo is protected using the selected protection tool and a secret key (or set of keys) given by the sender. The proper management of all the encryption keys used in the system is a relevant difficulty in addition to offering an appropriate security level and an effective implementation. A centralised strategy has been suggested in which the trusted Key Server stores all of the keys.

To produce unique keys for each image and region within it, the server must be able to detect images in a unique way. As previously noted, the encrypted image's metadata contains this particular ID. The encrypted image's metadata contains this particular ID. The hash of the image could be used as ID as an alternative strategy. The drawback of utilising the hash as the ID is that it must be performed in the mobile application, which could be costly depending on the size of the image and could result in security issues if hash collisions are discovered. More significantly, the key server would have the ability to examine some usage patterns and identify instances where two users encrypt the same image.

3.2. Photo and Message Encode/Decode

Image and Message Encoding

Form-sampling, residual, and down-sampling layers make up the encoder network. Fig. 2 depicts the encoder network's organisational structure. Numerous skip connections are used in the reset to combine shallow and deep features at various stages of convolution. The shallow feature is with numerous low level competent particulars about the framework and colour on the image that can be used to create steganographic images. The findings of constructing an encoder network havingtopology alike to the U-Net have shown how the skip connection can effectively reduce steganographic image distortion and improve visual quality.

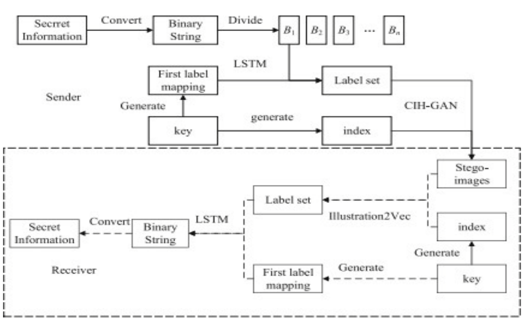

Fig. 3.3 Image and Message Encode and Decode

DOI: rp-9788770040723.083

a. original image

Image and Message Decoding

The decoding network, made up of 6 layer complete Convolutional Network (CN) that pulls out secret colour image-S' from the steganographic image-C'. The encoder and decoder networks from the previous part make form the generator in the proposed model HIGAN. Past studies have shown that both three-channel colour and single-channel grayscale secret images can be successfully recovered using the decoder network's architecture. Following each of the 3 convolutional layers having stride-1 and padding-1, the Batch Normalization method and Real Activation Function are used. However, Sigmoid Activation Function was employed subsequent to the ending layers. The decoding network eventually discloses the hidden image-S.

b. generated image

Here, the CNN parameters includes,

Designing: The nature of the shared images, the intended use case, and the system's performance needs will all have an impact on how the CNN architecture for a blockchain-based secure photo sharing framework for cross-social networks is designed.

Image Pre-processing: The images is necessary to guarantee that they are in a format that the CNN can use. The pictures may need to be resized, their pixel values normalized, and they may need to be converted to grayscale or RGB format, among other things.

Network Architecture: Given that it will have to analyse a lot of images in real time, the CNN architecture needs to be effective and scalable. Additionally, the architecture ought to be able to handle various picture sizes and aspect ratios.

Hyperparameters: It has a number of convolutional and pooling layers to acquire features from images and fully connected layers to categorise the images, is a well-known architecture for image classification.

The CNN should include security measures like encryption and secure authentication since the framework is built on blockchain technology to make sure that only authorised users can access the shared pictures.

3.3. Photo Blurring

A Gaussian function, commonly referred to as Gaussian smoothing, blurs an image. It is a typical effect in graphics software, usually intended to decrease detail and visual noise. Unlike the bokeh- effect due to the out-of-focus of lens / shadow on the object as a result of standard lighting. The proposed technique produce the smooth blur appearing same as translucent screen.

4. Privacy Violation

A policy's current state Individual users are in charge of the privacy policy's current state. The policy should take into account the person's exposure needs as well as their privacy demands. Defend or post If the policy is satisfied, the co-owner receives the notification. The photo is only posted once the owner has permission to upload it; otherwise, it is not.

5. Photo Chain Integration

Based on blockchain technology, the decentralized SN data sharing and storage system Photo Chain decouples user data and programs to return ownership of the data to the users.

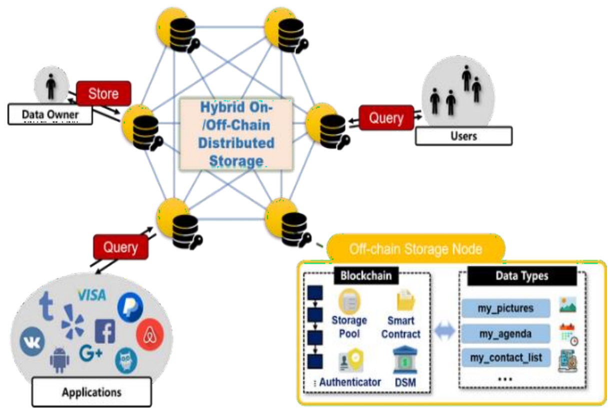

Fig. 3.4. Photo Chain Integration

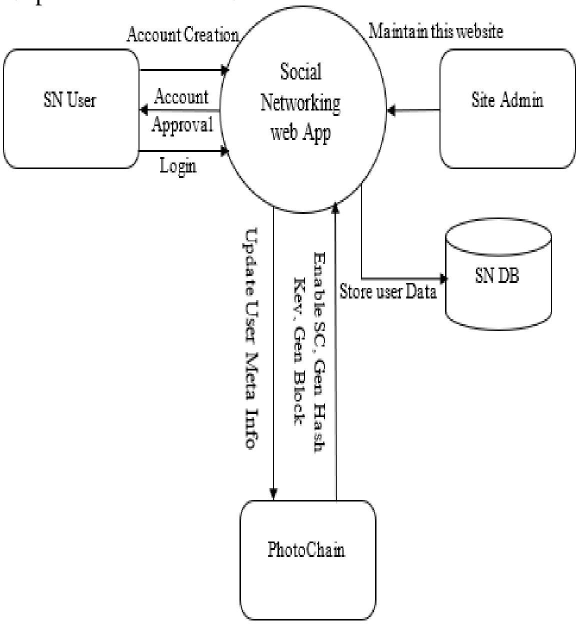
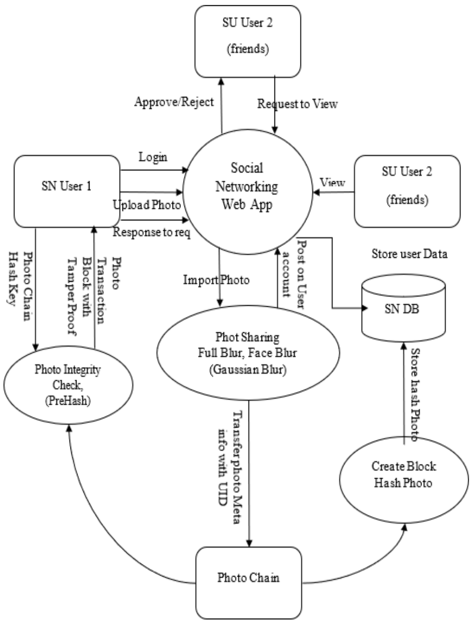
We employ Personal Data Store to increase off-chain storage for internet data. With the use of a distinctive identity assignment (i.e., Web-ID) and certificateless cryptography, we also established an identity establishment mechanism that can support Web ID- based authentication functions. In order to automatically store and securely distribute social data, we design a general framework that uses smart contracts.

Level – 0

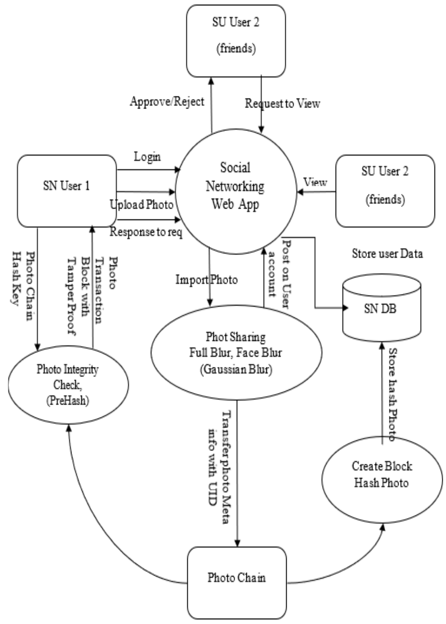
DOI: rp-9788770040723.083



Level – 1



Level – 2



IV. Implementation

- The framework's architecture should be created in a way that enables users to safely store and exchange photos across various social networks. It ought to be built on a blockchain network that offers a decentralised and impenetrable picture storage system.
- For instance, a smart contract can be created to limit who has access to shared photos.
- Integrate social networks: The framework needs to be linked with various social media platforms, including Twitter, Instagram, and Facebook. The social networks' APIs can be used to accomplish this.
- Implement a secure authentication method: A secure authentication method should be used to guarantee that only authorised users can access the shared photos. Digital signatures and public-key encryption can be used together to accomplish this.
- Implement encryption and decryption mechanisms: Encryption and decryption mechanisms should be used to ensure the privacy and confidentiality of the shared pictures. Algorithms like RSA or AES can be used for this.

Overall, a combination of technologies including blockchain, smart contract, encryption, and decentralised storage systems is needed to implement a blockchain-based secure picture sharing framework for cross-social network use. To enable users to safely keep and share their photos across various social networks, the framework should be created with security and privacy in mind.

V. Conclusion

Due to the widespread use of smart mobile devices with high-resolution cameras and user-friendly social networks programs, sharing photos has become an easy and popular hobby. Yet, the majority of photo sharing sites don't have a reliable method for safeguarding users' privacy. In this

DOI: rp-9788770040723.083

project, we created, put into practise, and assessed Photo Chain, an expanded control framework for blockchain-enabled, privacy-preserving photo sharing across several social networks. By regulating the actions of the users after them in a dissemination chain, it aids social networking users in maintaining the privacy criteria assigned to their uploaded photos. Without interfering with the display phase, it ties the access control policies to the images in the interim. Photo Chain may therefore enable social networking users to conceal private areas from prying eyes across many social networks. Photo Chain not only protects the shared photos so that no unauthorized users can access them, but also enables users to blur their image search so that the search can also be shared to a cross social networking site obliviously without leakage on the query contents or results. Additionally, Photo Chain not only safeguards user privacy but also minimises system overhead. Results of the evaluation showed that it is effective the idea of photo chain, which offers privacy, confidentiality, and integrity. The suggested plan prevents unwanted users from accessing the private information while also ensuring that legitimate users continue to share information without interruption.

In future work, we will further develop our system by taking into account more user-related attributes and security levels of various groups in order to provide access control with a finer grained. We plan to investigate how the most recent technological advancements, including federated learning, can protect user privacy in Cross SNs in the future.

TABLE 1: RESULTS OF ACCESSING THE PHOTOS

Groups	**Can't view**	**Viewable**	**Download**	**Re - upload**
Friends	5.6%	90.4%	76.4%	23.2%
Strangers	50.5%	50.4%	43.6%	8.1%
Others	75.2%	22.8%	11.3%	2.3%

Abstract*—Machine learning has proven to be an effective tool in enhancing the accuracy of agrometeorology predictions and agricultural production forecasts. By analyzing factors such as temperature, rainfall, humidity, soil quality, pH levels, and geographic location, advanced ML techniques such as Random Forest, Logistic Regression, and Naive Bayes provide valuable insights for farmers to make informed decisions. Utilizing these predictions can result in increased crop yields and more sustainable agricultural practices. The integration of machine learning into agrometeorology has the potential to revolutionize crop production and management. Therefore, machine learning plays a critical role in agrometeorology by improving predictions of agricultural production, enabling farmers to optimize crop selection and management practices, leading to higher yields and better sustainability. The evaluation show that the proposed approach using Bootstrap Aggregation and Streamlit can effectively predict crop yield based on weather and crop-related data. The web application provides an easy-to-use interface for farmers to input data and receive predictions, which can help them make informed decisions about crop management and planning.Overall, the integration of machine learning in agrometeorology holds great potential for transforming crop production and management.

Keywords— Machine learning, Random Forest, Decision Tree, Naïve Bayes, Streamlit.

I. INTRODUCTION

Agriculture has always been the main and most important activity in every culture and civilization that humans have ever known. It plays an important role in the developing economy and is essential to the existence. The Indian economy and the destiny of humanity depend on this area as well. Furthermore, it accounts for a sizable amount of employment. The amount of production needed has dramatically expanded as time goes on which depends on mean based absolute error [1].

People are utilizing technology incorrectly to create larger profits. The hybrid plant varieties are continually evolving. But unlike naturally grown crops, these types don't offer the necessary components. These artificial methods damage the earth. All of this causes a greater environmental impact [4]. A variety of machine learning classifiers, such as logistic regression, naive bayes, random forest, and others are used to push a pattern in order to perform accurate prediction and stand on the erratic patterns in temperature and rainfall. The random forest approach provides the best level of accuracy, according to this research of the aforementioned machine learning classifiers [14]. The system forecasts crops based on the collection of historical data. The information is provided using historical data on the weather, temperature, and a number of other variables [16]. This application runs an algorithm and displays a list of crops that match the inputted data and their anticipated yield values.

II. RELATED WORKS

Recent literature has examined the application of machine learning and data analytics in predicting agricultural production [2]. This involves using algorithms like random forest classification, Naive Bayes, decision tree, SVM, and improved extreme linear machine to forecast crops based on historical data such as weather, temperature, and soil quality. A mobile application for Android is under development, which will utilize user-entered criteria, such as temperature, to make predictions. The primary objective is to develop an affordable and precise weather forecasting system for remote regions. Previous studies have also explored the use ofmachine learning in plant biology, disease diagnosis, and image processing to enhance crop production and agricultural productivity [5].

The algorithms employed include random forest, naive bayes, decision tree, and others. An Android mobile application is being developed to aid farmers in selecting suitable crops based on various factors, including temperature, humidity, and soil quality [9]. The research employs various techniques such as Kalman Filter, linear discriminant analysis, and extreme linear machine to enhance crop yield prediction. Additionally, the study focuses on designing a weather forecasting system for remote areas using machine learning and data analytics approaches[15].

Aruvansh Nigam, et.al,..[1] agriculture has been recognized as the primary means of providing for human needs, serving as a vital occupation and a major industry in India. Traditionally, farmers relied on their observations of their crops and animals to ensure healthy yields without the use of chemical interventions, thereby maintaining diversity in their cultivation lands. However, in recent times, the changing weather patterns have adversely affected these elemental resources, resulting in a decline in food production and security. Unfortunately, this trend is

DOI: rp-9788770040723.084

reflected in the decreasing GDP in the agricultural sector. For instance, in 2005, the sector contributed 17.2% to the GDP, but this figure plummeted to 11.1% in 2012, 5% in 2018, and further down to 2% in the first quarter of 2019-2020. The majority of farmers, accounting for around 80%, hail from rural areas, and any drop in crop production revenues will have significant impacts on their livelihoods and the industry as a whole.

Nithin Singh, et.al,..[13] Weather forecasting involves predicting future weather conditions. In this context, a research paper proposes a method of predicting rainfall by analyzing real-time data from sensors that measure temperature, humidity, and pressure. The authors suggest that machine learning algorithms can improve data analysis and prediction without needing specific programming from users. Machine learning enables systems to learn from past data and improve their forecasting capabilities without requiring an understanding of the physical processes that govern the atmosphere. Therefore, this approach has the potential to be used as a weather forecasting method.

Prior research on the implementation of machine learning in agriculture, including investigations into plant biology, decision-making, soil, water management, and crop management, have been analyzed [3] and [7]. The current research indicates that further investigations are necessary to fully leverage data mining techniques in the agriculture sector.

Weather forecasting is a subject that has captured the attention of researchers from diverse fields due to its significant impact on human life worldwide. In recent years, the increasing availability of large-scale weather observation data and advancements in information and computer technology have encouraged many researchers to explore hidden patterns in vast datasets for predicting weather patterns [13].

H. Sak, et.al,..[16] Training both GMM-based and deep learning-based acoustic models for predicting speech recognition requires significant computation time. To overcome this challenge, researchers have proposed an acoustic model based on the CTC algorithm, which does not require the GMM-based acoustic model, since it does not use the forced aligned HMM state sequence. However, previous studies that utilized a LSTM RNN-based acoustic model using CTC were limited to small-scale training data. In this research, a large-scale training corpus was used to train the LSTM RNN-based acoustic model using CTC, and its performance was evaluated. The results showed that the proposed acoustic model achieved a Word Error Rate (WER) of 6.18% and 15.01% for clean speech and noisy speech, respectively, which is comparable to the performance of the hybrid-based acoustic model.

PR Naveen Kumar, et.al[14] The emergence of machine learning has led to its increasing application in diverse domains, including precision agriculture. Farmers often face unstable economic conditions due to the wrong selection of crops to grow in their fields. This problem can be tackled by leveraging machine learning techniques to recommend suitable crops. However, mapping crop recommendations using classification techniques can be challenging due to various factors that impact crop selection, such as soil characteristics, macro and micronutrient composition, pH value, humidity, rainfall, temperature, and more. Fortunately, machine learning algorithms are now capable of performing advanced tasks such as multi-class classification, multi-label classification, and multivariate regression. Various classification algorithms such as decision trees, k-nearest neighbors, logistic regression, support vector machines, AdaBoost, and XGBoost can effectively perform multi-class classification. Additionally, predicting suitable crops requires finding optimum parameter values. Currently, crop yield prediction is a popular task that is being integrated with remote sensing techniques.

III. Proposed Methodology

A Random Forest model can be employed to predict human dehydration by analyzing various physiological and environmental factors collected from wearable devices. The collected data will be pre- processed and used to train the model with the scikit- learn library in the Jupyter notebook, which will then be optimized to achieve the highest accuracy possible. The model will be deployed on a Flask web server and presented as a web application, enabling users to input their data and receive a prediction about their hydration levels. HTML, CSS, and JavaScript will be used to build the web application, which will send data to the server via an HTTP request.

The Jupyter notebook will be used for data pre-processing, model training, deployment, and testing, allowing for model fine-tuning by incorporating feedback from medical experts and continuously retraining the model with new data. A dataset for crop prediction typically includes a variety of input features related to the crop growth and health, as well as a corresponding output value indicating the expected yield or quality of the crop. Some common input features in a crop prediction dataset may include: phvalue, soil type, whether condition, humidity etc.. The size and complexity of the dataset can vary depending on the specific application and the number of input features and output values. Larger datasets with more input features and output values can help improve the accuracy and reliability of the predictions generated by machine learning models.

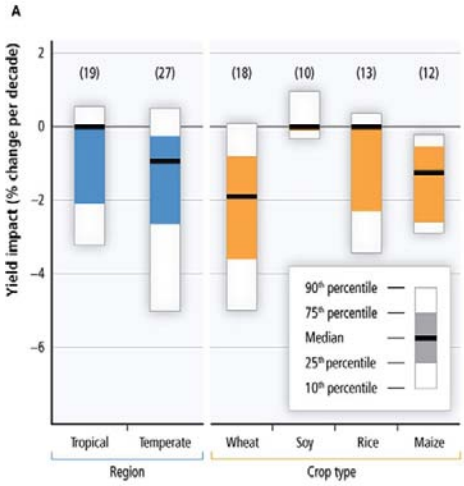

Fig. 1. Feature importance of the dataset

DOI: rp-9788770040723.084

The raw data is transformed into a clean data collection using a method known as data pre processing. Although the data are gathered from numerous sources, analysis is not possible because they are gathered in raw form. By utilizing a variety of techniques, such as the replacement of missing values and null values, it can transform data into a format that is understandable [6]. The final step in the data preparation process is the separation of training and testing data. Because training the model frequently necessitates as many data points as possible, the data has an uneven distribution [8] and [10]. The initial dataset used to teach machine learning algorithms how to learn and generate precise predictions is the training dataset, which in this case takes up 80% of the dataset [11] and [12].

A. *Factors Affecting Agrometeorology*

Crop productivity and yield depend on various factors that need to be considered to estimate the annual crop output. These factors include temperature, rainfall, humidity, soil quality, pH level, andgeographic location. In the early days of agriculture, only a limited number of crops were cultivated, and most food was obtained through foraging in the wild.underneath a wide.

Changes in climate patterns have a direct impact on agriculture. With increasing temperatures and changes in precipitation patterns, it becomes difficult to predict crop yields and patterns.The topography of a region plays a vital role in determining weather patterns. Mountains, valleys, and other landforms affect precipitation and temperature distribution, which in turn influence crop growth.The use of technology in agriculture has increased significantly over the years. Weather forecasting, remote sensing, and precision agriculture tools are some of the technologies that have revolutionized the way agriculture is practiced.

B. *Algoritms*

1) *Navie Bayes*

Naive Bayes is a probabilistic algorithm commonly used for classification tasks, including crop prediction. The basic formula for Naive Bayes can be expressed as:

$$P(A|B) = \frac{P(B|A)\,P(A)}{P(B)}$$

where P(Y|X) is the posterior probability of class Y given input features X, P(X|Y) is the likelihood of the input features given class Y, P(Y) is the prior probability of class Y, and P(X) is the marginal probability of the input features. To use Naive Bayes for crop prediction, you would typically start with a dataset of input features related to crop growth and health (e.g., soil quality, weather conditions, nutrient levels, etc.) and a corresponding output value indicating the expected yield or quality of the crop. Naive Bayes algorithm is used to build a model that can predict the output value based on the input features. The specific formula for Naive Bayes in crop prediction would depend on the particular features and output value being predicted, as well as the specific implementation of the algorithm being used.

2) Decision Tree

Decision trees are a popular machine learning algorithm used for classification and regression tasks. They are also commonly used in crop prediction to make predictions based on input data. Start with a dataset of training examples, where each example is a set of input features and a corresponding output value. Choose a feature from the input data that best separates the examples into different groups based on their output values. Create a node in the tree for this feature, and split the dataset into two or more subsets based on the feature's values. The formula for a decision tree can be expressed mathematically as:

$$Y=F(X)$$

where y is the output value being predicted, x is a vector of input features, and f is a function that maps the input features to the output value using a tree- based decision-making process.

3) *Random Forest*

Random forest is a popular machine learning algorithm that uses a combination of decision trees to make predictions. The formula for random forest can be expressed as follows:

$$Y=F(X)$$

where y is the output value being predicted, x is a vector of input features, and f is a function that maps the input features to the output value using a combination of decision trees. To use random forest for crop prediction, you would typically start with a dataset of input features related to crop growth and health (e.g., soil quality, weather conditions, nutrient levels, etc.) and a corresponding output value indicating the expected yield or quality of the crop. You would then use the random forest algorithm to build a model that can predict the output value based on the input features.

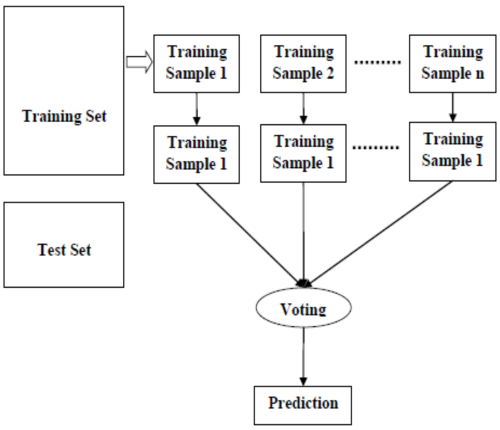

Fig. 2. Random forest classifier

C. *Analysis of Navie Bayes, Decision Tree and Random Forest*

Random forests are an ensemble learning method that consists of multiple decision trees, where each tree is constructed using a random subset of variables selected uniformly from the entire forest. By using the bagging technique to train the data, RandomForest improves the accuracy of the results. We chose the Random Forest approach to achieve high accuracy because it provides accurate predictions for both model-based predictions and actual results in the dataset. The model's predicted accuracy of 91.34% is evaluated.The proportion of true positive predictions among all actual positive instances in the dataset. This is useful when the cost of false negatives is high.

The proportion of correct predictions made by the model. This is a common metric used in classification tasks. A decision tree incorporates individual decisions, while a random forest combines multiple decision trees. Consequently, it is a slow but thorough process. On the other hand, a decision tree is quick and efficient with large datasets, especially linear ones. However, the random forest model requires extensive training.

It is important to consider the characteristics of the data and the goals of the analysis. Decision tree may be a good choice if the goal is to understand the relationships between the features and the target variable. Naive Bayes may be a good choice if the data is high-dimensional and the goal is to predict the class. Random Forest may be a good choice if the data is noisy and the goal is to improve the accuracy of the predictions. It is recommended to evaluate multiple algorithms and compare their performance using appropriate metrics.

TABLE 1. ALGORITHM WITH ACCURACY LEVEL

ALGORITHM	ACCURACY
DECISION TREE	87.82
NAÏVE BAYES	91.49
RANDOM FOREST	92.81

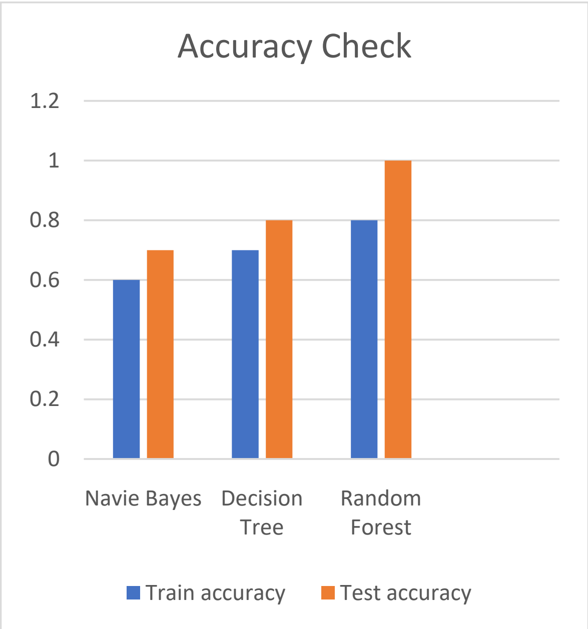

Fig. 3. Accuracy analysis

IV. SYSTEM ARCHITECTURE

The proposed system architecture involves using a weather API to retrieve data on temperature, humidity, rainfall, and other variables. The data is then sent to the server and stored in its database. Users can create an account on the mobile app by completing a single registration. The model used for prediction is Random Forest, which is a collection of tree predictors that utilizes the bagging approach to train data, leading to improved accuracy. The expected accuracy of the model is 91.34%.

Streamlit is an open-source framework that allows developers to create interactive web applications easily. In this step, a web application can be developed using Streamlit that allows users to input the data and get the output of the Bagging technique applied to agrometeorology.

The final step in the system architecture is to evaluate the accuracy of the Bagging technique applied to agrometeorology. The evaluation can be done by comparing the output of the Bagging technique with the actual weather data. The evaluation can be done on a regular basis to ensure that the system is accurate and reliable.

The application layer receives input from the presentation layer and retrieves data from the data layer. The machine learning algorithms are applied on this data to generate insights and predictions related to agrometeorology. Bootstrap aggregation, or bagging, is used as an ensemble method to combine the results from multiple decision trees to improve the accuracy of the predictions.The presentation layer is responsible for the user interface and visualizations, which are built using the Streamlit framework. The application layer is responsible for the business logic and analysis, and is built using the Python programming language with the Scikit-learn library for machine learning algorithms. The data layer includes the agrometeorological data that is collected from various sources and stored in a database.

The application layer are then passed on to the presentation layer, which displays them to the user in an interactive and user-friendly manner. The user can interact with the system through the web interface provided by Streamlit and explore the various visualizations and analysis generated by the system.

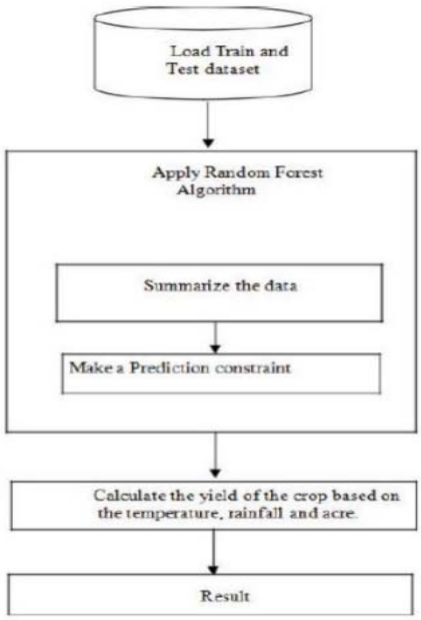

Fig. 4. System Architecture

DOI: rp-9788770040723.084

A. System Analysis

Python 3.8.5: Python is the programming language that serves as the basis for machine learning analysis. The necessary output is provided via Jupyter notebooks, which also show how the analysis is done.

Python Flask Framework: Flask is a Python microframework. WSGI (Web Server Gateway Interface) tools and the Jinja2 template engine are used in the development of Flask. Flask is used in this research as the back-end framework for building the application. Thanks to a collection of modules and libraries, the developer may design applications without writing the low-level code required for protocols, thread management, etc.

Streamlit : Streamlit is a popular Python-based open-source app framework that enables developers to create data science and machine learning applications quickly. With Streamlit, it is possible to develop online applications with ease. The framework supports several Python libraries, including NumPy, pandas, scikit-learn, Keras, PyTorch, and SymPy (LaTeX). Using Streamlit, developers can create interactive and visually appealing web applications without worrying about the underlying code.

V. Result and Discussion

This article uses machine learning approaches to improve agricultural output. The method that produces high accuracy forecasts the yield of the correct crop. With input libraries like Scikit-Learn, Numpy, Keras, and Pandas, Python 3.8.5 is used to implement the machine learning algorithms. An Android application that was created questioned the outcomes of the machine learning study. The crop name and accompanying yield were shown through an Android app built with Flutter.

The results of the evaluation would depend on the specific implementation and data used in the system. However, the Bagging technique is known to improve the stability and accuracy of a model, and applying it to agrometeorology can potentially improve weather forecasting in agricultural settings. Streamlit can also provide an easy-to-use interface for users to input data and receive real-time output. The evaluation of the system would require comparing the output of the Bagging technique with actual weather data to determine its accuracy and reliability.

The crop that can be cultivated in a certain district at a given period was predicted using the Random Forest Classifier, which had the highest accuracy.

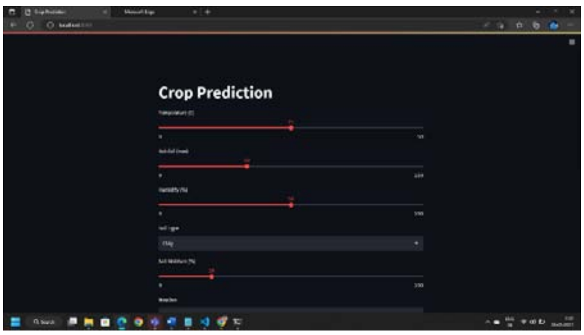

Fig. 5. Crop prediction before submit

This article uses machine learning approaches to improve agricultural output. The method that produces high accuracy forecasts the yield of the correct crop. With input libraries like Scikit-Learn, Numpy, Keras, and Pandas, Python 3.8.5 is used to implement the machine learning algorithms. An Android application that was created questioned the outcomes of the machine learning study. The crop name and accompanying yield were shown through an Android app built with Flutter.

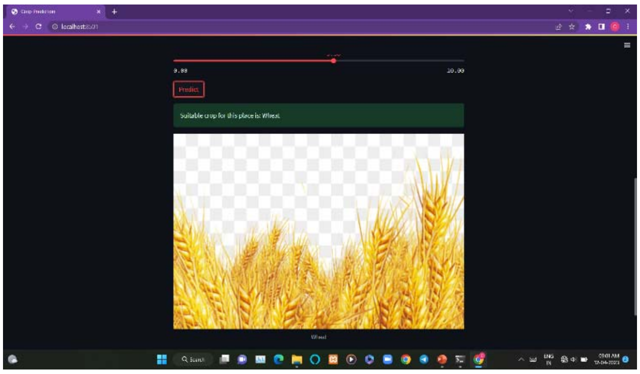

Fig. 6. Crop prediction after submit

VI. Conclusion

The objective of this project is to assess agrometeorology using Bootstrap Aggregation (Bagging) in combination with Streamlit. Bagging is a statistical method that employs bootstrapped samples to decrease the variance of machine learning models and enhance the consistency and accuracy of the outcomes. Streamlit is a free, open-source framework that streamlines the development and sharing of interactive data applications, including machine learning models.

The process involves collecting data on various agrometeorological variables such as temperature, humidity, rainfall, and others. This information will be utilized to train a Random Forest model employing the scikit-learn library in a Jupyter notebook. The optimized model will subsequently be deployed on a Flask web server and integrated into a Streamlit web application for straightforward use and interaction. The web application will permit users to input their data and receive predictions on their crop yields. The project aims to uncover the factors influencing crop yields and assist farmers in making informed decisions about crop selection and management.

The Bagging technique can improve the stability and accuracy of the model, while Streamlit provides an easy-to-use interface for users to input data and receive real-time output. The evaluation of the system's accuracy and reliability would require comparing the output of the Bagging technique with actual weather data. However, further development and implementation of the system are needed to determine its effectiveness in improving agrometeorology.

***Abstract*—Pneumonia is a lung disorder that can be brought on by infections with bacteria, viruses, and fungi. To identify the location of inflammation in a picture, a pneumonia detection system is being built. An experienced radiologist can identify the illness from chest X-ray images. This will examine how various pre-processing methods, including X-rays, can identify and categories numerous diseases. Computer-aided diagnosis systems are therefore required to direct the practitioners. For the purpose of predicting pneumonia, this system employs a deep neural network algorithm using the Xception framework. CT lung pictures are entered into the system and converted to pixels.Active contour technique analysis is used to determine the presence of holes in the lung lobes. The classification of CT scan images for consumer with coronavirus infections using CNN models is the main goal of this study. The test results revealed that the software can distinguish between photos that are infected and those that are not. The Xception network detects pneumonia cases more effectively.**

***Keywords*—Machine Learning, Deep Learning, CT Scanning, CNN.**

I. Introduction

Pneumonia is a lung inflammation that mostly affects the tiny air sacs known as alveoli. The most frequent infectious cause of death in the US is pneumonia. Although it affects people of all ages, the very young, the elderly, and the chronically ill experience the clinical signs that are the most severe. Pneumonia is typically brought on by bacterial or viral infections, while it can also be brought on by other microorganisms, certain drugs, and illnesses such autoimmune diseases. It typically appears on a chest radiograph as a region of increased opacity (CXR). Among them, millions of people, mostly those over 65 and those with chronic conditions like diabetes or asthma, are susceptible to the contagious and lethal infection pneumonia. Pneumonia is responsible for more than 15% of deaths worldwide, including those of children under five. Chest X-rays [2] are thought to be the most efficient way to diagnose pneumonia. For the purpose of classifying pathological and normal chest X-rays, we investigated the performance of various pre-trained CNN model [3] versions in this study, followed by various classifiers. The study's main contributions are as follows. The evaluation of the most effective pre-trained CNN model with hyperparameter tuning of the best analyses classifier to further enhance performance involves comparing them analytically, presenting them with various classifiers to suggest the best classifier in the same classification field, and presenting them with the most effective pre-trained CNN model.

II. Literature Review

PranatiRakshit [9] in 2020,lung nodules is classified and recognized using a convolutional neural network approach. Because of the large respiratory organ, double overlap with the ribs, and low contrast of the lesions, it can be challenging to identify respiratory organ nodules on an imaging test. For detection and classification from CT scan pictures, a CNN based deep learning (DL) strategy is suggested. Using common evaluation metrics, the findings are compared to those obtained using traditional machine learning techniques in the literature.

Anuradha. D Gunasinghe [5] predictions for lung disease in 2019. In the medical field, early lung disease detection and diagnosis are crucial because they facilitate the management of consumer subsequent clinical care. The initiative primarily considers pneumonia while also taking consumer respiratory issues into account. In this study, chest X-ray pictures are utilized to predict lung disease (pneumonia) utilizing convolutional neural networks (CNNs) and machine learning and deep learning frameworks.

SubratoBharati [15] using hybrid deep learning to identify lung conditions in x-ray pictures. This can include conditions including fibrosis, asthma, TB, chronic obstructive pulmonary disease, and pneumonia. The early detection of lung illness is crucial. a novel hybrid deep learning architecture that combines CNN [8], the spatial transformer network (STN), the VGG, and data augmentation. The innovative hybrid strategy used here is called VGG Data STN with CNN (VDSNet). The technologies for execution used are Jupiter Notebook, TensorFlow, and Kera's.

Ali Serener[6] lung illness forecast for the coming year, 2020. Early detection of lung disorders will enable the doctor to save the consumer life. This study explains how machine learning was used to predict and manage lung illnesses. The methodologies used in this study to identify lung problems include merging the analysis of consumer data with data from chest X-rays, as well as employing the Caps Net network and CNN's well-known pre-trained model for this type of data. N. Mohanapriya[11] using Deep Convolutional Neural Networks (DCNN),Lung Tumor Classification and Detection from CT Scan Images in

DOI: rp-9788770040723.085

2019[12]. Maximum or average pooling replaces input values with maximum or average values to lessen output sensitivity to minute input changes. To lessen the sensitivity of the output to minute input changes, maximum or average pooling replaces input values with maximum or average values.

III. PROPOSED SYSTEM

The Xception framework can be a useful tool for pneumonitis prediction. Convolutional neural networks are used by the Xception framework, a deep learning system, to identify photos. This is a suggested method for using the Xception framework to forecast pneumonitis. A sizable dataset of chest X-ray pictures, both with and without pneumonitis, will be gathered as data. In data pre-processing, the photos are resized to a uniform size, the pixel values are normalized, and the data is divided into training, validation, and testing sets. Using the Xception framework, a deep learning model may be created to categories chest X-ray [8] images as either normal or showing symptoms of pneumonitis. Models are trained using the training data set, and performance is enhanced by applying methods like data augmentationand transfer learning. Model performance on the validation set is assessed, and the model's performance is then improved by adjusting the model's parameters as needed. The goal of model testing is to evaluate the final model's performance using test data that hasn't been seen before. Deployment is the process of transferring the trained model to a local or cloud-based server environment and integrating it into a web or mobile application that can accept chest X-ray pictures as input and produce the anticipated diagnostic.

The images of CT [10] Pneumonia are supplied into the system and converted to pixels. Holes in the Pneumonia lobes are examined using the active contour approach. The fissure nodule is taken into account when doing the contour adjustment. With the aid of various lobe segmentation probability levels, the candidate nodules are extracted. Candidate nodules that have been pruned are used to extract the hybrid features, and various features are used to create feature vectors. Sort the Pneumonia lobes based on these characteristics to forecast Pneumonia illnesses. The Xception CNN [8] model is used in the proposed study to identify pneumonia infections from degraded CT scan pictures to a sparse matrix.To increase the detection accuracy, an Xception CNN-based detection model is suggested shown in **Fig 1**.

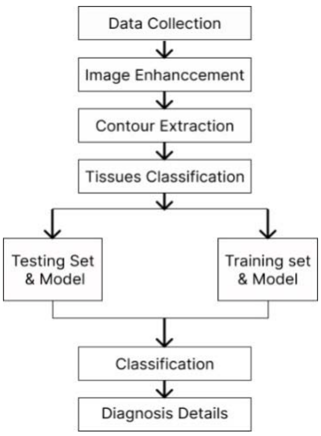

Fig 1.Proposed Architecture

A. Data Collection

To diagnose pneumonic nodules, computed tomography (CT) is used in conjunction with the most basic strategies. In this module, the image of theCT scan [5] with various sizes and formats. Dataset can be collected from KAGGLE environment.It is used to identifying relevant sources of medical imaging data, such as hospitals, research institutions, and publicly available datasets shown in **Fig 2.**

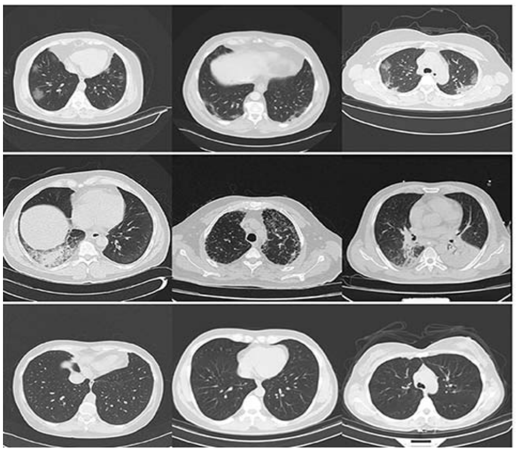

Fig 2. Data Collection

B. Image Enhancement

The lowest level of abstraction, intensity images, are used to describe operations where the input and output images are integration, transformation, and reduction pre-processing procedures. By the use of CNN algorithm to resize the scan image for future process. It can also implement median filtering algorithm to remove the noises in images. Contrast adjustment: This technique can be used to increase the image's contrast, making details more visible. This can be especially beneficial in improving lung structure and making the presence of pneumonia more visible.Sharpness enhancement: This technique can be used to improve the image's edges, making the boundaries of the lung and pneumonia more visible.Noise reduction: Noise can reduce image clarity, making it difficult to predict pneumonia accurately. To reduce noise and improve image quality, techniques such as median filtering and wavelet filtering can be used.

C. Contour Extraction

Lung related features areextracted based on shape features.Active contour modelling is used to first segment the lung. The initialization is this step's fundamental component. It causes nodules that are not isolated to become isolated. Then, using stochastic characteristics, regions of interest are found. Lung tissues are segmented and boundaries are detected. Histogram equalization: This technique improves image contrast by equalizing the distribution of pixel values. This can help to increase the visibility of the lung and pneumonia information. Multi-scale analysis: This technique analyses the image at various scales, allowing for a better understanding of the image structure and the presence of pneumonia. Before using machine learning algorithms to predict pneumonia, these image enhancement techniques can be applied to chest X-

DOI: rp-9788770040723.085

rays [8]. This can improve prediction accuracy and help healthcare professionals make more informed decisions. The borders of items or regions of interest can be extracted from an image using the contour extraction approach. Contour extraction can be used to segment and extract the areas of the lungs from chest X-rays or CT scans in the context of predicting pneumonia from medical imaging data. Then, machine learning models [14] that are trained to predict the existence of pneumonia can use the extracted contours as input features. Edge detection, thresholding, and segmentation methods like region-growing, watershed, or level set methods are a few of the methods used for contour extraction. Following the extraction of the contours, feature extraction and selection can be used to further reduce the dimensionality of the data and enhance the machine's accuracy. Shape descriptors, texture characteristics, and statistical measures of intensity are often retrieved features from contour data. While contour extraction can be a valuable technique for identifying useful features from medical imaging data, it should be noted that it is only one step in a more comprehensive process for predicting pneumonia. Data pre-processing, feature engineering, model choice, and validation are further crucial factors. Furthermore, using medical imaging data for diagnostic [7] purposes calls for specific knowledge and need to be carried out under the guidance of a qualified healthcare practitioner.

D. Tissues Classification

The classification is the final step of the system. Lung disease are classified using Convolutional neural network algorithm [10]. Gather and prepare the tissue image dataset for the CNN's training and testing. The collection ought to contain photos of various tissues that are labelled and creates the CNN architecture to analyze the incoming images and determine which tissue type corresponds. Convolutional, pooling, and fully linked layers are typically included in CNNs and used the prepared dataset to train the CNN. The CNN gains the ability to recognize the characteristics that distinguish between various tissue types throughout training. By placing the trained CNN to the test on a different collection of images that weren't used in training, taken for classification. This makes sure that the model has acquired the ability to generalize to fresh, unexplored tissue pictures. Use the trained CNN to categories fresh images of tissue. CNN receives a signal. The process of classifying tissue in order to anticipate the existence of pneumonia entails examining diagnostic pictures, such as chest X-rays or CT scans shown in **Fig 3**.

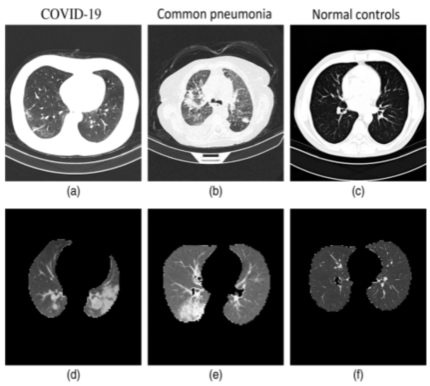

Fig 3.Image Classification

E. Diagnosis Details

Based on classified tissues, disease predicted. Diseases such as COVID [8], Pneumonia, Tuberculosis, and normal. Based on this disease prediction, we can provide the precaution details to users. Lung infection known as pneumonia can be brought on by a number of microorganisms, such as bacteria, viruses, and fungus. Clinical assessment, physical examination, and diagnostic testing are frequently used to diagnose pneumonia.The following diagnostic procedures may be carried out by a healthcare professional if a consumer exhibits symptoms that point to pneumonia:Chest X-ray: This examination can show whether the lungs are inflamed or filled with fluid.Blood tests: These tests can assist identify the kind of microorganism that is infecting you and gauge how serious your condition**.** Sputum culture: In this test, a sample of mucus or phlegm from the lungs is taken, and it is examined for the presence of bacteria or fungi.A flexible tube with a camera is used during a bronchoscopy procedure to see inside the lungs and collect samples for analysis.Depending on the origin of the infection, healthcare professionals can diagnose pneumonia based on the findings of these diagnostic tests and select the best course of therapy, which may include antibiotics, antiviral drugs, or antifungal treatments shown in **Fig 4**.

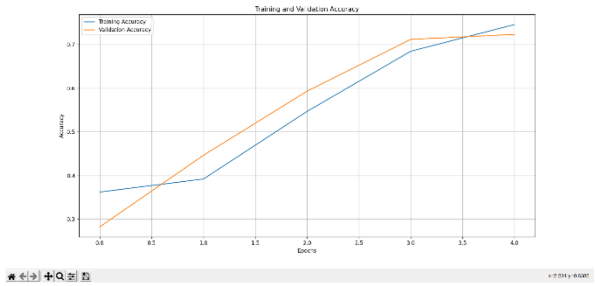

Fig4.Data Count

IV. Results and Experiments

Based on accuracy, we assess the system performance. An accuracy of 98.857% was attained by the suggested model, and high F1 and AUC scores of 99.002 and 99.809 supported its effectiveness. Accuracy is the capacity to differentiate between successful and unsuccessful cases.A method for identifying lung conditions using an X-ray [4] dataset. Images of CT Pneumonia are supplied into the system and converted to pixels. The feature vectors are created using various features, and the hybrid features are derived from trimmed candidate nodules. Based on these features, classify the Pneumonia lobes to predict the Pneumonia diseases. In 2016, Francois Chollet unveiled the deep convolutional neural network (CNN) architecture known as Xception. It is a variation on the Inception architecture where depth wise separable convolutions are used in location of the standard Inception modules. With fewer parameters and quicker calculation, the model can attain state-of-the-art performance on picture classification tasks thanks to this design decision. Pneumonitis, an inflammation of the lungs, can result from a variety of conditions, including allergies, infections, and contact with irritants. Chest X-ray pictures can be classified using deep

DOI: rp-9788770040723.085

learning models, like Xception, to assist in the diagnosis of pneumonitis [6]. The promise of deep learning models, such as Xception, for pneumonitis diagnosis has been demonstrated in a number of research. For instance, a study published in the Journal of Medical Systems in 2020 classified chest X-ray images as normal or abnormal, including anomalies including pneumonitis, using a deep learning model based on Xception. Using the Xception-based model, the study revealed an accuracy of 92.2% and an area under the receiver operating characteristic curve (AUC-ROC) of 0.981 [15]. A similar method was utilized in the Journal of Healthcare Engineering in 2021 to categories chest X-ray images as either normal or exhibiting signs of pneumonitis. This method combined the Xception model with transfer learning. The Xception-based model has an accuracy of 95.1%, sensitivity of 96.5%, specificity of 93.8%, and an AUC-ROC of 0.976. Using deep learning, the Xception framework has demonstrated potential in predicting pneumonitis, reaching good accuracy and AUC-ROC [11] values in numerous experiments. Before it can be employed in therapeutic settings, however, additional validation and testing must be conducted, as with any AI modelimplementation and the system configuration for training the CNN by using PyCharm shown in **Fig 5**.

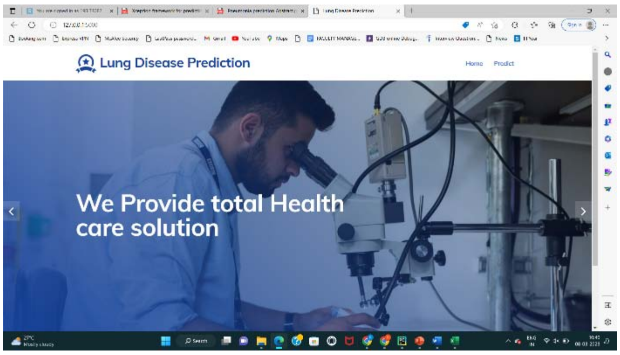

Fig5. Home Page

It cleaned up the data and provided it as input so that the model could be trained again to forecast the sickness. This work Pneumonia diseases are detected using Xception CNN model from CT scan [13] images decomposed to sparse matrix. An Xception CNN based detection model is proposed to improve the detection accuracy shown in **Fig 6.**

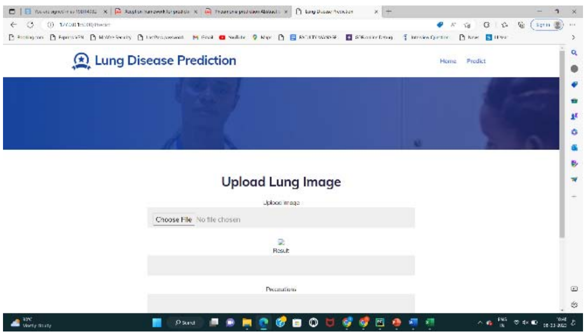

Fig 6. Predict Page

The number of datasets needed for training, validation, and testing a model for predicting pneumonitis using deep learning depends on various factors such as the complexity of the model, size of the dataset, and the variability of the images in the dataset. However, as a general rule of thumb, a minimum of 1000 images is recommended for a binary classification problem such as detecting pneumonitis in chest X-rays [9].Three sections of the dataset should be created: training, validation, and testing. The validation set is used to adjust hyperparameters and prevent overfitting, the testing set is used to evaluate the model's ultimate performance, and the training set is used to train the model. It is suggested that 70% of the dataset be used for training, 15% for validation, and 15% for testing [14]. The precise split, however, may vary based on the quantity of the dataset and the model's complexity. For example, if we have a dataset of 3000 chest X-ray images, we can split the dataset into 2100 images for training, 450 images for validation, and 450 images for testing. It is important to ensure that the images in each set are representative of the overall dataset and have similar characteristics, such as age, gender, and ethnicity, to avoid bias in the model shown in **Fig 7**.

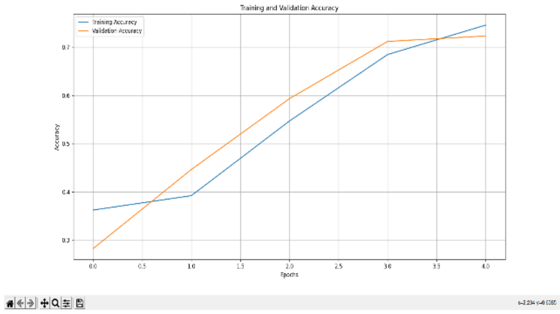

Fig7.Train, Validate, Test Dataset Count

V. Conclusion and Future Enhancement

To identify bi-classification and multi-class classification issues, as well as linear and nonlinear classification issues. This enables us to analyses high-dimensional data using this new methodology and also Compared to artificial neural networks, it is superior in some ways. Another suggestion for merging various topologies was to use a weighted classifier. The results of the experiment, including the accuracy, recall, precision, and AUC score, demonstrated how robust the model was. The proposed model achieved an accuracy of 98.857%, and its efficacy was validated by high F1 and AUC scores [15] of 99.002 and 99.809, respectively. The suggested methodology produced better results when compared to other approaches developed especially for this dataset. Future technologies that make it feasible to more accurately estimate weights for various models would be exciting, as would a model that predictions while taking into account the consumer past.

***Abstract*—India's economy and society are largely dependent on agriculture, and the nation currently has one of the highest percentages of farm producers in the world. Because they are ignorant of new technologies and criteria that could help them increase productivity, farmers lose production. Farmers require technological assistance and support. From January 2015 to September 2017, all call records from the Kisan Call Center (KCC) were made public by the Indian government. Farmers and agriculture experts provided the researchers with similar KCC datasets. We identified four key areas in need of information support based on both sources: plant protection, pests (diseases), weather, and best practices.Natural language and in-depth learning The use of chatbots has increased significantly in recent years. They are used in many different fields, such as personal assistance, reservation systems, and customer service. To overcome challenges in their fields, farmers continue to rely significantly on the advice of their colleagues. Inadequate usage of these technologies has prevented farmers from receiving the crucial information on time. This project aims to develop "AgriBot," a closed-domain ChatBot for the agricultural industry. Farmers can interact with closed-domain and get expert advice about their industry. The basis for "AgriBot" is the RASA Open-Source Framework. The "AgriBot" deciphers the user's words to determine the issue and entity, then retrieves and distributes the solution from the database.We tested the Bot with existing data and found it to be promising.**

Keywords—Rasa, Deep Learning, NLP, KCC, Agribot, Personal Assistant

I. INTRODUCTION

By leveraging natural language technology to respond to questions on agriculture, horticulture, and animal husbandry, our Agri Chatbot can have a significant influence on marginalized communities. The farmer will be able to access localized information and agricultural information, including weather forecasts and the current market prices of different crops in his or her region. On the Kissan website, a farmer can send a direct message to our AI-enabled Chatbot and receive a response in their native tongue. Our approach would make it possible for the farmer to ask as many questions as they like, whenever they like, which would help current farming technology spread more quickly and to more farmers.

Below are a few examples of chatbot developments in the field of agriculture:

This research uses a virtual conversational assistant to ask a question about agriculture and receive a text response. Further improvement is possible by responding in the respondents' native tongue, and production and rainfall predictions are also possible. In its path to efficiency, sustainability, and meeting the world's food demands, agriculture is predicted to experience exciting times in the future thanks to the use of cognitive technologies. Natural Language Processing techniques are used by this conversational assistant to comprehend user inquiries in their native tongue. This will enable the machine tounderstand input queries that are grammatically incorrect [1]. The user queries go through a pre-processing stage where they are first tokenized into words, stop words like a, is, and the like are eliminated to reduce the likelihood that the queries will be classified according to their respective classes, and finally the steaming process is carried out where the words are converted to their root words. For the classification method to process the words effectively, they are first transformed into a bag of words and then into a vector form. The training dataset is then used to train the bot. The gradient descent approach is used to form a neural network from the training set of data and optimize error [2].

The same pre-processing steps, classification steps, and neural network formation are applied to the test data set. To obtain accurate findings, the class with the highest probability is iterated.

We aim to create a chatbot that can respond to farmers' basic questions and possibly offer some agricultural information. We therefore have total visibility throughout the agricultural value chain thanks to the traceability software we are utilising from Source Trace. It affects how farmers live, aids in the adoption of data-driven agriculture by an organisation, and promotes improved stakeholder relationships and trust[6]. Half of India's workforce was involved in agriculture, which contributed 17–18% of the nation's GDP. In 2014, the employment rate in agriculture and closely associated businesses including forestry, animal husbandry, and fisheries was over 31%. In 2016, these sectors contributed 15.4% of GDP.

In order to enable remote contact between users/farmers and the agricultural environment, this project aims to develop a chatbot that makes use of natural language processing. Our goal is to develop a chatbot that can respond to common inquiries from farmers and provide knowledge and solutions related to agriculture. This chatbot can learn on its own and improvise responses because it has received training in natural language processing [3].Farmers or agriculturists are the study's intended audience. Their efforts will be based on the developed model. The results of the study will therefore be useful to agriculturalists.

DOI: rp-9788770040723.086

II. MATERIALS AND METHODS

We suggest an Agribot as a solution, which is interactive for farmers and can quickly and effectively respond to their questions[4]. The workflow begins with the bot responding with a "hello" message, after which farmers will ask questions and the bot will provide potential answers based on the trained dataset we provided for training. We use RASA as a tool to create personalised AI chatbots using Python and NLU (NLU). The user can train the model and add custom actions as well.

A. *Data Overview*

On the Rajasthan KCC dataset, we are working. The researchers received inquiries from farmers and agri-experts that were comparable to those they discovered in the KCC dataset.

They identified two key areas in need of information support based on both sources:

- Plant Protection: In the KCC dataset, 30.59 percent of the farming calls—or nearly half of the dataset—were about questions relating to plant protection.
- Weather: In the KCC dataset, 46.67 percent of the farming calls—or nearly half of the dataset—were connected to weather-related inquiries. Farmers eagerly awaited weather updates because rain can wash away expensive insecticides that have been sprayed and because the ideal time to harvest crops depends on the weather.
- Market Information: 13.5% of farming-related questions concerned market data. It primarily contains inquiries about the mandi rate and market rate of a select few crops, including guar, groundnut, and others.
- Fertilizer Usage and Availability: In the KCC dataset, 20% of the farming calls—or nearly half of the dataset—were connected to inquiries about plant protection. It informs the farmer on the type of fertiliser needed for the crops, among other things.
- Soil testing: In the KCC dataset, 10% of the farming calls—or nearly half of the dataset—were connected to inquiries about plant protection.
- Nutrient Management: In the KCC dataset, 28 percent of the farming calls were related to plant protection related questions which is almost nearly half of the dataset.It gives insight to farmers the nutrients that need to be given to the pulses and crops. The rest of the data set includes minor factors like varieties, Government schemes, etc.

Data from the Kisan Call Center (KCC) is comprised of questions posed by farmers and the KCC's replies. The complete corpus is accessible on the official website of the Indian government, "data.gov.in," under the name Kisan Call Centre[10]. Data in CSV format is available from the years 2006 through 2020. Every month, a different catalogue is kept for each district in each state. There are 11 fields total on each call log, including the KCC agri-response. expert's

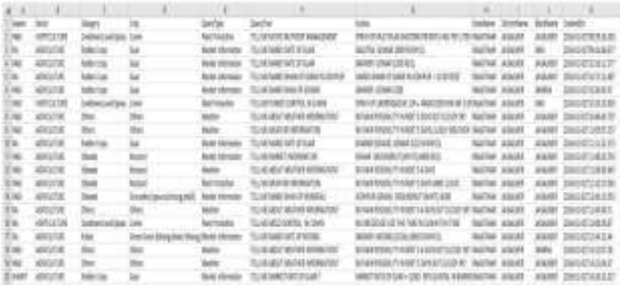

Fig.1 Different Variables in the data

- Season: Details about the season during which the query was posed.
- Sector: What industry was the question about? Examples include agriculture, horticulture, animal husbandry, and fishing.
- Category: Which category, for instance—vegetables, animals, cereals, drugs and narcotics, etc.—does the query concern within a given sector?
- Crop: Which crop is in question? Examples include potatoes, paddy, wheat, bananas, goslings, and others.
- Query Type: such as Plant Protection, Weather, Nutrient, Management, etc., fall within the general category of specific question posed.
- Query Test: The user's actual inquiry.
- KCC Answer: Response given to caller Kisan by the KCC agent.
- State Name: State in which the question has been asked.
- District: The state where the query was posed.
- Block Name: Block in the neighborhood where the question was posed.
- Created On: Date that the question was posed.

B. *Exploratory Data Analysis*

For our investigation and demonstration, we examined the Rajasthan data set from 2015 to 2020. There were 1,16,163 searches. More than 50% of inquiries are on the season Rabi, which is followed by Kharif and NA. According to industry-specific analysis, agriculture and horticulture account for about 85% of all enquiries.

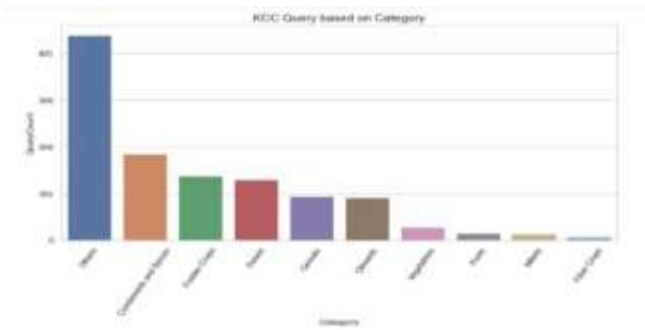

Fig. 2. Describes different Crop Types In each season

DOI: rp-9788770040723.086

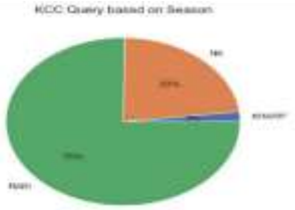

Fig 3 Shows the different Queries by the farmers across various sectors

As we look more closely at the questions, we discover that the two most important agricultural seasons in India, Kharif and Rabi, come up frequently. This data can be used to scale up or down the number of servers required and to calculate the infrastructure needed to host the solution [11]. Farmers ask questions in a number of subject areas, with agriculture and horticulture being the most popular ones. This is also in line with the fact that the majority of Rajasthan's agricultural production consists of cereals, vegetables, and pulses. This allocation could help the both of them become more effective.

Farmers have a wide range of queries, with season and crop-related inquiries being the most common.

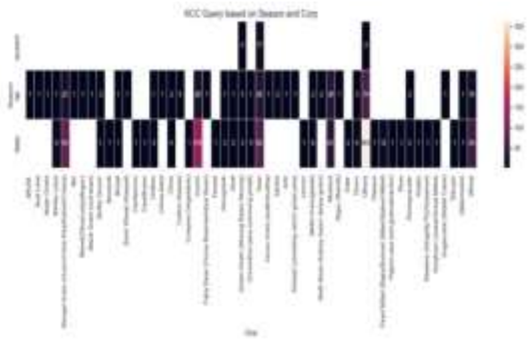

Fig 4 Shows different Queries from farmers on various crops and season of the region.

C. RASA Framework

Rasa is a tool that builds customized AI chatbots using Python and NLU (NLU). Rasa offers a platform for building AI chatbots that make use of natural language comprehension (NLU). Moreover, the user can train the model and add unique actions [12]. Slack, Microsoft Bot, and Facebook Messenger are just a few of the platforms where chatbots created by Rasa have been implemented. Rasa is composed of two primary parts:

- **Rasa NLU** (Natural Language Understanding: The open-source natural language processing programme Rasa NLU ascertains the user's request, extracts the entity from the chatbot in the form of structured data, and helps the chatbot understand what the user is saying.
- **Rasa Core :** Instead of utilising an if/else statement to determine the best course of action, a chatbot system with machine learning-based dialogue management forecasts the best path of action using a probabilistic model like an LSTM neural network. Under the hood, reinforcement learning is also used to improve the prediction of the best course of action.

D. ChatBot Implementation

Before beginning programming, Rasa must be installed because it is an open-source framework. Using a virtual environment to prevent version inconsistency across various components is strongly advised.

Environment Preparation

- Download and Install the latest python library using below commands for windows machine.

pip install python

- To create a virtual environment, decide upon a directory where you want to place it, and run the venv module as a scriptwith the directory path.

python3 -m venvchatbotenv

- Once you've created a virtual environment, you may activate it.

  \chatbotenv\Scripts\activate.bat

- Install the rasa framework on the same directory.

  pip install rasa

- initialize rasa project.

  rasainit

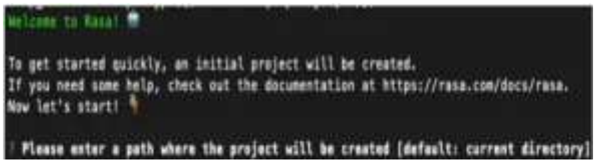

Fig 5. Shows the default screen of the Environment preparation.

E. Model Pipeline Design

A pipeline-based general framework is Rasa NLU. Rasa has a lot of versatility as a result.

Each component's data processing order is specified by a pipeline. Some components are dependent on one another. The pipeline will fail if even one of these dependence conditions fails. Rasa NLU examines each component's dependence requirements individually. Rasa will halt the program and issue the appropriate errors and warnings if any of the dependency requirements fail [13].

- **Language model component:** This loads the language model files to support the following components. There are multiple inbuilt language models available and we have used **LanguageModelFeaturizer in Agribot**.

Components	Model	Notes
SpacyNLP	spaCy	Pre-trained spaCy models need to be downloaded in advance. For more details, please check the spaCy official website.
MitieNLP	MITIE	MITIE needs a pre-trained model. You need to pre-train or download a model from the internet.
HFTransformersNLP	Transformer	To use the HFTransformersNLP component, install Rasa Open Source with pip install rasa[transformers]. HFTransformersNLP is deprecated in the newer version of Rasa 2.x, and LanguageModelFeaturizer now implements its behavior.

Fig 6 – Shows different language model files that supports Different components.

DOI: rp-9788770040723.086

- **Tokenizer component:** Languages and tokenizer components have a close relationship. All languages cannot be supported by a tokenizer. You should select the right tokenizer based on the language that will be your target. Space-splitable languages can employ "Whitespace Tokenizer." In other words, if English is your target language, you should utilise "Whitespace Tokenizer." You should utilise "JiebaTokenizer" for Chinese. In languages (like Japanese, Chinese, or Korean) that don't employ space to break words, "Mitie Tokenizer" (which makes use of a pre-trained model from MitieNLP) is typically used for word segmentation. The tokenizer you choose should be compatible with the language that your pre-trained model uses. [14] [17] Currently, "Spacy Tokenizer" supports 63 different languages. We have supported English language hence "**Whitespace Tokenizer" is used for our Agribot.**

Components	Requirement	Model	Notes
WhitespaceTokenizer			Tokenizer using whitespaces as a separator
JiebaTokenizer	Jieba	Conditional Random Field	For Chinese
MitieTokenizer	MITIE	Structured SVM	
SpacyTokenizer	spaCy	Multiple models	

Fig 7 – Shows DifferenetTokenizer for differentrequired languages.

- **Featurizer component:** Features supplied by upstream components are necessary for entity extraction as well as intent classification. To perform feature extraction, developers can employ a variety of components [18]. Developers can freely select and mix those components, as they have feature union functionality implemented. We have used **RegexFeaturizer in Agribot.**

Component	Requirements	Notes
MitieFeaturizer	MitieNLP	
SpacyFeaturizer	SpacyNLP	
ConveRTFeaturizer	Tokenization	Based on ConveRT from Poly AI.
LanguageModelFeaturizer	Tokenization	Based on Transformers from HuggingFace.
RegexFeaturizer	Tokenization	This component reads regular expression configurations from training data.
CountVectorsFeaturizer	Tokenization	Based on Bag-of-words model. Usually used in toy projects.
LexicalSyntacticFeaturizer	Tokenization	Gives linguistic features, for example, whether it is the head or tail of a sentence or whether it is a number.

Fig 8. Shows different type of feature Expressions used according to the Requirements.

- **Entity extractor component:** Rasa is compatible with several entity extraction components. With a few exceptions that can be utilized together under specific circumstances, the majority of those components shouldn't be used together. A few components can only create predefined entities; they cannot be educated on the entities that the developer creates. Rasa suggests DIETClassifier [21] because it typically performs better; as a result, we have followed her advice.

Components	Requirement	Model	Notes
CRFEntityExtractor	sklearn-crfsuite	**Conditional Random Field (CRF)**	
SpacyEntityExtractor	spaCy	Averaged perceptron	Pretrained entities.
MitieEntityExtractor	MITIE	Structured SVM	
EntitySynonymMapper	Existing entities		Standardization of synonyms.
DIETClassifier	Tensorflow	CRF on top of a transformer	
RegexEntityExtractor			Use lookups and regular expressions in the training data.
DucklingEntityExtractor			We need to run a Duckling server for it.

Fig 9. Different Entities that RASA supports.

- **Intent classifier component:** This element is used to categories each query's intent[13]. DIETClassifier is suggested by Rasa for improved performance.

Components	Requirement	Model	Notes
MitieIntentClassifier	MITIE	Structured SWM	
SklearnIntentClassifier	Scikit-learn		
KeywordIntentClassifier			Based on the keywords matching. Usually used in toy projects.
DIETClassifier	TensorFlow	CRF on top of a transformer	
FallbackClassifier			Set intent value to nlu_fallback if the other component gives too low a confidence score on intent.

Fig 10.Shows different Classifier to be used for better performance.

- **Structure output**: This generates structured data from the prediction results that have been organized. This portion of the pipeline is a built-in function rather than a component. It cannot be directly accessed by developers as a component.

Fig 11. - Shows the Pipeline of the Data Processing.

The following pipeline is designed for Agribot

```
pipeline:
 No configuration for the NLU pipeline was provided. The following default pipeline was
 If you'd like to customize it, uncomment and adjust the pipeline.
 See https://rasa.com/docs/rasa/tuning-your-model for more information.
   - name: WhitespaceTokenizer
   - name: RegexFeaturizer
   - name: LexicalSyntacticFeaturizer
   - name: CountVectorsFeaturizer
   - name: CountVectorsFeaturizer
     analyzer: char_wb
     min_ngram: 1
     max_ngram: 4
   - name: DIETClassifier
     epochs: 100
     constrain_similarities: true
   - name: EntitySynonymMapper
   - name: ResponseSelector
     epochs: 100
     constrain_similarities: true
   - name: FallbackClassifier
     threshold: 0.3
     ambiguity_threshold: 0.1
```

Fig 12. Shows the snippet of the Pipeline that was followed.

F. Session Configuration

The session is a conversation between the user and the bot. One session can persist for multiple dialogue turns. Currently,[22].

Rasa supports two types of session configurations

- **session_expiration_time:** specifies how many minutes after the user receives the most recent message the

DOI: rp-9788770040723.086

message will expire. If it is set to 0, there is no expiration time.

- **carry_over_slots_to_new_session:** decides if the system should carry over the slots from the previous session to the new session. If set to false, the previous session's slot values will not be sent to the next session.

G. Training Data Preparation

- **nlu.yml:** We have training data for several intentions in the NLU training data file. The name of the intent and the name of the entity make it simple to determine its meaning. All of the training data for our project is kept in the data/nlu.yml file. We'll show you a portion of the training file right here.

```
- intent: bot_challenge
  examples: |
    - are you a bot?
    - are you a human?
    - am I talking to a bot?
    - am I talking to a human?

- intent: guar_rate
  examples: |
    - TELL ME MANDI RATE OF GUAR
    - TELL ME MANDI BHAV OF GOWAR
    - TELL ME MANDI BHAV OF GWAR

- intent: weather
  examples: |
    - Asking about weather forecast?
    - TELL ME WEATHER FORECASTING
    - TELL ME ABOUT WEATHER INFO
    - TELL ME WEATHER REPORT IN JAISALMER
    - TELL ME WEATHER INFORMATION
    - TELL ME WEATHER INFORMATION?

- intent: fertilizer_in_wheat
  examples: |
    - TELL ME FERTILIZER IN WHEAT
    - what will be the good fertilizer in wheat
```

Fig 13. Shows the stored training data in yml file format.

- **stories.yml:** Rasa gains knowledge from conversations and organises it through story-based instruction. A high-level semantic method of capturing talks is the tale. Together with user expressions, it also documents when the system's state changes correctly.

```
- story: happy path
  steps:
  - intent: greet
  - action: utter_greet
  - intent: mood_great
  - action: utter_happy

- story: sad path 2
  steps:
  - intent: greet
  - action: utter_greet
  - intent: mood_unhappy
  - action: utter_cheer_up
  - action: utter_did_that_help
  - intent: deny
  - action: utter_goodbye

- story: path3
  steps:
  - intent: guar_rate
  - action: utter_guar_rate
  - intent: goodbye
  - action: utter_goodbye

- story: path 4
  steps:
  - intent: weather
  - action: utter_weather

- story: path 5
  steps:
  - intent: pest_mus
  - action: utter_pest_mus
```

Fig 14.Shows the stored user expressions from user's.

- **domain.yml:** All the knowledge a chatbot requires is defined by a domain, including intents, entities, slots, actions, forms, and responses. All of this information provides precise definitions of a model's inputs and outputs. This is the domain file that has been prepared for Agri Chatbot.

```
intents:
  - greet
  - goodbye
  - guar_rate
  - weather
  - fertilizer_in_wheat
  - fertilizer_in_kalonji
  - disease_control_of_onion
  - disease_control_of_cumin
  - fungal_disease_control_of_gram
  - pest_mus
  - pest_must
  - control_of_blight

responses:
  utter_greet:
  - text: "Hey! How are you?"

  utter_goodbye:
  - text: "Bye"

  utter_guar_rate:
  - text: "BALOTRA  GOWAR 2900 RUPAY/Q."

  utter_weather:
  - text: "Partly cloudy,No Possibility of Rain."
  - text: "NO RAINFALL NEXT FIVE DAYS"

  utter_fertilizer_in_wheat:
  - text: "SPRAY ZINK SALPHET 33% 5 GM+BUJHA CHUNA 2.5 GM/LITER WATER"

  utter_fertilizer_in_kalonji:
  - text: "SPRAY SOLUBLE NPK  18:18:18 GRADE 10 GM/LTR WATER"
```

Fig 15. Shows the clear definitions of the inputs and outputs of a model

H. Train the Model

We can start the model to modify the weights based on training data once we have prepared all of the training data and placed the file or appropriate folder structure. In order to verify the accuracy of the module, we may also prepare the testing data. The interactive shell creation and execution commands are listed below.

- **rasa train**

This command will train the model using the NLU train data, story data, and configuration. By doing this, the model zip file will be created and saved in the default model folder.

- **rasa shell**

With this command, you can interact with the bot by running the Rasa server and launching the interactive command line interface.

III. Result And Discussions

The user was able to communicate with AGRIBot and it was able to recognise the entity and intent for which it was taught.The Bot shared the user with the proper response it had found in the database. Even for questions that were beyond the capabilities of the Bot, it performed effectively. The AGRI ChatBot is intended to seamlessly respond to beneficiary questions, and it is an effort to give mass farmers access to a channel of communication through which they can ask questions and receive answers at any time without having to be concerned about call centre operating hours or network congestion problems. We decided to add the chatbot to this platform because the Kissan website has one of the most popular chat platforms in India. The user can then continue with their questions when the bot responds to their greeting with an appropriate welcoming message about itself. The bot will check to see if the user is satisfied with the response after providing the information and will then welcome any additional questions. If the response is unsatisfactory, the bot will give the farmer the phone number to call the call centre during business hours.

The NLP algorithms can be integrated in a variety of ways to build up a solution on the RASA platform, which is the foundation around which the bot has been constructed.

DOI: rp-9788770040723.086

We can use the platform's pre-built models or feed it any custom models to create the final model utilising transfer learning with the given data.

Fig 16. The above figures show the snippet of the response from the bot for all scenarios where the confidence rate was high enough from our bot.

Possible Queries from the "FARMER"	Output From "THE AGRIBOT"
TELL ME MICRO NUTRIENT MANAGEMENT	SPRAY OF MULTIPLEX (MICRONUTRIENT) 4 ML PER LITER WATER
TELL ME MANDI RATE OF GUAR	BALOTRA GENWAR 2900 RUPAYE/Q
TELL ME MANDI BHAV OF GWAR IN JODHPUR	MANDI BHAV OF GWAR IN JODHPUR = 5150 RS/QT
TELL ME MANDI BHAV OF GENWAR	BARMER GENWAR 5200
TELL ME FUNGUS CONTROL IN CUMIN	SPRAY OF CARBENDAZIM 12% + MANCOZEB 63% WP 2 GM PER LITER WATER
TELL ME ABOUT WEATHER INFORMATION ?	NO RAIN POSSIBILITY IN NEXT 5 DAYS BUT CLOUDY SKY
TELL ME WEED CONTROL IN CUMIN	NO WEEDICIDE USE THIS TIME IN CUMIN THIS TIME
TELL ME MANDI RATE OF MOONG	BARMER MOONG (LOCAL) [illegible] RUPAYE/Q
TELL ME ABOUT WEATHER INFORMATION ?	NO RAIN POSSIBILITY IN NEXT 3-4 DAYS BUT CLOUDY SKY
TELL ME ABOUT MARKET INFORMATION OF TIL	JODHPUR (GRAIN) TIL (BAJAR) [illegible] RS/QT
TELL ME PEST DISEASE CONTROL IN MUSTARD	DRENCHING OF HEXACONAZOLE 2 ML PER LITER WATER IN ROOT ZONE
TELL ME CONTROL OF APHID IN MUSTARD ?	SPRAY OF DIMETHOATE 30% EC 2 ML PER LITER WATER
TELL ME DOSE OF UREA IN MUSTARD FOR TOP DRESSING	DOSE OF UREA IN MUSTARD FOR TOP DRESSING= 65 KG PER HECTER
TELL ME ROOT ROT CONTROL IN CUMIN	DRENCHING OF CARBENDAZIM 1 KG PER HA IN ROOT ZONE WITH IRRIGATION
TELL ME PEST CONTROL IN GUAR	SPRAY OF IMIDACLOPRID 17.8% SL 0.5 ML PER LITER WATER

Fig 17 – Shows all the Queries from the Farmer tested by us and the Replies captured from the Agribot developed in Tabular form.

A beneficiary may ask some questions that are not relevant to the FAQ in response, which the bot might not be able to address. When this occurs, the bot will choose for a fallback response because it has less than a 70% confidence in its ability to respond to the inquiry.

We have tested the built model and found it to be satisfactory in providing a relevant response.

A. *Discussion on the Result*

Almost half of the population in India depends on agriculture for a living, making it a significant source of employment. The general public requires information on a variety of topics, including weather, seeds, crop protection, schemes, etc. The KCC was created with this objective in mind, and it has been assisting farmers for a number of years. The weak network connectivity and scarcity of contact centers, however, impede the flow of information that is so important to farmers. In an effort to close this gap, AGRIBOT chooses the advantages from both ends.

We strive to use a chat channel to provide farmers with the information they require, while at the same time using the massive KCC dataset.

In an effort to test the bot, we have built out a FAQ-like chatbot that can respond based on previously asked questions using a tiny portion of Rajasthan's KCC data set for the last five years. Our goal was to have the bot react to the beneficiary's general inquiries. The bot responds to the queries fairly well in our minified dataset.

IV. Conclusion

Agribot is the first attempt to combine two previously distinct economic sectors for the laudable goal of providing Indian farmers with information promptly and easily. In order to provide the end users (farmers) with a smooth user experience via the Kissan Website and assist them in finding answers to their questions at any time, big data technology and mobile technology have been combined.

On the one side, this will save call centre expenses, and on the other, it will allow the beneficiaries to get the information whenever they need it without having to wait for KCC to open or worry about network congestion problems. The system also introduces a balancing act in that it either responds to inquiries that it can understand from the current corpus or else offers the end users a seamless way to contact a call center for support by supplying the call center number.

Although the solution in this paper is only a proof-of-concept, it can absolutely be developed further and made into an enterprise solution because the sample testing results were encouraging. The following stage allows us to include additional solutions to expand the corpus depending on any new queries submitted by users and their resolution using the KCC representative's suggestions.

A. *Future Scope of AgriBot*

Virtual Conversational Assistant Chatbot

Here, a text response to a question about agriculture is provided. Further improvements can be made by responding in their own native tongues, and productivity and rainfall predictions can be added. In its path to efficiency, sustainability, and meeting the world's food demands, agriculture is predicted to experience exciting times in the future thanks to the use of cognitive technologies. Natural Language Processing techniques are used by this conversational assistant to comprehend user inquiries in their native tongue. This will enable the machine to interpret input queries that are grammatically incorrect. The user queries go through a pre-processing stage where they are first tokenized into words, stop words like a, is, and the like are removed to reduce the likelihood that the queries will be classified according to their respective classes, and finally the stemming process is carried out where the words are converted to their root words. For the classification method to process the words effectively, they are first transformed into a bag of words and then into a vector form. The training

DOI: rp-9788770040723.086

data set is then used to train the bot. The gradient descent approach is used to form a neural network from the training set of data and optimize error.

The same pre-processing steps, classification steps, and neural network formation are applied to the test data set. To obtain accurate findings, the class with the highest probability is iterated.

- TEXTUAL ASSISTANT CHATBOT: Agricultural chatbots are essential to the agriculture sector since they help all farmers and those with an interest in agricultural operations by assessing their questions and giving them the right answers. Most questions may be answered by this Question-Answer system accurately and without the need for human intervention. Greater human resource utilization and the avoidance of unnecessary costs related to the opening of additional contact centers would result from this. Natural Language Processing techniques are used by this conversational assistant to comprehend user inquiries in their native tongue. This will enable the machine to interpret input queries that are grammatically incorrect. The user queries go through a pre-processing stage where they are first tokenized into words, stop words like a, is, and the like are removed to reduce the likelihood that the queries will be classified according to their respective classes, and finally the stemming process is carried out where the words are converted to their root words.
- GPT BASED CHAT BOT: Generative Pre-Trained Transformer is referred to as GPT. The term "generative language model" refers to Chat GPT. In reality, it is regarded as an AI chat that has been programmed and created to carry on normal conversations. OpenAI, a research firm, owns Chat GPT. By creating innovations and attempting to raise their levels by assessing the quantitative and qualitative data in various ways, GPT-based chat bots have provided solutions. Upgrading to these tiers will definitely assure two-way communication. The worst error any chatbot can do is to make the user wait for a response; in this case, the farmer. This will let the user down and make them look for other options. Based simply on online data, this new machine-learning model was able to produce any kind of writing. And it was the most accurate representation of its kind ever made! The GPT-based chatbots are so advanced, according to Open AI, the company that created the technique, that they can pass the Turing test.
- INTEGRATING BERT MODEL WITH RASA: BERT is an acronym for "Bidirectional Encoder Representations from Transformers." It is a machine learning method based on transformers that Google created for pretraining natural language processing. Jacob Devlin and his Google colleagues developed and released BERT in 2018.In order to understand the context of the statement, BERT uses bidirectional training, which reads the sentence from both directions. Just keep in mind that BERT is an encoder. It is lacking a decoder.

Abstract—Language is the foremost method of human communication which consists of grammar and vocabulary. Language majorly consists of words which are structured in a meaningful way. The natural human language is expressed through speech or writing. A computer is a binary machine i.e., it understands codes which are strings of 0s and 1s aka binary digits ("bits"). Binary Language is also known as Machine Language. A computer does not understand the natural human language. In an endeavour to bring the computers and the humans closer, by allowing a computer to analyse the sentence spoken by a user aka input speech recognition and process what does it mean, Natural Language Processing (NLP) was devised. NLP combines the fields of Artificial Intelligence (AI) and analyticalsyntax so that humans and computers can communicate with each other effortlessly. Today, mobile devices have applications such as Alexa, Siri, among others, that make it easy to do tasks like add activities to a calendar or search for a contact using voice command. All these applications use in some form or another natural language processing and machine learning.

Keywords—LSTM, RNN, Bidirectional, Embedding, English, German, Machine Translation

I. INTRODUCTION

Language is the foremost method of human communication, which incorporates both grammar and vocabulary. On the other hand, a computer understands Machine Language, which are numeric codes in the form of algorithms. Machine Language allows a computer to directly execute operations. These codes or algorithms are strings/combinations of 0s and 1s aka bits. A computer cannot understand the human language in its natural form.

To overcome the gap between the machines and humans, Natural Language Processing (NLP) was devised. It enables a computer to process the input speech recognition and analyse what the user stated. NLP combines the fields of computational linguistics and Artificial Intelligence (AI) so that both computers and humans can communicate effectively.Today, applications such as Alexa, Siri, among others, in the smartphones have made it easy to do tasks like add activities to a calendar or search for a contact by voice.

To be able to talk with mankind, a computer program should understand grammatical syntax, word meanings or semantics, correct use of tenses aka morphology and conversational pragmatics. Numerous regulations which are to be taken care of are staggering and explains the reasons of failure of previous attempts at NLP. Instead of taking a rule-based approach, of lately NLP has changed its method to a pattern learning based computer programming. Here we have attempted to develop a Machine Translation model that can translate sentences from the given source material into other language, without human intervention. We have taken sentences of German language as database which is to be converted into English language and vice-versa. The idea behind this project is to allow the two parties to communicate and exchange ideas from different countries.

II. LITERATURE REVIEW

For translation of text or speech among different set of languages, Machine Translation (MT) was devised. It uses software which substitutes word in one language with an equivalent word in the target language. Results produced with this approach were not satisfactory, as at times an appropriate word match might not be available in the target language. Also, a single word, depending upon the context, may have multiple meanings.

To overcome this issue, modern machine translation took a holistic approach. Here an attempt has been made to check whether there is meaningful translation of the entire sentence from one language to another rather than simple mechanical substitution of words. It analyses the influence of all the text elements and words on one another.

Machine Translation models are found to give the best results in domain or occupation specific test samples, as it reduces the scope of allowable substitutions.

A. *Machine translation origin*

The origins of machine translation can be found in the works of Al-Kindi, a ninth-century Arabic cryptographer who developed methodology for systemic language translation, which included cryptanalysis, frequency analysis, probabilityand statistics, all used in modern machine translation.

On the 7th January 1954 the IBM-Georgetown experiment was conducted in which an IBM machine translated 60 sentences from Russian to English for the first time in the history. To advancing research in the field of machine translation, researchers continued to get together by making forums like Association for Machine Translation

DOI: rp-9788770040723.087

and Computational Linguistics was formed in 1962. The French Textile Institute used Machine Translators to translate abstractsvarious languages like French, English, German and Spanish in the 1970s. Brigham Young University began a project to translate Mormon texts using automated translation in 1971.

In the research done by M.D.Okpor[11] it is evident that more innovations were included as the time passed. In 2012, Google made a pathbreakingannouncement that Google Translatetranslates roughly enough words to fill 1 million books in one day.

B. *Machine translation methods and techniques*

i) *Statistical machine translation*

Statistical machine translation or SMT is a machine translationmodelwhere language translation is done using the statistical probability of the words, which are extracted from the analysis of multi-language texts. Warren Weaver in 1949, first thought of statistical translation models,including the idea of applying Claude Shannon's information theory to the model. Statistical machine translation produces translations using statistical methodsas probability, mean, mode, variance, standard deviation et ceterabased on multi-language text collections. When such compilations are available, good results can be achieved translating similar texts.However, such collections arerare for many language pairs. Though, newer approaches into Statistical Machine translation such as METIS II and PRESEMT use minimal collection sizes. Theyfocus on derivations of semantic structure with the help of pattern recognition that prediction of words. With some additional development, these techniques allow for SMT models to operate off a monolingual text compilation. SMT's biggest flawis thatit depends on large amounts of parallel texts to learn. It faces problems with linguistic-rich languages and is oftenunable to correct errors with single words.

C. *Neural machine translation*

Deep learning-based approach to MT, neural machine translation has made great progress in machine translations overtaking the SMT as the primary commercial way of machine translation. In this model, the word sequence modelling is first accomplished using a recurrent neural network (RNN). A bidirectional recurrent neural network, also known as an encoder, is used by the neural network to encode a source sentence whereas for second RNNa decoder,is used to predict words in the target language. RNNs, however, face difficulties in encoding long inputs into a single vector as shown by D.Bahdanau [14]. Itwas compensated by a mechanismthat allowed the decoder to focus on different parts of the input while generating wordsfor the output. NMT has become a widely used technique for machine translation, and other related NLP tasks such as dialogue, parsing, and summarization.To address the multi-word expression translations like idiomatic phrases, and low-frequency words, language-focused linguistic features have been used in state-of-the-art neural machine translation (NMT) models as mentioned by F.Meng[12]. Through his research C. Kobus[7] has showed that the neural machine translation (NMT) as a methodology for machine translation has led to astounding improvements in machine translation, particularly in terms of human evaluation, compared to statistical machine translation (SMT) systems.

III. MATERIALS AND METHODS

A. *Sample Data*

We have data from News commentary Ion the same topic in German and English. We will also use Europarl V7 and Common crawl in German and English. We will use this data to train two models:

1) English to German
2) German to English

These two models will be incapsulated in a layer where the user can select which model to use. We would use different NMT methods such as RNN, LSTM, Bi-directional RNN, Bi-directional LSTM, Bi-directional RNN with embedding and Bi-directional LSTM with embedding. This is done so as to evaluate the performance of various Neural Network algorithms to find the algorithm best suited for the task. We will define the Neural networks in functions so we can initialize two objects. One object shall handle English to German translation and the other will handle German to English translation. Ouraim is to make an application that is an End-to-End translator which has the most optimum performance.

B. *Exploratory Data Analysis*

We have 3 sets of files in English and German each. Each data set contains about 2 million sentences.Sentences from each dataset are cut into 300 sentences each, to get a smaller training set which has 900 English sentences and 900 German sentences. This now is usedto train the neural networks. This is done as to limit the size of the dataset and ensure it can work on a machine with a limited computing capability. The different datasets are combined into respective English and German datasets to provide a consolidated dataset. We first read these files into lists to clean the data and perform tokenization. In general pre-processing, we make all the data in lower case, remove the spaces at front and back of the dataset and remove the punctuation marks. Further pre-processing is required to make sure that each index of the list contains a sentence. In the second pre-processing, we tokenize all the words of the sentence and get a tokenized sentence and a tokenizer. The tokenizer is a list of all the words of the language with their corresponding id number. This helps to give a numerical value to words and helps in putting the file in translator. We define two tokenizer an English Tokenizer and a German tokenizer.

DOI: rp-9788770040723.087

Fig. 1. Data after Pre-processing

C. Base Model and Architecture.

We have used RNN models, LSTM models, Bidirectional RNN models, Bidirectional LSTM models, Bidirectional RNN Models with Embeddings and Bidirectional LSTM Models with Embeddings. We made the models as functions that can be used to define separate models for both English to German and German to English translation using the same model definition function. We trained the model to 20 epochs, for each model the optimizer is Adam with a learning rate as 0.1.Sparse Categorical Cross-entropy has been used as loss function. The models do not have a lot of layers. This is done to ensure that the models can even work on the limited computing power. We are using a GRU layer and Time Distribution layer in RNN. An Embedding, LSTM and Time Distribution layer in LSTM. A bidirectional layer, GRU layer and Time Distribution layer in Bidirectional RNN. A bidirectional layer, LSTM layer, Repeat Vector layer, LSTM layer and Time Distribution layer in Bidirectional LSTM. An Embedding Layer, bidirectional layer, GRU layer and Time Distribution layer in Bidirectional RNN. An Embedding Layer, bidirectional layer, LSTM layer, Repeat Vector layer, LSTM layer, three dense layers with ReLU activation and one dense layer with Sigmoid Activation layer and Time Distribution layer in Bidirectional LSTM.

```

Fig. 7.Bidirecteional LSTM with Embeddings

IV. Results

The LSTM model was the most accurate model. However, it suffered from overfitting. The rest of the models struggled to learn from the given datasets and were unable to give any predictions. To improve the model, we need a larger dataset with more computing power, which is possible with the use of cloud computing, to increase the model accuracy. The model needs to be deployed on Cloud services to use the optimum infrastructure available for translation and be available on demand. Cloud services can help the model to be accessible anytime. Using the cloud infrastructure will increase the speed of translation as well as the speed of processing training data. Cloud infrastructure also helps in multiple users using the model at any given point of time. We can then use this data to further increase the accuracy of the translation. Analysing the user base, we can optimise the model to be more available in regions where the model is used the most.

V. Discussion And Conclusions

The above results illustrate the need for bigger datasets and as a result increase in computing power. This could be done on the cloud where the computing power is available on demand. The increased computing power will allow us to feed more data into the model leading to better learning and accurate predictions of the model. Using cloud infrastructure, we can also make the application be accessible anytime and anywhere. This results in multiple users accessing the application at a time. Increase in user base can then be further used to feed more data to the model and further increasing accuracy.

Also, from the available models, the LSTM model is the most preferred although it suffers from overfitting.

***Abstract*—This paper aims to study influence of social media in Indian elections to forecast the mood of the public. Taking the Gujarat election of 2022 as a case study, the paper attempts to gauge, what is the public sentiment in social media (twitter in this case). It attempts to understand public opinion and sentiment towards political figures, parties, policies, and events. It attempts compare the actual election result output with the model prediction. During the study Twitter data was extracted for certain hash tags to extract domain data. The different process like, natural language processing (NLP) and sentiment analysis are used to determine the emotional tone of any tweet relates to a particular hashtag. The goal of sentiment analysis was to classify tweets into different categories such as positive (In favor of ruling party), negative (not in favor of ruling party), or neutral, based on the text of the tweet. Attempts were made to implement a model using Transformer based model for sentiment analysis. The steps for the same is described in this paper.**

***Keywords*—Gujarat Elections 2022, Forecasting, Bagging, Boosting, AFINN, Sentiment Analysis, Natural Language Processing.**

I. Introduction

Sentiment analysis is the method of identifying the mood or sentiment of a the text content. It classifies the words or combination of words as positive, negative or neutral sentiment in text. It's regularly utilized by businesses to come across sentiment in social facts, gauge emblem recognition, and apprehend customers. It makes a specialty of the polarity of a textual content (advantageous, neutral, bad) but it additionally goes beyond polarity to discover specific feelings and feelings (irritated, glad, unhappy, and so forth), urgency or even intentions[1]. Depending on how we need to interpret customer comments and queries, we can outline and tailor your classes to meet our sentiment evaluation desires.

Social media has become a powerful tool in the political domain, allowing political candidates and parties to connect with voters and promote their agendas. Social media analytics, the practice of analyzing social media data[3] to extract meaningful insights, has become an essential tool for political campaigns. It offers a way to measure sentiment, identify trends, and gain a deeper understanding of voters' preferences and behaviors.

One of the primary applications of social media analytics in the political domain is sentiment analysis. By analyzing social media content, such as tweets, posts, and comments, sentiment analysis can provide insight into how voters feel about a particular candidate or issue. This allows political campaigns to adjust their messaging and outreach strategies accordingly.

Another application is social network analysis, which can identify influential users, communities, and networks. By understanding the structure and dynamics of social networks, political campaigns can target their messaging to key influencers and amplifiers, who can help spread their message to a broader audience.

Social media analytics can also provide insights into voter demographics and behaviors. By analyzing social media data, political campaigns can identify patterns in how voters engage with different types of content, such as videos, images, and articles. This information can be used to optimize content and messaging for maximum impact.

In present times, humans express their feelings and thoughts more freely than ever. As a result, sentiment analysis has become an essential tool for monitoring and identifying sentiments across various forms of data. By automatically analyzing consumer feedback, such as survey responses and social media conversations, businesses can determine what satisfies or frustrates their customers[2]. This facilitates the customization of products and services to better meet customer needs.In this paper, we would be focusing on the sentiment analysis of twitter data on the backdrop of certain Assembly elections in India. We would explore whether the data conveys positive, negative or neutral sentiments towards a political party prior to elections. We would be exploring Machine Learning techniques to understand how to utilize twitter data to analyze the sentiment and give insights for political parties on how to improve their public appeal.

The future scope for social media analytics in the political domain is immense. As social media continues to play an increasingly significant role in politics, the need for advanced analytics tools and techniques will only grow. Here are some potential areas for future development:

DOI: rp-9788770040723.088

Predictive Analytics: Predictive analytics involves using machine learning algorithms to forecast outcomes based on past data. In the political domain, predictive analytics could be used to forecast election results, predict voter behavior, and identify emerging trends.

Real-time Analytics: Real-time analytics allows for immediate insights into social media conversations. In the political domain, real-time analytics could be used to monitor political events, track sentiment, and identify emerging issues.

Personalization: Personalization involves tailoring content and messaging to specific individuals or groups. In the political domain, personalization could be used to target specific demographics, such as age, gender, or location, with customized messaging and content.

Ethical Considerations: As social media analytics becomes more advanced, there will be increasing ethical considerations around the use of personal data[4] and privacy. Political campaigns will need to be transparent about how they are using social media analytics and ensure that they are not violating individuals' rights.

In conclusion, the future scope for social media analytics in the political domain is promising. As technology continues to evolve, new tools and techniques will emerge, providing political campaigns with even more advanced insights into voter sentiment, behavior, and preferences. However, ethical considerations will need to be at the forefront of development to ensure that social media analytics is used responsibly.

II. Literature Review

A. *Ensemble Learning*

Ensemble Learning is a technique based on combining multiple classifier algorithms to produce an output that has greater accuracy in the text classification in comparison to using these algorithms individually for the same task. Ensemble approach is found to improve the accuracy of individual classifiers using methods like Bagging, Boosting, Stacking and Voting.

Bagging: It is short for Bootstrap Aggregating, is a commonly used ensemble method in machine learning that enhances the accuracy of a single model by merging the predictions of multiple models. The Bagging technique works by generating multiple sub-samples of the training data, obtained by randomly selecting instances from the data with replacement, and then training a distinct model on each sub-sample.

Boosting: It is an ensemble learning technique in which multiple weak learners are combined to create a single strong learner. Unlike bagging, which creates independent weak learners, boosting uses a sequential approach in which each weak learner is trained to focus on the mistakes of the previous weak learners. The final prediction is made by combining the predictions of all the weak learners, with more weight given to the predictions of the stronger learners.

Stacking: It is an ensemble learning technique that combines the predictions of multiple base models using a meta-model, or "stacking model". The basic idea behind stacking is to train several diverse base models that have different strengths and weaknesses, and then use a meta-model to combine their predictions. The stacking process involves splitting the training data into two or more sets, where the base models are trained on one subset of the data and the meta-model is trained on another subset. The base models can be of different types and can use different learning algorithms, while the meta-model is typically a simple model, such as linear regression or logistic regression, that is trained on the predictions of the base models.

Voting: It is an ensemble learning technique that combines the predictions of multiple base models by taking a majority vote. The idea behind voting is to train multiple diverse base models, each of which makes predictions on a given set of inputs, and then use a voting scheme to combine their predictions into a final prediction. In binary classification problems, voting can be done by taking a simple majority vote, where the class that receives[5] the most votes is chosen as the final prediction. In multi-class classification problems, voting can be done by taking a plurality vote, where the class with the highest number of votes is chosen as the final prediction.

B. *Deep Learning*

Deep learning is a subset of machine learning that is characterized the use of neural networks with multiple layers. In traditional machine learning approaches, feature engineering is often a critical step, where features are manually defined and extracted from the input data. However, in deep learning models, features are automatically learned and extracted from the data during the training process. This is achieved by passing the data through multiple layers of nonlinear transformations, which allows the model to learn more complex and abstract representations of the input data.

Deep Neural Networks (DNN): This is a type of artificial neural network (ANN) that incorporates multiple hidden layers between the input[6] and output layers. These hidden layers enable the network to learn intricate and abstract representations of the input data. A typical DNN architecture includes an input layer, one or more hidden layers, and an output layer. Each layer comprises a group of interconnected neurons that are linked to the neurons in the adjacent layers. The neurons perform nonlinear transformations on their inputs using activation functions, generating outputs that are transmitted to the next layer.

Convolutional Neural Networks (CNN): This is type of deep neural network that is particularly suited for video and image recognition tasks. It is designed to automatically learn spatial feature layers from raw inputs such as pixels in images. CNNs are designed to automatically learn and extract features from raw image data without manual feature engineering. A key feature of CNNs is that they use convolutional layers. A convolutional layer consists of a set of filters[7], each filter being a small matrix of weights. These filters are applied to the input image in sliding window mode to compute the dot product between the filter and each local input region. The result of the convolution operation is a series of feature maps representing the presence of different patterns or features in the input image.

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.088

Recurrent Neural Networks (RNN): Recurrent Neural Networks (RNNs) are a specialized type of deep neural network that excel at processing sequential data, such as time series or natural language text. Unlike feedforward neural networks that treat each input independently, RNNs maintain an internal state that enables them to capture the temporal dependencies of the input sequence. The distinctive characteristic of RNNs is their utilization of recurrent connections, which enable information to be propagated from one time step to the next. At every time step, the input is combined with the prior hidden state to produce a new hidden state. This operation is executed for each time step in the sequence, and the final hidden state is utilized to generate a prediction. This concept was introduced by Hochreiter and Schmidhuber in 1997.

C. *Transformer Architecture*

Transformer-based models have revolutionized the field of natural language processing (NLP) by outperforming previous state-of-the-art models on a wide range of NLP tasks, including sentiment analysis. In a transformer-based model, the input text is first transformed into a sequence of embeddings, which capture the meaning of each word in the text. The embeddings are then processed by a series of transformer layers, which learn to model the relationships between the words and their context.

During training, the model is fed a large dataset of text that is labeled with their corresponding sentiment. The model learns to predict the sentiment of the text by adjusting the weights of its parameters to minimize a loss function. Once the model is trained, it can be used to predict the sentiment of new text by feeding it through the same process of embedding and processing. The output of the model is a probability distribution over the possible sentiments, which can be used to determine the most likely sentiment. Overall, transformer-based models have shown to be highly effective in sentiment analysis and have achieved state-of-the-art results on several benchmark datasets.

A pre-trained model named "distilbert-base-uncased-finetuned-sst-2-english" was used.DistilBERT-base-uncased-finetuned-SST-2-English is a pre-trained language model developed by Hugging Face that is based on the BERT architecture. It has been fine-tuned on the Stanford Sentiment Treebank (SST-2) dataset for English language text classification. The model uses a smaller and more efficient architecture compared to the original BERT model, which makes it faster and easier to deploy on devices with limited computational resources.

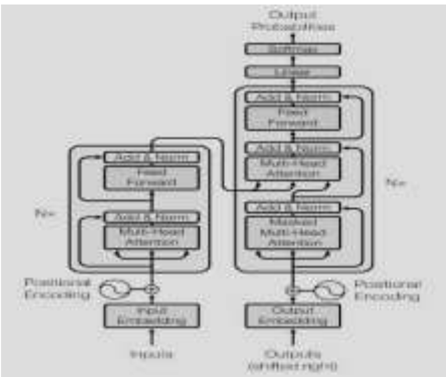

Fig1. Steps in Transformer Architecture

Advantages of Transformer Architecture

Large Vocabulary: Transformer models can learn to understand a much larger vocabulary, which allows them to capture the sentiment of text that contains words that are not included in a pre-defined word list.

Context Awareness: Transformers can consider the context in which words are used, which can lead to more accurate sentiment analysis.

Cultural Relevance: Transformer models can be trained on text from multiple cultures and languages, making them more suitable for sentiment analysis in a global context.

Up-to-date: As transformer models can be re-trained on new data, they can adapt to changes in language usage and sentiment over time.

Sophisticated Methodology: Transformers are a complex type of deep learning architecture that have demonstrated exceptional performance in numerous Natural Language Processing (NLP) tasks, such as sentiment analysis, surpassing previous state-of-the-art results.

III. MATERIALS AND METHODS

A. *Dataset*

With the advent of a wide range of social media applications, there are millions of data generated which involves a wide range of topics across the globe. It is observed that people are more vocal about their opinions on the social media platform. Twitter is one such platform which serves as bridge between common people and the authorities involved in the governing body.

Recently we have seen surge in the usage of twitter by political parties to orchestrate their political campaigns and to reach out to people to every corner in the country. People are becoming more and more vocal about their political opinions which gives us an immense opportunity to mine these data points and try to arrive at some conclusion based on people sentiments.

This research involves the study of Twitter data associated with Indian State elections conducted during 2023.The study aims to analyze and understand the sentiments and opinions of people through their twitter comments.

B. *Model Building : Steps*

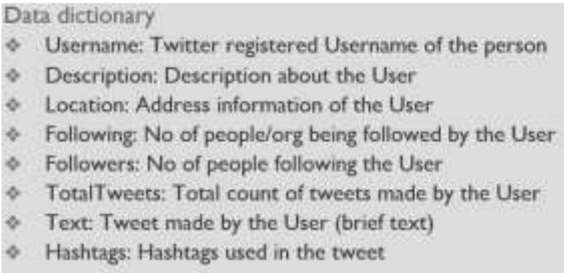
1. Data extraction using Twitters APIs
2. Data understanding through data dictionary
3. Tokenization
4. Data preprocessing
5. Data Encoding
6. Sentiment Analysis using Transformer Architecture (DistilBERT base uncased finetuned SST-2)

C. *Sample Dataset*

As for initial model, sample dataset containing 1212 tweets were taken which are associated with Gujarat State election. The dataset used is extracted from Twitter using the hashtag #gujaratelections2022

DOI: rp-9788770040723.088

Fig. 2. Sample Tweets



Data dictionary

- Username: Twitter registered Username of the person
- Description: Description about the User
- Location: Address information of the User
- Following: No of people/org being followed by the User
- Followers: No of people following the User
- TotalTweets: Total count of tweets made by the User
- Text: Tweet made by the User (brief text)
- Hashtags: Hashtags used in the tweet

Fig. 3. Standard Data Dictionary for Twitter Extract

D. Data Pre-processing

The twitter data is unstructured and it contains a lot of noise and unwanted information. Data pre-processing is required to filter out such noise and unwanted information. Further, it simplifies the vocabulary used for analyzing sentiments from the tweets. The model will use different data prepossessing techniques such as Tokenization, Lower case conversion, Stop words removal, Punctuation removal,Stemming,Lemmatization and Parts of Speech Tagging.

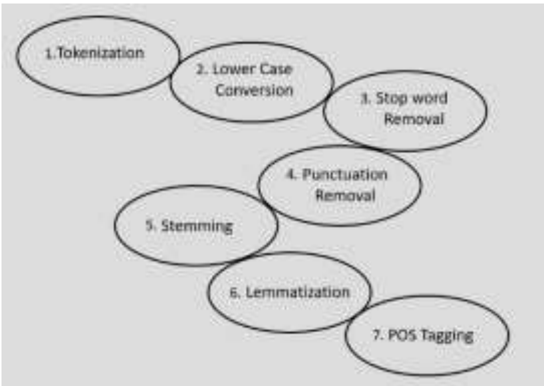


Fig. 4. Data Pre-Processing Steps

Encoding Techniques: Encoding techniques refer to methods used to represent data in a format that can be easily processed by a computer system. Techniques like Bag of Words, Binary Bag of Words, Bigram, Ngram, TF-IDF(Term Frequency-Inverse Document Frequency) are being utilized in this study.

Fig. 5 Encoding Steps Used

IV. RESULTS

This model reaches an accuracy of 91.3 percent on the development corpus from which it was trained. This reduces our training time drastically instead of training the model fresh from start using our data. The model output shows that the sentiment of the people is positive towards the ruling party in the State of Gujarat during 2022 India State Elections.

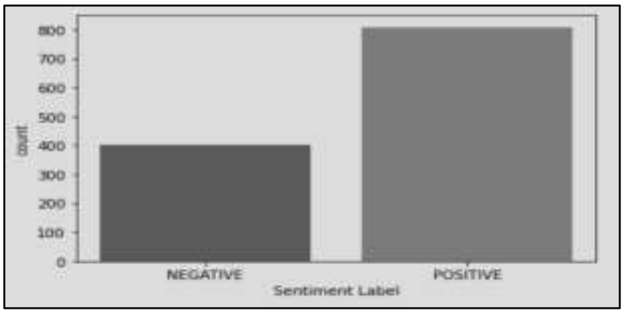

Fig. 6. Sentimental Labelling

The bar graph shows the distribution of the tweets after applying the sentiment analysis using Transformer model (distilbert-base-uncased-finetuned-sst-2-english). Majority of the comments in this dataset convey positive sentiment towards the ruling dispensation.

On analyzing the most frequently occurring words in the set of positive tweets, we found that there is a generic positive sentiment towards 'amitshah' (as shown in word clouds below).

Fig. 7.Positive (In favor of ruling Party) tweets WC

The above word cloud captures the basic sentiments of the Tweets, that were identified as supporting the Ruling dispensation prior to the 2022 election. The words like Choose and Amit Shah were repeated multiple times.

DOI: rp-9788770040723.088

Fig. 8. Negative (Against ruling Party) tweets WC

The above word cloud captures the basic sentiments of the Tweets, that were identified as opposing the Ruling dispensation prior to the 2022 election. The words like change and Shah ignored were repeated multiple times here. However, the word cloud for Negative comments also have used words like Amit Shah Magic and Shah for Gujarat, which in a way also conveys positive sentiment. Hence Word Cloud is not a apt representation for Negative Sentiments as such.

V. Discussions and conclusions

A. Conclusion

Through this study it is concluded that Transformers models have been shown to be very effective in performing sentiment analysis of social media data. Social media platforms like Twitter, Facebook, and Instagram generate huge volumes of text data that contain a wide range of sentiments, opinions, and emotions. Transformer models excel in handling this type of unstructured and noisy text data because they can capture complex relationships between words and their context, as well as handle variations in sentence structure and grammar.

The results indicate high positive sentiment towards ruling political party.The influence of Third-Party Social Media Agencies and paid tweets has the potential of introducing a bias in the final outcomes. Techniques and Methods to identify and eliminate this bias is an opportunity, that can be considered as a future scope.

Abstract—Cost prediction for customer acquisition is a very significant assignment because it has evolved into a critical business metric that aids companies in determining the resources they will need to continue to expand and acquire new clients. So, customer acquisition cost is the sum of money that a business pays to bring on a new client. Nevertheless, developing an appropriate cost prediction model for customer acquisition is not a straightforward process because there are numerous independent variables in both the presented Food Mart X data set and real-world situations, as well as numerous categorical data with high cardinality. The hardest challenge that draws the attention of researchers and practitioners is estimating the required cost.

In order to estimate the cost of acquiring a customer, this paper uses a machine learning approach. The findings demonstrate that, in comparison to conventional estimating methods, machine learning techniques may be utilised to anticipate Cost on Acquiring Customers with High Accuracy Rate.

The proposed model in this research was trained on the Food Mart X data set, having the records of 48k customers. An analysis of the results of the implementation for the proposed methods showed that the cost Predicting process using Decision Tree algorithm (DT), Random Forest algorithm (RF) and Bagging Forest algorithm (BF) has the ability to predict the costs required to acquire the customer. Out of those, Random Forest algorithm (RF) has shown highest accuracy inpredicting the required cost to acquire customer compare to decision tree and bagging method. Literature also shows the development of neural network model for predicting the cost but it's not cover here in this study.

Keywords— Decision Tree (DT), Random Forest (RF), Bagging Forest (BF), Deep learning neural Network (DNN), Root Mean Squared Error (RMSE).

I. INTRODUCTION

Customer Acquisition cost is being vastly used by the business to improve the vision and positioning of the resources and capital. "Even in well-managed organisations, there can be a high level of client churn," it has been noted. We must find replacements for these lost clients.Clients could leave as they get older and move through the family life cycle. If their personal circumstances change and they no longer require or appreciate your product, we could lose our current clientele. These unpredictable reasons of client loss suggest that customer acquisition will always be required to replace natural attrition. Hence in today's world, there is a need of accurate model through which a businessman can simulate those condition and can able to forecast the cost. These types of models can be used at various places such aspredicting the cost of goods, raw material, commodities such as steel price etc as these prices directly hit the final product prices as well the overall business.

II. RELATED WORKS - LITERATURE SURVEY

Regression analysis, which is nothing more than a statistical approach used to assess the relationship between a dependent/target variable (here, the cost of customer acquisition.) and one or more independent (interdependent) factors, may generally be used to create cost prediction tasks.

Cost forecasting is typically carried out using descriptive, predictive, and prescriptive analytics.

*Descriptive Analytics:*Statistical techniques used in descriptive analytics [19] include data gathering, analysis, interpretation, and presenting of results. In essence, this form of analytics aids in determining what occurred.

*Predictive analytics:*In the context of price predictions, predictive analytics [19] involves analysing recent and previous data to estimate the likelihood of upcoming occurrences, outcomes, or values. Many statistical methods, including machine learning and data mining (the detection of patterns in data), are needed for predictive analytics.

A. Cost Prediction methods and techniques

The development of considerably more efficient and precise predictive algorithms has been made feasible by the developments in statistics during the past 20 years. What potential uses are there for cost modelling and estimation?

Traditional Costing Models

DOI: rp-9788770040723.089

1. ***Analog Method:***

By evaluating similar products that have been manufactured or purchased in the past, this method calculates the cost of a new product. Although this strategy is unreliable, it can be utilised in very early stages (such as a feasibility study) when the details of the project or service are unknown. In this study, we won't linger on this kind of fundamental estimate.*Analytical Method*

By simulating the industrial production process, it calculates a product's cost. This approach is based on the product's cost structure, and it estimates each intermediate component using the materials & components used, the process costs (labour and machine), as well as any additional structural expenses.

This kind of approach necessitates a thorough understanding of the subject; thus it occasionally fails when particular precautions are not taken or when methods are changed abruptly.

2. *Parametric Method*

This technique uses statistical modelling to determine the price of a good or service. This method models the evolution of the cost as a function of specific factors known as "cost drivers" by using historical data from similar goods and services to build equations or statistical laws.

These models are typically based on regressions that are linear, multilinear, polynomial, or logarithmic.

- Major problems with this type of method are as below:They don't handle missing data well, so highly clean databases are needed.
- They manage "breaks" or threshold effects ineffectively. Because the manufacturing process can change, the price, for instance, may behave linearly up to a certain point before drastically changing (size, weight, volume, etc.).

3. *Non-Parametric Method*

The shortcomings of conventional parametric approaches have mostly been resolved by the advancements made in the fields of algorithms and machine learning, which have also improved their performance and scope of application.

The "random forests" approach, which Leo Breiman and Adèle Cutler formally proposed in 2001 (Breiman, L., Random Forests. Machine Learning. 45, 5-32 (2001)) is a statistical method. nonparametric that uses "Bootstrap" approaches to create numerous decision trees that are trained on slightly different data subsets.

In both regression and classification, Pierre Geurts [2] introduced and described how bias-variance trade-off is accomplished. The bias and variance of the statistical model are significantly influenced by the choice of variables and attributes.

In order to assist farmers in predicting the amount of rain that will fall, Wanie M. Ridwan et al. [1] employed four distinct regression algorithms: Bayesian Linear Regression (BLR), Boosted Decision Tree Regression (BDTR), Decision Forest Regression (DFR), and Neural Network Regression (NNR).

A. Krishna et al. [2] attempted to identify the best algorithm by using various machine learning techniques to predict the sales of a retail store. They used both conventional regression approaches and boosting techniques, and discovered that the boosting algorithms produced superior results to the conventional regression algorithms.

Based on a number of independent variables, a regression model is used to forecast or predict the value of the dependant variable—cost.With the evolution of Machine Learnings and advancement in internet speeds, Machine learnings are now being extensively used to predict the continuous numerical as well classification problem. The two giant E-commerce Industry- Amazon &Flipkart are extensively using the machine learning algorithms in predicting their customer acquisition cost.

B. Machine Learning Algorithms focussed here are as follows:

1. Decision Tree Regression
2. Random Forest
3. Bagging Forest

Some of the case studies has been done for improvement of sales forecasting problems by Deep Neural Network also.

III. Proposed Work

A. Materials and methods used

This dataset has sourced from https://www.kaggle.com/datasets/ramjasmaurya/medias-cost-prediction-in-foodmart. It contains the information regarding demographics of existing customers. This dataset has two files, one for training (36,256 rows & 41 columns) and other for testing (12086 rows & 41 column). Also, one additional file was provided, which contain information about feature values and their description.

In these features, Cost is a dependent variable and the remaining features are called as independent variable. Here we need to predict the value of dependent variable using independent variable. For validation of model in the last, we have created a validation data set from the training data set.

From the literature survey & preliminary study, we applied following 3 regression models on the dataset:

1. Decision Tree Regression
2. Random Forest Regression
3. Bagging Forest Regression.

IV. Implementation

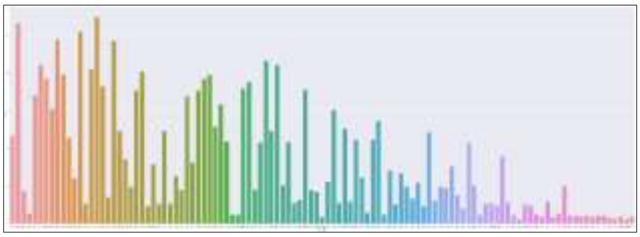
A. Dataset, data collection, data pre-processing

After collection of datasets- we started to understand the datasets. During data pre-processing, we faced challenges like “high Cardinality”, “Non-Linearity”, “Collinearity” as these data set has 16 categorical type data. Out of these 16 categorical data, 6 categorical data have a high unique value, such as., “Media Type”, “Store City”, “Brand Name”, “Promotion Name”, “Food Department”, “Food Category” thus suffering from high cardinality issue.

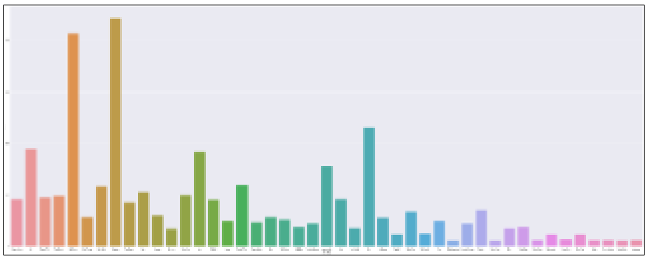
DOI: rp-9788770040723.089

Some of the categorical type data count plot has been plotted to understand the curse of dimensionality which are as follows:

1. Brand Column Count plot is as follows to shows the number of unique values:

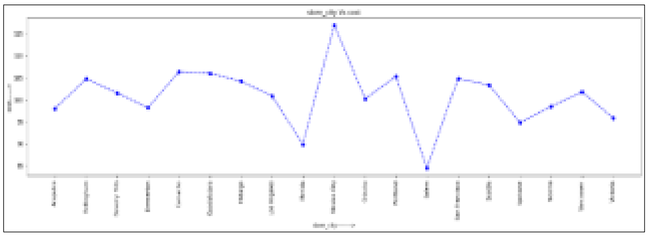


2. Similarly, food column category count plot is as follows:

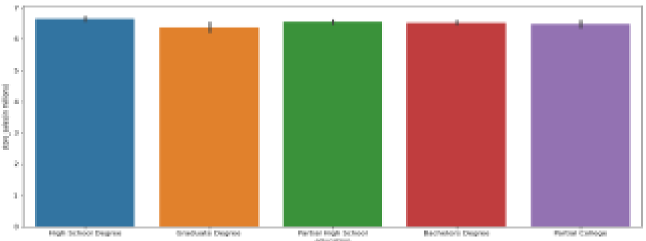


Through “One Hot Encoding” – when have converted all these categorical types data & it leads to final 298 column leading to large dimensions. We have also tried to check the relation between dependent and independent columns. Some of the relation is as follows:

- *Relation between Store city and Cost*



- *Education vs Cost*



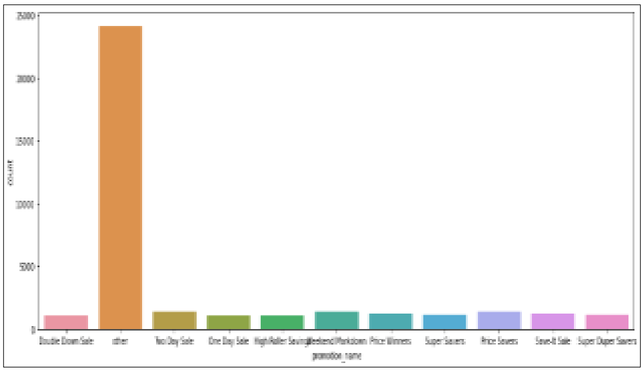
To reduce the dimensions, we have also calculated another attributes from some of the related columns, for e.g., we have calculated & made a new column for “Profit” from the two given columns namely store_sales& store cost to overcome the problem of large dimensions.

B. Exploratory Data Analysis and Evaluation of Models

1. EDA for Analysis-1:

Model has been made using only Top 10 features & grouping rest into “OTHERS”. Thereafterconverting Category data to numerical type using Label encoders.

- Top 10 features for Promotions is as below:



- Top 10 features for Food Department is as below:

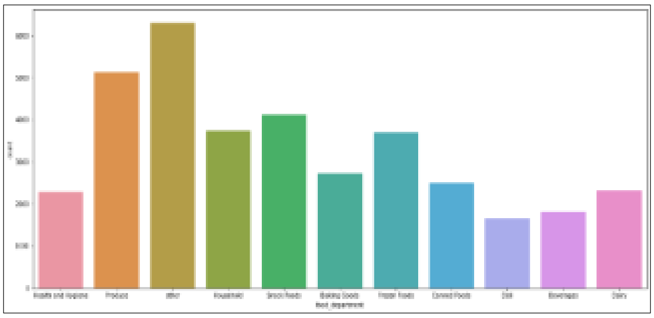


TABLE-1: RMSE AND SCORE FOR ANALYSIS-1

Model	**Test RMSE**	**Train RMSE**	**Test R2 Score**	**Train R2 Score**
Decision Tree	28.22	28.18	0.11	0.11
Random Forest	14.60	7.41	0.76	0.93
Bagging	15.11	7.95	0.74	0.92

Result of test score for both random forest and Bagging reveals that the model is overfitting. Overfitting might happen due to the high variance which might have introduced. Hence another analysis is envisaged where instead of label encoding, one-hot encoding shall be applied.

Joint Plot for analysis-1 is shown in fig 1, 2 & 3:

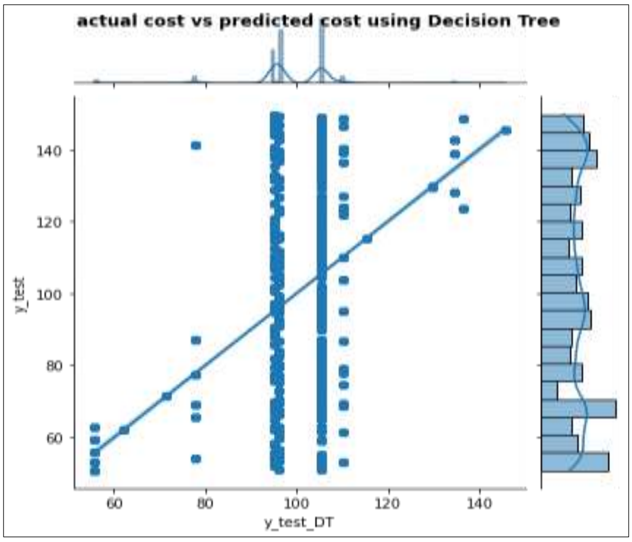

Fig.1. DT Based Model

DOI: rp-9788770040723.089

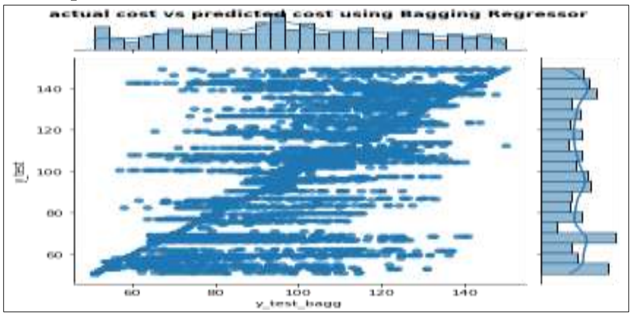

Fig.2. Bagging Based Model

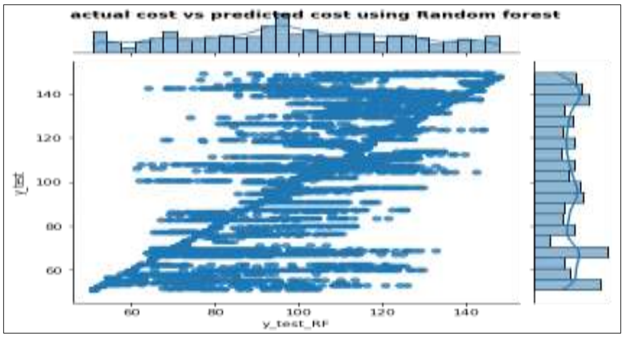

Fig.3. Random Forest Model

2. *Analysis-2*

Model has been made using all features but this time instead of using Label Encoder, One hot encoding has been used to remove the bias error which might have come due to Label encoder in Analysis-1.

Results are mentioned under section-5.

However, since frequency encoding was applied on only one feature, it is not sure whether this will work in real life problems as well. So, - Analysis-3 with another method of encoding called as target encoding has been done.

Target encoding involves replacing a categorical feature with average target value of all data points belonging to the category. *Python Code for Target Encoding which shall be used in Analysis-3:*

```
fromcategory_encoders import TargetEncoder
te=TargetEncoder ()
te.fit(X,y)
```

3. *Analysis-3*

Model has been made using all features but this time instead ofLabel Encoder & One hot encoding, “Target Encoding” has been applied on the categorical columns and results were further found to be improved compared to the results of Analysis-2.

TABLE3: RMSE AND SCORE FOR ANALYSIS-3

Model	Test RMSE	Train RMSE	Test R2 Score	Train R2 Score
Decision Tree	1.49	0.34	0.99	0.99
Random Forest	1.18	0.59	0.99	0.99
Bagging	1.38	0.59	0.99	0.99

Joint Plot for analysis-3 is shown in fig 4,5&6:

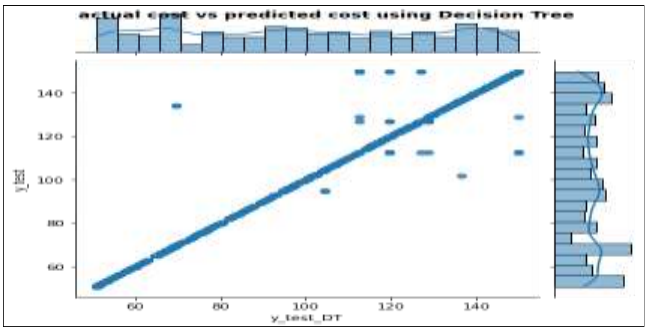

Fig.4. DT Based Model

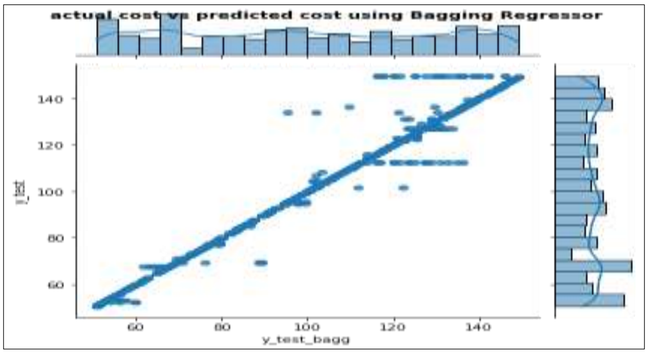

Fig.5. Bagging Based Model

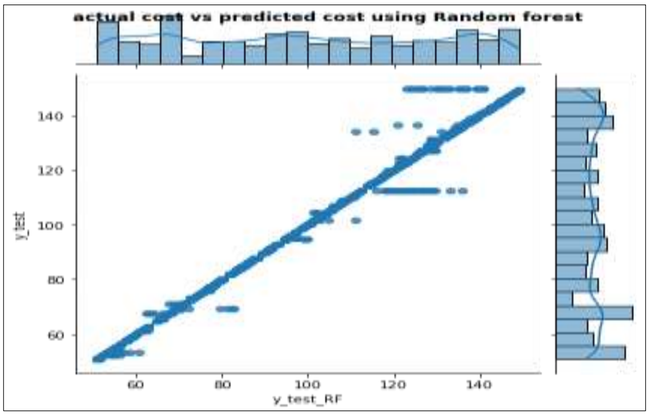

Fig.6. Random Forest Model

V. RESULTS AND DISCUSSION

The methods and procedures utilised for machine learning as applied to observational datasets that can provide information on customer acquisition cost were thoroughly studied and described in this work. The summary of this work does not necessarily apply to all machine learning-based investigations because machine learning approaches have been utilised much more broadly throughout observational studies than in the context of individual decision making. This study focuses on a topic that is still relatively unexplored: how to leverage massive datasets in a way that can enhance customer acquisition cost prediction outcomes.

With the application of Frequency Encoding Technique on categorical column having highest unique values, results improved compare to Analysis-1.

Result of RMSE & Score are tabulated below after the application of Frequency Encoding:

DOI: rp-9788770040723.089

TABLE2: RMSE AND SCORE AFTER FREQUENCY ENCODING APPLICATION ON "BRAND COLUMN" IS AS BELOW:

Model	Test RMSE	Test R2 Score	Train R2 Score
Decision tree Regression	1.52	0.9975	1.0
Random Forest	1.23	0.998	0.999
Bagging Forest	3.23	0.988	0.988

Similarly with the application of Target Encoding Technique on all categorical column, results found even better then Table-2 and has been tabulated below:

TABLE3: RMSE AND SCORE FOR ANALYSIS-3

Model	Test RMSE	Test R2 Score	Train R2 Score
Decision tree Regression	1.49	0.997	0.999
Random Forest	1.18	0.998	0.999
Bagging Forest	1.38	0.997	0.999

VI. CONCLUSION

As can be seen from this study, problem(data) having high number of categorical data and that too with high unique values, then Target encoding is working best among popular encoding method such as Label Encoder and One hot Encoding.

Among the models, after applying the target encoding during pre-processing steps, random Forest model performs well with respect to other model in terms of root mean square error.Performance analysis for all the three-analysis done here are as below:

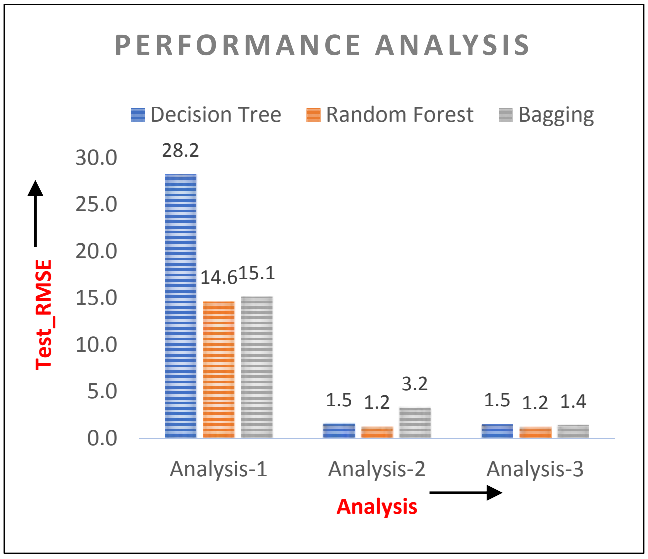

Fig.7. Performance analysis of different models

By doing various analysis, we found out that target encoding works better.

Additionally, seeing the performance of various modelsbeing studied here, Random Forest gives better accuracy compare to other two models. Hence, we propose to use Random Forest with target encoding for such high category type data set in future in predicting the cost.

Yet, as evidenced by our literature review, we believe external validation is also necessary to guarantee model fidelity but is rarely done. There may be a number of causes for this, including a dearth of pertinent datasets or a failure to recognise the significance of external validation. Before applying models to any cost forecast, there is an increasing necessity for external validation as machine learning model development rises.

***Abstract*—The increasing volume of information available online calls for more effective and individualized methods of information management. Recommendation systems address this challenge by providing personalized recommendations to users based on various factors, such as their interests and interaction history. This paper focuses on the development of a conversational chatbot that offers product recommendations and related images based on multiple input features. The chatbot utilizes Term Frequency-Inverse Document Frequency (TF-IDF) vectorization and a linear kernel matrix to generate product recommendations. Unlike traditional recommendation systems, the chatbot employs a conversational interface, resulting in a more human-like and intuitive interaction. The use of natural language processing techniques and a conversational interface provide a novel and improved way to make recommendations, enhancing the overall user experience. Our approach to product recommendations is unique and has the potential to bring a new level of personal- ization and interaction to the recommendation system field.**

Index Terms—Recommendation System, Chatbot, TF-IDF, Kernel Matrix, Deep Learning

I. Introduction

The rise of digitization has led to the transfer of the world's largest movie libraries to online streaming platforms such as Netflix, HBO, and YouTube. These platforms have enhanced their offerings with AI-powered tools that aim to make the task of choosing a movie a more seamless experience for users.

A movie recommendation system is a critical component in enhancing this experience. It is a machine learning-based approach that utilizes data about the user and movies to predict the user's film preferences. The main objective of a movie recommendation system is to provide users with tailored and relevant movie recommendations.

The system operates by treating movies as products and users as the target audience. By utilizing data gathered on users and movies, the system can predict future user preferences based on that information. To generate movie recommendations for users, this recommendation systemer employs a linear kernel similarity matrix and utilizes Term Frequency-Inverse Document Frequency (TF-IDF) methodology within its algorithm.

Treating movie as a product, the paper outlines a movie rec- ommendation system that utilizes machine learning and data analysis techniques. The system's design and implementation are presented, and its performance will be evaluated using a publicly available movie dataset. Additionally, the system will be compared with existing movie recommendation systems. The results of this study will provide valuable insights into the design and development of advanced and effective movie recommendation systems.

II. Related Work

The field of product recommendation has seen a tremendous growth in recent years with the advent of online shopping and streaming platforms. Several experiments have already been conducted to improve the accuracy,effectiveness and speed of product recommendation systems.

The most important and common form of recommendation system is to predict the preference for items which are unseen or even unknown and choosing those with the highest estimation values. The common applications using recommendation systems are music, movies, news, E- commerce sites, travel guides,grocery online dating, books, hotels and restaurant etc. Recommendation systems are broadly categorized as collaborative filtering, contents-based filtering and hybrid approach. Contents-based filtering systems recommends items based on a description of items the user history suggest that user has liked before. Collaborative filtering is a technique that can filter out items that a user might like on the basis of reactions by similar users. Hybrid techniques are the combination of both theseapproaches.

One of the most popular techniques used in product recommendation is Collaborative filtering. The technique uses the idea that users who have similar preferences observed during their shopping experience in the past are likely to have similar preferences in the future too. A number of approaches have been taken to improve the accuracy of collaborative filtering-based product recommendation systems. For example,[1] proposed a neighborhood-based collaborative filtering approach that takes into account the relationship between users and items

DOI: rp-9788770040723.090

to make recommendations. [2] proposed a matrix factorization-based approach that utilizes singular value decomposition to predict user preferences.

Content-based filtering is another popular technique used in product recommendation. The technique is based on the idea that the characteristics of an item can be used to predict the preferences of a user. [3] proposed a content-based filtering approach that utilizes the textual description of items to make recommendations. [4] proposed a hybrid approach that uses the combination of both content-based filtering and collaborative filtering to make recommendations. The approach leverages the strengths of both techniques to improve the accuracy of recommendations.

Recently, deep learning techniques have been applied to product recommendation. [5] proposed a deep neural network- based approach that utilizes user-item interaction data to make recommendations. The approach outperformed traditional collaborative filtering and content-based filtering approaches in terms of accuracy. [6] proposed a graph neural network- based approach that takes into account the relationship between users and items to make recommendations. The approach showed promising results in terms of accuracy and efficiency.

Another hybrid model in [7] has discussed the combination of both collaborative and content based recommendation system is used in to predict the ranks of the users for a set of items by presenting sets of three results—one anecdotal and two statistical in nature —with a small number of users in a controlled experiment . This approach also showed promising results in terms of performance other than bringing two additional benefits. First, the common scaling problems to all Web services are addressed—constantly increasing number of users and an increasing number of documents. Second, it enables enhanced communications and group awareness by automatically identifying the emerging communities of interest in the user population.

Collaborative models have been often used with different perspective for recommendation system. [8] Talks about preference-based graphic models for collaborative filtering that considered the fact that users can have very different rating patterns even if their interests are similar in items.

Two new graphic models were proposed that addresses the differences between user ratings and preferences. In one of the models, called the “decoupled model”, two different variables were introduced to decouple preferences of a user from his ratings. In the other one, called the “preference model”, the orderings OF items preferred by a user were modeled, rather than the numerical ratings of items by the user. Empirical study over two datasets of movie ratings shows substantial and consistent improvement in the performance on appropriately modeling the distinctions in user preferences and their ratings.

Recommendation Systems takes into account the similarities among either the contents or the users who are accessing those contents. There similarity between two items can be measured in several ways. Similarity matrix like correlation matrix is used by the recommendation systems to recommend the next most similar product to the user. In this article, a machine learning algorithm will be built that would recommend movies based on the user likes. This Machine Learning model would be based on Linear Kernel.In recommendation systems, linear kernel is used to measure the similarity between items in the dataset and determine which items are most similar to each other.

A linear kernel is a method used to calculate the similarity between two data points [9]. In recommendation systems, linear kernel is used to measure the similarity between items in the dataset and determine which items are most similar to each other. The Linear Kernel is frequently utilized when a data set has a large number of features. This is particularly the case in text classification where each individual alphabet can be considered a separate feature. Thus, the Linear Kernel is commonly used in text classification to manage the high number of features. Linear kernel is simple to implement and computationally efficient, making it a popular choice for recommendation systems. The linear kernel is combined with the kernel trick to create a powerful tool for measuring similarity in the recommendation system. This helps to improve the accuracy of the recommendations.

In conclusion, there have been numerous studies on product recommendation in recent years, and the field is still rapidly evolving. The above-mentioned works have made significant contributions to the field and have provided valuable insights into the design and development of more effective product recommendation systems. The use of TFIDF and Linear Kernel significantly increase the performance and efficiency.

III. Methodology

A. Data set description

1) *Movies metadata:* Movies metadata.csv is a csv file that contains information about a variety of movies. Each row in the file represents a single movie and contains several columns with data about that movie.

title	ancient	ancient feud	andi	andi birthday	andi heart	andi toy	angel	angel crime

Fig. 1. TF-IDF matrix: Document vs N-gram

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.090

2) *link small:* The ”link small.csv” file in the movie dataset provides information about the mapping between the movie entries in the Internet Movie Database (IMDb) and the TMDb (The Movie Database) for a subset of the movies in the dataset.

3) *credits:* The ”credits.csv” file in the movie dataset provides information about the cast and crew members involved in the production of a movie.

4) *keywords:* The ”keywords.csv” file in the movie dataset contains information about keywords associated with each movie in the dataset.

B. Base Model

For the base model TF-IDF vectorization and Linear Kernel was used [10]. The new column called soup was added, it is a combination of tagline, overview, cast, keywords and director of the movie. The director’s name was repeated thrice in the soup to give it a higher weight-age.

Each row’s soup column is considered as one document which collectively forms the corpus. Then we take as input the string describing the type of movie that the user wants to watch. This input string is considered to be the latest document in the above-mentioned corpus. Next, we apply TF-IDF vectorization to the corpus, which gives us a matrix of TF-IDF vectors for each document. Refer to Fig. 1, which illustrates the TF-IDF matrix where each row represents a document and each column represents an n-gram.

Next, the similarity matrix between every document is calculated using linear kernel [12], since it is shown to provide faster results compared to calculating cosine similarity [11]. This results in a matrix with values between 0-1 where 0 means no similarity and 1 meaning that they are the same . Refer to Fig. 2, which illustrates how the similarity matrix would look. Note that the diagonals are 1 since that represents the document being compared with itself.

Fig. 2. TF-IDF matrix using Linear Kernel

Next, we check the similarity of input string with each document in the corpus and select the top 10 documents with the highest similarity scores. Each one of the 10 documents represent a movie title from our original data-set. We correlate the document to its title and display the top 10 title to the user as the final output.

IV. Results

A. Results of using NLP for the formation of Movie Recom- mendation System

1) *Results of using TF-IDF matrix:* TF-IDF (Term Frequency-Inverse Document Frequency) is used in information retrieval and natural language processing to quantify the importance of individual words in the dataset. TF-IDF is used here to find the most significant words in the movie datset’s descriptions and genres. TF-IDF is also used to compare them with the words according to the user’s preferences.

Here’s how it works:

Term Frequency (TF): Term Frequency helps to represent the frequency of a word in a dataset (movie description or movie genre). A higher value of TF indicates that the word is more important in the datset model.

Inverse Document Frequency (IDF): Term Frequency helps to represent the inverse of the frequency of a word in all the datsets (movies). A higher value of IDF indicates that the word is rarely used and more significant in the dataset.

TF-IDF: The final score is generated by multiplying the TF and IDF scores of a term in the datset. The higher score of the TF-IDF, the more significant the word is in that datset.

By applying TF-IDF to movie descriptions, plots, and genres, we can find the most significant terms (words) that represent each movie and use that information to make recommendations to users. We can then compare the TF-IDF scores of these terms in the user’s preferred movies with the scores in other movies to find the most similar movies and make recommendations.

This approach is useful because it takes into account not only the frequency of words in movie descriptions, plots, and genres but also the significance of those words in the entire movie corpus dataset. This process will help to provide more accurate and personalized recommendations to an user.

Refer to the below figure for the TF-IDF matrix, each row represents a review of a movie and each column is representing n-gram.

Fig. 3. Results of using TF-IDF matrix

2) *Results of using Similarity Matrix matrix on TF-IDF matrix:* A similarity matrix is used on a TF-IDF matrix to measure the similarity between different movies based on their TF-IDF scores. The similarity matrix is a matrix that contains the similarity scores between all pairs of movies in the dataset.

DOI: rp-9788770040723.090

The similarity score is calculated using Linear Kernel Similarity technique. Linear kernel helps to calculate the similarity between two vectors, and it is well-suited for sparse data, like the TF-IDF matrix.

Similarity score between two movie vectors is calculated as the dot product of the movies divided by the magnitude of each movie. The similarity score ranges from -1 to 1, where 1 indicates that the movies are perfectly similar and -1 indicates that they are perfectly not similar.

Once we have the similarity matrix, we use it to make recommendations to users. If a user has watched a movie, we can find the most similar movies to that movie based on the similarity scores and recommend those movies to the user.

In summary, using a similarity matrix on a TF-IDF matrix in a movie recommendation system project can provide more accurate and personalized recommendations to users based on the similarity of the movies' descriptions, plots, and genres.

Figure is how the similarity matrix would look. Note that the diagonals are 1 since that represents the document being compared with itself.

B. *The process of processing the users input*

Next the code check the similarity of input string with each document in the corpus and select the top 10 documents with the highest similarity scores. Each one of the 10 documents represent a movie title from our original data-set. We correlate the document to its title and display the top 10 title to the user as the final output.

The process of processing the users input are as follows: The user's query is parsed to understand the intent behind it and extract relevant information such as movie name, genre, actor, director, release year, etc.

```
[ ] getPredictionsV2("war movies", test1).head(10)

7648                Inception
6218            Batman Begins
8613             Interstellar
3381                  Memento
6981          The Dark Knight
8031    The Dark Knight Rises
8231             Side by Side
Name: title, dtype: object
```

Fig. 8. Prediction of movie where christophernolan presents

For example, "Movies directed by Christopher Nolan" can be recognized as a request for movies directed by the named entity "Christopher Nolan".

DOI: rp-9788770040723.090

By using NLP techniques, a movie search option provides a more natural and intuitive interface for users, allowing them to find the movies they are looking for more easily and accurately.

V. Conclusion

For the Movie Recommendation System, we created a custom corpus of documents where each document represents a movie. We used TF-IDF on this corpus to create the TF-IDF matrix, linear kernel was applied on this matrix to get the similarity matrix. Using this we identified the best movies that are related to the query string entered by the user and recommended these movies to the user. This was done on the basis of different factors such as the tagline, overview and cast of the movie.

TF-IDF helped us identify the most important words having the most context for a given movie, this helped improve our recommendation accuracy. Linear kernel was found to be a fast and effective way to compute the similarity matrix. The results from the recommendation system were found to be satisfactory.

After building the similarity matrix, we extract the top 10 movies with the highest similarity scores with our query string. While this gives us good results most of the time, there are instances when the returned movies are weakly correlated to the query string. This happens because we seldom observe a sharp cutoff in the similarity scores. If we were to make a descending list of similarity scores, ther is a point where the score drops off drastically, typically the movies after this score are not optimal recommendations. We need to do something to give better results in this scenario. One of the options is to detect this cutoff and return only the movies above this cutoff to the user, which can be taken up as future work.

For example when we ask the model ”Give me movies directed by Christopher Nolan”, the model returns 10 movies that best match this criterea. While there is a guarantee that movies directed by Christopher Nolan will be returned, there is no guarantee that the user will be satisfied by the top results. To make this better, once we get the top 10 movies that match the query string, next we can sort the movies within this list based on rating and reviews. This will ensure that a user is more likely to pick one of the recommended movies.

In TF-IDF while considering the scores for each n-gram in a document, we consider the number of times it appears in the current document as well as the number of times it appears in all the documents. In our method, we add the query string as the latest document in the existing corpus and re-calculate the TF-IDF matrix every time we get a new query, this is because the score of each n-gram depends on the whole corpus and every time a new document is added to the corpus, the scores for each n-gram in each document will change. As a possible future work, we can consider certain trade-offs and try to re-use the TF-IDF matrix instead of creating a new one for every query we get.

Given the advancements in AI available to the common man, specifically the emergence of ChatGPT. Instead of looking at this as our competitor, we can try to leverage its capabilities to imporove the quality of our results, which can be take up as future work.

This paper mainly goes over the implementation of ths use of TF-IDF matrix in conjunction with some clever usage of the available data to provide movie recommendations. We have not established a formal method of measuring the metrics of chat based recommendation systems which can bea separate topic by itself. Once we have established a way to measure the metrics, we can try alternate techniques and comapre their results or try to use a combination of them to provide the best results to the user.

After deciding to go ahead in the field of recommendation systems, we went ahead in an attempt to provide a chat bot interface for movie recommendations. The model we used mainly relies on TF-IDF vecotrization and linear kernel method for distance calculation. The model is able to take an input string in the form of a conversational request for a movie. It then recommends the top 10 movies that match the users request. The recommended movies were found to be in accordance with the request that was made by the user. We have identified future work which can potentially further improve the quality recommendations. Using the research and methodology mentioned in this paper, we were able to achieve good results. The methodology used in this paper can be used as a building block to build sophisticated chat based recommendations systems of not only movies, but also any product in general.

***Abstract*— Road accidents are predominantly caused by the distracted drivers and nearly 1.3 million deaths are automobile accidents, of which, drivers are held responsible for 78% of accidents. There are various reasons for driver distractions which are drinking, operating instruments, mobile usage, interacting with fellow passengers etc. For the scope of this project, we intend to develop a model to successfully identify whether thedriver is driving safely or is distracted using a combined dataset from the State Farm Distracted Driver Detection challenge on Kaggle& the AUC (American University in Cairo) Project. Convolutional Neural Network with ResNet architecture was used in developing the model. Grad-CAM technique was used to identify gradients in parts of images which impacted classification of images.Explainable AI can help build better models. This approach was able to provide us with promising accuracy and definite results. Experimental results show that our system achieves an accuracy of 99% on the Kaggle dataset and82% on the AUC data set.**

Keywords—Driver distraction, Deep learning, Convolutional Neural Network, Transfer Learning, Resnet101, GradCAM, Explainable AI.

I. Introduction

The problem at hand is related to the automotive domain. With approximately 1.3 million deaths every year attributed to motor accidents, India accounts for 11% of global death in road accidents [22]. The motor insurance claims in India amounted to Rs. 58456.9 crores in FY 18-19 [20]. Every year, a significant portion of the country's GDP, about 3-5%, is allocated to road accidents [20]. According to [20], drivers are responsible for 78% of all accidents. Distracted driving has become a significant issue worldwide, and it is expected to worsen before improving. Visual distraction refers to taking one's eyes off the road, while cognitive distraction involves losing focus on driving even though physically present. This can happen due to daydreaming, being lost in thoughts, and other similar reasons. Manual distraction is when the driver takes his/her hands off the wheel while driving to perform different actions like drinking,, reaching behind, adjusting the radio, texting, talking on the phone, or conversing with passengers while driving.

We propose to detect such distractions in real time and alert the user to prevent any adversity. This solution can be deployed on an edge device set up on the vehicle to give aninstant alarm and it can also interact through IoT devices to process data and give insights in an asynchronous mode. For the scope of this project, the primary focus is to detect the manual distractions when the driver is not primarily focused on driving and accurately classify these activities which lead to driver distraction, through a highly efficient ML model at runtime using computer vision.

II. Related Work

With the advent of Convolutional Neural Networks (CNN) in the early 2000s, deep learning algorithms have registered significant progress in the domain of image recognition. However, zeroing in on the perfect CNN architecture can still be a very difficult task. Among the many architectures proposed in the past, such as VGGNet, AlexNet, GoogLeNet (i.e., Inception), the deep residual network (i.e. - ResNet) was of help to us in this study. Other architectures like the recurrent neural network (RNN) gives impressive results on time series problems and it is a frequently used algorithm. Also problems involving long sequences such as speech recognition and machine translation.

As far as detecting distracted drivers using computer vision based approaches [1] [2], convolutional neural networks (CNNs) have become the most adopted and popular approach. The Distracted Driver Detection through image classification gained traction with the release of a Kaggle competition by State Farm in 2016. In this regard, YehyaAbouelnaga et al [13] [14] had created a new dataset that is often referred to as the AUC Dataset. This proposed a novel system based on posture estimation and achieved a ~96% classification accuracy. Hong Vin Koay et al. [10] focused on exploring the technique that uses both the original image as well as pose estimation images to classify the distraction. The pose estimation images were generated from HRNet and ResNet. The ResNet101 and ResNet50 architectures are used to classify the original and pose estimation images respectively following which a weighted

DOI: rp-9788770040723.091

approach was followed to arrive at the final classification. This resulted in an accuracy of 94.28% and a F1 score of 94.27% on the American University of Cairo (AUC) Distracted Driver Detection dataset.

Another study by NarayanaDarapaneni et al [1] focused on developing the CNN Method of transfer learning on four architectures namely CNN, VGG-16, ResNet50 and MobileNetV2. The model was trained with images from a publicly available dataset containing ten different posture categories. It was observed that the ResNet50 and MobileNetV2 models provided higher accuracies of 94.50% and 98.12% respectively.

Some studies approached the problem by modifying architecture like the one done by Md. UzzolHossaina et al.[18]. In this study, the VGG-16 Architecture was modified using regularization techniques to improve model performance. According to the results, the system achieved an accuracy of 82.5% and processed 240 images per second on a GPU. The pre-trained ImageNet model was used for weight initialisation and the concept of transfer learning was applied.

Two similar studies by H. Varun Chand et.al [4] and Md. TanvirAhammed et al. [5] were done on driver distraction involving drowsiness and fatigue. The study by H.Varun Chand et.al [4] used machine learning with multi-layer perceptrons to detect microsleep and drowsiness using neural network-based methodologies. The accuracy of this paper was improved by using a CNN to classify drowsiness in the facial expressions detected by the camera. The ability to provide a lightweight alternative to heavier classification models with more than 88% accuracy for the category without glasses and more than 85% for the category night without glasses is the accomplishment of this work. In all categories, more than 83% accuracy was achieved on average as well as in usability. Furthermore, the new proposed model had a significant reduction in model size, complexity and storage when compared to the benchmark model (Max Size = 75KB).

Md. TanvirAhammed et al. [5] used MobileNet CNN Architecture with Single Shot Multibox Detector. Based on the output of the SSD MobileNet v1 architecture, a separate algorithm was used. To train the model, a dataset of approximately 4500 images was labeled with the object's face yawn, no-yawn, open eye and closed eye variations. Using the PASCAL VOC metric, 600 randomly selected images were used to test the trained model. The proposed method was intended to improve accuracy and computational efficiency. [23] Bing-Ting Dong et al. used an approach which detected driver fatigue and distracted driving behaviors using a single shot scale-invariant face detector (S3FD). This was first used to detect the face in the image and then the face alignment network (FAN) was utilized to extract facial features. Post that, the facial features were used to determine the driver's yawns, head posture, and eye movements. Finally, to analyze the driving conditions the random forest technique was used. The average accuracies achieved were ~100% for both face and eye detection.

Another experimental study using CNNs was done by RobinsonJime`nezet al.[24] which targeted detection of driver fatigue and emotion analysis of the driver in order to avoid reckless driving. The proposed model had a 93% accuracy rate in detecting the driver state and classified as normal, fatigued, drunken or reckless. A study [24] by Robinson Jime`nez et al. identified driver distraction states by using eye, mouth, and head movement and orientation as parameters for classification. Course segmentation using the Haar classifier techniques were used in conjunction with Adaboost techniques. Rectangular descriptors to detect faces in an image and Fine segmentation using Hough circle detection algorithm and Hough transform were used to determine the position of eye iris. A precision of ~86% was achieved.

III. DATA SET

The Kaggle competition "StateFarm distracted driver detection" published in 2016 [21] is a dataset widely used for different experiments and studies. It comprises ten classes. Creation date and other metadata has been removed from the images. The images are created in a controlled environment where drivers are not actually driving but posing. It is ensured that the driver appearing in train images will not appear in test images. The images are a collection of left-hand drive vehicles only. Each class contains close to 2300 images.

We also used one more recent dataset [13] [14] that was created by students of the American University in Cairo (AUC). Individuals (Males=29; Females=15) were wearing different clothes and videos were produced with different driving conditions. These individuals are from seven different countries, the USA, Palestine, Morocco, Canada, Uganda, Egypt and Germany. The dataset has been divided into train and test datasets distributed over 10 classes with a total of 14,478 images.

TABLE 1 :DATASETS CLASSES

Classes	**Driver actions**	**Kaggle Images**	**AUC Train**	**AUC Test**
c0	safe driving	2489	2640	346
c1	texting - right	2267	1505	213
c2	talking on the phone - right	2317	1062	194
c3	texting - left	2346	944	180
c4	talking on the phone - left	2326	1150	170
c5	operating the radio	2312	953	170
c6	drinking	2325	933	143
c7	reaching behind	2002	891	143
c8	hair and makeup	1911	898	146
c9	talking to passenger	2129	1579	218
	Total	22424	12555	1923

IV. TECHNICAL APPROACH

From the source datasets mentioned in Table 1 and Table 2, we apportioned the data for the purpose of Training, Validation & Testing with data distributed as shown in Fig 1.

DOI: rp-9788770040723.091

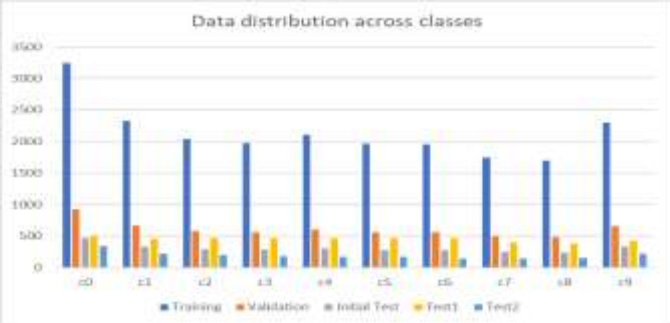

Fig 1. Data distribution across classes

In our approach to build the model , base models were identified namely ResNet101V2, ResNet50 and MobileNet and were trained on an “imagenet” dataset. In our initial findings, the model based on ResNet101V2 had a significantly better accuracy than the other models. Hence ResNet101V2 was selected to further experiment and optimize to achieve better results. Different model variations, Key approaches used for experimenting are described below.

Model 1 and Model 2 have been trained with similar strategy but with a different number of layers that can be retrained. In Model 1, we used transfer learning with 34 last layers trained. The top layers will contain a global average pooling and a dense layer of 10, activated with softmax producing the classification. Categorical cross entropy was used as loss function and adam was used as an optimizer.

In Model2, the number of layers that are retrained are 150. The remaining architecture remains the same as Model 1.

The accuracy on Kaggle data is good with 99% in both the models. However, the model accuracy on AUC dataset has come down to 58% from 66% in Model 1.

To improve the AUC test accuracy, we sought to experiment again the transfer learning approach but by removing some data in AUC test dataset as they were right hand driving images and our model was trained on left hand driving images only. The availability of right hand driving images is very less compared to left hand driving images implying data imbalance problem.

Model 3 & Model 4 were built with similar architecture and strategy as Model 1 & 2. The main difference will be the reduced data by removing the right hand driving images.

Few parameters were changed in our fourth model like transfer learning with top 35 layers with dense 1000 was used keeping all other parameters same as third model

Almost no change was observed in accuracy of both the test data. On kaggle data, validation and test accuracy is 99% in both the models while AUC test accuracy at 58% for third model & 59% for fourth model.

Observations from all four models clearly indicated that our approach of transfer learning was not being useful for AUC data set and experimenting with hyperparameters is not making any impact on the model. To understand why the model was not performing as expected, a grad cam analysis was then used to understand activation and prediction of the model [15][16][17]. The intent is to understand the model with scientific facts and approach the model building with Explainable AI.

Grad Cam Analysis : The Grad CAM technique uses the feature map of the last convolutional layer and the classification score of the class in interest. It calculates the gradient between them. The larger gradients in the places of the image are the one impacting the final classification score.

In our analysis there were mainly two observations made. First, we could see that most of the activation in our models were wrongly placed implying that our trained model was not correctly identifying parts of the image that could result in correct classification. Sometimes even if the predictions were right the activation on the images were not rightly placed. Examples of the above mentioned observation is shown below in Fig 2 and Fig 3.

Fig 2. Grad-CAM Adjusting Radio

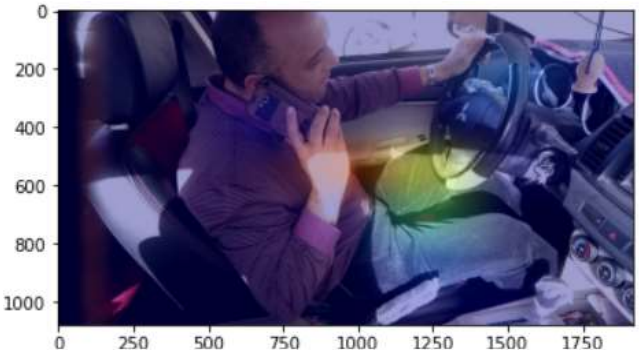

Fig 3. Grad-CAM Talking on phone right

By this study we understood that our trained transfer learning models are not enough to classify our images into the right category. Second, to understand the GradCAM on the dataset with pre-trained ResNet101V2 Model, we did grad cam analysis. Most of the images are classified as minibus, seatbelt, golf cart, etc and the activations are showing away from the person sitting on the driving seat. For example (as shown in fig 4) the activation shows on door windows which will never be useful for classification required for this model. It is inferred that the transfer learning would be inappropriate for the dataset of Distracted Driver Detection.

DOI: rp-9788770040723.091

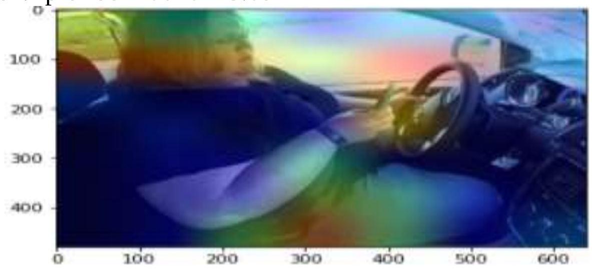

Fig 4. Grad-CAM with ResNet101 pretrained on Imagenet

With all the above stated observations we inferred and acted upon that the usage of transfer learning in our model with few or more layers is not making any significant impact on accuracy of our test datasets. Hence we chose to train the entire network of the ResNet102V2 model.

In Model5, we trained the entire network, without any modifications to the ResNet101V2 architecture. The starting learning rate is chosen as 0.0001 instead of default 0.001.

With this change in approach we could see a significant change in the accuracy of the AUC test data which now improved from 58% in our previous model to 76%.

To validate the model further apart from accuracy of classification, a GradCAM analysis is done on the training data and as well predicted data with the new model. It is observed that the activation on the training data and as well as predicted data is more appropriate such as classification of an image as “operating a Radio” activates the Radio and lower hand of the person. Fig 5 shows the same as below

Fig 5. Grad-CAM Adjusting Radio

On further observing the wrongly classified images by the model, we understood that the model has learnt specific features that alone may not be sufficient to classify an image. For eg., an image with a slight open mouth is considered to be Talking rather than safe driving. Or an image where a cup in the left hand is covered by the right hand position, so the model is unable to understand it as drinking. To give more learning capability to the model, we augmented the data of AUC training set with shear 30 degrees. The idea is to provide more images with a small shift. This augmented approach should improve and generalize the model.

Architecture of our sixth model is exactly the same as the fifth model, except that it is trained with more data (augmented data).

With this change in approach we could see a change in the accuracy of the AUC test data which now improved from 76% to 82%

TABLE 2: KEY PARAMETERS USED IN EACH MODEL

Model	Hyper Parameters
ResNet101V2_Model_1	Activation- leaky_relu Epoch - 20 Batch Size - 50 Dense Layer -10 Optimizer - Adam (beta_1=0.9, beta_2-0.999lr=0.001) Loss - Categorical_crossentropy
ResNet101V2_Model_2 Key Change in Approach: Reducing lr for every 5 epochs with 0.1 factor if val_loss is not improving	Activation- relu Epoch - 20 Batch Size - 32 Dense Layer -10 Optimizer - Adam (beta_1 = 0.9,lr=0.001, beta_2 = 0.999) Loss - Categorical_crossentropy
ResNet101V2_Model_3 Key Change in Approach: Global average pooling, flatten and a dense layer of 10	Activation- relu Epoch - 20 Batch Size - 32 Dense Layer -10 Optimizer - Adam (beta_1=0.9, beta_2-0.999lr=0.001) Loss - Categorical_crossentropy
ResNet101V2_Model_4 Key Change in Approach: Kaggle and AUC cam1 data. Cam2 data is discarded as it is right wheel driving and has very few images.	Activation- relu Epoch - 20 Batch Size - 32 Dense Layer -10 Optimizer - Adam (beta_1=0.9, beta_2-0.999lr=0.001) Loss - Categorical_crossentropy
ResNet101V2_Model_5 Key Change in Approach: Complete Network retraining.	Activation- relu Epoch - 50 Batch Size - 32 Dense Layer -10 Optimizer - Adam (beta_1=0.9, beta_2-0.999lr=0.001) Loss - Categorical_crossentropy
ResNet101V2_Model_6 Key Change in Approach: Augmented for Cam1 - shear 30 degrees	Activation- relu Epoch - 50 Batch Size - 32 Dense Layer -10 Optimizer - Adam (beta_1=0.9, beta_2-0.999lr=0.001) Loss - Categorical_crossentropy

IV. RESULTS AND DISCUSSIONS

Based on our experiments, we discovered that our model is able to learn prominent features with a small number of parameters. With sufficient training data the model is able to give accurate results. Moreover, we could see the performance of the proposed ResNet model as shown in Table 4. In the table, it's clearly observed that the Model performed very well with the State Farm Distracted Driver data-set on the pre-trained as well as transfer learning model. However that was not the case when trained on AUC Distracted Driver Set. We found that training the entire network is very optimal for our model. The accuracy increases, prediction and activation is also appropriate.

TABLE 3: ACCURACY ACROSS MODELS

Model	Training Accuracy	Validation Accuracy	Kaggle Test Accuracy	AUC Test Accuracy
ResNet101V2_Model_1	100%	99.23%	99%	66%
ResNet101V2_Model_2	100%	99%	99%	58%

ResNet101V2_Model_3	100%	99.58%	99%	59%
ResNet101V2_Model_4	99.94%	99.23%	99%	59%
ResNet101V2_Model_5	100%	99.53%	100%	76%
ResNet101V2_Model_6	99.99%	**99.58%**	**100%**	**82%**

TABLE 4: CLASS WISE ACCURACY FOR FINAL MODEL

Class	Driver Action	Kaggle Dataset F1-Score	AUC Dataset F1-Score
c-0	safe driving	98.99	66.99
c-1	texting - right	100	85.62
c-2	talking on the phone -right	100	94.95
c-3	texting - left	99.57	84.61
c-4	talking on the phone - left	99.78	98.34
c-5	operating the radio	99.45	98.30
c-6	drinking	99.89	88.88
c-7	reaching behind	100	77.30
c-8	hair and makeup	99.47	77.12
c-9	talking to passenger	99.53	68.76

We would like to mention some pertinent points based on our observations as below:

Data balancing (CAM 2 data had to be removed from the model because of very few images found in right wheel driving)

Data Verification - due to improper data extraction, the AUC data was improperly classified which resulted in significant delays in the initial stages of model training.

The Learning Rate(lr) turned out to be significantly important for convergence due to the lengthy model architectures

Understanding of when to use Transfer Learning & when to use the architectures

Techniques like GRAD CAM were important from a model validation perspective

Availability of more quality data would have helped the model to generalize better

We can conclude that existing state of the art architecture like the ResNet101v2 Model alone can be sufficient if trained and optimized well

Scope for future enhancements

Model training for right seat driving

The solution will be improved by adding more convolutions to the end of the architecture. The ResNet101 for imagenet architecture's last convolution outputs 7x7x2048 activation maps and it is connected to 1000 dense layers for the classification of 1000 classes. Since there are 10 classes in the problem, connecting 2048 to 10 could have decreased the accuracy. So we will introduce 1 or 2 convolutions before connecting into 10 dense layers.

Based on the observations of the predictions and class activation mappings in the v6 model, we propose to add one more convolutional network trained on imagenet parallel to the existing network. The purpose of this network is to establish face detection with classification of face or not face. Then the classification will be used along with the classification of the original network to give the final classification. The purpose of this approach is to activate the facial features that contribute to the final accuracy.

At the onset of our study, we had considered a benchmark of 88% on the test set of the KaggleStateFarm dataset with the ResNet50 and 82% on the MobileNet models [11]. Models performed way better by achieving an accuracy of up to 96% on the combined Kaggle and AUC datasets.

ROC Curve for Safe Driving Vs rest of the classes is provided below on ResNet101V2_Model 6. The AUC value of 98% and 100% shows the larger coverage of the model's on different datasets.

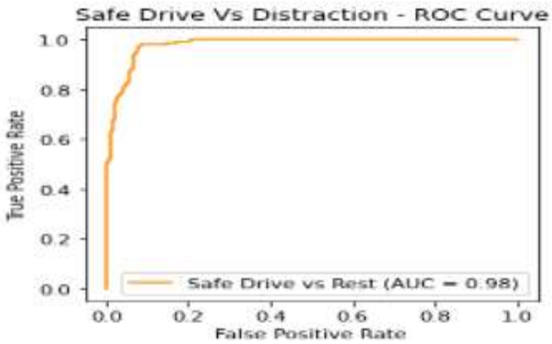

Fig 6: ROC Curve for AUC Test Data

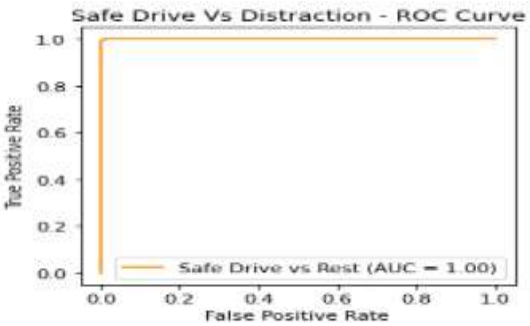

Fig 7: ROC Curve for Kaggle Test Data

***Abstract*—The evolution of the Industry 4.0 is initialized through block chain technology with cloud computing techniques. This includes the integration of digital environment with internet of things (IoT) and cyber security systems. Thus the amalgamation of advanced technologies paved way for the rise of Industry 4.0. This helps in providing security and privacy without any consequences. This helps to save and interchange the information within the network without any centralized organizations. It plays a prominent role in the production and manufacturing sectors by trusting built in the supply chain management system. They adopt numerous advantages in adopting secure financial transactions. This helps to maintain the end-user sustenance. The monitoring and prediction of the supervision system is performed by SCADA (Supervisory Control and Data Acquisition) system that employs various intelligent systems in manufacturing and production sectors. This supports in accumulating and processing the real time data in the industries. The supervisory organization shows an essential character in the performance efficiency of the industrial sectors.**

Keywords—Industry 4.0, SCADA systems, distributed power generation, renewable energy, photovoltaic system, block chain technology, cloud computing techniques

I. Introduction

The growth and advancement of industrial sectors are due to the rising demand and numerous innovations in the technology. It paved way for the introduction of digital technology with communication systems. The integration of the physical and virtual environment with real time implementation is in progress to adopt a newer environment [1], [2].

Thus the evolution of the manufacturing and the production sectors are termed as the Industry 4.0. This is also denoted as the fourth industrial revolution [3]. This includes the conversion and transformation of traditional manufacturing and production sectors with digital technologies to enhance productivity in the system. This helps to improve the product outcome with higher efficiency in production and supply systems [4].

This helps in the development of two way communication system to adopt various benefits. The Industry 4.0 tends to implement the technology to interact with the physical world with the virtual environment. This is enhanced through the aid of digital twin [5]. The integration of physical environment into virtual world helps to improve the performance proficiency of the fabrication and manufacturing sectors. Thus the digitalization of the industries leads to adopting two way communication system with artificial intelligence techniques [2], [6], [7].

The two-way communication system helps in participating the customer in an active way. The innovative technology in the production and manufacturing sectors in the industry leads to use optimization techniques with smart productivity and marketing techniques. The smarter manufacturing system leads to the rise of digital twin concept. The overall technique is adopted under the branch of Internet of Things (IoT) [8]–[10]. This helps in the amalgamation of communication system with manufacturing and production sectors in industries. The resource management shows a dynamic role in the improvement of advanced techniques in the industrial sectors. To extract higher benefits, the implementation of the outcome in 3D virtual environment leads to improve the productivity with improved efficiency. The complexity in the implementation of outcome in the real time environment

DOI: rp-9788770040723.092

is neglected through employing the optimization techniques. Thus the monitoring of the product outcome is evaluated and verified in the digital environment [11], [12].

The improvement of the product design and outcome are analyzed through the data and the sensing parameters. This includes various sensors and actuators to sense the external parameters. The digital shadows forms the important part in the development of industrial sectors. The implementation of the digital twin was first came to existence in the field of aerospace industry. [13]–[15]Thus the digitalization of the manufacturing and production helps to enhance the development through the analyzing the cause and effects to solve the problems. The decision making techniques and problem solving are implemented through optimization techniques. They are implemented with artificial intelligence accompanied with the block chain technology and cloud computing techniques [3], [16], [17].

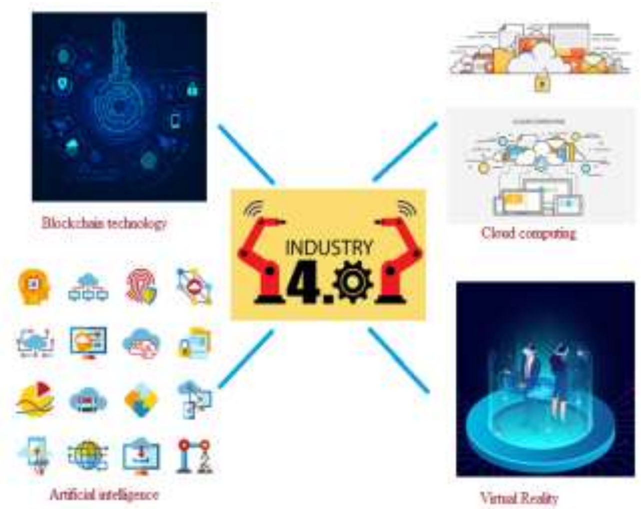

Fig 1: Industry 4.0

The figure 1 represents the functioning parameters of Industry 4.0. The block chain technology is defined as the shared network that functions without the need of a centralized organization. Here the data are stored with higher security and privacy without any malfunctioning of hackers. Simply the block chain technology is the opaque sharing network of data and information. This includes the integration of cryptocurrency and distributed network systems. This helps to obtain efficient ledger storage systems. It provides an opaque system in data transmission and processing. They play a versatile role in diverse field such as banking transactions, cyber security, legal, business and healthcare sectors. This paved way for the evolution and improvement of e-governance.

As the name suggests, the information are stored in a blocks that are interconnected further in a chain network. The artificial intelligence is defined as the exact replica of function and decision making as similar to the human intelligence. This helps in processing and storing the data in an online platform to enhance the two way communication systems [2], [18], [19].

These forms the smart manufacturing system to improve efficiency. Thus the deep learning techniques are adopted to improve the innovations and advanced techniques in the manufacturing and production sectors. The smart manufacturing system includes the configuration of data, execution and optimization to obtain the performance outcome of the system. This includes both the accumulation of structure and function design parameters [11].

The functioning of digital twin involves the reflection of real time, convergence parameter and evaluation of the product outcome in the production sectors. The overall performance is interlinked with the block chain technology and cloud computing techniques.

This helps to convey the processed data in the network. They gave rise to the concept of augmented and virtual reality [12]. This helps to view the virtual world formed by the replication of the real world environment. The important parameter involved in the smart manufacturing and production sector involves the security and privacy with supervision system concerns. This is accomplished through the cloud computing techniques. Thus the supervision system is implemented through the aid of cloud computing and block chain technology.

II. Proposed System

The enhancement of Industry 4.0 focus on the progress of advanced technologies to improve performance parameter in the industrial sectors. This includes artificial intelligence with internet of things and cloud computing technologies. In the proposed system, the deep learning techniques with optimization techniques such as decision tree algorithm is implemented.

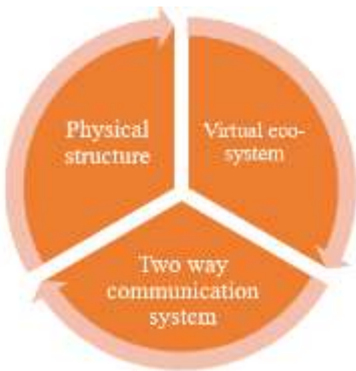

Fig 2: Parameters of Industry 4.0

The figure 2 demonstrates the various parts of industry 4.0. The evolution of industrialization was done through the concept of virtual and augmented reality. This helps to create a virtual 3D space.

This helps in interaction of virtual world enabling both audio and video mode of interlinkages. This includes the development of virtual environment through the physical world. The exact replica of the physical environment into a virtual world is denoted as digital twin. This is done through the data with the process of acquision and processing. Thus it is an integration of the physical and virtual ecosystem to

DOI: rp-9788770040723.092

develop improved performance in the industrial sectors. This inculcates both the static and dynamic structures to obtain the optimum solutions [20]–[22]. This aids to analyse the presentation of the system before implementing in the real word. This helps to save time and cost. The privacy and security are controlled through the block chain technology and cloud computing techniques. This supports to store the data in blocks to avoid various limitations. Thus the prediction of the supervisory control is done through SCADA systems. The control and monitoring are the important aspect in the industrial sectors to improve the efficient of the system. The supervision system includes the monitoring and control of manufacturing sectors, quality enhancement and management through various optimization techniques.

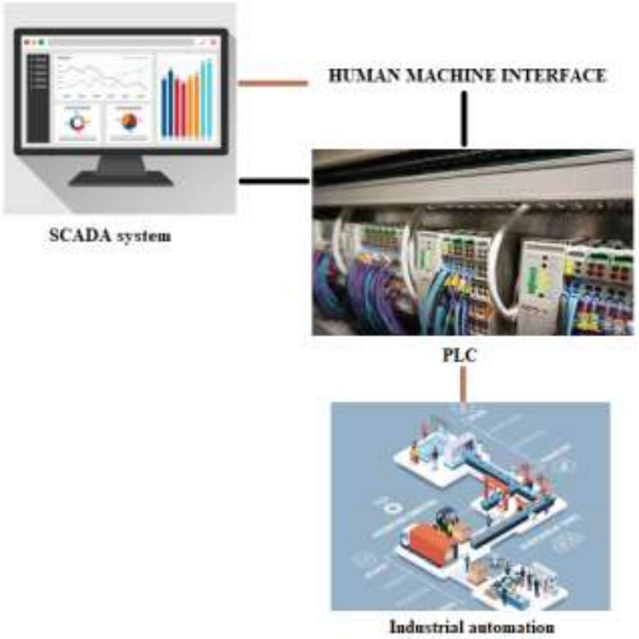

Fig 3: SCADA system

The figure 3 demonstrates the functioning of SCADA system in the industrial sectors. This controls and monitors the manufacturing and production unit. This is done through the accumulation of data in real time to monitor the overall network in the industries. This is referred as the integration of hardware and software to improve automation in the industrial process accompanied with the internet of things. This helps to provide the two way communication system.

Fig 4: Components of SCADA

The figure 4 represents the necessary components of SCADA systems. The Supervisior Control and Data Acquisition (SCADA) system is referred as the software system used to control and monitor the performance and functioning of the industrial sectors. The overall process are sensed through the sensors. This includes programmable logic controllers, graphical user interface and various sensors .

The input information of the manufacturing and production sectors are sensed through the sensors. The actuator is used to monitor the overall functioning and control mechanisms of the industrial sectors. The controllers interface with the sensors and actuators in the network. The data and information from the industrial sectors are collected through the supervisory system. They provide the command to control the system units in the industrial sectors. These commmands are followed by the industrial equipments to function properly.

The human machine interface software is used to amalgamate the data in the system. The overall process is accompanied with the communication system that are used to gather the data and process them. They provide the communication network to sensors and controllers in the network. The industrial systems also uses the industrial internet of things for monitoring and controlling. There is a overlap in the SCADA system and the industrial internet of things. The overall process and information interchange are keenly recorded and saved in the block chain technology with cloud computing techniques.

TABLE I. COMPARISION OF SCADA AND IOT

SCADA system	**Industrial Internet of Things (IIoT)**
It enables communication protocols for control and monitor the system in industrial sectors	They provide communication linkages through the standard protocols.
The sensors and actuators are connected to the organises for operation and functioning.	The sensors and actuators are not directly in contact with the controllers.
The collection of data are done directly from the controllers without the aid of intermediate devices.	They are data collected and saves in the cloud system.
Integration with various devices cannot be done and they are restricted.	Integration with various devices can be implemented enabling open access.

DOI: rp-9788770040723.092

The above table I represents the functioning and classification of SCADA system and industrial internet of things.

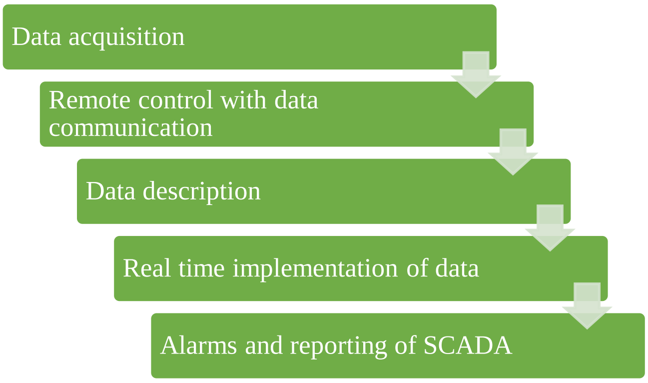

Fig 5: Features of SCADA systems

The figure 5 demonstrates the various features of SCADA systems. The evolution of SCADA system ranges from first generation to fourth generation. They are classified based upon the technology used in monitoring and control structures. This includes the collection of data, control strategies, description of data, implementation of data with real time implementation and alarms with reporting the functioning and monitoring of industrial process [16], [18]. The various advantages of SCADA system includes the higher scalability with improved communication system with support structures. The SCADA system are largely used in transmission and distribution sectors, automotive industries, transportation system and daily service processing.

Fig 6: PLC progam code

The figure 6 represents the PLC program code for monitoring and control of industrial process.

III. SCADA Architecture in Monitoring and Control Process

The SCADA control process is classified into five stages ranging from level 0 to level 4. This helps to control and monitor the industrial sectors.

LEVEL 0 - This includes the accumulation of sensors that are used to collect the data from the industrial sectors and control process are done through the actuators.

LEVEL - 1 – This includes the programmable logic controllers to interface with the devices directly without the aid of intermediate devices in the network. This helps to accumulate the data from the sensors and tend to provide command for functioning.

LEVEL 2 – The local supervisory system are includes in this stage. This includes the level controllers.

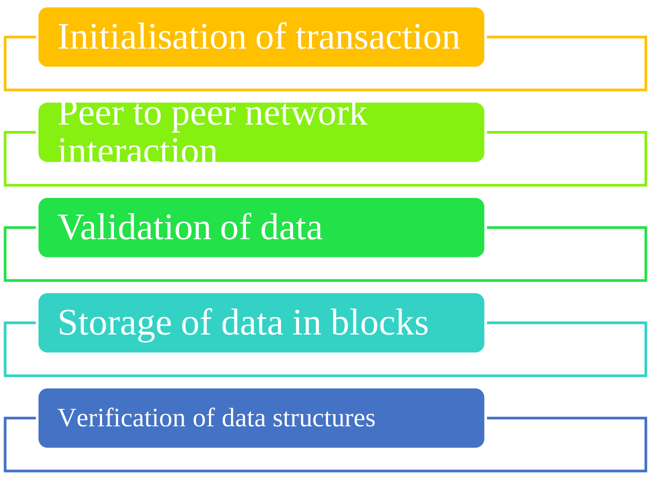
LEVEL 3 – The scheduling level of the process in the supervisory system embedded with the production control network. This extracts the data from the level 2 of the architecture. This is intimated through alert system.

LEVEL 4 – In this stage, it manages the current functioning and processing in the industrial sectors.

Thus the monitoring and control parameters are done through the following stages to enhance the industrial sectors to achieve higher productivity. They are enhanced through the two way communication system to improve sustainability and reliability in the system. These supervisory system are accompanied with the internet of things with cloud computing techniques. It helps to save the data or information in the network without any external barriers. They are further monitored through the blockchain technology in which the data are stored in blocks without any centralized infrastructure.

IV. Security and Privacy with Blockchain Technology

The block chain technology has been formulated by the Ministry of Electronics and Information Technology. A block chain technology is a database which is used to store the data or information in blocks accompanied with network structure with higher security and privacy. This includes five stages.



DOI: rp-9788770040723.092

Fig 7: Block chain network

The figure 7 demonstrates the stages in the block chain network.

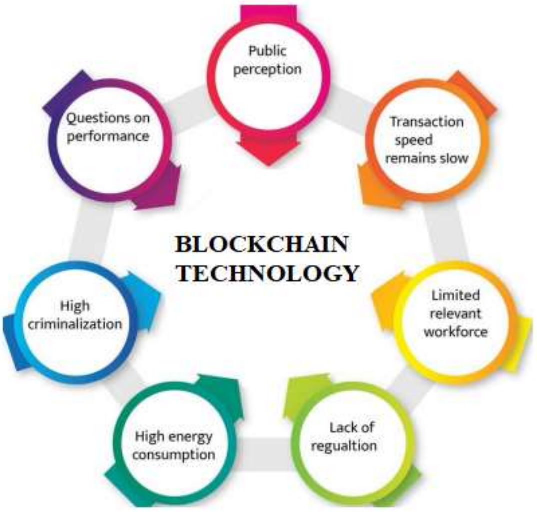


Fig 8: Challenges in blockchain technology

The figure 8 demonstrates the various challenges in the adoption of block chain technology. The cloud computing is denoted as the on-demand data access accompanied with information storage and management system.

This helps in rapid innovations with storage of data in an efficient manner. This includes the internet of things to store the information. There are various services provided by the cloud computing techniques. This also enhances server less computing structures. Thus the large amount of data are protected and saved in the cloud storage system. They are done with the sensor that senses both the structured and unstructured data in the network.

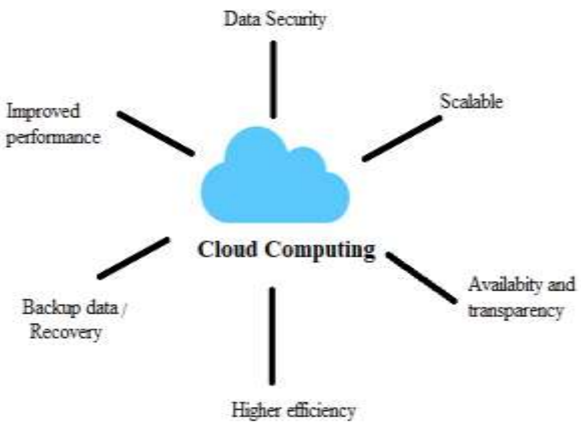

Fig 9: Cloud computing

The figure 9 demonstrates the various benefits of cloud computing techniques. This is done without the actively involvement of the user in the network. The larger amount of clouds are sectioned into smaller clouds in which the individual cloud is demonstrates as a data center. This is a space for the distribution of computing techniques. In cloud computing, the hardware, software and the external arrangement is governed by the cloud supplier.

V. Performance Analysis And Outcome

The supervision control system for industrial manufacturing and production system is achieved through the SCADA systems. This is executed in software application to analyse the results.

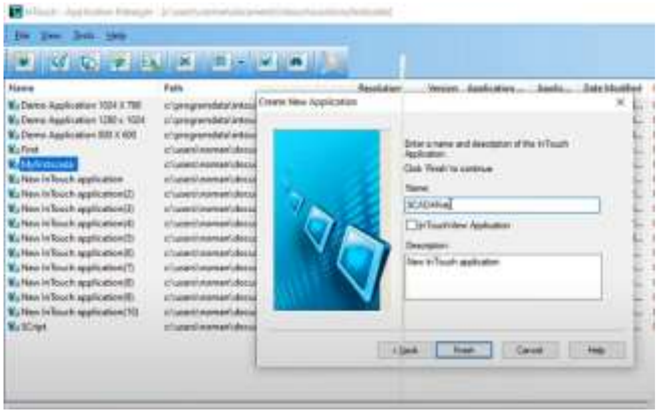

Fig 10 : Intouch software

The figure 10 demonstrates the execution of wonderware intouch data software for the implemntation of SCADA system.

The figure 12 demonstrates the data sensing through sensors and actuators.

Fig 13: Control parameters

The figure 13 demonstrates the control parameters. This includes the functioning of level 0 to level 4 in SCADA systems. The overall information is secured through the blockchain technology with cloud computing techniques. Thus the data are secured.

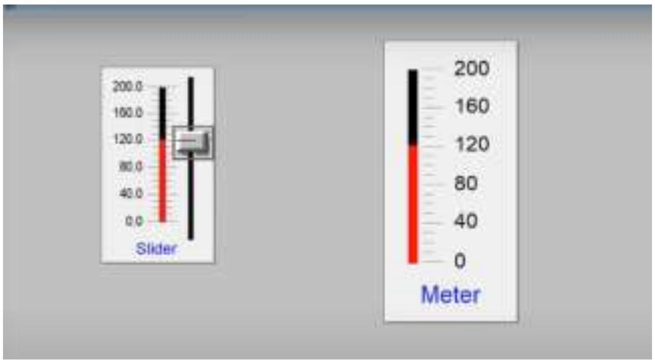

Fig 14: Monitoring and controlling

The figure 14 represents the monitoring and control parameters done through the SCADA systems. The overall industrial performance are analyzed and monitored through the system to improve the performance efficiency.

VI. Conclusion

The evolution of Industry 4.0 is due to the advancement of newer technology. This includes internet of things, block chain technology, virtual environment and cloud computing techniques. They help to give rise in the automations ranging from industrial manufacturing and production sectors. These forms the important governing aspect is the monitoring and supervision of the industrial systems. This is done through the SCADA system. This helps to monitor and control the functioning of the industrial sectors. The information are highly secured through the block chain technology and the cloud computing techniques. This helps to secure the data and transactions without the aid of any centralised infrastructure. Thus the implementation of artificial intelligence with cloud computing techniques helps in the overall development of industrial sectors thus enhancing industrialisation and digitalisation.

***Abstract*—The proposed system for tracking the movement of a blind person using wearable IoT devices appears to be a potentially useful and practical approach to assist individuals with visual impairments. The ability to communicate information about the surroundings via wireless technology and headphones could greatly enhance the mobility, independence, and safety of blind individuals. The incorporation of suitable connectivity methodologies to avoid interference between devices in crowded spaces is also an important consideration, as this could impact the accuracy and reliability of the system. It would be interesting to know more about the specific methodologies used and how they were tested and optimized, as this could provide valuable insights for future projects and developments. The evaluation of the device's effectiveness through experiments and statistical analysis is also a positive aspect of the paper, as this provides quantitative data on the functionality and performance of the system. However, it would be helpful to have more details on the experimental methodology and conditions, as well as the statistical analysis techniques used, in order to better understand the results.**

Keywords*—Artificial Intelligence (AI), Internet of Things (IoT), wearable IoT, Blind Persons' movement

I. Introduction

As technology advances, software tools are created to make life easy for people with physical disabilities. At least 2.2 billion people around the world have impaired vision or are blind. They may fall into one of three categories: moderately visually impaired, severely visually impaired, or completely blind. The majority of blind people move using traditional methods such as canes and the assistance of another person. With the rise of technology, there is an increasing demand for the development of user-friendly devices that will aid blind people in mobility. As a result, visually impaired people can travel independently and confidently and take part in daily activities. Many research papers that discuss various methods are discussed in this section. The system assists the user with locomotion and obstacle detection by combining artificial vision and GPS. In a silicon glove, an ultrasonic sensor, GPS, and GSM were combined.

II. Literature Review

Kumar et al. (2019) and Sivakumar P (2015) proposed an effective wearable navigation system for the blind that uses an Internet of Things (IoT) platform to process a raspberry pi camera and ultrasonic sensors to provide information about nearby obstacles for the mobility of blind people with the help of audio assistance.. It measures the distance between an object and the user using an ultrasound sensor. This image is processed, and the result is presented as an audio signal. Tayyaba, Shahzadi, et al. (2020), Karnan B et al (2022), and Latchoumi TP et al (2022) proposed a smart home model for blind people's safe and robust mobility. For simulation, fuzzy logic was used. The fuzzy controller receives input from IoT devices such as sensors and Bluetooth. To generate decisions as output, restrictions are imposed based on the blind person's conditions and requirements. These outputs are transmitted via IoT devices to help the blind person or user move safely. The proposed system allows the user to navigate easily and avoid obstacles. Jayatilleka et al. (2020), Vemuri et al (2021), and Monica.M et. al. (2022) examined the benefits, techniques used for data analysis, identifying problems, and defensive measures for each disease in the human body. In this study, Kiruthika, V., et al. (2021) proposed a new methodology for wearable technology devices with multiple features that will assist both blind as well as elderly people in their daily lives. This device allows blind and elderly people to move around in any environment while also monitoring their health conditions. Various sensors, including an ultrasonic sensor, an infrared sensor, a water sensor, a blood pressure sensor, a pulse sensor, an accelerometer sensor, and GPS/GSM technology, are embedded in this device to assist the blind and elderly in a variety of situations. A Hand Wearable Radio Frequency (RF) Locator with Intelligent Walking Aid for the Blind was presented by Joseph et al. (2022). Blind people have suffered greatly because they are unable to

DOI: rp-9788770040723.093

move freely unless they are assisted by someone close to them. Those who have previously acquired a walking aid may have misplaced it without realizing it. This has been a significant challenge for blind people, who feel marginalized in society. A. Karmel et al. (2019), Sridaran K et. al. (2018), and Buvana M et al (2021) sought to develop a single device solution that is simple, fast, accurate, and cost-effective. The main goal of the device is to give people with disabilities a sense of independence and confidence by seeing, hearing, and speaking for them. The paper describes a blind, deaf, and dumb assistance system based on the Google API and Raspberry Pi. The suggested device enables reading for people with visual impairments by taking an image. While translating documents, books, and other commonplace materials, image-to-text transition and speech synthesis are also carried out, converting it into audio that reads out the derived text.. Pawan Whig (2021) proposed a system for blind people to walk safely. This system consists of a wireless sensor within the stick that provides information about the obstacles in the path. The main benefit of this system is that it keeps blind people safe on the road and allows them to walk independently. When an obstacle is detected, the user will receive an alert via buzzer and vibration. This research study's proposed system is 60% more efficient than a conventional system. Bisht, et al. (2021) investigated and evaluated the most predominant wearable devices on the market. The hardware and software specifications of various devices are covered in this section. The sensor is perhaps the most important component in information collection. Sensors have examined a full range of boundaries closer to recognition during ongoing years of progress in semiconductor innovation. Because these devices communicate via the internet, some users may be concerned about their privacy. Tyagi, Noopur, and others (2021)

III. Proposed Work

Fig. 1. Wearable IoT Devices Assisting Blind Person

A microcontroller board, proximity sensor, wearable IoTs, wireless connectivity, and GPS modules, answer solar panels for charging the batteries are the system's main components (Ref: Figure 1). The system uses a set of sensor devices to track the user's path and alert them to any obstacles in their path. The user is notified by a buzzer and noise and vibration on the elbow, which is useful in a noisy environment. Furthermore, the system notifies people in the vicinity when the user needs support, and the alert SMS with the location is sent to authorize mobile phones of caregivers. Furthermore, the authorized mobiles can be used to obtain the location and initiate real-time monitoring of the blind person as needed. The controller is connected with the Alarms, sensors, and Power modules. Figure 2 illustrates the architecture of the proposed model. We put the system prototype through rigorous testing to ensure its capabilities and effectiveness. The proposed system includes more features than comparable systems. It is anticipated that it will be a valuable tool in raising the standard of living for blind people.

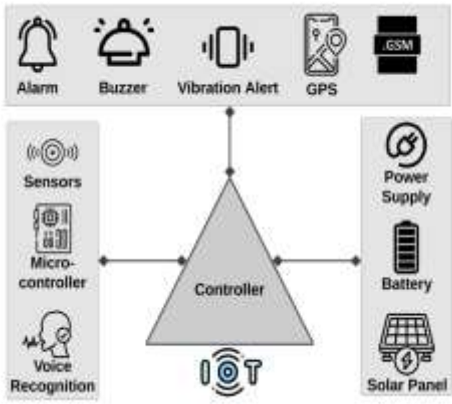

Fig. 2. Architecture diagram of the proposed system

Random noise T is ended up caused by v circuit design noise as well as IoT sensor noise related to $h$igh voice and guidance of blind people. This is the most common type of noise. The probability density for $T(c)$it is written as equation (1)

$$T(c) = \sum \frac{1}{\sqrt{2\pi h}} + \sum_{c=1}^{h\to v} f^{\frac{-(c-v)^2}{2f^2}} \tag{1}$$

Another name for salt and pepper noise is the method of guiding blind people according to their activities. The eq (2) shows its probability distribution as follows:

$$(c) = \sum_{j=1}^{j>k} \begin{cases} T_j c = j, \\ T_{i,} \quad c=i \end{cases} + \int e^{-(c-v)^2/2f^2} \tag{2}$$

The additive noise only has grey levels with i and j, as well as the blind people guidance noise that seems to be salt in the image. Equally distributed noise has an equal distribution of noise, and its cumulative distribution equation (3) is represented as follows

$$T(c) = \int e^{\frac{-(c-v)^2}{2f^2}} + \sum \begin{cases} 1, & i \le c \le j \\ i-j, & \\ & 0 \end{cases} \tag{3}$$

DOI: rp-9788770040723.093

The mean filtering appears to be a regularly used image computing technique, and the Kalman filtering algorithm is utilized in the machine learning models to reduce noise. It operates based on equation (4), which uses the total average of the pixel intensities of a particular pixel to reduce noise. Its grey value is a created pixel.

$$g(x,y) = \prod \frac{1}{ps} \sum_{(f,k)\in E_{yx}} \int (e,k) + \sum_{c\in f} e^{-(c-v)^2/2h^2} \qquad (4)$$

The basic idea is that each pixel in the guiding the blind people according to the grey value set to the median of all the ranges in that neighborhood frame of the point. It can eliminate all separated points, clear up the problem of an unclear enhanced image, and make the guidance values of the surrounding image closer to the final image pixel. The equation (5) follows:

$$\begin{aligned} g(y,x) = \int (e,k) + \sum_{c\in h} e^{-(c-v)^2/2h^2} \\ + median\left\{\int (y-u, x-v) \right. \\ \left. \times (s,u \in O)\right\} \end{aligned} \qquad (5)$$

Here therefore the $\int (y-s, x-v) \times (s, v \in 1)$ represents the limitations for connecting the sensors, $g(y,x)$ represents the median filter in the Table 1 represents the framework.

IV. Experimental Results

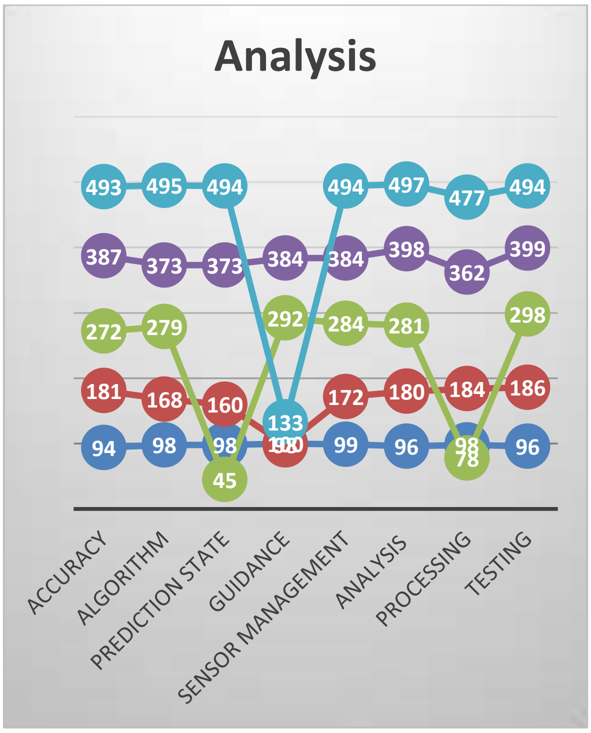

Fig. 3. Performance Analysis for the process of Prediction and Diagnosis of Guiding Blind people

The above statement summarizes the key findings and contributions of the study related to wearable devices for visually impaired people. The study reveals that conventional navigation devices do not provide all the essential features necessary to assist visually impaired individuals in independent navigation. This is where IoT technology comes in, providing better solutions to overcome navigation deficiencies with the help of GPS trackers and sensor-enabled navigation devices.

The study highlights that wearable devices designed to assist visually impaired individuals provide a wide range of benefits, not only in terms of navigation assistance but also in areas such as healthcare, security, mapping, and more. The use of wearables can significantly impact the lives of visually impaired individuals, enabling them to navigate independently and perform daily activities with greater ease and confidence.

The primary goal of this study is to provide a comprehensive understanding of the wearable devices that are currently in use by visually impaired or blind people. By gaining a better understanding of the use cases and benefits of these wearable devices, stakeholders can work towards improving their design and performance to better serve the needs of visually impaired individuals in the future.Dmytro Zubov (2022) presented Review Study on Arduino and Raspberry Pi Wearable Devices and a Mesh Network of eHealth Intelligent Agents for People Who Are Blind were presented during this talk.

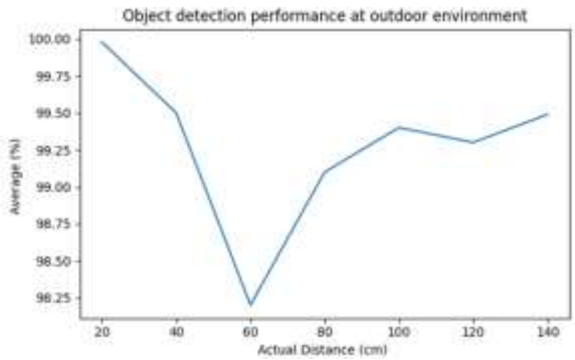

Fig. 4. Accuracy Analysis on Outdoor Object Detection

Figure 4 displays the results of the object detection process using an intelligent system in an outdoor environment. The system's performance was analyzed based on the distance of the detected objects, which was measured in centimeters. The graph presents the data in terms of the number of objects detected on the y-axis against the distance in centimeters on the x-axis. According to the graph, the intelligent system detected the highest number of objects in the distance range of 0 to 50 centimeters. At this distance, the system detected approximately 65 objects. However, as the distance increases, the number of detected objects decreases significantly. For instance, at a distance range of 50 to 100 centimeters, the system detected approximately 40 objects. The number of detected objects reduced further to around 25 at a distance range of 100 to 150 centimeters. At a distance range of 150 to 200 centimeters, the number of detected objects was only around 10, and beyond that distance range, the system detected very few objects.

DOI: rp-9788770040723.093

These results suggest that while the intelligent system has good object detection capabilities, it is most effective at detecting objects at closer distances. To improve the system's effectiveness at longer distances, further optimizations or modifications may be required. Overall, the information provided by Figure 4 is valuable for improving the performance of the intelligent system for object detection in outdoor environments.

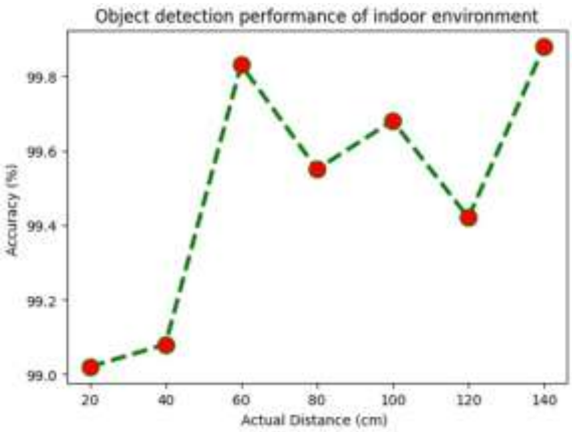

Fig. 5. Analysis of the proposed system on indoor object detection

Analysis is also performed on the indoor basis for object detection is represented in the Figure 5 ranging with 20 cm variations. It can be observed fluctuations in accuracy analysis for the indoor environment.

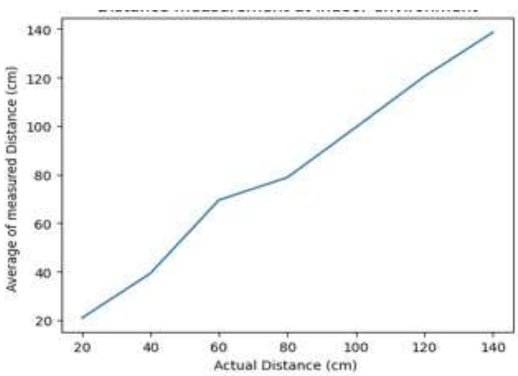

Fig. 6. Distance measurement at indoor Environment

Figure 6 shows the analysis of an intelligent system in an indoor environment based on the distance measurements. The graph represents a decreasing trend in the accuracy rate as the distance increases. The x-axis denotes the distance in centimeters, while the y-axis provides the accuracy rate in percentage. The graph shows that the accuracy rate is the highest at a distance range of 0-50 cm, where the intelligent system detects objects with an accuracy rate of around 98%. The accuracy rate decreases as the distance increases, dropping to 86% at a distance range of 150-200 cm and going below 80% at distances beyond 200 cm.

Table 1, on the other hand, represents the analysis of two algorithms, namely the Kalman Filtering Algorithm and the mosaic method, in terms of their performance regarding preprocessing, prediction and diagnosis, guidance, and accuracy for a given application implementation. The table presents quantitative metrics for both the algorithms in terms of accuracy percentage for each of the categories. The table shows that the Kalman Filtering Algorithm performs better than the mosaic method across all categories and has an overall accuracy percentage of 92.78%, while the mosaic method has an overall accuracy percentage of 91.67%. Both Figure 6 and Table 1 provide valuable insights into the performance of intelligent systems in different environments and under different scenarios. Figure 6 highlights the effect of distance on the accuracy rate of an intelligent system in indoor environments, while Table 1 compares the performance of two different algorithms in terms of accuracy percentage, providing valuable information on which algorithm performs better.

TABLE 1: COMPARISON RESULT ANALYSIS FOR THE EXISTING SYSTEM

Algorithm	Pre-Processing	Prediction and Diagnosis	Guidance	Accuracy
Kalman Filtering Algorithm	96.89	94.35	94.78	92.78
Existing Method: mosaic method	97.98	89.67	91.89	91.67

Table 1 displays a comparative analysis of the Kalman Filtering Algorithm and the mosaic method in terms of their performance on pre-processing, prediction and diagnosis, guidance, and accuracy metrics. According to the table, both algorithms exhibit strong performance in pre-processing, with the mosaic method scoring slightly better than the Kalman Filtering Algorithm, with 97.98% accuracy compared to 96.89%. However, the Kalman Filtering Algorithm significantly outperforms the mosaic method in prediction and diagnosis, guidance, and overall accuracy. The Kalman Filtering Algorithm achieves a prediction and diagnosis accuracy of 94.35%, while the mosaic method only scores 89.67%. The guidance accuracy for the Kalman Filtering Algorithm is 94.78%, whereas the mosaic method scores 91.89%. In terms of overall accuracy, the Kalman Filtering Algorithm achieves an accuracy of 92.78%, while the mosaic method scores 91.67%.

From this analysis, it is clear that the Kalman Filtering Algorithm is more suitable for this specific application, as it outperforms the mosaic method in prediction and diagnosis, guidance, and overall accuracy. However, it is important to keep in mind that the suitability of an algorithm depends on the specific requirements of the application and further testing may be required to validate these results.

V. CONCLUSION

The statement highlights two types of technologies used in assistive devices for the visually impaired. Firstly, it mentions a walking stick equipped with radio frequency identification (RFI) technology that was designed to assist visually impaired individuals in navigating sidewalks. Secondly, it mentions the prevalence of range-based sensors in most assistive devices. While the walking stick with RFI technology may have its benefits, the statement suggests that range-based sensors are more commonly used in assistive devices for the visually impaired. These sensors are

DOI: rp-9788770040723.093

popular due to their low cost, widespread availability, and user-friendly nature. They work by detecting and localizing obstacles in the user's path using IR sensors for short range, ultrasonic sensors for medium range, and LIDAR for long range.These range-based sensors have proven to be effective in providing obstacle detection and navigation assistance to visually impaired individuals. By using multiple sensors for different ranges, they can provide more comprehensive and accurate information on the user's surroundings, allowing for safer and more independent navigation.the statement highlights different technologies used in assistive devices for the visually impaired and suggests that range-based sensors are more commonly used due to their effectiveness and ease of use. However, it is important to continue exploring alternative technologies and improving existing ones to provide the best possible solutions for visually impaired individuals.

Abstract- The digital revolution has contributed to the simplification of previously time-consuming tasks. In this research, we are going to study machine learning techniques in the defense sector for intrusion detection. An intrusion prevention system (IPS) is a mechanism for security management that notifies a network managing the system of malicious activity and also attempts to safeguard it. Machine learning is the study of understanding and developing learning methods on its own using the information to optimize performance on a set of tasks. It is classified as a segment of artificial intelligence.

Keywords: Machine learning (ML), defense sector, intrusion detection, intrusion prevention system (IPS)

I. INTRODUCTION

In recent years, technological advancements have coincided with a significant rise in hacking and cybersecurity management. Internet connects the entire world, and one of the vulnerable controlling machines can be considered the starting point for the chain of unfortunate events. Some of the motivations for similar events can range from managing financial gain to understanding the political regulations to having fun. However, the main person of the attack may suffer a greater loss than the person intended. A successful hack of a technological company's website, for instance, results in a loss of reputation, which is crucial for any firm. Every day, businesses, governments, and even individuals face this issue without knowing how to address it. The solution is to install a prevention system (IPS). This is a security device that keeps an eye out for and tries to stop hostile activities on a network and system.

An intrusion detection system, often known as an IDS, is a kind of system that monitors the traffic on a network in search of potentially malicious activities and gives warnings when it finds suspicious activity. It is a piece of software that does a search across a network or system to look for potentially dangerous behaviour or violations of rules. Any potentially harmful activity or policy breach is often reported to an administrator or compiled and centralised using a security information and event management (SIEM) system. In order to discriminate between malicious behaviour and false alerts, a SIEM system aggregates outputs from many sources and applies alarm filtering mechanisms.

In spite of the fact that intrusion detection systems keep an eye out for potentially harmful activities on networks, they are also prone to producing false alarms. As a result, businesses have to do additional configuration steps after installing their IDS systems for the very first time. It entails correctly configuring the intrusion detection systems so that they can distinguish between regular traffic on the network and malicious activity based on how the two seem to one other.

Additionally, intrusion prevention systems scan the network packets that are coming into the system to see whether or not they include any harmful code and then immediately send out warning signals.

II. LITERATURE REVIEW

Ahmim, Ahmed, et al. (2020) conducted a comparison of twelve supervised ML methods. This comparative study aims to demonstrate the best ML methods for network traffic classification in specific types of attack or benign traffic, categories of attack or benign traffic. CICIDS'2017 is used as the data set for our experiments, with Random Forest, Jrip, and J48 performing best. Pawlicki et al. (2020) investigated the availability of degrading the performance of the optimized algorithm used here during testing by devising attacks at the time of adversarial using the 4 proposed systems, then proposed a method to identify the attacks. Information is provided under both ANN and the methods of composing attacks as we discussed above. The detection technique is thoroughly understood, and the outcomes of 5 distinct classifiers are differentiated. Detecting adversarial attacks on ANN, to the best of our knowledge, has not been thoroughly researched within the frame for reference of detection of intrusion systems. Nadia Chaabouni et al. (2019) and Sivakumar P (2015) investigated NIDS implementation resources already in existence, including free and open-source network sniffing software and datasets.Then, it analyses, examines, and contrasts government NIDS ideas in the context of the IoT in terms of design, detection methodologies, validation approaches, dangers that have been addressed, and algorithm

DOI: rp-9788770040723.094

implementations. The review discusses ML and conventional NIDS methods as well as potential future developments. Because learning algorithms have a high success rate in privacy and security, our emphasis in this study is on IoT NIDS implemented through ML. Maleh, Yassine. (2020), Karnan B et al (2022), and Latchoumi TP et al (2022) deployed the Cooja IoT simulator in IoT 6LoWPAN networks to generate high-fidelity attack data. The most efficient network architecture is chosen for all by evaluating the effectiveness of various network topologies and network scenarios. Test results reveal that ML models for detection of intrusion outperform traditional methods in terms of accuracy, and detection rate by 99 percent. It also necessitates a low rate of energy model overhead and memory, proving that the generated models can be used in confined settings, such as IoT sensors. A denial of service attack-specific DL-based infiltration model was developed by Kim, Jiyeon, et al. (2020), Vemuri et al (2021), and Monica.M et. al. (2022). The most popular dataset for assessing intrusion detection systems is the KDD CUP 1999 dataset, which we utilize for the intrusion dataset (IDS). The four forms of KDD attacks include DoS, user to root, remote to local, and probing. A detailed investigation of rule learning methods and their suitability for IDS in SG was carried out by Liu, Qi, et al. in 2021. It also summarises the most crucial element for understanding and assessing intrusion detection algorithms. This paper not only provides an overview of several important rule learning methods but also the first assessment of their prospective uses in SG security by examining their use in IDS.

Potluri, Sasanka, et al (2018), Sridaran K et. al. (2018), and Buvana M et al (2021) evaluate the efficiency of CNN-based intrusion detection for recognizing various attacks classes using datasets including such NSL-KDD and UNSW-NB 15. Several performance metrics, which add to the precision score, recall score, and F-measurement, have been compared to existing DL approaches. Mishra, Nivedita, et al. (2021) presented a review paper that compares and concentrates on Intrusion Detection models for mitigating DDoS attacks. In addition, the classification is according to Detection of intrusion Systems, various anomaly techniques, distinct Detection of intrusion System models based on the data information, and different ML and DL models for pre-processing also for malware detection. Finally, while addressing research challenges, proposed solutions, and future visions, a broader perspective was envisioned. Ferrag, Mohamed Amine, and colleagues (2021) provided a thorough categorization of intrusion detection systems in each technological innovation. They presented public datasets as well as frameworks for evaluating the performance of Agriculture 4.0's intrusion detection systems. Finally, they list the issues and possible future study areas for Agriculture 4.0 cyber security intrusion detection. Ferrag, Mohamed Amine, et al. (2021) suggested new methods and a sequential model based on the model's features. The proposed system can gather information from the network layer that is using dump packets from the layer using a system of application routines. Because they can create sequential data according to the language model, text-Convolutional Neural networks, and GRU methods were chosen. When compared to traditional methods, deep learning methods extract additional features from the given data, and results show that they have a higher F1 score. They concluded that a sequential prototype intrusion detection system based on DL can help to secure IoT servers.

III. Proposed Work

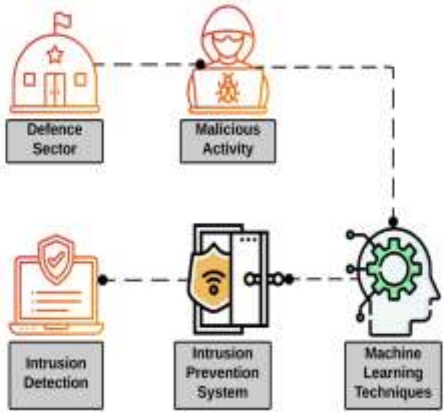

Fig. 1. Intrusion prevention system (IPS)

Malicious activity includes sending/distributing Viruses or information about the creation of Viruses, bouncing, flooding, mail bombing, denial of services, as well as other activities that disrupt or interfere with others' ability to use networks, systems, services, software, or equipment effectively. Machine learning is a field of study concerned with comprehending and developing methods for learning on its user data to improve performance on a set of tasks. It is considered a part of artificial intelligence. Machine learning employs two techniques: supervised learning, which involves training a model on established input and output data to help predict outputs, and unsupervised learning, which employs hidden patterns or structural components in the input data to predict future outputs.

In actual reality, the algorithm of subsidies distribution among the regional efforts aimed at boosting the military sectors by the algorithm output has shown to be a potent force, especially in bigger countries. Following equation (1), we may generally assume that regional authorities have supplied a T_L set of subsidized computations, which we shall refer to as types:

$$T_L = \sum_{m=1}^{c} \left\{ T_1(c_1, \dots\dots, c_n) + \sum_{m=1}^{T} T_l(c_1, \dots\dots\dots, c_n) \right\} \quad (1)$$

The quality of funds supports D_l^n given to enterprise m in terms of rule T_l is the quantity of most recent financial statement performance indicators serves as a benchmark. The subsequent equation (2)

$$D_l^n = \sum_{l=1}^{T} T_l((c_1^n) \quad , \dots\dots\dots, (c_m^n) \quad (2)$$

Each subsidized allotment of the Defense Managing Zones Algorithm of subsidy allocation among the regional

DOI: rp-9788770040723.094

ventures is financially sound. To explain the equation (3) indicates that the total amount of a subsidy cannot be greater than the whole amount of such a budgetary provision.

$$\bar{E} = \sum_{n=1}^{N} D_l^n \leq D + \sum_{l=1}^{t} T_l((c_1^n) \qquad (3)$$

The$\bar{E}$ has been described as an algorithm for allocating funds among regional projects in the defense sector. The following equation (4) determines for each indicator the quantitative relationship between its value and the enterprise's performance measurements.

$$E_j = \sum_{j=1}^{E} E_j(c^1, c^2, \dots\dots\dots, c^N) + \sum_{l=1}^{n} D_l^n \leq D \;\; j = 1, \dots\dots.J, \qquad (4)$$

E ach cash allotment can be represented by a modified worth $p_n(D_n,$ Dl). The following equation (5) will result in the maximum potential output growth thanks to the idea of acceptable resource allocations by incursion, which is concerned with creating a management plan.

$$D_l^n = \sum_{n=1}^{l} \pi^n\left(c^n, q_n(D_n, D_l^n)\right) \qquad (5)$$

To enhance the defense sector for intrusion on the condition by the equation (6).

$$C_m^n = \sum_{m \to n}^{c} \varphi_m^n\left((c^n) \;\; ,, q_n(D_n, D_n^l)\right), \qquad m1, \dots\dots., M \qquad (6)$$

IV. Experimental Results

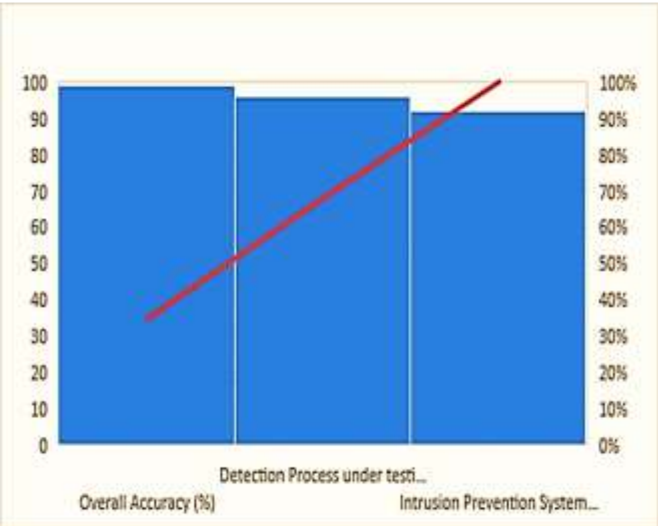

Fig. 2: Performance Analysis Computational ML model based on Intrusion Detection

An IPS is a networking tool (either hardware or software) that overcomes and manages a default network for illicit behavior and that takes action to prevent it, such as blocking and reporting, or dropping the functions, if it does occur. IPS is a security solution that provides active prevention. An IPS sit in the path of network traffic. The primary role is to prevent the system from intrusion. An intrusion prevention system (IPS) slows down entire traffic. An IPS is also known as an IDPS due to the services it provides. An IPS, in essence, sits in line with stable and secured network traffic and supervises it. It detects malicious network activity by analyzing intrusion signatures, generic behavior, and heuristic methods and takes the action of dropping all of the packets and obstructing the traffic. When such an event occurs, it also sends alerts to the administrator. The numerical analysis is presented in Table 1.

TABLE 1: Comparison of Result Analysis with the Existing Method

Algorithm	Intrusion Prevention System Training (%)	Detection Process under testing (%)	Overall Accuracy (%)
Intrusion Detection Algorithm	91.98	95.98	99.12
Existing Method: Naïve Bayes	85.98	90.59	91.87

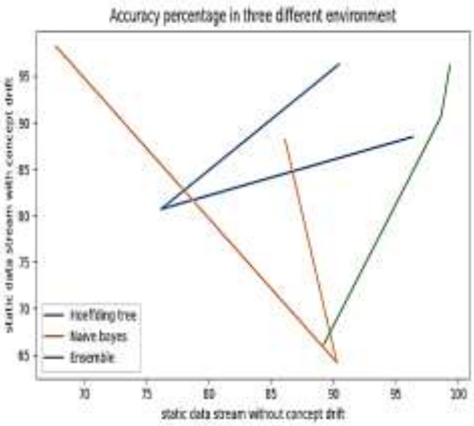

Fig. 3. Performance analysis of different algorithms based on Accuracy

The above Figure 3 depicts the accuracy variations in identifying the intrusion in any given network based on different algorithms. The analysis is performed over the static data of the given environment.

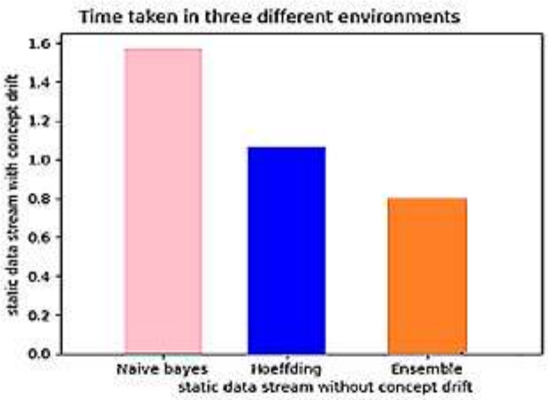

Fig. 4. Performance based on the time taken for intrusion detection

DOI: rp-9788770040723.094

Performance analysis based on the time taken for the detection is presented in the Figure 4 in which the Naïve Bayes Algorithm has taken longer duration for identification than other proposed algorithm is presented. Kappa value Analysis is presented in the following Figure 5.

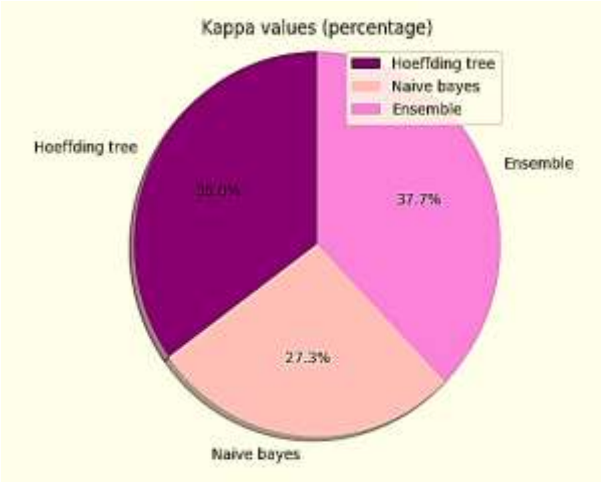

Fig. 5. Kappa Value Analysis

V. Conclusion

The proposed Intrusion Prevention System (IPS) is a security device that keeps an eye out for and tries to stop hostile activities on a network and system. Sensing and perception layer security concerns and vulnerability evaluations exist, as well as information security risks that differ from traditional network era characteristics. Nonetheless, ML methods have fundamentally altered the assessment of cybersecurity threats. To detect network anomalies, the system employs a variety of techniques, along with intrusion detection and managing the flow of identification. Nonetheless, the system has some kind of limitations, such as the integrity of the entire data controllence used to produce the input with its output. New ML methods are becoming progressively popular as a result of the need for quicker and more useful evaluation using the data.

Abstract—The integration of computer vision and machine learning techniques has led to significant advancements in pattern recognition and image categorization. One of the most sophisticated machine learning techniques for encoding features based on hierarchical relationships is the capsule network. Unlike convolutional neural networks (CNNs), which lose much spatial location information and require extensive training data, capsule networks use inverted graphics and a network of capsules to represent objects as separate pieces and establish their interconnections. This paper aims to present an overview of various capsule network architecture designs employed in different applications, highlighting their pros and cons. The objective is to provide readers with a comprehensive understanding of the current state-of-the-art capsule network topologies.

Keywords—Capsule Neural Network, CNN, Deep Learning, Image Classification

I. Introduction

Computer vision is a crucial field of artificial intelligence that has numerous real-time applications, such as security, character recognition, object segmentation, and image recognition [1-2]. Convolutional neural networks (CNN) and recurrent neural networks (RNN) are the primary deep learning techniques used in computer vision, as traditional symbolic AI approaches are insufficient for complex real-time problems [5]. Among these techniques, CNNs are the most widely used and effective solution for image classification, image identification, and picture recognition tasks, ranging from simple to complex objects [6-7]. Nonetheless, CNNs suffer from the pooling process, which leads to the loss of vital details like object position and posture [8]. Additionally, CNNs lack rotational invariance and require extensive training data [9]. To overcome these limitations, alternative methods such as reinforcement learning [10] and end-to-end connected layers have been proposed. However, these approaches did not yield significant improvements, leading to the development of Capsule Network (CapsNet).The CapsNet has been shown to improve model accuracy by up to 45% compared to CNNs. This paper aims to review the shortcomings of CNNs while highlighting the positive results of CapsNet in the literature. Therefore, the primary contributions of this paper are:

- Inspire researchers by presenting cutting-edge capsule models.
- Investigate potential future research fields related to capsule networks.
- Provide a comparison of the most advanced CapsNet architectures to aid in selecting the most suitable model for specific applications.
- Examine the variables that influence the performance of these architectures with modifications and applications, allowing for a better understanding of the strengths and weaknesses of CapsNet.

This study aims to clarify the fundamental concepts of capsule networks, which have gained popularity as a recent research area. Additionally, we provide a comparative analysis of CapsNet designs used in various applications to overcome the limitations of CNNs, including their advantages, disadvantages, and potential future approaches.

The paper is structured as follows: Section 1 outlines the study's objectives and provides background information on the topic under review. In Section 2, we summarize literature survey of CapsNet architectures, including their limitations, modifications, and applications. Section 3 describes the performance analysis. Finally, Section 4 concludes the paper.

A. *Convolutional Neural Network (CNN)*

Let's discuss the attributes of an image required for its recognition by a CNN. Specifically, let's consider a gray scale 2x2 pixel image, with each pixel represented by an 8-bit value ranging from 0 to 255. These values denote the intensity of the corresponding pixel, where 0 represents black and 255 represents white. The gray scale range between black and white spans from 0 to 255. Figure 1(a) illustrates the computer's interpretation of the gray scale image, while Figure 1(b) depicts the computer's representation of its features.

Pixel 1	Pixel 2
Pixel 3	Pixel 4

Deep Learning (DL) algorithms designed for image categorization are referred to as Convolutional Neural Networks (CNNs). Their primary purpose is to interpret image data, assign importance to various features, and differentiate between different classes. A CNN is composed of a fully connected layer with an activation function, a pooling layer, and a convolutional layer [11].

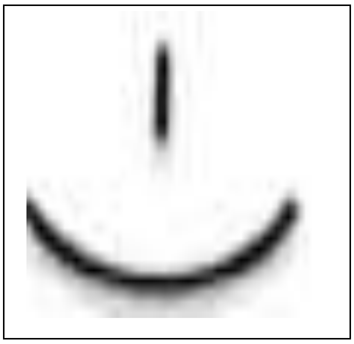
The input image is scanned by the convolutional layer to extract low-level characteristics, such as edges. This layer performs convolution between the input image and a set of

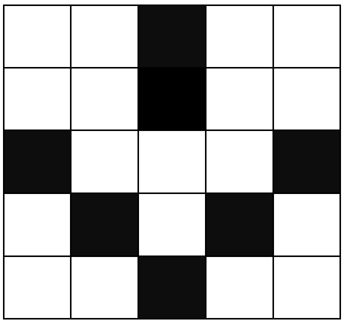
DOI: rp-9788770040723.095

learnable filters, resulting in the production of feature maps that highlight different patterns and features of the image. The Rectified Linear Unit (RELU) activation function [12] is applied to introduce nonlinearity in the model's computations and improve its accuracy.

The pooling layer, also known as down-sampling, is utilized to reduce memory requirements and recognize the same object in multiple images. Different types of pooling methods such as maximum, minimum, sum, and average pooling are employed based on the requirements of the model.

Figure 2 demonstrates the fundamental organizational structure of a CNN. It includes multiple convolutional and pooling layers that extract and reduce the image features' dimensions, respectively. The fully connected layers at the end use these features to classify the image into different categories.





0	**0**	**1**	**0**	**0**

Fig. 1.(b) Image Representation on a computer

The main issue with the pooling method in CNNs is the loss of valuable features from the input image. As a result, CNNs lack equivalence, meaning that different inputs with similar features may result in different outputs. This lack of invariance is a significant limitation of CNNs, which require substantial amounts of training data and processing time to improve their accuracy [13].

Furthermore, CNNs are susceptible to misclassifying objects when the input pixels are perturbed. Even small perturbations can significantly affect the output of the network, leading to incorrect classifications [14].

B. Capsule Network (CapsNet)

Capsule Network, also known as CapsNet, is a deep learning architecture designed to encode the connections between different entities, such as scales, location, pose, and orientation, to improve object recognition [15]. Unlike traditional Convolutional Neural Networks (CNNs), which may misclassify an image containing mouth, nose, and eyes as a face, CapsNet can effectively identify such images as not being a face by learning the relationships between different features. CapsNet is a type of neural network that can also generate inverted visuals. When detecting an object, CapsNet breaks it down into components and creates a hierarchical relationship between all the components to represent that object.

The implementation of CapsNet includes three major components: input layer, hidden layer, and output layer. The input layer processes the input image, and the hidden layer uses dynamic routing to capture the relationships between different features. Finally, the output layer produces a vector that represents the likelihood of the input image belonging to a particular class [16].

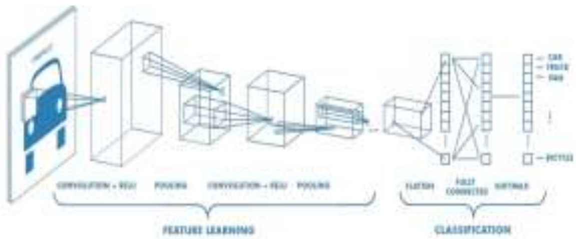

Fig .2. Basic Structure of CNN [15]

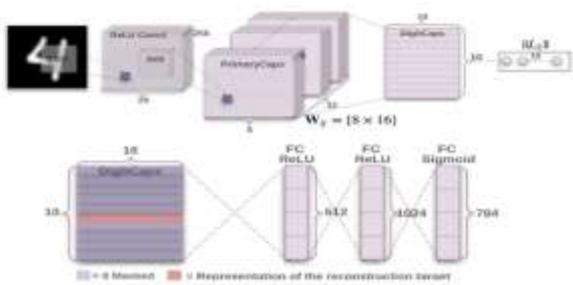
The Capsule Network was developed by Sabour and Hinton in 2017, with the goal of improving object recognition. The network includes two convolutional layers, with the first layer consisting of 256 channels and 99 filters. The stride for this layer is 1, and it uses the RELU activation function.

The second layer of the Capsule Network is a convolutional layer with 6632 capsules, and it uses a stride of 2. Each major capsule in this layer consists of 8 convolutional units and uses a 99 kernel. The squashing function is employed as the activation function in this layer.

The last layer of the Capsule Network is called the DigitCaps layer, which is a fully connected layer made up of 16D capsules in size 10. These capsules gather information from every capsule in the network and use it to classify data into ten different categories.



DOI: rp-9788770040723.095

Fig.3. Structure of Capsule Network [15]

Figure 3 shows the structure of the Capsule Network, which includes the different layers and capsules used in the network. The unique architecture of the Capsule Network allows it to encode the connections between different features, making it effective in object recognition tasks.

C. *Modification in CapsNet*

The Capsule Network has been subject to various modifications to enhance its performance beyond its initial implementation. Some researchers have suggested using densely connected convolutional layers instead of the original convolutional layer in CapsNet to generate a more discriminative feature map. However, this can lead to the vanishing gradient problem, which can be addressed by adding a dense connection to create a feature connection between each layer in a feed forward manner. Additionally, CapsNet can be improved by adding more convolutional and fully connected layers to perform better on datasets beyond MNIST. The initial routing technique in CapsNet used the SoftMax algorithm to normalize routing coefficients, but other routing strategies have been proposed to enhance CapsNet's performance against adversarial attacks, including Self-Routing, Expectation-Maximization Routing, Variational Bayes Routing, and Inverted Dot-Product. Despite these improvements, CapsNet is still susceptible to deception like CNN. Other methods, such as representing an entity with a matrix rather than a vector, and coupling CapsNet with advanced Convolution Network modules like skip connections and dense connections, have also been proposed to increase CapsNet's parameters and improve its performance. These novel routing strategies and architectures can enhance the resilience of affine translation in CapsNet.

II. Literature Survey

In 2017, Hinton et al. introduced the Capsule Network (CapsNet) as a solution to overcome the limitations of CNNs. The CapsNet not only extracts and learns information about visual features, but it also learns how these features relate to one another, resulting in a more accurate model. Tests were performed on the MNIST digit dataset, and the CapsNet model outperformed the latest CNN models.

In [17], the authors proposed Failure to detect gastrointestinal (GI) tract diseases early can have severe consequences, including the development of cancer and even death. Traditional procedures for detecting these diseases are often painful and cannot cover the entire GI tract. Wireless capsule endoscopy (WCE) offers a painless and efficient alternative, but generating a large number of images makes it challenging to identify abnormalities. RAt-CapsNet offers a methodical approach to identifying GI abnormalities in WCE images and has the potential to become a promising diagnostic tool.

Researchers conducted a study that was published in [18], The Multilevel Capsule Weighted Aggregation Network (MCWANet) is proposed in this paper. The MCWANet utilizes a decoupled dynamic filter (DDF), a new multilevel capsule encoding module, and a new capsule sorting pooling (CSPool) method to extract and fuse multilevel and multiscale features, resulting in strong semantic feature representations. Experiments on two challenging datasets, AID and NWPU-RESISC45, demonstrate that the proposed MCWANet performs competitively in RSSC.

In [19], the authors proposed FRCapsNet is a new CapsNet proposed in this paper that aims to deal with the heavy computational burden of traditional routing algorithms. The proposed fast routing algorithm allows low-level capsule information to be sent to all high-level capsules simultaneously, reducing computational costs. Future work aims to connect capsules of different levels in a convolutional way, which would reduce the number of trainable parameters.

The authors suggested this in [20], a novel image classification model named Dense Caps is proposed. The model is based on dense capsule layer connection and hierarchical feature combination, composed of multiple dense capsule blocks. This is the first attempt at capsule-level dense connection, and the paper conducts an in-depth study on the feature capsule redundancy problem.

The authors suggested this in [21]. Botnet detection is the process of identifying botnets in network traffic. This paper proposes the LSTM-Capsule Net model, which combines the k-means routing algorithm with the original dynamic routing algorithm for ablation experiments. The proposed model offers better feature map clustering and generalization ability than the original dynamic routing algorithm. Experiments show that the LSTM-Capsule Net model performs better than comparison models in the DGA domain name recognition task and in multi-classification of the DGA domain name family and recognition of Real-Dataset and Gen-Dataset.

In [22], researchers proposed a capsule network called MIXCAPS, which eliminates the need for fine annotation by using a combination of experts and automatically dividing the dataset using a gating network based on convolution. The model achieved an accuracy of 92.88%, sensitivity of 93.2%, and specificity of 92.3% while being independent of pre-defined hand-shaped traits.The proposed method's unique design enables it to achieve high accuracy in object recognition tasks while eliminating the need for hand-crafted features.

The proposed [23] CapsPhase is trained using the SCSN earthquakes. The input is divided into S-probability, P-probability and noise probability. It is tested using STEAD & Japanese dataset. Here, convolutional, primary capsule and digit capsule are mainly used. Convolutional is used to create feature maps (4 s-three components). Primary capsule is used to produce the combination of feature maps. Dynamic routing is used to keep the spatial relations of the output. Digit capsule layer produces the P-Wave and S-Wave arrival time. Median filler is used here to smooth the output.

The author proposed [24] the method of feature extraction using Self-attention generative capsule network which is optimized with Sunflower optimization algorithm to overcome the high over fitting problem in previous methods done by others. This method makes use of the NIH chest x-ray image dataset from Kaggle to train and extract the features to detect the lung cancer and other lung related diseases.

The author [25] makes use of the optimized hybrid deep learning model to detect the liver disease called liver cirrhosis. Many modalities for the detection of this disease is done but it lacked the higher detection accuracy. So to overcome that, 1232 MRI images collected from hospital is used to train using two deep learning algorithms, CNN and capsule network (HCNN-CNN) are integrated to detect the liver disease with high accuracy rate.

Numerous alternative methods are utilized in Q-CapsNet to find color and facial form, according to the authors' proposal [26]. Quaternion algorithms are initially paired with capsule network layers. The input from facial color is then converted into capsules using a quaternion routing approach and a convolutional layer (RGB). Quaternion convolutional would incorporate the quaternion matrices in order to extract geometric descriptions and capture the internal dependencies between the color channels. The RGB input color matrix and the length and width input geometry are then provided in the QConvCaps layer, where they are combined into a single output. Quaternion routing algorithms of the QConvCaps Layers and QFCCaps Layers are utilized to combine it into a single prediction.

TABLE I. PERFORMANCE SUMMARY OF SOME CAPSULE NETWORK

Ref. No.	Author Name	Methods	Advantages	Disadvantages	Dataset
17	M.D. Jahin	A Novel CNN	Achieved better classification of images.	Insufficient Dataset to compare the images.	• Kvasir Capsule
18	Chunyuan Wang et.al	A Novel Capsule Network for RSSC name MCWANet	Achieved better Accuracy 95.89 and 92.15%	Further improve its classification	• AID • NWPU-RESISC45
19	R. Zeng and Y. Song	Fast Routing algorithm	Achieved better performance in 71.2% of better classification accuracy.	Reduced the Computational cost	• MNIST • CIFAR10
20	Guangcong Sun et.al	DenseCaps	More accurate and trained models	Data imbalanced in dataset	• MNIST • Fashion-MNIST • CIFAR-10 • SVHN
21	Xiang, C et.al	Capsnet	Accuracy can be increased by varying the number of feature map	Accuracy can be increased by varying the number of feature map	• MNIST
22	Afshar, P., Mohammadi, A. and Plataniotis, K.N	MIXCAPS	Lung nodule malignancy prediction	The MNIST used in this paper is simplistic image and additional experiments needed using complex datasets. CapsGAN have the ability in capture geometric transformations.	• LIDC dataset • IDRI dataset
23	Omar M. Saad, Yangkang Chen	CapsPhase – Convolutional, primary capsule & digit capsule layers	Ability to learn from small datasets. No loss of data about position, location & texture. Robust performance even with background noise.	Needs the accurate arrival time to perform. Cannot be done for continuous data. Training time is more. Low resolution	Southern California Seismic Network(SCSN), Stansford Earthquake Dataset(STEAD), Japanese Seismic Data
24	N.B. Mahesh Kumar	Self-Attention Generative Adversarial Capsule Network	Reduced high over fitting problem	Classification method is challenging	NIH chest X-ray image dataset
25	H. Shaheen	Optimized hybrid deep learning model	Achieved higher detection accuracy	Classification method is challenging	1232 MRI images from hospital
26	Yu Zhou , Lianghai Jin, Guangzhi Ma and Xiangyang Xu	Quaternion technique is used to process the colour information like different skin colours and illumination variation.	Q-CapsNet achieves higher accuracies than the Capsule Network	Low resolution facial images cannot be recognized	• MMI • Oulu-CASIA • RAF-DB • SFEW

III. PERFORMANCE ANALYSIS

In this section, we compare CapsNet's accuracy, number of parameters, and network speed. We choose the most appropriate hyper-parameters for this comparison. We carried out multiple trials to identify the best set of hyper-parameters.

TABLE II. CAPSNET: ACCURACY OF THE DATASET

Dataset	Accuracy (CapsNet)
MNIST	99.63%
F-MNIST	91.35%
CIFAR-10	71.63%
CIFAR -100	72.65%
SVHN	93.04%

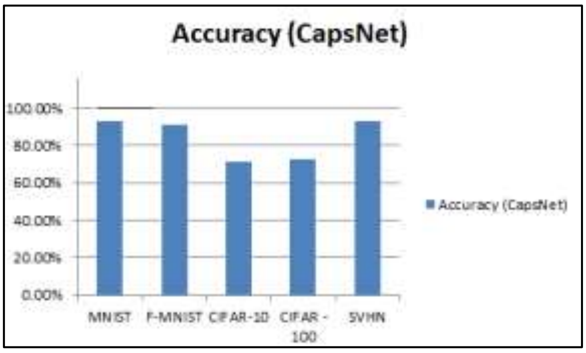


Fig. 4. CapsNet : Accuracy of the Dataset

The performance of the capsule network design is examined using the dataset, an older MNIST dataset, the CIFAR-10 dataset, and iterations. It should increase performance based on the noval capsule architecture. We are currently developing a novel architecture to evaluate multiple types of image classification datasets with high accuracy. The outcomes of the various datasets are shown in the table and figure above.

IV. CONCLUSION

The Capsule Network was introduced as a solution to the limitations of the classic CNN algorithm and has shown great promise so far. However, to fully realize its potential, further research and development are needed. In this study, we evaluated the effectiveness of various algorithms that have an impact on the field of computer vision. We specifically focused on examining how the current capsule network architecture was put into practice and provided more information about its achievements, drawbacks, and possible modifications.

The findings of this research will be beneficial to the computer vision community as they can use the successes and failures of the capsule network to develop a more reliable machine vision algorithm. By considering the structure of the capsule network and exploring ways to improve it, we can work towards achieving more accurate and efficient object recognition and classifications.

***Abstract*—There are several sign recognition algorithms that produce word output to facilitate communication between mute persons and non-mute people. Our suggested approach focuses on translating sign language into text and voice. With the aid of Natural Language Processing (NLP) techniques, which include automatic word completion and sentence creation, appropriate English sentences are framed with expected words before being transformed to speech. Live video is used as input, then video is framed and segmented. For monitoring hand and facial gestures, Media Pipe Holistic algorithm is utilized.**

Keywords—Natural Language Processing, Holistic Media Pipe

I. Introduction

People with hearing loss frequently utilize as a communication method, sign language is used. A sign language is nothing more than a collection of varied hand signals created by varying hand shapes, movements, and orientations, together with face expressions. 34 million of the 466 million people with hearing loss in the world's population are children. Deaf individuals have minimal to no hearing abilities. They communicate using sign language. Around the world, many sign languages are used by people. They are quite few in number when compared to spoken languages. Indian Sign Languages is the name of the sign language used in India (ISL). There aren't many deaf-specific schools in poor nations. Gestures are naturally performed by humans.

Gestures are made intentionally, as signals or indicators, or unconsciously to communicate attitudes or intentions. Even though they entail the entire body's movements, studies frequently concentrate on the arms and hands since they are necessary for movement and dialogue. Facial expressions play a significant part in communication and are also regarded as gestures. Most everyday human actions or activities involve gestures, which take part in human interaction through either completing speaking or standing in for someone else for uttered words in situations requiring silent communication (under water, in noisy environments, in secret, etc.) or for those who have hearing impairments.

Between the speaking community and the deaf and mute population, there has always been a communication barrier. This is particularly clear when there is an emergency. A human interpreter is typically used in order to translate. However, everyone cannot afford a professional translator, and in times of crisis, the presence of a human interpreter cannot be guaranteed. This undertaking tries to remove this obstacle. The process of image processing and machine learning are used to complete the assignment. For picture categorization and recognition, very potent tools like the process of processing images and machine learning are frequently used.

Image processing is concerned with the image, its elements, and the actions taken to extract information from it. The research into algorithms and statistical information that are used to carry out tasks utilizing different data patterns and conclusions is known as machine learning. A camera will be used to capture the images of sign language for this project. The features are then retrieved from the photos using image processing. These photos are then compared using the datasets that are readily available, and the indications are deciphered using deep learning. The information is shown on a display so that individual seeing a deaf or mute person can comprehend their sign language

This project seeks to bridge the communication gap between a person with a physical impairment and a person who is specially challenged by identifying symbolic expressions through photographs and translating them into voice or text. To provide output in the form of words, various sign recognition algorithms are applied. Our suggested approach focuses on translating sign language into speech. Natural language processing techniques, such as automatic word completion and sentence creation, are used to construct appropriate English sentences with expected terms. Live video is used as the input, then video is framed and segmented. For tracking hand and facial gestures, Media Pipe Holistic algorithm is employed.

II. Literature Survey

There are four basic steps in the implementation: Enhancement and segmentation of images 2. Detection of orientation Extraction of Feature 4. Categorization.

In [1], The system uses video sequences from which convolutional neural networks were built and adds photographs of the train data. Predictions for individual frames were made using the Trained Convolutional Neural Network model in order to provide a sequence of predictions. The system was created for the purpose of translating Indian sign language and producing legible output, the proposed system creates a trustworthy communication interpretation programmed Static sign-language motions were identified using a deep learning system. This algorithm was developed for use with a Raspberry Pi. A camera was used to capture the photos, after which the features were retrieved using HSV filtering.

DOI: rp-9788770040723.096

The values for the skin tones were chosen to distinguish the hands from the background. The image was then changed to a grayscale format in order to recover the hand's characteristics. Following this, the groupings of these images were separated into training and test groups, and the model was fed with them. The proposed model had two dense layers, the first of which served as the activation layer and the second of which served as the tanh layer [2].

The suggested solution makes use of a hand glove to recognize unique patterns and gestures. They employed Flex Sensors. Processing was carried out using Arduino Mega. To mimic the user's hand movements and patterns, a glove was used. Flex sensors are positioned here along the thumb and fingers. The sensors determined how much the fingers were bent and produced a voltage fluctuation as an output [3].

The technology designed produced a variety of words, voice, and gestures. This suggested method let normal people and people with disabilities communicate with one another. By using a high-definition camera to record various hand motions, a training dataset is built. A minimum of ten photos are taken for each gesture. The median filter is used to denoise the collected images. By removing the backdrop information, the hand gesture alone was segregated for better training [5].

For this system's implementation, the suggested system offered audio as input, and pattern matching techniques were utilized to match the audio. The results displayed the indicators for audio matchups. Second, for the system to record the Sign movements, a web camera was required. The result of the identified sign language gesture in audio form was shown [5].

[6] The device provided real-time audio, making it simpler for those with hearing loss to communicate with others who can hear them. If the phrase is saved in the database, the system will be able to recognize it in the sentence and present sign language videos that are relevant to it. Almost a thousand films, a combination of the author's own recordings and freely accessible lectures by ISL professors, were stored in the database.

The proposed device is a personal communication system designed to assist people who are deaf, dumb, and/or blind in communicating with others. The device is adaptable and incorporates various technologies such as text-to-voice conversion, OCR, and speech-to-text conversion to enable users to interact with each other through text or spoken language. For dumb individuals, the device offers a text-to-voice conversion feature that reads out the text for them. Visually impaired individuals can use the device's OCR feature to read text, and the e-speak technology can read the text aloud for them. Deaf individuals can use the device's speech- to-text conversion feature to read what others are saying or communicate using written text that can be converted to speech for others. Blind individuals can also use the device's OCR feature to read text or paragraphs. [7].

[8] Using a three-dimensional hand point as input, the hand pose estimator precisely and successfully regresses the hand joint locations. A folding-based encoder is used in the proposed model to fold a converted into the appropriate joint coordinates from a 2D hand skeleton. Folding was guided by multi-scale characteristics that included global and joint-wise local features for increased estimation accuracy.

The "intelligent robotic arm voice-controlled assistance device for physically challenged person" was part of the planned system. The joystick was used to control a robotic arm that was installed on a rail system. The movements were recognized as input by both the gloves and the camera. The gestures were converted into speech with the use of the pre-defined dataset, which had a gesture corresponding to each word [9].

The proposed device enabled interaction between the blind, deaf, and dumb by using a glove-based communication interpreter system. A three-axes movement tracking inertial sensor was part of the glove system. (x,y,z). Data from the accelerometer sensor was analyzed by the microcontroller before being sent over Bluetooth to the mobile device, where it was converted into text or speech [10].

[11] The suggested approach made it possible for a deaf person to interact with hearing people without the use of an interpreter. The authors made use of the Tensorflow library and the Keras framework. The camera captured the image, compared it to the previously recorded photographs, and then assigned it to the appropriate pre-defined character. The result was created once the words were placed together into a phrase that made sense as a sentence.The suggested technique uses self-comparisons to accurately estimate the hand positions on three publicly available hand pose datasets. For the ICVL and NYU datasets, the suggested method outperformed methods that were based on 2D CNN, and it also did well on the MSRA dataset. The suggested technique determined the mesh vertices of each individual human part, including the body, hands, and face regions, in a 3D environment [12].

The proposed model makes use of CNN and Attention-Based Hierarchical RNN to quickly identify URLs. They were able to develop an accurate model to recognize phishing URLs by integrating these URL models using a three-layer CNN [13].

The first stage in developing sign language detecting systems was accurate hand segmentation. The hand in the original image was recognised by the authors in the proposed study, and they gave this part of the image to the multi-class classifier, which can identify static motions. The proposed approach first built the data collection, converting each image into a feature vector (X) and giving each one a label that matches to the sign language alphabet given by (Y). The projected classifiers correctly identified 65% of the aforementioned images [14].

[15] The purpose of this approach was to close communication gap between those with hearing and speech impairments and the general public. The available alternatives either don't provide real-time data or provide data with a low level of precision. This system produced positive results for both parameters. 33 hand motions were

DOI: rp-9788770040723.096

identified, along with a few ISL gestures. A smartphone camera captured frames of Sign Language, which were then transferred for processing to a distant server. It is user-friendly because no additional hardware, such as gloves is required. A Grid-based Feature Extraction approach is used to represent the pose of the hand in the image.

III. Methodology

A. Data Generation

Data generation refers to the process of creating or generating data for use in various applications, such as machine learning, data analytics, and artificial intelligence. This data can be created using a variety of methods, including simulations, surveys, experiments, and data scraping.

Data generation is an important aspect of many applications, particularly in the fields of artificial intelligence and machine learning, where large amounts of data are required to train models and algorithms. However, it is important to ensure that the data generated is of high quality and is representative of the real-world situations being modeled or analyzed.

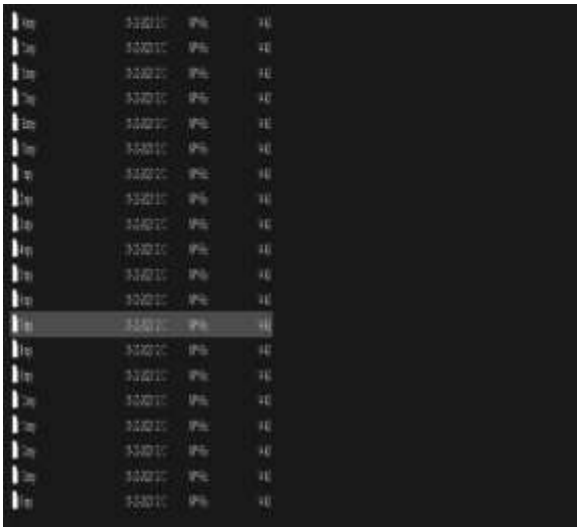

Fig. 1. Data Generation

Sign Translator application is divided into 3 modules:

1) Handgesture Recognition

The input image is pre-processed and the Region of Interest is extracted. The media pipe holistic framework extracts body pose coordinates, hand pose coordinates and face pose coordinates. Then the coordinates are transformed into NumPy arrays. For each gestures up to 30 NumPy arrays are already generated and collected in respective class and the model has been trained with the collected data. So that the gestures will be recognized and corresponding words will be produced.

There are several approaches to hand gesture recognition, including using depth cameras, 2D cameras, and machine learning algorithms. Depth cameras, such as Microsoft's Kinect, use infrared technology to capture depth information, making it possible to distinguish between the hands and other objects in the environment. 2D cameras, on the other hand, rely on image processing techniques to detect and track the hands.

Machine learning algorithms, such as convolutional neural networks (CNNs), are commonly used for hand gesture recognition. These algorithms are trained on large datasets of hand gesture images, allowing them to recognize a wide variety of gestures. They can also adapt to different lighting conditions, camera angles, and hand positions.

Hand gesture recognition has numerous applications, including controlling devices without physical contact, assisting people with disabilities, and improving human-robot interaction.

Fig. 2. Handgesture Recognition

2) Gesture to text and speech

The process of gesture to text and speech typically involves using a camera to capture hand gestures, which are then interpreted by computer vision algorithms. These algorithms can recognize different types of hand gestures, such as pointing, waving, or making a specific hand shape, and translate them into text or speech output. One common application of gesture to text and speech technology is sign language recognition.

From the hand gesture recognition module, the keywords are produced. Using the Long Short Term Memory Natural Language Processing (LSTM NLP) model, meaningful statement from the produced words will be framed. Also using the face pose marks and body pose marks the proper meaningful expressive sentences can be generated with proper tenses.

DOI: rp-9788770040723.096

Fig. 3. Gesture To Text And Speech

3) Speech Or Text To Gestures

From the Mic the voice will be recorded and sent to Natural Language Processing (NLP) model. The Speech will be processed by Natural Language Processing (NLP) model. Then the keywords are extracted. For each word animated gesture video are made and stored. The extracted words will be mapped to the respective video file. Finally, all the mapped videos will be merged and produced as a single video which can be understood by Speech impaired people.

Fig. 4. Speech or text to gestures

IV. Results and Analysis

The classification model's performance is measured in terms of how well it can properly identify instances that belong to a particular class using precision, recall, and F1 score. These metrics are necessary for evaluating the efficacy of a machine learning model and deciding whether to use it in practical applications. The Long Short-Term Memory (LSTM) is a type of recurrent neural network (RNN) architecture used in deep learning. LSTM is particularly useful for processing sequential data, such as speech, natural language, and time- series data. LSTM can produce an accuracy of 100% on train data and 98% on test data.

Fig. 5. Classification Report

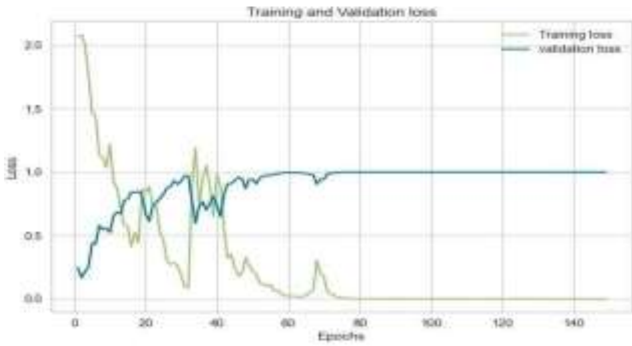

Fig.6. Training and Validation Loss

V. Conclusion

In this study, the existing systems are examined, and a proposed application is created to address the drawbacks of the earlier systems. After studying a number of algorithms and works that give output results with various degrees of accuracy, it is clear that the current systems are either unable to recognize hand gestures accurately or struggle to translate them into speech. The majority of the way the current system operates doesn't happen in real time.

***Abstract*—Diabetes interacts with the capacity of our bodies to turn food into energy. It is a chronic health issue. Your pancreas is prompted to generate insulin when the sugar levels in your blood rise since an enormous portion of the food you consume gets transformed into sugar (glucose) and communicated into blood for circulation. Nowadays, deep learning is used in the healthcare industry to try and forecast diseases. Data is the most essential component of deep learning. p A deep learning model is constructed using the previous dataset, which is gathered. Univariate and bivariate analysis, among other essential pre- processing techniques, are used. A classification model is built using a machine learning algorithm only after data is shown to facilitate with feature interpretation. Algorithms are evaluated based on performance metrics like accuracy, F1-score, recall, etc.**

Keywords— BMI, Deep learning, Dietary plan, F1score, Diabetes

I. Introduction

Humans face a wide range of health problems, including mental and physical health problems. Numerous studies demonstrate that in adequate dietary intake and poor nutrition quality are the primary cause for numerous illnesses and health issues. Heart attacks, ischemic heart disease, and gastrointestinal cancer are the leading causes of death around the world, according to WHO research. Everyone should eat a well-balanced diet to overcome this. A healthy diet is essential for your organs and tissues to function properly. A healthy diet can help strengthen the immune system and prevent disease, according to medical research. A balanced diet includes a wide range of substances, notably water, vitamins, minerals, carbohydrate, proteins, and fats. Medical research has revealed that proper diet plan helps to build up the immune system and fight against diseases. Consumption of proper diet provides energy, vitamins, carbohydrates, proteins, fats, vitamins, minerals, and water multinomial analysis and random forest algorithm is to be integrated to provide healthy diet plan recommendation according to user characteristic.

This diet advice project intends to convey nutrition information in an adaptive manner to enhance the life of both healthy and sick people. The project offers food recommendations based on the attributes and assists users in keeping track of their calorie target based on their BMI. The system offers culinary recommendations to users using a ML algorithm. The system informs the user of the effects and reasons for ignoring the suggested diet.

The existing system just creates a week diet plan based on user attributes like height, weight, and BMI. This application technique develops a diet plan and health recommendations using the random forest algorithm. The system will generate a diet plan based on a healthy diet, weight growth or loss, past user assessments of food flavor and food type with suitable calorie levels, and information about weight increase or loss (carbohydrate, protein, vitamins, calcium, fats, fiber and iron). The strategy will help consumers become healthier and identify the kinds of foods to stay away from to lower their risk of illness.

II. Literature Survey

The objective of the diet recommendation project is to improve the health and wellbeing of individuals, both those who are generally healthy and those with chronic illnesses. To achieve this, the project provides personalized nutrition guidance that takes into account the user's features and assists them in monitoring their calorie intake based on their BMI. The system offers nourishment suggestions that are tailored to the user's preferences and provides explanations for why it is important to follow the recommended diet. Users can also learn about the latest nutrition news and health tips in the system's section.

In [1], The system was built with a strong emphasis on developing a seven-day feeding plan based on an individual’s personal needs and dietary preferences. It incorporates a content-based filtering approach that employs Euclidean Distance to offer alternatives for food allergies or dislikes. Due to the variety of preferences, likes, and dislikes among people, it also addresses the usage of the Pearson correlation coefficient for nutrient assessment and alternative meal selection.

The platform where consumers can locate their preferred food and its nutritional value. Anyone who cares about the health or wants to lose weight can benefit from this. This application can be used independently or as part of a more sophisticated application. Web scraping was used to collect the data set, which was then pre-processed based on attributes. The Content Based Filtering Algorithm was then used in the food recommendation system [2].

The approach was created to take into account the latest innovations in dietary evaluation setups, which are a more beneficial way to monitor daily food intake and manage dietary patterns.

A framework for estimating food, calories, and nutrition is incredibly helpful for individuals’ groups to measure and manage their daily food consumption. AI will offer recommendations based on the benefits or prior experience that the customer has had. These computations are also used to make diet recommendations to the customer. [3].

DOI: rp-9788770040723.097

In [4], An Android application was developed to provide consumers a personalized diet. Similar to a genuine dietitian, it serves as a nutrition advisor. This system operates similarly to a nutritionist. A person must provide the nutritionist with certain details, such as their weight, height, gender, etc., in order for them to gain knowledge about their diet plan. In a similar manner, this system also offers a diet plan based on the data given by the user. To provide the user with the diet plan, the system collects all of the user's information and analyzes it.

The system was designed to operate in a machine learning environment. It evaluates user information comprising age, gender, height, weight, and body fat percentage, as well as choices for weight loss or weight gain, and then recommends dietary habits in three categories for lunch, breakfast, and dinner. Problems encountered in relation to the user. This system uses K-Means and then Random Forest algorithm approach. Problems encountered in relation to the user. The Nutrition dataset from Kaggle is used for recommendation [5].

The study suggests that individuals with diabetes should have snacks due to their specific circumstances and the risk of hypoglycemia between meals. To generate a list of significant items based on user characteristics, environment, and behavior, the approach employs various strategies such as collaborative sifting, knowledge-based, roulette wheel, and content-based sifting (CF) algorithms. In this paper, a recommendation system for various food ingredients is proposed, considering the small test measurement during the assessment phase and the absence of the primary meal. The proposed recommendation system suggests ingredients that are frequently consumed together. [6].

In [7], The recommendation system makes use of a web interface to take into account user inputs and make recommendations for food items based on the user's current requirements. Random Forest Classification, K-Means Clustering, LSTM and Python-based Tkinter GUI. The user interface and dataset in this system need to be improved. Regarding the recommendation of recipes, a system plan for putting recipe search into action takes into account the combination of numerous food ingredients, nutrition, and budget. This app is extremely useful for cooking a wide range of recipes with minimal internet research. Additionally, this app lets users create and save recipes for later reference. It will save people time and effort searching for recipes for both everyday meals and special occasions.

The suggested algorithm improves classification accuracy while producing effective classification. There are numerous approaches for the classification of medical data utilizing various metrics and techniques, and the subject of categorization in medical data has been well investigated. The approaches still struggle to improve classification accuracy performance. The classification algorithm was developed using MLIIM is employed in this study to increase classification effectiveness. By removing the incomplete information, the tool estimates the submitted collection of data to resolve the interference problems. During the subsequent stage, the algorithm periodically and at various levels examines the impact of the measure. Additionally, the method determines the class influence weight (CIW) for distinct classes. [8].

The approach offers personalized suggestions mostly to customers who are dealing with issues like diabetes or heart disease. Dynamic product recommendations enable for the provision of an appropriate product that adapts to consumer preferences over time. The algorithm for product categorization is in charge of data cleansing, tokenization, and frequency calculation. The association between the product and the user should be established via genetic algorithms. The food goods in this application must be acquired by the product buying module. The project doesn't include more product categories so that it can offer recommendations to different people who like items with distinctive nutritional benefits [9].

In [10], The system proposed the target by using their BMI as an input and by taking into account their allergies to let them track their daily calorie intake. Collaborative Filtering algorithm with fuzzy logic. As it is, collaborative filtering systems might need substantial financial support as well as a lot of computational power. Algorithms of machine learning are used in this research. Custom recommendations are a feature that has been added to this project specifically for individuals who have had coronary artery disease, diabetes, or hypertension. Here, nutrition is divided up into four categories: salts, sugar, energy, and proteins. Although the user's or buyer's genetic information is always constant, the product recommendations are dynamic in order to deliver an accurate product that consistently meets user preferences.

The Proposed is a system that aims to provide a comprehensive solution to the intelligent systems layer. The objective of the food recommendation approach is to establish personalized meal plans based on the user's nutritional needs and food preferences. Previous research has focused on developing computational tools for food intake recommendations, but few have integrated user preferences and dietary data. This approach combines a short-term intelligent system with an optimization scenario that considers both tangible and intangible nutritional and personal taste knowledge, as well as nutrient context systems that use an MCDA approach to filter out inappropriate food choices. [11].

In [12], The system uses machine learning techniques to examine users' data such as age, gender, height, weight, body fat percentage, and preferences, such as weight loss or weight gain, to suggest diet plans for three categories: breakfast, lunch, and dinner. The system employs the K-Means and Random Forest algorithms to address individual challenges. Additionally, the system uses a dietary dataset from Kaggle for recommendations.

The proposed system that considers both the major meals, diabetic patients should have appetizers because of a scheme that considers their special circumstances and the danger of hypoglycemia. This system offers suggestions for a list of items that could be useful based on the user's traits, situations, and behavior. In this study, a system for recommending snacks to type II diabetics is developed and evaluated. It makes use of a roulette wheel algorithm, a

DOI: rp-9788770040723.097

knowledge-based approach, and constraint-based reasoning. This system implements a content- based filtering system that uses Euclidean Distance to suggest substitutes for food intolerances or distaste and generates a seven-day food plan based on an individual's requirements and food tastes [13].

In [14], The proposed system recommends a list of food items based on the patient's medical conditions and nutritional value. The user selects a main culinary component, and the system provides a recommendation for the ideal food to eat from the database based on the patient's health. The system evaluates the user's health and suggests foods based on any chronic illnesses or ailments they may be dealing with. The user's medical history is obtained from the specific hospital as soon as they log in, and the application offers the appropriate meal based on their health issue or disease. The system operates precisely and fully maintains the user's health.

The proposed system aims to enhance people's diets by responding to dietary advice with personalized, nutrient-rich recommendations. To calculate these recommendations, the system will rely on the USDA nutrient dataset, which contains valuable information on the nutritional value of various foods. Additionally, users will need to provide their BMI values as an input, which will be used to tailor the recommendations to their specific needs. Another key input for the system is the user's daily food intake, which will be used to calculate the deficit nutrition and identify the missing nutrients that need to be included in the recommendations. To ensure the recommendations are as effective as possible, the input nutrients dataset will be sorted based on the user's BMI value. Finally, any deficit nutrients will be filled by selecting the appropriate foods from the sorted grocery dataset, resulting in a personalized, well-balanced diet recommendation for the user. [15]

III. METHODOLOGY

A. *Data Generation*

Data generation involves collecting datasets from various sources, which can be labelled or unlabeled. If the data is unlabeled, it needs to be manually labelled to represent the class to which the object belongs. This labelling helps the learning model to identify the particular class when it encounters data without a label. As there were no publicly available datasets that considered specific user conditions such as kidney stones and diabetes, the data for this project was collected using web-scraping. Since the proposed method involves multi-label classification, the raw unlabeled data was manually labelled into chronic, anemic, and diabetic data, which were further labelled as breakfast, lunch, or dinner.

	A	B	C	D	E	F
1	cholesterc	glucose	Nutritiona	Hemoglob	age	gender
2	193	77	49	14.9	19	female
3	146	79	41	15.9	19	female
4	217	75	54	9	20	female
5	226	97	70	14.9	20	female
6	164	91	67	14.7	20	female
7	170	69	64	11.6	20	female
8	149	77	49	12.7	20	female
9	164	71	63	12.7	20	male
10	230	112	64	14.1	20	male
11	179	105	60	14.9	20	female
12	174	105	117	13	20	male
13	193	106	63	16.7	20	female
14	132	99	34	13.4	21	female

Fig. 1. Data Generation

B. *Data Preprocessing*

Data pre-processing is performed on raw data. It has traditionally been an important preliminary step. It includes cleaning, instance selection, transformation, feature extraction, and selection. It eliminates the irrelevant noises in the given input. The data collected in this project is obtained through web-scraping. Hence pre-processing of them had to be done to adjust them to the format of machine learning methods. The collected raw data may be labelled or unlabeled. The raw unlabeled data are manually labelled into chronic and diabetic data.

C. *Multinomial Analysis*

Supervised artificial intelligence faces several challenges, and one of the most common ones is multiclass classification. Multiclass classification problems arise when there are at least two types of outputs that need to be classified. This involves organizing data into categories based on their similarities and differences. To achieve this, we need to identify and select relevant features or independent variables that are critical for grouping the data into different categories. Multiclass classification is the process of separating data into multiple categories based on our dependent variable of interest.

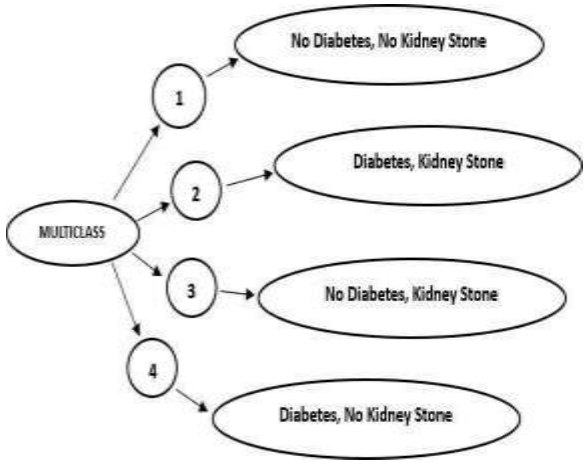

Fig. 2. Multiclass classification

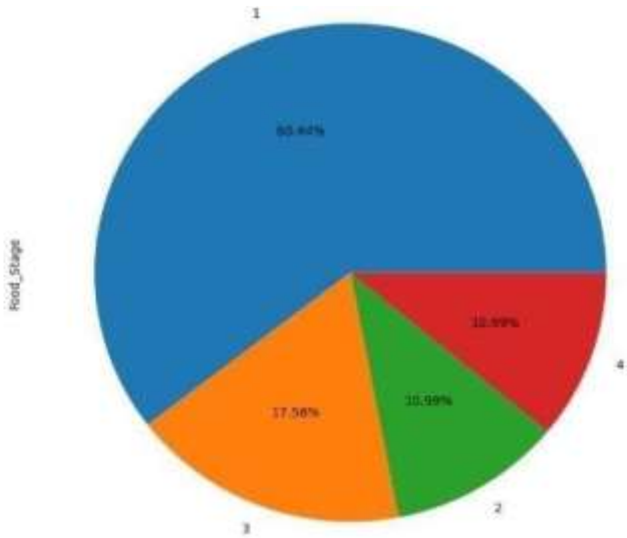

Fig. 3. Multinomial Analysis

DOI: rp-9788770040723.097

D. Experimental Environment Setup

The system architecture diagram provides a visual representation of the system's architecture, illustrating the connections between various system components, along with the purpose of each component. The general system representation depicts the primary system functions and the connections between different system parts. Pre-processing is done on the food dataset here, and the pre-processed data is then subjected to multinomial analysis and clustering to generate diet recommendations.

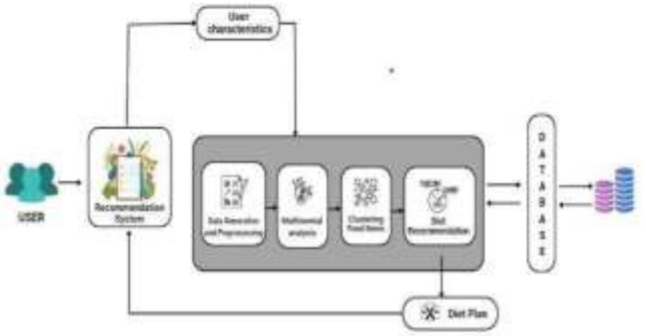

Fig. 4. System Architecture

E. Machine Learning Algorithms

1) Support Vector Machine

SVM among the most commonly employed methods for supervising learning, that is commonly used for classification and regression task. With the help of the SVM algorithm, researchers can classify new data points to make it easier in the future by creating a line of best, or decision boundary, that divides the n-dimensional space into groups. A hyperplane is this optimum decision boundary. SVM operates for producing the hyperplane by choosing the extreme points and vectors. The scientific name for the optimization technique as an SVM— one of the most popular techniques for Supervised Methods sustained vectors, and these extreme examples are defined as supported vectors.

2) Random Forest Classifier

Random Forest is popular ml algorithm that is commonly used as regression and classification task. The algorithm based on concept of ensemble learning, which involving combining many classifiers to enhance the accuracy of the particular model. It is a type of model that uses an ensemble of the decision tree, which are trained on using subsets of the provided datasets. The algorithm then takes mean of that predictions of all decision tree to enhance accuracy of the overall prediction. Unlike relying on just one decision tree, a Random Forest makes predictions based on the collective assessments of all decision trees in the ensemble, selecting the result based on the majority of predictions. By using multiple decision trees in the ensemble, Random Forest can increase accuracy and avoid the sampling.

3) Decision Tree Classifier

Decision trees classifiers can also be used for feature selection, where the most important features are identified based on their ability to split the data and classify instances correctly. This can help can also help to reduce the dimensionality of the input space. A decision tree is composed of a decision node and a child node. A leaf node represents the outcome of a decision without any subsequent branches, while a decision node represents the decision and has multiple branches. To make decisions, decision trees consider the features of the provided dataset. A decision tree is a visual representation of every possible solution for solving a problem or making a decision on given parameters. It is known a decision tree because it starts at root of the tree and grows in subsequent branches, resembling a tree. The Regression and Classification Tree (CART) technique is used to construct a decision tree.

4) MLP Classifier

Neural networks called multilayer perceptron produce result from predetermined inputs. A graph which is directed connect output layer and input layer of mlp consists of a several layers of modern output nodes. A multilayer perceptron is a powerful learning technique that creates an organization. Originally developed for image recognition, perceptron commonly referred to as computations. It carries out the human-like task of seeing, viewing, and it carries out human-like task of seeing, viewing, and identifying images. In essence, a multilayer perceptron is a cutting-edge neural structure with three different sorts of layers: input, output, and hidden. An input flag is delivered to an input layer for processing. The output layer carries out activities like prediction and categorization.

F. Clustering Food

The system could recommend a healthy diet plan according to the personal condition. Food is clustered into breakfast, lunch, dinner for recommendation. For the diet recommendation, we have devised our own algorithm which splits the foods into nutrients like fats, fiber, vitamins, etc.

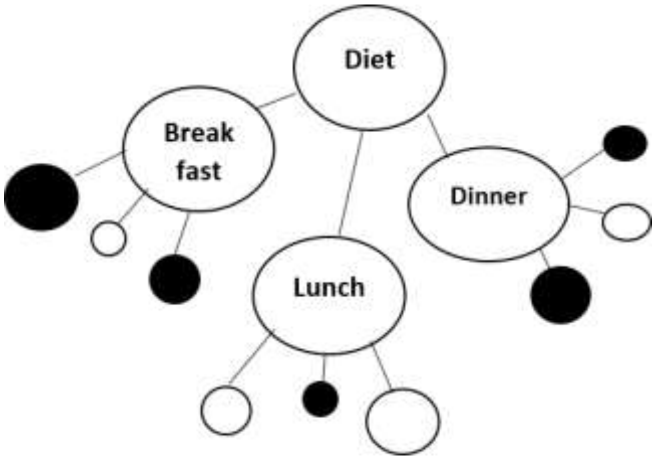

Fig. 5. Clustering food

And based on the nutritional requirements needed for a day a balanced diet is provided. The system also displays the BMI value under consideration and provides a diet plan to maintain them at normal. system could recommend the related diet plan to fulfil personalized needs by using multinomial analysis. Therefore, it would provide better service and experience for users.

DOI: rp-9788770040723.097

IV. Results and Analysis

Evaluating recall, F1 score and precision are commonly used to know the performance of classification models in accurately identifying instances belonging to a particular class. These metrics are crucial in determining the suitability of machine learning models for real-world applications and assessing their effectiveness. The Random Forest algorithm is a highly effective method, capable of handling complex nonlinear problems, managing large input datasets, and providing fast predictions. It has demonstrated an accuracy of 99% on various datasets.

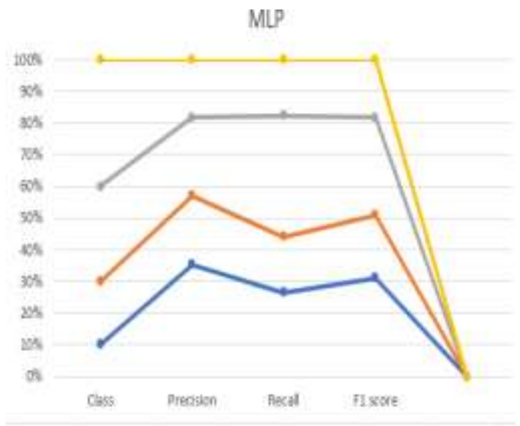

Fig. 6. MLP Analysis

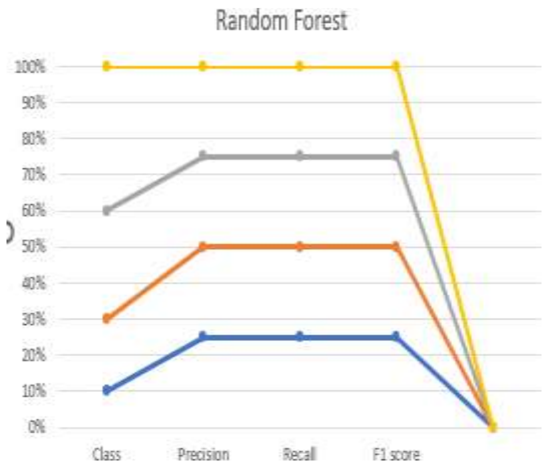

Fig. 7. Random Forest Analysis

Fig. 8. SVM Analysis

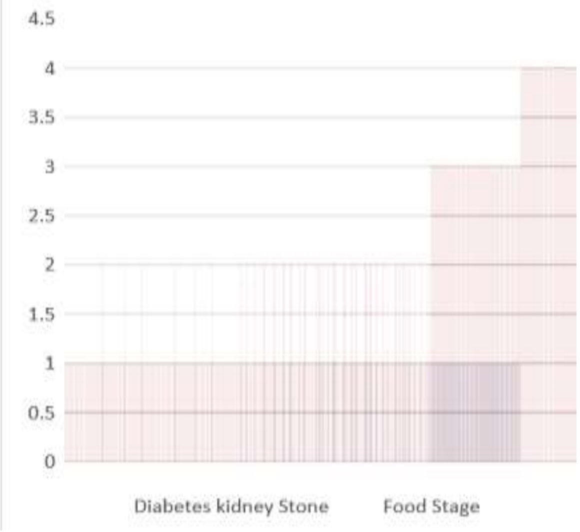

Fig. 9. Diabetes Kidney stone analysis

V. Conclusion

This study aimed to develop a web application that could provide personalized diet plans for patients based on their health status and other characteristics. The system used a machine learning algorithm to generate nutritional recommendations tailored to each patient's unique needs and medical conditions. Patient data was collected from various online sources, sorted, preprocessed, coded, and analyzed for similarities in order to train the model. Rapid prototyping was used to create and test the models using web scraping techniques. The results of the training and testing phases demonstrated that the proposed system was highly accurate and precise in generating personalized diet plans for patients.

***Abstract*—The development of this project is meant to serve as a general reference for you in the case that you require emergency medical care, particularly for a condition like pandemic. This website app essentially lists the top hospitals in Chennai City that are close to you. Several private hospitals charge exorbitant rates during emergency and epidemic circumstances by taking advantage of the circumstance. To make it easier for users to locate hospitals.**

Keywords—HTML, API, CSS

I. INTRODUCTION

The WHO has said that, about ½ of the whole population today lives in countries with a lack of access to high-quality healthcare (WHO).In actuality, according to the WHO, just 8% of the world's population has access to basic medical care. It's crucial to locate a reputable hospital that offers high-quality care if you want to make sure that everyone receives the greatest possible healthcare. Locating a closest hospital is also crucial. Some might be far and others might be found in urban areas. So that you won't have to worry about getting sick while you're there, make sure the hospital isn't too far from your house. Thus, it is crucial to select the best hospital for yourtheir locations and the treatments they offer, this project comprises hospital registration, saving their information in the system, and mentioning the availability of beds, treatments offered, ambulance service, and other services offered. PHP, Html, CSS, and JavaScript will be utilized for the application's front end, and Java technology and APIs will be used for the back-end processing.

Average length of stay for hospital patients, and encouraged interdisciplinary collaboration across departments.

System for scheduling hospitals that uses multi-agent correlation.In order to support hospital planning decisions, the hospital must organise a greater expansion in the interaction between physicians, hospital’s resources, care staff, and users. The need of this work is to give a system for planning hospitals. This employed data set, which contains about 110,500 medical appointments with the about 15 important characteristics, was assessed based on patient’s arrival, waiting , and completion time.Following hospital sections employ a few of these variables: For the best price for hospital scheduling, diseases including hypertension, diabetes, and alcoholism add aneeds.

The main goal of this project is to search hospitals based on specialised diagnoses, use hospital locations, bed availability, and ambulance service to accelerate your search for the closest hospital using KNN algorithm, and store the data of Private Hospitals that are being updated by hospital administrators to improve the user's searchfor hospitals. There are several excellent hospitals that use cutting-edge medical technology and equipment in addition to the best medical professionals to deliver top-notch care. Finding a goodhospital that offers high-quality care is crucial if this effort is topercentage of priorities to each patient's appointment. A simulation-based strategy is suggested for managing hospital schedules.

Precise predictions of the inpatient bed capacity are particularly crucial for capacity reserve at hospitals where judgements about acceptable rates of elective admissions are established in advance based on anticipated available bed capacity and emergencyrequests.The patient’s prediction who will be discharged thefollowing day can be used to establish the bed capacity for that day given the number of available beds.The quirks of daily dischargevariations, make it difficult to choose the best options, even if time-guarantee that everyone receives the greatest possible healthcare.

II. RELATED WORK

Hospital information systems, one of the important subfields of medical informatics, are intended to link all hospital departments to a wide information network in order to streamline the entire hospital system, according to the International Academic Community. The HID-Hospital information department used the Oracle database to create a number of secure, dependable, and user-friendly beds resource management information systems in response to the difficultyin receiving medical care in China. This article describes the functional requirements for HIS. This strategy enhanced the efficiency of bed resource management, considerably decreased theseries models may capture these qualities effectively.A seasonal regression and ARIMA model, a seasonal ARIMA multiplicative model, and a combinatorial model based on weighted Markov Chain models are all investigated in this paper. These simulations aim to predict daily outflows. The models are calibrated using hospital discharge data spanning three years.

For the hospital triaging system, they have created a mobile application and desktop platform. The process of triaging involves ranking the priority of a patient's care at a hospital. Triage profiles for patients, which include name, age, gender, medical data, and triage category, can be stored in and accessed by the system's knowledge base. Many user experience features built into the created graphical user interface (GUI) make the system simpler to operate. Both

DOI: rp-9788770040723.098
desktop and mobile devices can use the system because it has been turned into an application.

Registered nurses used the application to test it out by using it to respond to sets of questions that included walk-in patient triage scenarios. The nurses' opinion was mostly positive, stating that the software made the process more efficient than it would have been if it had been done manually.

This article discusses the best patient scheduling issue with targeted acceptance ratios as well as the best inpatient room allocation for a variety of patients in public hospitals.Hospitals must limit patient access and distribute limited resources across a range of patient categories in order to maximise hospital income and preserve service equity.Two steps are taken to present the models for the problem. Our model takes into account any variations in patient arrival and stay times.By employing a simulation model and a linearization technique to reformulate the constraints as the constraints of knapsack, we are able to solve this problem. CPLEX.

The paper provides a distributed, integrated framework for the Hospital's in National Taiwan University Hospital Information Systems (HIS) and Healthcare Enterprise Information Portal (HEIP) (NTUH). A single solution has been created for the customer relationship management system for a Hospital, offered by HEIP . The latest HIS outpatient information systems (OIS) are discussed in terms of their results. Future HEIP initiatives are mentioned, including e-learning, RCD, and online immunisationprogrammes. Also offered are middleware-based integrated HEIP and HIS designs and practical fixes.To assess the performance of the architecture. Almost 25 years ago, the hierarchical IMSDB databases and IBM/SNA were used to develop the healthcare information system (HIS) for the National Taiwan University Hospital (NTUH).

The prevalent poor management of hospitals has recently come to light because to First Come, First Serve (FCFS) hospital bed rules. Importantly, the General Utility Function is used by our proposed system to decide the hospitalisation orders of patients. We employ our own TOPOSIS Method that is Modified as the assessment method for the Six-stage HBAMS, with the Monte Carlo Simulation Algorithm serving as a second layer of verification.The results show that this system is an effective method for addressingthe poorly situated hospital beds that currently exist. We provideis then used to solve the deterministic programming model that ishospital administration with a mechanism to adapt the model to theproduced from the challenging NSP model. In addition, we provide a mixed-integer two-stage stochastic programme and a target programme to optimize the patient scheduling based on allotted capacity and anticipated AR.

Lower death rates are a positive indicator of a nation's efficient healthcare system. To reduce the fatality rate, a critical patient should be transferred as quickly as possible to a hospital with the required tools. It is not necessary to emphasise the importance of Golden Hour in cases of traffic accidents. To do this, ambulances should be able to travel freely on our highways.The autonomous ambulance management system uses the internet of things. Thiswill find the nearest hospital, determine the quickest way, provide critical information to the hospital beforehand, and control the traffic signal as well to ensure that the ambulance can move forward without incident. An effective and successful way to contribute to lifesavingacts in order for the Six-stage HBAMS to be extensively deployed.

[1] The electronic ward bulletin board system and the self- service guidance system are now part of the standard hospital information system (HIS). The touch screen for the self-service guide system could be positioned in the outpatient lobby. Patients benefit from choosing and finding a doctor or specialist based on where they are ill.Visitors can access the ward's electronic bulletin board system to learn about visitation times and other safety information. The idea of pervasive computing makes it possible to combine actual healthcare services with online informational offerings. After then, patients could easily access information services. The Hospital Information System will function better as a result, increasing efficiency and service quality. By pervasive computing, information and computing are incorporated into people's homes. As a result, the virtual world in the information realm and our physical world converge. Information and computing services are available to residents whenever and wherever they need them.There are numerous online services available in almost every business thanks to contemporary web technologies. Every major sector is converting to digital and building a digital face for all of its fundamental operations in order to compete more effectively in the expanding digital market.Using duplicate approaches will not benefit either the individual or the organisation in the modern environment due to the highly quick flow of information. Internet access is arequirement for all contemporary enterprises that want to operate effectively. One of these industries where information should be swiftly and effectively digitised is healthcare.This research focuses on that particular problem and paves the way for the creation of software that makes it easier to convert paper-based documents to electronic ones. The article suggests E-Medical Management, which would increase the efficiency of patient management, doctor scheduling, and provide access to patient data to all hospital staff, and describes a plan for a web-based platform that would replace the need for paper prescriptions in hospitals.

[2] There are numerous online services available in almost every business thanks to contemporary web technologies. Every major sector is converting to digital and building a digital face for all of its fundamental operations in order to compete more effectively in the expanding digital market.Using duplicate approaches will not benefit either the individual or the organisation in the modern environment due to the highly quick flow of information. Internet access is a requirement for all contemporary enterprises that want to operate effectively. One of these industries where information should be swiftly and effectively digitised is healthcare.This study concentrates on that specific issue and lays the way for the development of software that facilitates the conversion of paper-based

DOI: rp-9788770040723.098

documents to electronic ones. The article describes a proposal for a web-based platform that would replace the need for paper prescriptions in hospitals and suggests E-Medical Management, which would improve the effectiveness of patient management, doctor scheduling, and give access to patient data to all hospital employees.

[3] India's health care system, like those of many other nations, is dealing with an increase in the demand for medical services and care. The full medical history of the patient must be included in the medical records. Because this record serves many objectives, doctors must keep perfect records. In order to address the issues associated with the manual technique, this study on hospital management systems is intended to convert the manual way of looking for, classifying, storing, and retrieving hospital information (files) into an electronic medical record. After researching the current system, computer-based software was developed to take the role of this manual process. As patients enter and exit the hospital, these computer-based systems generate patient reports.

[4] A computerised or web-based system called a hospital management system makes it easier to oversee how a hospital or other medical facility runs. This programme or technology will assist in making the entire operation paperless. It incorporates all patient, physician, hospital administrative, etc. information into a single piece of software. It has sections for the many types of hospital personnel. The receptionist can immediately check the availability of rooms and beds using HMS in order to change patienttransfers from one ward to another or assign the bed to the incomingpatient. To keep tabs on patients who have been discharged, this data is updated continuously. The comprehensive schedule for the operation theatres is also included in this section. Knowing assists the front desk agent or the nurses.

[5] An intelligent HMS was developed for the benefit of patient’s checking in at a hospital. They will have access to information about the doctor’s, appointment times, relevant offices, laboratory testing, and specific medications for his or her condition.At the hospital entrance, the system will offer patients an intelligent front desk information service. Also, it will give doctors software aid so they can diagnose quickly and efficiently by utilising the program's decision-making process. A hospital's administrative, financial, and clinical aspects are managed by the developed system, a thorough and integrated information system. The system seeks to provide the greatest electronic data processing assistance for patient care and administration as a subfield of medical informatics. This includes both electronic and mechanical data processing as well as information processing on paper.

[6] Many benefits of an advanced hospital management system include improved patient care, strict cost control, enhanced profitability, and better administration and control. IHMS was created and intended to provide hospitals with quantifiable benefits. It is strong, adaptable, and simple to use. More significantly, it rests on solid and trustworthy foundations.The object-oriented, networking, and database ideas are the foundation of the "Advanced Hospital Management System" project. We employ MY SQL software, one of the greatest and most user-friendly programmes, even though we maintain records in databases across a range of fields.The front-end software for the project is created in Java, an Object-Oriented Programming language with MY SQL support. To address the requirements of big and mid-sized hospitals worldwide, the Advanced Hospital Management System was developed.All of the necessary modules and functionalities have been developed with your requirements in mind. Customers in India and abroad have largely approved of this bundle.

[7] The objective of this article is to automate hospital front office management through the development of user-friendly, efficient, and inexpensive software. It focuses on gathering patient data, including details on diagnoses, etc. In the past, it was manual. The objective of the system is to enter, store, and retrieve patient and physician data as needed, as well as to modify this data in an usable manner. Data pertinent to the patient and diagnostic make up the system input, and the system output are the details which are shown on the screen. The HMS can only be accessed with the proper credentials. It is accessible to administrators and front-desk employees. Only they have the ability to add information to the database. Access to the information is simple. Data processing is quick since the data is securely safeguarded for personal use. The human body is ahighly clever and complex structure that performs millions offunctions. He was able to understand all of these complex activities through his research and tests.

[8[To manage daily operations and hospital activities, a well-organized computerised system known as a "hospital management system" was built. The application can handle inpatients, outpatients, records, database treatments, status ailments, pharmacy billings, and labs. It also records hospitalinformation such as ward IDs, in-charge physicians, and department administrators. Receiving a report after a consultation is currently the biggest problem facing patients.Patients cannot view hospital records outside the building, despite the fact that many hospitals maintain reports in their systems. We will offer the option to store the report in a database as part of this project, making it accessible from anywhere in the world. The hospital management system project involves data storage, lab and pharmacy automated billing, and patient registration. The software, which also automatically stores staff and patient information, can provide each patient with a unique ID. You can use the search option to see the current performance of each room.

[9] Nowadays, web-based technology provides a wide range of online services in nearly every industry. As almost everything can be done online, less tasks, expenses, and efforts are involved. The idea of a web platform that would provide access to various medical and hospital processes online using Web, networking technologies is discussed in the article. This platform could be crucial in implementing the capabilities of online medical administration. This will aid in the administration of patients, the management of doctor schedules, and the maintenance of patient data that are accessible throughout the hospital. online patient data

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.098

storage, management, communication, analysis, and updating.

[10] A smart hospital system is a part of the infrastructure whose efficient operation, upkeep, and maintenance heavily rely on the actual resources made available to them. This paper's goal is to outline the technological foundations for a smart hospital management system. In fact, widespread adoption of IOT has a significant impact on raising hospital administration standards, enhancing patient convenience, and enhancing medical treatment quality. Then, a review of the smart hospital system is given, along with various approaches for analysis and modeling. Smart systems integrate sensor, actuators, and control capabilities so that the characterise and evaluate a condition and make decisions based on the availability of data in a adaptive way.A healthcare system is actually an arrangement of individuals, organizations, and assets that provide health services to fulfill the needs of target populations. The public's opinion of healthcare is evolving quickly as a result of medical advances.

[11] In Oman, there are numerous private hospitals. Several hospitals have their own web-based programmes that manage patientappointments and provide information on the services the hospital offers. Yet, there isn't a web-based tool that offers a standard, integrated platform for comparing the services offered by different hospitals and managing patients' doctor visits. The goal of this study paper is to integrate the services offered by several private hospitals. The aim of this project is developing a web-based application prototype and offer an implementation plan for creating an integrated solution. By allowing patients to quickly compare the services of several hospitals and select the hospital of their choice by conveniently scheduling appointments from their homes and avoiding lengthy waiting lines at hospitals, this research aims to serve the community in Oman. The proposed prototype system may track a patient's medical history and handle the details of their therapy.

[12] A state-of-the-art database idea that includes patient and hospital's details. It is a particular type of database that also records patient data. Record manipulation can be prevented by utilising this concept. The potential of losing crucial data exists, but by putting this idea into practise, we can maintain a backup of all data. Also, the data are completely safeguarded. Data must be made accessible in a way that everyone may use it. Every single patient will have their own unique ID and password. Updates are also made to the patient's registration form, which includes the patient's name, address, phone number, and date of birth. The data will be shared throughout hospitals, and each patient will have access to their own personal information. Hospital management is related to the integrated hospital information system, which encompasses every operational aspect of multi-specialty hospitals. Aspects of hospital administration include improvedpatient'scare,safety,confidentiality, effectiveness, and a better management information system.

III. SYSTEM ARCHITECTURE

In order to improve the user's ability to search for hospitals, the suggested system seeks to store Private Hospitals' information as it is updated by hospital administrators. Search hospitals based on the specialised diagnosis, use hospital locations as an input to the KNN algorithm, bed availability, doctor availability, quality of the doctor's care provided, success rate of the operations performed by the respective doctors, success rate of the hospital, and ambulance service which are the key factors to speed up your search for the best nearby hospital.

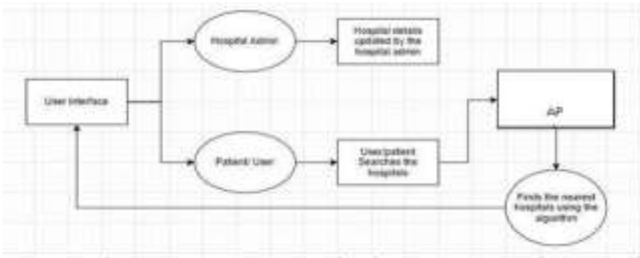

Fig. 1. System Architecture

IV. RESULTS

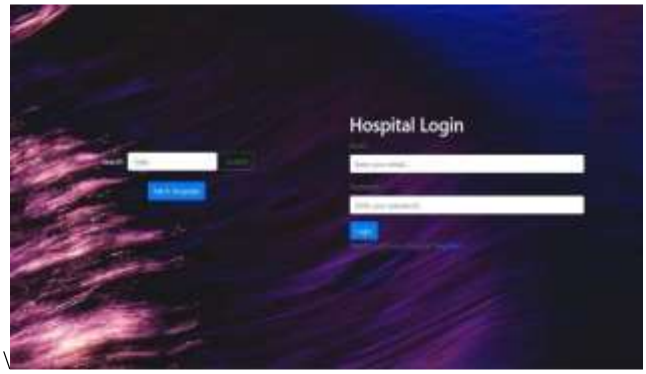

Fig2. Home page

The Home page or the index page is the heart of the system since the whole process starts from this page. It consists of three fields and four buttons where one field is used of searching the hospitals based on the name ,treatment and diagnostics provided and submit button triggers the keyword search and the Fetch hospitals button will provide all the hospital's details which will be sorted so that the nearest hospital will be viewed first. On the other side there are the fields required for the hospital admin's for logging into the system by providing the required credentials and the Register button will be used by the hospital's admin to register their hospital into our system for the first time.

Fig. 3. Admin page

DOI: rp-9788770040723.098

In the admin page the current details of the hospital will be available along with the option to update the details of the hospital such as treatments provided,diagnostics provided, availability of ambulances and beds, details of the doctors working in that hospital and the location of the hospital.

Fig. 4 User's Page

In this page the details required by the user or patient will be provided with accurate location and even the direction to that hospital is provided using the google map.

V. CONCLUSIONS

This study focused on the hospital management system, which enables users to look up patient records at the closest hospitals. The significance of time is now complete. The database aims to cut down on the patient's time spent looking up hospitals for their particular therapy. Also, this lowered the amount of space the data took up and gave the patient's medical records acceptable protection. According to the study's findings, the problem with the existing manual approach of manually searching the hospital will be solved by the design of hospital database records.

***Abstract*—A growing demand for lightweight, flexible operating systems is being driven by the exponential growth of smart gadgets. A framework for creating lightweight operating systems for smart devices has been created and put into place in answer to this demand. This framework offers a configurable system that may be set up to satisfy the particular needs of various smart devices. The design and development of this framework, as well as its salient characteristics and practical uses, are presented in this study.**

In recent years, there has been a tremendous increase in the development of smart gadgets, with more and more devices being created to offer diverse functionality in many industries. However, the necessity for particular operating systems that are tailored to the needs of the devices has slowed down the development of these gadgets. This has made it more expensive and time-consuming to produce new products, and it has also made it more difficult to quickly adopt to changing market conditions and cutting-edge technological advancements. In this study, we suggest creating a lightweight operating system architecture for smart devices that is both programmable and adaptable.

The suggested framework has been created to offer a flexible environment for creating smart devices. The framework is compact and offers only the capabilities that are absolutely necessary for the gadget to run properly. This minimizes development time and costs by ensuring that the framework may be readily adapted to other devices. Additionally, the framework offers developers a flexible environment by enabling operating system customisation to fit the unique requirements of the device.

The suggested framework is based on a modular structure that enables simple system component customization and change. As a result, the operating system may be improved and tailored to the particular device by adding new functionality or removing unused ones. Additionally, the modular structure makes it simple to test and debug individual components, making it simpler to find and address any problems that could occur during development.

The suggested framework has built-in security mechanisms that offer defense against potential assaults to guarantee the security of the system. These characteristics, which ensure that the system is safe even in the case of a security breach, include secure booting and secure storage.

A software development kit (SDK) that gives programmers a selection of tools for creating apps for the device is also included in the proposed framework. The SDK makes it simple for developers to create apps that run on the device by providing libraries and tools for creating programs in various programming languages. The SDK also has examples and documentation to aid developers in starting the development process.

We created a proof-of-concept prototype and integrated it into a smart thermostat to test the suggested framework. The framework's adaptability and customizability wereproven by the prototype, which also showed how the operating system could be changed and tailored to fit a particular device's needs.

The suggested lightweight configurable operating system architecture offers a versatile and effective environment for creating smart devices. Developers will have the flexibility to tweak and personalize the operating system to match the unique requirements of the device thanks to the framework's modular and configurable nature. The system is safe even in the case of a security breach because to the built-in security mechanisms, which defend against potential assaults. It is simple to create programs that operate on the device thanks to the software development kit, which gives developers a collection of tools for designing applications for the device. The suggested framework offers a versatile and effective environment for creating smart devices while also having the potential to dramatically cut down on development time and expense.

Keywords*—*operating system, framework, smart devices, design, development, apps, configurable, lightweight.

I. Introduction

An increased need for lightweight, flexible, and adjustable operating systems has arisen as a result of the widespread use of smart devices. A framework for creating and creating lightweight operating systems for smart devices has been created in answer to this demand. This framework offers a configurable system that may be set up to satisfy the particular needs of various smart devices. The design and development of this framework, as well as its salient characteristics and practical uses, are presented in this study.[1]

With more gadgets being created to offer various functionality in numerous industries, smart devices have experienced a major increase in popularity. Smart gadgets, which offer ease and functionality that was previously unthinkable, have become indispensable tools in our everyday lives. Examples include smart thermostats, smart home security systems, and smart health monitors. However, the necessity for particular operating systems that are tailored to the needs of the devices has slowed down the development of these gadgets. This has made it more expensive and time-consuming to produce new products, and it has also made it more difficult to quickly adopt to changing market conditions and cutting-edge technological advancements.

The creation of an operating system for smart devices is a difficult process that needs a lot of time, money, and knowledge. The operating system must be modified to fit the device's unique requirements, including its hardware and

DOI: rp-9788770040723.99

software requirements. Particularly for small to medium-sized businesses that do not have the means to design their own operating system, this procedure can be time-consuming and expensive.

We suggest creating a lightweight operating system architecture for smart devices that is programmable and flexible in order to address this problem. The framework has been created to offer a flexible environment for creating smart devices. The framework is compact and offers only the capabilities that are absolutely necessary for the gadget to run properly. This minimizes development time and costs by ensuring that the framework may be readily adapted to other devices. Additionally, the framework offers developers a flexible environment by enabling operating system customisation to fit the unique requirements of the device.

The suggested framework is based on a modular structure that enables simple system component customization and change. As a result, the operating system may be improved and tailored to the particular device by adding new functionality or removing unused ones. Additionally, the modular structure makes it simple to test and debug individual components, making it simpler to find and address any problems that could occur during development.

The suggested framework has built-in security mechanisms that offer defense against potential assaults to guarantee the security of the system. These characteristics, which ensure that the system is safe even in the case of a security breach, include secure booting and secure storage.

A software development kit (SDK) that gives programmers a selection of tools for creating apps for the device is also included in the proposed framework. The SDK makes it simple for developers to create apps that run on the device by providing libraries and tools for creating programs in various programming languages. The SDK also has examples and documentation to aid developers in starting the development process.

The flexible and effective environment for designing smart devices is made possible by the adaptable and customizable lightweight operating system architecture, which also has the ability to dramatically cut development time and costs. Better user experiences may be achieved by developing more effective and optimized systems, which are made possible by the ability to adjust and tailor the operating system to match the unique needs of the device. Additionally, the system is protected from potential assaults by the built-in security safeguards, guaranteeing that even in the case of a security breach, the system is secure.

The suggested lightweight configurable operating system architecture offers a versatile and effective environment for creating smart devices. The framework is designed to be modular and adaptable, enabling programmers to change and adapt the operating system to suit the particular needs of the device. The system is safe even in the case of a security breach because to the built-in security mechanisms, which defend against potential assaults. It is simple to create programs that operate on the device thanks to the software development kit, which gives developers a collection of tools for designing applications for the device. Overall, the suggested framework offers a versatile and effective environment for creating smart devices while also having the potential to dramatically cut down on development time and expense.

II. Background

Operating systems that are tailored for these devices are now necessary due to the extensive use of smart gadgets including smartphones, tablets, smartwatches, and smart home appliances. While conventional operating systems like Windows and Linux can function on these gadgets, they frequently use a lot of resources, which causes sluggish performance and shorter battery life. Additionally, the unique requirements of smart devices are not always taken into consideration when standard operating systems are developed.[2]

Lightweight operating systems that are tailored for smart devices have been created to solve these problems. These operating systems' reduced resource requirements lead to better performance and longer battery life. Moreover, they are frequently flexible and adjustable, enabling them to be adapted to the unique requirements of many smart devices.[3]

Nevertheless, creating a lightweight operating system that is specifically tailored for a certain smart device can be difficult and time-consuming. A framework that offers a configurable system that can be set up to match the particular needs of various smart devices has been designed to streamline this procedure. With the help of this framework, programmers may rapidly and effectively design unique lightweight operating systems, cutting down on both development time and expenses.[4]

The framework's flexibility and scalability make it suitable for usage in a variety of smart devices, from tiny wearables to substantial smart home systems. It offers a number of capabilities, including as support for various hardware architectures, device drivers, and frameworks for application development.[5]

This framework's conception and creation mark a significant advancement in the creation of thin operating systems for smart devices. The framework enables developers to build operating systems that are tuned for the unique requirements of various smart devices, enhancing performance and battery life while cutting down on development time and costs.[6]

III. Methodology

The following stages were taken during the design and development of the adaptable and lightweight operating system architecture for smart devices:[7]

1. *Requirements identification*: The first phase entailed determining the framework's needs. This involved determining the characteristics that would be necessary in the operating system to fulfil the demands of various smart devices and comprehending their unique requirements.

DOI: rp-9788770040723.99

2. *Hardware architecture selection*: The choice of the hardware architecture that the operating system would support came next. This required choosing the hardware that the operating system would require compatibility with, such as the CPU, memory, and other hardware elements.

3. *Selection of software components*:The third phase entailed choosing the software elements that the operating system would need. Choosing the kernel, device drivers, and application frameworks needed to build a lightweight operating system was part of this process.

4. *Component customization*:After choosing the software components, the following stage was to tailor them to the unique needs of various smart devices. To make sure that the kernel, device drivers, and application frameworks were compatible with the chosen hardware architecture, this required modifications.

5. *Integration of components*:The operating system foundation was then updated to include the modified components. In order to establish a solid and dependable operating system, it was necessary to make sure that all of the parts coordinated perfectly.

6. *Testing and validation*: The operating system framework was tested and verified in the last stage. To make sure the operating system was stable, dependable, and worked effectively on a variety of smart devices, this meant completing a number of tests.

IV. APPLICATIONS

The creation of smart devices can use the lightweight operating system foundation in a variety of ways. The following are a few uses for this framework:

1. *Wearables*: The architecture may be applied to the development of thin operating systems for wearables including smartwatches, fitness trackers, and smart eyewear. These operating systems may be modified to match the particular requirements of various wearables, enhancing performance and battery life.

2. *Smart home appliances*: The framework may be used to design compact operating systems for appliances in the smart home, such as cameras, locks, and thermostats. These operating systems offer enhanced performance and interoperability since they can be modified to cater to the unique requirements of various smart home devices.

3. *Automotive*:The framework may be used to develop lightweight operating systems for telematics, entertainment, and advanced driver assistance systems in automobiles (ADAS). These operating systems may be modified to cater to the particular requirements of various automotive systems, improving performance and usefulness.

4. *Industrial automation*: The framework may be used to design compact operating systems for SCADA, PLC, and HMI systems used in industrial automation. These operating systems may be altered to satisfy the particular requirements of various industrial automation systems, enhancing performance and dependability.

There are several uses for the lightweight operating system architecture in the creation of smart devices. The framework gives programmers the tools they need to construct operating systems that are tailored to the unique requirements of various smart devices, enhancing performance and compatibility.

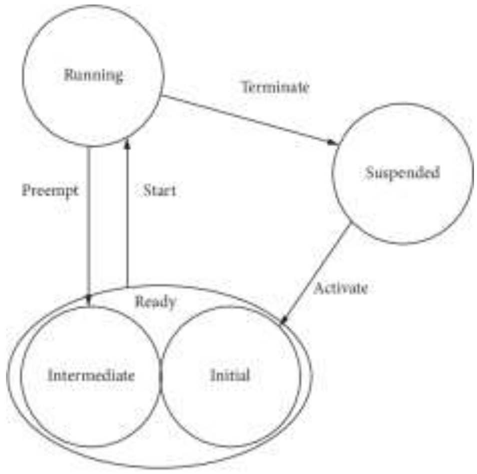

Fig. 1.Lightweight operating system framework

V. RESULTS

The goals of this project have been accomplished through the design and development of the lightweight operating system framework for smart devices that is adjustable and adaptable. The principal outcomes of this initiative are as follows:

1. *Customizable and Configurable*:The operating system framework enables developers to modify the operating system to fit the unique requirements of various smart devices. Its adaptability guarantees that the operating system operates at its best on various hardware architectures, which enhances performance and battery life.

2. *Lightweight:*Because the operating system foundation is lightweight, it uses less system resources, which leads to quicker boot times and better performance.

3. *Steady and Trustworthy*: The operating system architecture has undergone comprehensive testing to guarantee that it is dependable and stable, offering a solid foundation for the creation of smart devices.

4. *Support for Multiple Hardware Architectures:*The operating system framework is appropriate for a broad variety of smart devices since it supports diverse hardware architectures.

5. *Open-Source*: The operating system framework is open-source, which means that developers are allowed to use and modify it.

VI. CONCLUSIONS

The limits of conventional operating systems have been overcome, and a new platform for the creation of smart devices has been created through the design and

DOI: rp-9788770040723.99

development of a programmable and adjustable lightweight operating system framework. The following are the project's main conclusions:

1. *Personalization is Important*: A one-size-fits-all approach to operating system development is insufficient for smart devices since their needs differ. With the help of the operating system framework created for this project, programmers may construct operating systems that are tailored to the particular requirements of various smart devices.
2. *Lightweight Operating Systems Improve Performance*:The project's lightweight operating system foundation uses less system resources, which leads to quicker boot times and better performance. This is crucial for smart gadgets that run on batteries.
3. *Creativity is Encouraged by Open-Source Development*: The operating system framework is being made open-source as part of this project to promote developer cooperation and creativity. With the help of this open-source methodology, developers may build on one another's work to create better operating systems for smart devices.
4. *Improved Compatibility*:This project's operating system framework supports many hardware architectures, making it appropriate for a variety of smart devices. As a result, interoperability is increased and programmers may make operating systems that run on many smart devices.

The flexible and adaptable lightweight operating system architecture created in this research offers a new development environment for smart devices. The framework's adaptability, reliability, and lightweight architecture make it a desirable choice for developers who want to construct operating systems for a variety of smart devices. The open-source strategy also promotes developer cooperation and creativity, which will help the operating system framework grow over time.REFERENCES

Abstract—Virtual brain research is ramping up the development of low-cost real-time brain-computer interfaces (BCI). Hardware advancements that improve the capabilities of Virtual brain analysers and Brain Computer wearable sensors have enabled the development of various new software frameworks for developers to leverage and construct applications integrating BCI with IoT. It also offers various sensory channels for larger-sized data transmissions to users' brains. The intersections of these two research lines are advancing both sectors and will drive the requirement for an energy-aware infrastructure to serve the mobile cloud's broader local bandwidth demands. In this study, we conduct a survey of BCI in IoT from several viewpoints, including EEG-based BCI models, machine learning, and current active platforms. Based on our research, the key findings of this study emphasise three important BCI development trends: EEG, IoT, and cloud computing.

Keywords—EEG, IOT, Virtual Brain, Cloud Computing.

I. INTRODUCTION

The capacity to map the human brain at multiple sizes with better throughput and resolution is at the top of the list of the US Government's BRAIN Initiative. A full depiction of the brain anatomy will reveal fresh insights into how the human brain works and may aid in the development of novel therapies and drugs for brain illnesses. Recent advancements in intact brain imaging, such as the CLARITY and MAP (Magnified Analysis of the Proteome) tissue clearing procedures, allow for the collection of huge volumetric pictures of brain tissue at cellular and subcellular levels[3]

However, the tremendous volume and resolution of brain images presents a difficulty for effective processing and interpretation. We created an automated dense axonal fibber tracing process that can track long-distance fibbers and build 3D connection maps that contain not only the vertices and edges of a network graph, but also the 3D position information associated with each fiber's track. In addition to standard graph analysis, we are interested in discovering long-distance neuron fibre connections and fibre crossings, both of which might show interesting patterns when evaluated at cellular resolution and at a long distance (1 mm). Brain graphs provide a framework for representing structural or functional topology at several levels. There are several software tools available for analysing the topology of brain networks utilising graphs[4].

The Apache Accumulate database is based on Google's Big Table database and enables for quick ingestion and extraction as well as the storage of enormous amounts of data. The Dynamic Distributed Dimensional Data Model (D4M) is a mathematical framework based on associative array mathematics that has been used to a variety of disciplines including cyber security, biology, free text, and social media data. D4M may also be utilised within a database to execute linear algebraic calculations.D4M integrates easily with the pMatlab parallel computing environment, which enables MATLAB/Octave programmers to employ a single-program-multiple-data (SPMD) parallel programming approach. PMatlab is a message passing interface library that has been used for a number of parallel applications[1].

Synchronized activity appears to offer functional connections, both locally and between distant brain areas. Thus, brain networks are made up of physically dispersed but functionally coupled information-processing areas. Brain connection analysis is based on three distinct but related types of connectivity. (i)Anatomical connection (AC), also known as structural connectivity, is a type of connective formed by synaptic interactions between neighbouring neurons or fibre trackslinking neuron pools in geographically distant brain areas. White matter refers to the whole set of such fibber tracks in the brain. Anatomical connections are extremely enduring and robust on short time scales (sec, min), although significant plasticity can be detected over longer time spans. (ii)Functional connectivity (FC), defined as the temporal dependence of neuronal activity patterns from physically distinct brain areas[2].

These network topologies represent two fundamental concepts underpinning brain information processing: functional segregation and functional integration. Neuroimaging techniques (EEG, MEG, fMRI, PET, and SPECT) and neuroanatomical approaches provide the majority of the experimental evidence supporting such network topologies. Signal transmission across different brain areas necessitates connecting fibre tracts, which provide the structural foundation of the human connective.

As a result, 3D-PLI enables an independent review of DTI data. Brain connection may be measured by encoding neighbourhood relationships into a connectivity matrix, the rows and columns of which correspond to distinct brain areas[5].

This form lends itself to mapping to a graphical model, which allows for the quantification of many topological properties of the connectome. Graphical models provide a flexible mathematical framework for studying pairwise relationships between interacting brain areas in general. In recent years, there has been an exponential development in

DOI: rp-9788770040723.100

the number of papers relating to the use of graph theory to uncover structural, functional, and effective connection aspects from neuroimaging investigations[6].

This is not meant to be exhaustive, but rather to highlight some common works in this topic.

Following that, various interesting applications and contemporary computational approaches dealing with functional connectivity are gathered. This is followed by a brief review of recent research on effective connectedness. Finally, the critical notion of graphical models applied to such complicated brain networks is presented, as well as potential applications to connection analysis[7].

II. Literature Survey

T. R. Insel et.al., discussed about the BRAIN Initiative, which aims to create breakthrough technologies to investigate how the brain's cells and circuits interact at the speed of thinking and, ultimately, to uncover the intricate relationships between brain function and behaviour. The problems are unique because brain architecture ranges from the size of chemical interactions at trillions of synapses to the billions of cell bodies that join to build local networks that subsequently integrate across different brain regions. There are temporal scales in addition to spatial scales since brain circuits are not static but constantly alter as a result of neuronal activity, developmental stage, and ageing.

K. Chung et al. explained how hydrogel-based structures may now be formed from within biological tissue to allow future removal of lipids without mechanical disassembly of the tissue. This method results in a tissue-hydrogel hybrid that is physically stable, retains fine structure, proteins, and nucleic acids, and is permeable to both visible-spectrum photons and foreign macromolecules. Here, we emphasise the approach's significant limitations and prospects, particularly in terms of integration with other approaches for brain-mapping investigations.

J. Swaneyet.al., discussed about magnified analysis of the proteome (MAP), which linearly extends whole organs fourfold while maintaining their general architecture and three-dimensional proteome structure. The concept of MAP is based on the finding that limiting crosslinking between and between endogenous proteins during hydrogel-tissue hybridization allows for spontaneous expansion following protein denaturation and dissociation. The protein composition, tiny subcellular features, and organ-scale intercellular connections are all preserved in the enlarged tissue. We employ commercial antibodies for repeated rounds of immunological labelling and imaging of a tissue's enlarged proteome, and our results show an 82 percent success rate (100/122 antibodies tested). We showthat in the mouse brain, specimen size may be reversibly changed to scan both inter-regional connections and precise synaptic topologies.

S. M. Smith et.al.discussed aboutto evaluate alternative connectivity estimate methodologies, FMRI data for a wide range of underlying networks, experimental protocols, and problematic confounds in the data were collected. Our findings demonstrate that correlation-based approaches may be highly successful in general, methods based on higher-order statistics are less sensitive, and lag-based approaches perform extremely badly. More specifically, several methods, including partial correlation, regularised inverse covariance estimation, and several Bayes net methods, can provide high sensitivity to network connection detection on good quality FMRI data; however, accurate estimation of connection directionality is more difficult to achieve, though Patel's can be reasonably successful.

III. System Analysis

A. *Existing Method*

- In terms of identifying brain activity, BCIs are currently pretty incorrect.
- Outside-of-the-head BCIs have limited ability to interpret brain impulses.
- They can be implanted under the skull, but this involves major surgery.
- Reading people's inner thoughts raises a slew of ethical concerns.

B. *Proposed Method*

A full depiction of the brain anatomy will reveal fresh insights into how the human brain works and may aid in the development of novel therapies and drugs for brain illnesses.

➢ We examine extant BCI VR research from three critical perspectives: EEG-based BCI models, machine learning, and platforms. The findings can be utilised as a starting point for future relevant study.

IV. System Requirements

Hardware Requirements

- ➢ EEG Electrodes
- ➢ Signal conditioning
- ➢ Amplifier
- ➢ TFT controller
- ➢ PC 2.5

Software Requirements

- ➢ MPLAB IDE
- ➢ Embedded C Language
- ➢ Hi-Tech Complier

V. Working Modules

- ➢ Sensors Architecture
- ➢ Serial Communication System & Sensor Monitoring
- ➢ Sending Mail & Storage

A. *Sensor Architecture*

DOI: rp-9788770040723.100

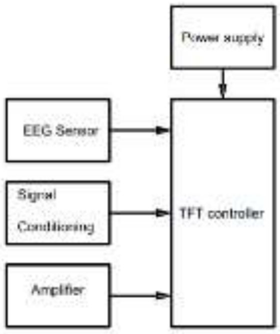

Fig. 1. System Architecture

- The power supply provides total power to the sensors and TFT controller.
- An electroencephalogram (EEG) is a test that measures electrical activity in the brain.
- Electrical impulses allow brain cells to communicate with one another. An EEG can be used to detect possible issues connected with this activity. Signal conditioning is a data collecting procedure that uses an equipment called a signal conditioner.

B. *Serial Communication System & Sensor Monitoring*

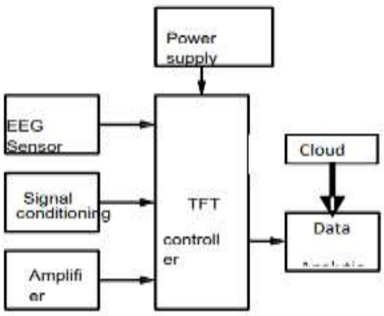

Fig. 2. Block Diagram

- Communication between Data Analytical and Cloud occurs in this Module.
- A healthcare unit would need to invest considerably in infrastructure and maintenance resources if the cloud performed all functions related to storage, data modification, transfer, and collaboration internally.
- Analytics makes it possible to evaluate vast amounts of healthcare data gathered on a daily basis and get important insights into problems that would otherwise be difficult to foresee. In fact, doctors will soon use analytics to learn the full history of their patients.

C. *Sending Mail & Storage*

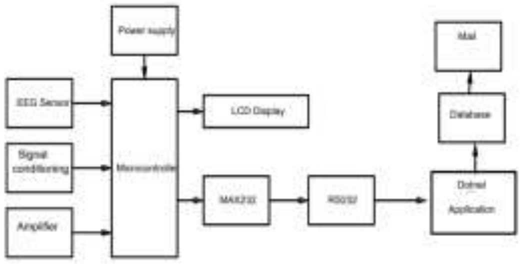

Fig. 3. IOT

- The computer has a database and a Dot Net application.
- The Database is where the sensor values from the microcontroller are saved.
- The sensor values are sent to the specified email address via the dot net application.

VI. Methodology

A real-time web-based 3D user interface that queries data from accumulating and flat files displays the fibre traces.

A. *Technologies and Platform Design*

1) Imaging Pipeline: The first step of the pipeline is to divide the original large data into sub volumes and apply image processing algorithms in parallel using pMatlab. The main image processing algorithms include a convolutional neural network (CNN) for segmenting the axon fibers, and a number of morphological operations for extracting fiber tracks, from which a network graph of vertices, edges, and 3D coordinates of the fiber tracks are computed. Our CNN has three convolutional and two fully connected layers. The last layer uses sigmoid activation, and all other layers use rectified linear units (ReLU) . In the graphs, vertices correspond to the start/end of the fiber tracks and edges represent the connections (fiber tracks) between the vertices. These parsed graphs are then converted into an associative array format, which is amenable for graph analysis.

2) Accumulate and D4M: After converting the graphs to an associative array format, they may be placed into accumulate or saved to flat files. Based on our benchtop testing, we discovered that a hybrid strategy that uses both the accumulation database and the file system provides the best performance. The fibre graph vertices and edges are saved in accumulate, whereas the fibre track 3D coordinates are saved in flat files. When opposed to vertices and edges, 3D coordinates are much denser data and would significantly slow down retrieval time if kept in accumulate. Furthermore, because 3D coordinates are primarily employed for morphological analysis and visualisation, they are not as often accessible as vertices and edges.

3) Binary tree encoding based on geohashing for sub volume indexing: Gustavo Niemeyer devised the geohash, which is a geocoding method based on a hierarchical spatial data structure that subdivides space into an easily identifiable grid. The structure of geohashed data provides two advantages when utilised in a database. First, geohash data will comprise all of the points for a specific rectangular region in continuous slices.

4) Data Schema: In the following form, nodes are graph vertices and links are edges that connect nodes in the network. The node ID is the node's locally unique number in each sub volume. The binary code where the node is placed is represented by the sub volume number. End Yes is either 0 or 1 depending on whether the node is an end node, with 1 indicating the beginning

DOI: rp-9788770040723.100

or end of a fibre track and 0 indicating a junction that links to numerous additional nodes. End Node is the node ID of the other nodes to which this node is linked. Links refers to the link IDs of the links that connect to this node.

VII. Algorithm

The BFS method traverses a network data structure to locate vertices that are related to one another. BFS intuitively informs us which neurons are related to other neurons in our application. Using the previously mentioned associative array structure, we can immediately apply BFS to a node (or collection of nodes) by multiplying two associative arrays. To apply BFS to a node, we must first extract the sub volume of interest from accumulate in order to generate an incidence matrix E. The required node is then added to an associative array and multiplied by the incidence matrix of the relevant subgraph of the sub volume.

As a consequence, an associative array with information about the nodes related to the input nodes is created.

The desired node link information is then extracted. This method can be done indefinitely to locate all nodes linked to the resulting.

VIII. SIMULATION RESULTS

Fig.4. Status Page

Fig.5. Login Page

This is an example of php server page development for IoT.

Here I built by providing a location for the formation of our virtual storing of data in memory, which will be preserved indefinitely until the owner of the virtual brain maker edits or deletes the page source.

It also has the opportunity to enter and save email addresses for recipients.

A. Hardware Results

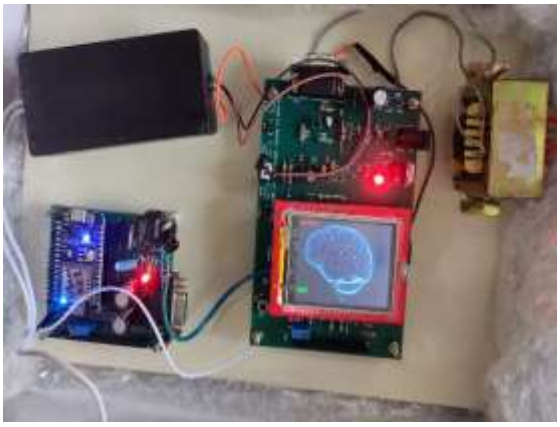

Fig.6.Normal State of Brain

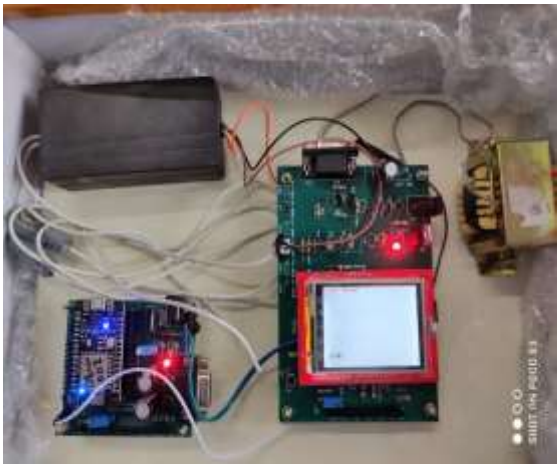

Fig.7.State of brain dead

IX. CONCLUSION

Using Apache Accumulate and D4M, we developed a cloud-based solution for undertaking large-scale brain connection analyses. We proved that our method can perform quick data querying and extraction for graph analytics and visualisation. With geo hashing-based binary tree encoding, which provides a Google Maps-like viewer with numerous zoom levels, indexing of sub volumes is straightforward and logical. There are several opportunities for future employment. First and foremost, we want to improve the online GUI by making it more interactive and user pleasant.

Furthermore, we want to scale it to analyse considerably bigger datasets (terabytes and higher), with the eventual objective of doing such analysis on the human brain. We're looking on using Graphology to perform graph analytics directly into accumulate.

We are also investigating the usage of a poly storage database, such as Big DAWG, as a data viewer that displays the original data as well as a zoomed-in view of four nearby sub volumes extracted using a management solution that closely aligns data sources with data management technologies.

At collecting data from sensors and updating it on the hospital's main server. As a result, this procedure proceeds

DOI: rp-9788770040723.100
regardless of whether the doctor or a patient's relative is there beside the patient. By examining the patient's health, the doctor can advise the patient on any therapy. This project will use IOT technology to simplify the medical evaluation procedure, allowing the patient to enjoy a carefree life.

***Abstract*—The creation of tiny electronic devices with the potential to transform computing has been made possible by advances in nanotechnology. Yet, because of their tiny size and complexity, the design and modelling of these nanodevices and their digital circuits present substantial problems. The use of soft computing techniques like neural networks, fuzzy logic, and evolutionary algorithms holds great promise for resolving these issues and enhancing the precision and effectiveness of circuit and nanodevice modelling. In this article, we give an overview of how soft computing methods may be used to improve the modelling of nanodevices and associated digital circuits. We examine current research in the area and emphasise the benefits and constraints of various soft computing strategies. We also go through some of the main difficulties using these approaches and make recommendations for further study.**

New avenues have been made possible for the creation of digital circuits and smaller electronics via nanotechnology. Yet, because of the intricate interactions that take place at the nanoscale level, designing and simulating such devices and circuits may be difficult. Soft computing technologies have become a potential strategy to deal with these problems. In this article, we investigate how to better represent nanodevices and their digital circuits using soft computing technologies.

A subfield of computer science known as "soft computing" is focused on the creation of intelligent systems that can draw conclusions from data and act on ambiguous or hazy information. It includes a variety of methodologies, such as swarm intelligence, fuzzy logic, genetic algorithms, and neural networks. These methods are excellent for simulating complicated systems with nonlinear behaviour, which nanodevices frequently exhibit.

The significant degree of variability in nanodevice behaviour brought on by manufacturing flaws and environmental conditions is one of the issues in nanodevice modelling. Fuzzy logic and neural networks are examples of soft computing methods that may be used to simulate the variability in device behaviour and forecast how well it will function in certain scenarios. This may aid in optimising the device's design and enhancing its functionality.

Lack of precise physical models that can accurately represent the behaviour of the device at the nanoscale level is another difficulty in modelling nanodevices. Empirical models based on experimental data may be created using soft computing techniques in order to imitate the behaviour of the device. Having a more realisticdescription of the device behaviour can assist to get over the limits of physical models.

Techniques from soft computing can also be utilised to improve the layout of digital circuits that include nanodevices. For instance, neural networks may be used to forecast how well a circuit will function under various operating conditions, while genetic algorithms can be used to find the ideal placement of transistors in a digital circuit. The effectiveness and dependability of the digital circuit may be enhanced as a result.

In conclusion, a potential field of research is the use of soft computing techniques for improved nanodevice modelling and associated digital circuits. The performance and effectiveness of digital circuits can be increased by utilising soft computing approaches, which can also assist in overcoming the difficulties associated with nanodevice modelling, such as device unpredictability and a lack of precise physical models. This may result in the creation of novel and cutting-edge goods and services based on nanotechnology.

Keywords—digital circuits, modelling, design, fuzzy logic, neural networks, nanodevices, and soft computing.

I. Introduction

In today's world, mobile computing is a common technology that has completely changed how we work and communicate. With enabling workers to work remotely and access mission-critical information on the go, it has allowed enterprises to expand their reach and increase operational efficiency. Yet, the increased usage of mobile devices in business settings has also brought forth fresh security issues, notably with regard to data security and privacy.[1]

Business data is frequently extremely private and sensitive, and any unauthorised access or data breach can have serious repercussions, such as monetary loss, reputational harm, and legal penalties. Also, enterprises must develop strong security measures to safeguard their mobile computing systems and data due to the growing sophistication of cyberattacks and the rising amount of mobile security flaws.[2]

A possible answer to these security issues is coming in the form of forensic-enabled safe mobile computing platforms. These systems can identify, assess, and respond to security issues in real-time because to the advanced forensic techniques they include into their architecture. Enterprises may reduce the risks related to mobile computing and strengthen their overall security posture by using forensic-enabled technologies, which offer a thorough and proactive approach to mobile security.[3]

Data encryption, access restrictions, device management, and incident response are the essential elements of a secure mobile computing system that supports forensics. Together, these elements make sure that corporate data is safeguarded at every stage of its lifetime, including storage, transport, and usage. Moreover, forensic-enabled solutions may offer thorough records and audit trails of mobile device activities, enabling businesses to monitor and look into any potential security problems.[4]

For businesses wishing to take use of mobile computing's advantages while maintaining the security and

DOI: rp-9788770040723.101

privacy of their data, forensic-enabled secure mobile computing platforms are an essential tool. Because businesses are relying more and more on mobile devices, they must implement sophisticated security solutions that can keep up with the changing threat environment.[5]

II. BACKGROUND STUDY

Nanodevice design and modelling call for precise and effective simulation techniques that can represent the intricate behaviour of these devices. Due to their high processing costs, accuracy, and scalability restrictions, traditional simulation approaches like finite element analysis (FEA) and computational fluid dynamics (CFD) are frequently insufficient. As a result, academics have looked into alternate strategies that could offer more accuracy and effectiveness.[6]

Soft computing methods, which offer flexible and adaptive methodologies that can capture complicated and nonlinear behaviour, offer intriguing answers to these problems. For instance, neural networks are able to recognise intricate connections between input and output variables and make precise predictions even when there is noise and ambiguity. On the other hand, fuzzy logic can accommodate ambiguous and inaccurate input by allocating varying degrees of membership to various groups. With a wide solution space, genetic algorithms can search for the best solution to optimise complicated objective functions.[7]

Several research have looked into how soft computing techniques are used in nanoelectronics. For instance, neural networks have been used to forecast the electrical characteristics and behaviour of carbon nanotube field-effect transistors (CNTFETs). By varying the degree of connectedness between cells, fuzzy logic has been utilised to improve the design of quantum-dot cellular automata (QCA) circuits. By looking for the ideal placement of nanoscale components, genetic algorithms have been utilised to improve the design of nanoscale logic gates and circuits.[8]

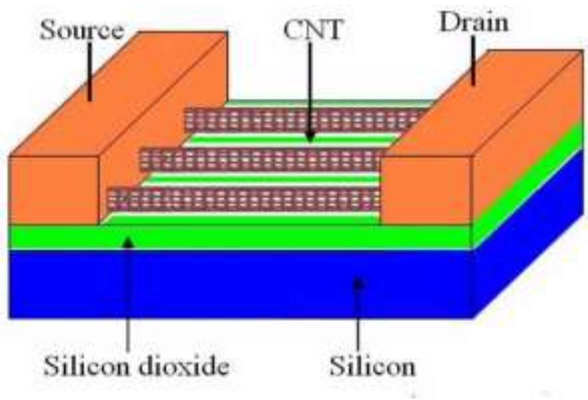

Fig. 1. CNTFETs (Structure Carbon nanotube field effect transistors)

Notwithstanding these achievements, using soft computing methods in nanoelectronics still presents difficulties. The absence of precise and trustworthy data for training and validation is one of the major issues. Although the size of the solution space expands exponentially with the number of components and variables, another difficulty is the restricted scalability of these approaches. Thus, extra research is required to examine the capabilities and restrictions of these tactics and create fresh strategies that can handle these difficulties.

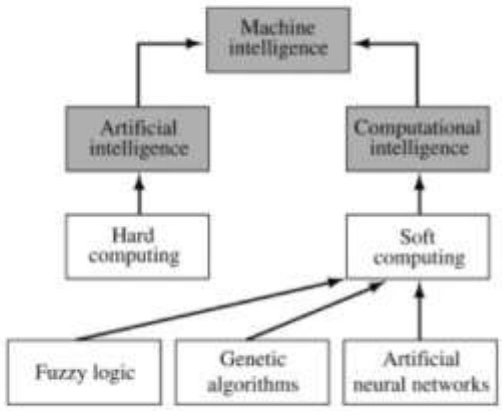

Fig. 2 Soft Computing by B

The study of developing algorithms and methods to address complicated issues that are challenging or impossible to resolve with conventional computing approaches is known as soft computing. It is a group of several computing techniques that draw inspiration from the natural functions of the human brain and its capacity for learning, adaptation, and reasoning.

Fuzzy logic, neural networks, evolutionary algorithms, and probabilistic reasoning are examples of soft computing techniques. These techniques can be combined or applied separately to address a variety of issues, including those relating to prediction, control, classification, and optimization.

A set of optimization algorithms known as evolutionary algorithms draws their inspiration from the ideas of natural selection and evolution. By emulating the evolutionary process, in which the most fit individuals survive and procreate, they are used to identify the best solutions to issues. Many applications, such as engineering design, scheduling, and logistics, employ evolutionary algorithms.

Using probability theory, probabilistic reasoning is a technique for handling uncertainty and inadequate data. It is used to forecast outcomes and make judgements based on speculative evidence, model complicated systems, and make predictions. Many processes, such as decision-making, risk assessment, and natural language processing, involve probabilistic reasoning.

III. METHODOLOGY

Data gathering and pre-processing, model construction and training, model assessment and validation are all phases in the process of applying soft computing methods for better modelling of nanodevices and their digital circuits. A broad approach that may be used to various soft computing methods and applications is as follows:

1. *Data collection and pre-processing:*The data needed for model building and training must first be gathered and prepared. Data from simulations, experiments, or a combination of both may be used in this. The

DOI: rp-9788770040723.101

information must be reflective of how the nanodevice or circuit behaves in various environments, including those involving temperature, voltage, and input signals. To get the data ready for modelling, pre-processing could entail feature extraction, normalisation, and data cleaning.

2. *Model development and training:*The soft computing model must next be created and trained using the pre-processed data. In order to do this, the model architecture and parameters may need to be defined together with the proper soft computing approach, such as neural networks, fuzzy logic, or evolutionary algorithms. The pre-processed data is then used to train the model, which is done using methods like backpropagation, particle swarm optimization, or genetic algorithms. To improve the performance of the model, the training procedure could include numerous iterations.

3. *Model evaluation and validation:*When the model has been trained, it must be reviewed and validated in order to determine its precision and dependability. This may entail comparing the model predictions with the actual measurements while using a different set of data from the one used for training. Metrics for measuring model performance, such as accuracy, correlation coefficient, or mean squared error, can be used to assess the model's performance. Based on the outcomes of the review, the model may need to be updated or fine-tuned in order to perform better.

4. *Application to circuit design and optimization:*The validation of the soft computing model paves the way for its use in circuit design and optimization. This might entail optimising the circuit settings for optimal performance and simulating the behaviour of the nanodevice or circuit under various scenarios. Soft computing techniques may be used to find the best circuit layout in a vast solution space in order to maximise objective functions like power consumption, speed, or noise immunity. Using experimental or simulation data, the improved circuit design may subsequently be verified and put to the test.

5. *A broad framework:*That may be modified to fit various soft computing methods and applications is the methodology described above. Depending on the application domain and the soft computing paradigm employed, the methodology's specifics may change. For instance, the model complexity and kind of data may affect the neural network design and training procedure. Based on the particular needs of the application, the fuzzy logic rules and membership functions may be modified. The size and complexity of the solution space may influence the genetic algorithm's parameters and selection criteria.

IV. Results

In order to improve the accuracy and reliability of nanodevice modelling and circuit optimization, soft computing technologies have been successfully used to nanodevices and associated digital circuits. Many soft computing methods, including neural networks, fuzzy logic, and evolutionary algorithms, have been used to optimise circuit design, anticipate device behaviour, and represent various aspects of nanodevice modelling. The following are some particular findings from more recent studies:

- Many types of nanodevices, including carbon nanotubes, graphene, and nanowires, have been modelled using neural networks. Especially when dealing with less-than-ideal circumstances like noise, fluctuations, and faults, these models have demonstrated better accuracy and durability compared to classic analytical models.
- Intelligent control systems for nanodevices, such as nano sensors and nanorobots, have been created using fuzzy logic. The accuracy and productivity of the devices can be increased by these systems' ability to adapt to changing surroundings and input signals.
- Nanocircuits with logic gates, memory, and sensors have been designed and performed with the best efficiency possible using genetic algorithms. These methods can find the best options in sizable design areas and enhance the circuits' dependability, speed, and power consumption.
- To integrate the benefits of various soft computing approaches and enhance the precision and effectiveness of nanodevice modelling and circuit optimization, hybrid soft computing techniques, such as neuro-fuzzy systems and genetic-fuzzy systems, have been created.

Applying soft computing tools to nanodevicemodeling and circuit optimization have shown significant improvements in accuracy, efficiency, and flexibility compared to traditional approaches. These results have the potential to accelerate the development and application of nanotechnology in various fields, such as electronics, medicine, and energy.

V. Conclusion

The use of soft computing methods to enhance the modelling of nanodevices and their digital circuits has the potential to significantly increase the precision, efficacy, and adaptability of nanotechnology. Soft computing methods, including as fuzzy logic, neural networks, and genetic algorithms, have been effectively used to improve the design and performance of circuits as well as numerous elements of nanodevice modelling.

The benefits of soft computing technologies above conventional strategies like analytical models and brute-force search techniques. Soft computing models can depict the intricate and nonlinear behaviour of nanodevices in a variety of environments, including noise, temperature, and voltage. Large design spaces may be searched for ideal circuit designs using soft computing optimization methods, which can also increase the circuits' speed, reliability, and power efficiency.

Despite these encouraging outcomes, using soft computing technologies for nanotechnology still has its difficulties and restrictions. Large and representative

DOI: rp-9788770040723.101

datasets are required, soft computing models are challenging to understand and explain, and soft computing techniques are computationally complicated and scalable, among other issues.

Future research in this area may focus on creating more sophisticated and hybrid soft computing methods, fusing experimental data with soft computing models, and using soft computing tools with new nanotechnologies like quantum computing and molecular electronics. Overall, the use of soft computing techniques has the potential to transform the way we design, model, and optimise digital circuits for nanodevices. It also has the potential to lead to new advances in engineering and research.

***Abstract*— The healthcare sector is one of the largest focus areas in the world today. Health related problems are becoming increasingly common. Early diagnosis and treatment of diseases can play a vital role. The solution is adopting healthcare chatbots. The proposed solution is a healthcare chatbot application that can provide solutions based on user queries. The NLP component of the chatbot allows it to understand the intent of the user's query and extract relevant information from the user's input, making it more effective at providing accurate and helpful responses. The chatbot is designed to be easy to use for patients, making it a useful tool for providing basic healthcare information and assistance. Deep Learning algorithm was used and gives an accuracy of 91%.**

Keywords—Chatbot,Health support, NLP, Deep Learning, LSTM, Seq2Seq, Document - Term Matrix, Bag of words

I. INTRODUCTION

Welcome to our healthcare chatbot, designed to assist you in finding the information and resources you need to navigate the complex healthcare system. We understand that the healthcare landscape can be confusing and overwhelming, with various challenges such as long wait times, lack of information, and difficulty in finding the right provider. This can make it difficult for people to access the care they need and make informed decisions about their health. This chatbot is here to help alleviate some of these issues. With this chatbot, you can quickly access a wide range of information about medical conditions, treatments. We also understand that cost is a major concern for many people when it comes to healthcare. That's why this chatbot is designed to help users to find the most cost-effective options available. Our chatbot is a valuable tool that can help you take control of your health and make the healthcare experience more efficient and accessible for you.Artificial Intelligence is creating an era that it is going beyond human imagination and thinking. The technological experts with their tremendous skills and expertise developed the science of AI. The study mainly focusses on bringing up Chatbots which are developed using Natural Language processing. These are the virtual assistants powered by built-in features of AI.

Michael Mauldin in 1994, formulated the term ‘Chatbot’ which is a combination of words ‘Chat’ and ‘Robot’.

We are fairly familiar with Amazon’s Alexa, Apple’s Siri and Microsoft’s Tay – these are the conversational agents that would respond and act according to the queries that users would probe.

Our capstone project focuses on the Healthcare Chatbot which is meant for early diagnosis of diseases and treatments thereof. The reason why we chose Healthcare chatbot in particular is because we all seek medical assistance at some point of time because we live a sedentary lifestyle due to which we get exposed to various diseases. Healthcare industries play a significant role when it comes to life expectancy and quality of lifestyle.

Many are the roadblocks and challenges that the healthcare industries in India are facing these days especially when it comes to the people living in rural areas who lack medical facilities. The census show high mortality rates due to deadly disease that is taking away lives of people and due to unavailability of medical professionals in the rural areas where physical consultation has become a major challenge and totally expensive. When our health goes upset we all want immediate treatment, early diagnosis to avoid any serious consequences. None of us want to wait longer to take appointments with the physician or to meet the concerned doctor just to know what went wrong and what medication we would need to take.

So, the best solution to overcome this problem is to integrate Chatbots in the Hospital’s IT systems. By doing so this would serve thousands of customers or patients at a single point of time and at a very low cost. Also that the patients can get access 24/7 to their health information from anywhere and anytime that they need. The healthcare chatbot that we have come up with uses text, or instant messaging for natural interaction with the patients and all it’s users. What we’ve developed is the QA Chatbot with the the built in AI features, NLP text processing techniques and Deep

DOI: rp-9788770040723.102

Learning Algorithm. When I say QA chatbot this would actually answer the given question that the user would type in. Meaning this would mimic human intelligence. It gives an impression as though the user is talking to the medical professional on the other end as they have meaningful conversation with the patients or users in real-time.

The healthcare chatbots can be used for making appointments, pulling out medical history of a patient, setting up reminders for consuming medicines and other proactive alerts that would inform the medical staff to let them know what's in their action for treating patients.

The usage of chatbots in every business sector is becoming increasingly popular these days. Turning the clock back to 1966 where the first chatbot named Eliza was invented. The sole purpose of Eliza was to provide responses to users based on different keywords. This was purely the role based chatbot. Then came Parry, Jabberwacky, Alice, Smarterchild, Cortona, Siri, Alexa, GoogleNow and then the latest Microsoft Tay – which is a twitter chatbot. The goal was to analyze the tweets on twitter in order to understand the conversations.

Here with the Healthcare chatbot system, the dataset or the model is preloaded is with the set of keywords, set of data. Meaning we have trained the chatbot with word cloud where it picks up keywords from questionnaires and then responds with the answers from the word cloud of answers.

For text pre-processing, NLP has been used with NLTK toolkit that's available in python. The algorithm that we've used is the Deep Learning technique with 4 layers. Dense layers along with dropouts of 20% is used and last layer, output layer contains no. of neurons = no. of intents is used to predict output intent with softmax.

Relu activation function has been used in the dense layers. Stochastic gradient descent is used as an optimizer.

Finally, GUI is created using tkinter to provide the chatbot experience where user can enter their query and the system's response is shown in the GUI.

II. Literature Survey

The proposed solution [1], focuses on predicting agent response for user's query given in the electronics e-commerce industry. They have used the dataset from the support tickets created at Robocraze platform. Initially, they have performed basic NLP operation using NLTK packages like removing stop words, identifying the most common words, bi-grams and basic EDA and word cloud analysis. During, the cleaning of the data they have divided the data in to query – response pairs. Here, they have used an encoder-decoder structure wherein the encoder is customer queries and decoder are the agent response. Further, these inputs are converted into a simple Seq2Seq LSTM model with a bi directional layer and dot product of this is sent to dense layer to generate the final model predictions.

The proposed solution[6], focuses on creating a chatbot on general knowledge-based question and answer. Here, they have compared the model performance through both transformer model and Seq2Seq learning and later they found that the one with transformer model was giving a better result. The model Architecture has i) Encoder ii) Decoder adds another layer apart from 2 sub layers which perform multi head attention. iii) Transformer which further helps to find the a) Scaled-dot product b) Multi Head attention c) Position-wise FFN with ReLU activation function and d) Position encoding. In the training, data was split at 80:20 and batch size as 28 or epoch as 120. The final result of Seq2Seq model was giving 23.5 BLEU of dataset whereas the Transformer model was giving 85 BLEU. Higher the BLEU better is the model for automatic chatbot.

In this model[7] they have used NLP techniques, first tokenizing the corpus, removing stop words, correcting any spelling mistakes, lemmatizing the corpus, vectoring the input and then applying Cosine Similarity between input and training set to find the best suitable output for the question. They tried experimenting both with cosine similarity and Euclidean distance as well. In this example, 2 examples of Dhoni's Wikipedia page, one small para and another big one is taken into account and another one is Sachin's Wikipedia page. The distance between Dhoni's similar type document is much lesser than the distance between them and Sachin's. Thus, questions can be identified nearest to the training set even though user's language for asking question is different. To improve the model even further they can train the vocabulary on Google's word embedding, which will give words similar in meaning almost identical vector. Thus when computing Cosine distances, even though the word is different from what was originally used in our question set, the difference between those words will be minimum. Thus it can give more accurate replies in Chatbot UI.

III. Dataset

A. *Overview*

This paper provides appropriate answer to the patient's health related query. The Healthcare JSON dataset is a collection of data that includes question and answer pairs related to healthcare information. The dataset is structured in JSON format with 465 records, which makes it easy to use and integrate with other systems. Each question-answer pair in the dataset contains a question that is related to healthcare and a corresponding answer that provides information about the topic of the question. The questions in the dataset cover a wide range of healthcare topics, including diseases, treatments, symptoms, and general health information. The answers provided in the dataset are accurate, up-to-date, and written in a clear and concise manner. The dataset can be used to train a healthcare chatbot or other applications that require healthcare knowledge. Additionally, the dataset can be used as a resource for healthcare professionals and researchers, providing a valuable source of information for their work.

B. *Characteristics of the Data*

The dataset features information on 465 QA pairs. We removed stop words from the dataset along with a few custom stop words. Here, We looked at the Bigram and Trigram words from the answers in the dataset.

DOI: rp-9788770040723.102

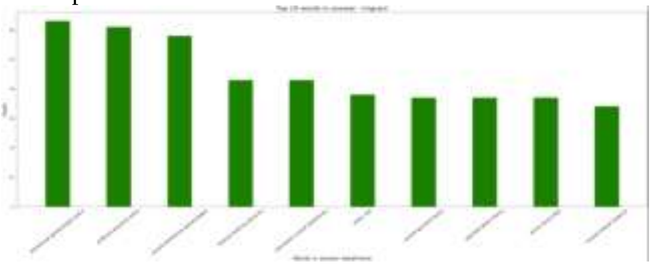

Fig. 1. Top 10 words in answer - trigram

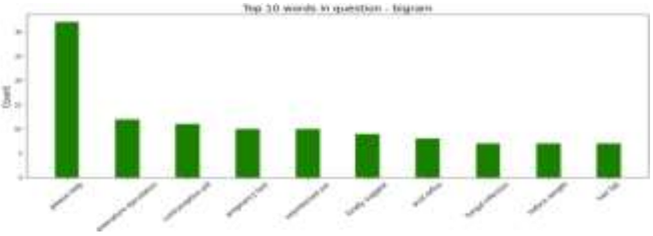

Fig. 2. Top 10 words in question - bigram

The word cloud representation of texts from QandA responses are seen as below. Fig 3 and 4

Fig. 3.Word Cloud of Questions

Fig. 4.Word cloud of Answer

IV. Materials And Methods

The proposed system consists of a user-friendly chat interface through which a user can communicate with the system. Depending on the user input, the chatbot will provide relevant information about his queries.

The system has pre-processed the question answer(icliniqQA) dataset, for training of the Deep Learning model. The system has trained and compared different number of layers and number of neurons in Deep Learning model and got the best accuracy of around 91%.

First, a dataset of healthcare-related questions and answers were collected and pre-processed. Dataset is converted from json file to pandas data frame for preprocessing. We dropped “question text” and “url” columns from the data frame which were not required for chatbot. The data frame is remained with question, answer and tag. The question and tag columns goes through text processing techniques of NLP.

They are tokenized into smaller units or words. Further the tokenized words are converted to lower case. After that we removed punctuations and stop words in question and tag columns. Also lemmatization is done to bring words to its meaningful base form. We converted variable-length texts into a fixed-length vector using the Bag-of-Words technique.

The cleaned dataset is loaded as intents. Each question is tokenized to words and then it is mapped to it’s respective tags and stored as documents. Unique tags are stored in one variable. Then a document-term matrix is created against its tags and used as training data. This dataset was then used to train a deep learning model. This process allows the model to understand the meaning of the user's input and provide a relevant response.

After the model was trained, it was tested on a set of unseen data to evaluate its performance. Fine-tuning was performed to improve the model's accuracy by adjusting the hyperparameters of the model.

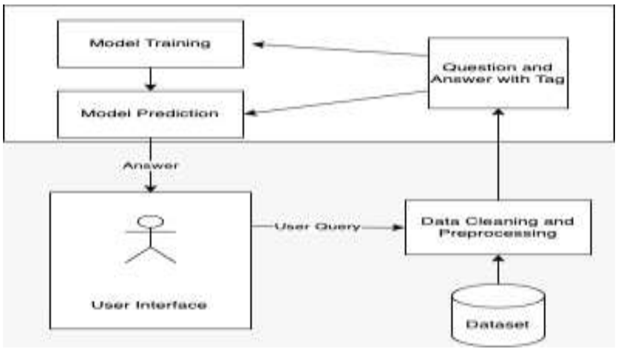

Fig. 5. Flow Model - Chatbot Architecture

Lastly, the model (Fig 3) was integrated into the chatbot interface, allowing users to interact with it through text-based inputs and receive text-based responses. The chatbot also includes a Knowledge base where it can retrieve information to answer user's queries.

A. *Data Preprocessing*

The dataset is retrieved from git hub [11] which contains data of 465 records, including the mapping of answers with the corresponding questions and tags.

The dataset was checked for inconsistencies and removed unwanted data. Then the missing values were imputed. The answer column contained “--><link>” at end of each record, so replaced it with empty string.

B. NLP text pre-processing

The user input has to be pre-processed in order to provide appropriate response. Pre-processing methods – punc-

DOI: rp-9788770040723.102

tuation, tokenization, stop words and lemmatization have been used to generate an appropriate response for the user query.

1) *Punctuation removal:* Python’s string module contains the following list of punctuation ‘!"#$%&\'()*+,-./:;<=>?@[\\]^_`{|}~'. Using this list , punctuation is removed from the user’s input.

2) *Tokenization:* Here the user input is converted into a bag of words using tokenization.

3) *Stop words removal:* Removal of stop words is necessary as they take valuable pre-processing time and space. eg:- ‘a’, ‘an’, ‘the’, etc.

4) *Lemmatization:* lemmatization considers the context and converts the word to its meaningful base form. For example, lemmatization would correctly identify the base form of ‘caring’ to ‘care’.

Wordnetlemmatizier is used to achieve lemmatization in our case.

C. Deep Learning Algorithm

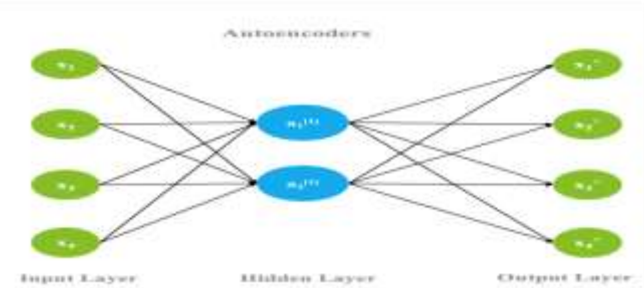

Fig. 6. Deep Learning Architecture

Components used in the model

1) *Dense Layer:* In natural language processing (NLP), a dense layer is a type of layer in a neural network that is fully connected to all the neurons in the previous layer. It is called a "dense" layer because each neuron in the layer receives input from all the neurons in the previous layer, as opposed to a "sparse" layer where some neurons do not receive input from all the neurons in the previous layer.

Dense layers are commonly used in NLP tasks such as language translation, text classification and language generation. They are used to process the input data, extract useful features, and make predictions based on the learned features. Dense layers are usually followed by an activation function such as ReLU or sigmoid, which helps introduce non-linearity into the model and allows it to learn more complex relationships in the data.

2) *Activation Function:* Activation functions are mathematical functions that are used in artificial neural networks to introduce non-linearity into the model. They are applied element-wise on the output of each neuron, allowing the network to learn and represent more complex relationships in the data.

ReLU (Rectified Linear Unit): It is defined as f(x) = max(0, x). It is commonly used in the hidden layers of neural networks and has the advantage of being computationally efficient.

Softmax: The softmax function is a popular activation function used in the output layer of neural networks for multi-class classification problems. It is a generalization of the sigmoid function, which is typically used for binary classification problems.

The softmax function is useful in multi-class classification problems because it converts the output of the neural network into a probability distribution over the classes.

The softmax function is computationally efficient and differentiable, which makes it easy to train the neural network using gradient-based optimization methods.

3) *Optimizers:* Optimizers are algorithms used to adjust the parameters of a neural network in order to minimize the error between the predicted output and the true output. They are used during the training process of a neural network to update the weights and biases of the network in order to improve its performance.

Stochastic Gradient Descent (SGD): It is one of the most basic and widely used optimization algorithm for training neural networks and other machine learning models. It updates the weights and biases of the network based on the gradient of the error with respect to the parameters.

The update rule for the parameters in SGD is given by:

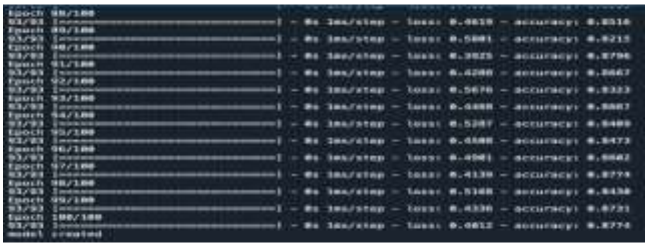
w <- w - learningrate * gradient

where w is the parameter to update, learningrate is a scalar that controls the step size.

D. Methodology

The deep learning model utilizes a multi-layer perceptron architecture with 3 layers. The input data is fed into the first layer, which consists of 128 neurons. The outcome of the first layer is then passed through the second layer, which contains 64 neurons. Dropout with a rate of 20% is applied to these layers to prevent overfitting. The outcome of the second layer is then passed through the final layer, which contains neurons equal to the number of intents. These neurons use a softmax activation function to predict the output intent.

The dense layers in this model use the Rectified Linear Unit (ReLU) activation function, which helps to introduce non-linearity and allows the model to learn more complex relationships in the data. The optimizer used for training the model is stochastic gradient descent (SGD) algorithm. The model is trained for 100 epochs with a batch size of 5 and achieved accuracy of around 88%



DOI: rp-9788770040723.102

Fig. 7. Model accuracy for 3 dense layers

It was further improvised by adding another layer with 32 neurons. So now the model utilizes a multi-layer perceptron architecture with 4 layers, where the first layer contains 128 neurons, second layer with 64 neurons, third layer with 32 neurons. Dropout with a rate of 20% is applied to these layers to prevent overfitting. The outcome of the third layer is then passed through the fourth and final layer, which contains neurons equal to the number of intents. These neurons use a softmax activation function to predict the output intent.

The model uses the same activation function, optimizer, and is trained for the same number of epochs and batch size and achieved accuracy of around 91%.

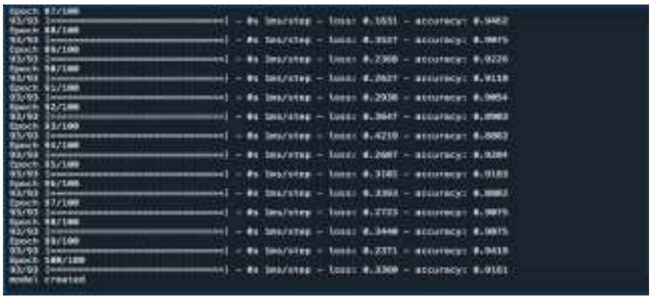


Fig. 8. Model accuracy for 4 dense layers

E. User Interface

A Chatbot GUI, or graphical user interface, is a type of interface that allows users to interact with a chatbot using graphical elements, such as buttons and images, rather than just text. This can make the chatbot more user-friendly and intuitive to interact with, as users are able to see options and make selections more easily. Some popular chatbot GUI platforms include Dialogflow, Botpress, and Microsoft Bot Framework.

Tkinter is a Python library for creating graphical user interfaces. It is built on top of the Tcl/Tk GUI toolkit and provides a simple and easy-to-use interface for creating windows, buttons, labels, and other widgets. Tkinter is included with the standard Python distribution and is widely used for creating simple GUI applications. Some of the features of Tkinter include support for events and callbacks, geometry management, and support for various types of widgets.

Tkinter library is used to view the gui for providing the chatbot experience.

Here the user input is processed with necessary techniques, then using the bag of words technique, a document-term matrix is created. Then it is sent for prediction. Error threshold is considered as 0.25. A tag is extracted after model prediction which is matched with the tag in the dataset and appropriate answer is returned to the user.

V. Evaluation and Model Results

The approach involves testing the dataset using deep learning algorithm using few dense layers and dropout to prevent over fitting. The algorithm has provided with accuracy around 91%. The model analyses user's query accurately and provides the user with appropriate answer.

Example 1 –

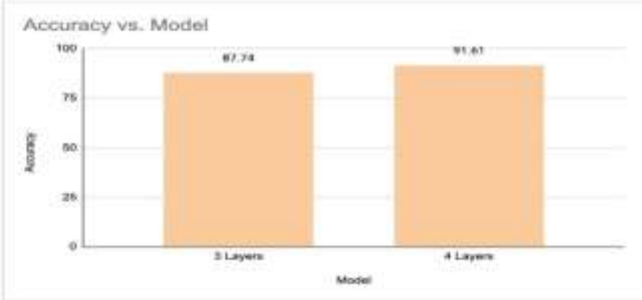

Fig. 9. Accuracy graph between models containing different layers

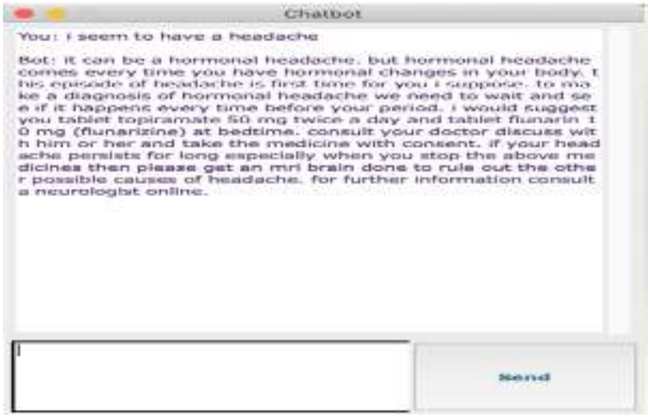

Fig. 10. Chatbot example1

Example 2

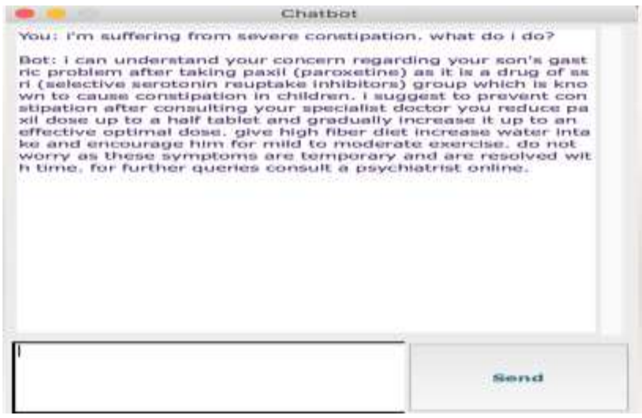

Fig. 11.Chatbot example2

VI. Discussion And Conclusion

The study was done within a very short span. All the possibilities are not considered in this study and a lot of improvement is possible. There are several features or algorithms that can be implemented for improving the overall performance of the model. By using NLP techniques such as unigrams, bigrams, and trigrams, healthcare chatbots can understand and respond to user's inquiries more accurate and appropriately.

There is a definite scope of development in this area, we can enhance the current model and work towards slowly eliminating the limitations such as :

- Currently negative scenarios are not handled. For any irrelevant query, random answer from the dataset is provided. It doesn't prompt the user to enter a relevant query.
- There are no greetings. The algorithm presented currently only works as a simple question answer healthcare chatbot.

Future work can involve improving the model by making use of optimizers, different algorithms, multilingual ability. Using different dataset system will be able to predict diseases based on the symptoms provided by the user. We can also incorporate voice to text and text to voice functionality to make it user friendly.

***Abstract*— Diabetes is a type of illness or problem which can't be treated surgically or operated on. Lack of consciousness regarding lifestyle can easily cause diabetes. Diabetes is generally caused because of a gain of weight, laziness, not taking a proper diet, etc. A person who is having diabetes should be very proactive about his health as it can also lead to death or more severe complications. One of such complications is Diabetic Foot Ulcers(DFU). One of the leading reasons of death in the world, diabetes can also result in complications like diabetic foot ulcers. (DFU). A patient's foot may be removed if their diabetic foot ulcer is handled improperly and late. With the use of a computer-assisted classifier, thermal imaging may be utilized to detect DFU signs early on. With the aid of deep learning neural networks, we plan to develop a model that may be utilised to aid patients by providing an early warning of diabetic foot ulcers. Big Data Analytics plays a noteworthy role in healthcare industries. With the help of big data, we can store a wide variety of data on different patients and have a wide range according to age groups. So, this will be helpful in getting hidden features from stored data. As we see the classification of data nowadays this is not that reliable. The use of the same dataset and different models are not giving that much accuracy. So our main focus is on increasing accuracy and getting better results for classification. We have referred few types of research which were done before so came to conclude we will use EfficientNet for better understanding the features of the images and it helps in increasing the accuracy of classification.**

Index Terms— Deep Learning, Convolutional Neural Network, EfficientNet, Artificial Intelligence, Classification, Diabetes Diagnosis, Diabetic Foot Ulcers, Healthcare Domain, Supervised Learning.

I. Introduction

Diabetes is an illness in which insulin level in blood get depleted below the normal level which is needed to stay healthy. This will cause malfunction of organs of body like patient will gets frequent urination, etc. If it is not treated on time, it can cause central numerous complications. This difficulty leads to demise. There are some specific diseases, which includes diabetes, kill around 19% of world's population. In 2000, deaths caused by diabetes increased by 72%, and in 2023, these deaths are expected to rise by 85%. Diabetes can be caused by many lifestyles' routine such as laziness, taking pills, heavy weight, etc.

Foot ulcers are among the most devastating effects of diabetes. Diabetes-related foot wounds known as diabetic foot ulcers (DFUs) are significant diabetes cases. According to reports, there were only 151 million diabetics globally in 2000; by 2014, that number had risen to over 422 million, and by 2021, it was projected to reach over 537 million.

The incidence of diabetes illness increased by 10.5% among persons over the age of 18 between 2000 and 2021. The major goal of our study is to develop a model that can be utilised for early diabetic foot ulcer prediction so that it may be treated appropriately and the patient doesn't have to lose a limb.

In this situation different Deep learning algorithms can be used to create a model which can predict whether ulcer is abnormal or normal. Diabetes can be cured at early stages if proper care is taken and proper medication is given to the patient. Artificial Intelligence approaches can assist in the earlydetection of this disease. The analytical model can identify and understand the incoming data, allowing it to make more specific decisions.

TABLE 1: Prevalence facts and countermeasures for diabetes and diabetic foot ulcers

At the glint	Year			
	2000	2021	2030	2045
World adult (19–79 years) population (in billion)	3.2	7.9	8.6	9.5
Number of people with diabetes (in million)	151	537	643	783
Prevalence of diabetes (in percentage)	4.6%	10.5%	11.3%	12.2%
Diabetic foot ulcer with 15% prevalence (in million)	22.65	80.55	96.45	117.45
Number of people with diabetes in India (in millions)	32.7	74.2	101	124.9

Since the dataset consists of images we are using the concept of Convolutional Neural Networks (CNN). There are different CNN architectures that can be used for classification whether the ulcer is normal or not such as VGG, AlexNet, EfficientNet, etc.

We can use different architectures for better understanding the features of the images or dataset and this helps in for forecasting the disease. Deep Learning methods can help in detecting diabetic foot ulcers at its preliminary stages. This can help patient in detecting disease priory and taking necessary precautions in order to stay healthy.

II. Literature Survey

It is known that patients' understanding of the effects of diabetes is low or non-existent, which contributes to complications. Analysts' assessment of DFU's findings included the use of different sensors and CNN models, although one or two widths, depths, or definitions of images were being considered. Thus, three highlights are taken into account when broadcasting the prediction of diabetic foot ulcer conclusion in this broadcast of a deep learning experiment, EfficientNet. By accurately distinguishing a diabetic foot from a normal foot, he can detect the severity of the foot ulcer and take timely action.

DOI: rp-9788770040723.103

Through an in-depth survey of the misconceptions (IA) articles that have supported DFU verification strategies, it is conceivable to consider the priorities of these strategies as well as the challenges facing them difficult to coordinate them in a realistic and solid system to achieve unattainable satisfaction understand governance.

To recognize diabetic foot ulcers, they examined the associated optical sensing and imaging strategies. The reflection takes into account the strength of the sensors as well as the physiology of the patient. The news source allows for a wide range of verification strategies and they have established restrictions on the adoption of AI innovation.

The use of a non-invasive photonic device has been recommended for the treatment of diabetic foot ulcers in diabetics. Using the concepts of hot and hyperspectral imaging, this utility studied the condition of the ulcer. The oxyhemoglobin and deoxyhemoglobin biomarkers were evaluated using these photon imaging methods. By combining flag management strategies that use deep learning to improve pixel accuracy and reduce stutter with super-resolution strategies, this utility has evolved.

Programmed DFU image classification has been proposed using a deep CNN called DFU QUTNet. When there are more layers, a normal CNN becomes very deep, but the implementation makes no progress. To extend the width of the network while maintaining the depth compared to current systems, the QUTNet DFU arrangement was implemented.

The ubiquity of corners seems to benefit mainly from sloppiness transmitted through the DFU QUTNet system on a number of different channels.

III. Problem Statement

Diabetes is becoming increasingly prevalent in today's environment. The major source of this significant condition is the individual's lifestyle. Diabetes can induce a variety of problems, some of which are life-threatening. One of these serious effects is diabetic foot ulcer. If adequate treatment is not received in time, a limb may be amputated.

When the person suffering from an ulcer is unable to walk properly, travelling to a nearby hospital or clinic is a challenging chore for such a person. With this project, a doctor or any family member may determine whether the ulcer is normal or pathological.

In addition, not all doctors are knowledgeable about all dis- eases, making it difficult to locate a doctor you can trust with such understanding.

Yet, in everyday life, the diabetic patient must determine whether he or she is indeed diabetic. A computerised system that can anticipate the right response without making any of these mistakes is required in order to prevent these blunders, and this may be accomplished with the use of DL.

TABLE 2: CNN Architectures and their number of layers

Model	No. of layers	Salient feature
AlexNet	8	Depth
VGG16	16	Very Deep CNN
VGG19	19	Very Deep CNN
GoogleNet	22	The depth and width-based CNN
DFUNET	14	The depth and parallel Conv. with homogeneous kernels.
DFU_QUTNet	30	Width-based network compared to the depth of the model.
DFU_SPNet	22	The depth and parallel Conv. with heterogeneous kernels.
EfficientNet	237	Depth, width, and high resolution

IV. Scope

Diabetic Foot Ulcers Prediction System is a project which will help both diabetic and non-diabetic people. Our project will be helpful for everyone but more helpful to non-diabetic people. We are thinking of adding the following features to our project

A. *Diabetic Foot Ulcer Test:*Using this feature any per- son can check whether the ulcer he/she having is abnormal or normal in nature.

*B.Doctor Consultation:*Using this feature anyone can consult to doctors and experts who will suggest you different activities which will help in improving your health as well as lifestyle.

C. *Expert System:*A person who doesn’t have knowledge about this domain can use this project and get knowledge.

V. Methodologies Used

Artificial Intelligence

The Artificial Intelligence seminar provides an overview of AI that will enable you to understand the guiding principles of AI. These days, technology is ubiquitous, meaning that it is everywhere and that it is developing at a rapid rate. Artificial intelligence is one of the many booming computer science technologies that is being employed increasingly in a variety of fields. The world is being ruled by artificial intelligence, which is also providing us with fresh ideas daily to help us think critically and do something new.

Deep Learning & Convolutional Neural Networks

Deep Learning is a concept which is quite popular these days. It is basically the subset of machine learning and it uses neural networks for its working. Artificial neural networks make an effort to mimic how the human brain functions, however they fall far short of being able to match it, enabling it to "learn" from vast volumes of data.

Deep learning networks works by finding hidden and complex patterns in the data they process. The networks may develop several degrees of abstraction to describe the

DOI: rp-9788770040723.103

data by constructing computational models that are made up of many processing layers.

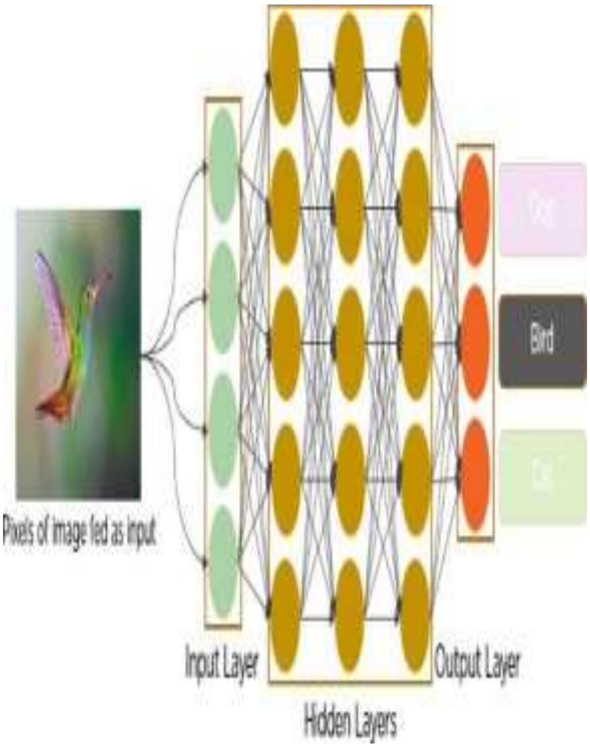

Fig. 1. Convolutional Neural Networks

Convolutional Neural Networks is one of the algorithms of deep neural networks which consist of different architectures. A neural network type known as convolutional neural net- works, or CNN or ConvNet, is focused on processing input with a grid-like architecture, such as images.

CNN basically consist of 3 types of layers which are convolutional layer, pooling layer and fully connected layer. Different of arrangement of these layers makes different architectures of CNN.

Efficient Net

Efficient Net is one of the important architectures of convolutional neural network and project about understands the features of images of foot ulcers and this architecture can help us in better understanding the features of the images and hence better accuracy in predicting. The design of the solution was influenced by the image's width, depth, and resolution. Since our project is realted to images with higher resolution and more pixels, therefore we are using EfficientNet which is the best option.

These intuitions suggest that scaling multiple dimensions re- quires coordination and balancing as opposed to the more traditional single-dimension scaling. The compound scaling method grows the network's depth, breadth, and resolution logically and uniformly using a compound coefficient.

Since DFU classification requires a more complicated network architecture to distinguish between normal and abnormal classifications, the number of layers in a CNN model does not guarantee correctness.

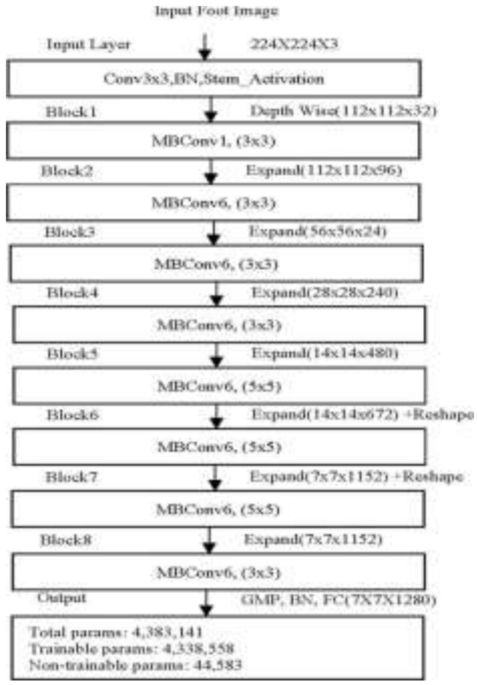

Fig. 2.EfficientNet Architecture

In some cases, network performance degrades as the number of levels increases, and a network with few layers and a simple topology is sufficient.

VI. Workflow Of Model

The model is built using a CNN architecture which is going to classify out data into whether a person is having normal or abnormal ulcer. The training of model is done using training data and train accuracy is provided. The given flow chart ex- plains the workflow of our model.

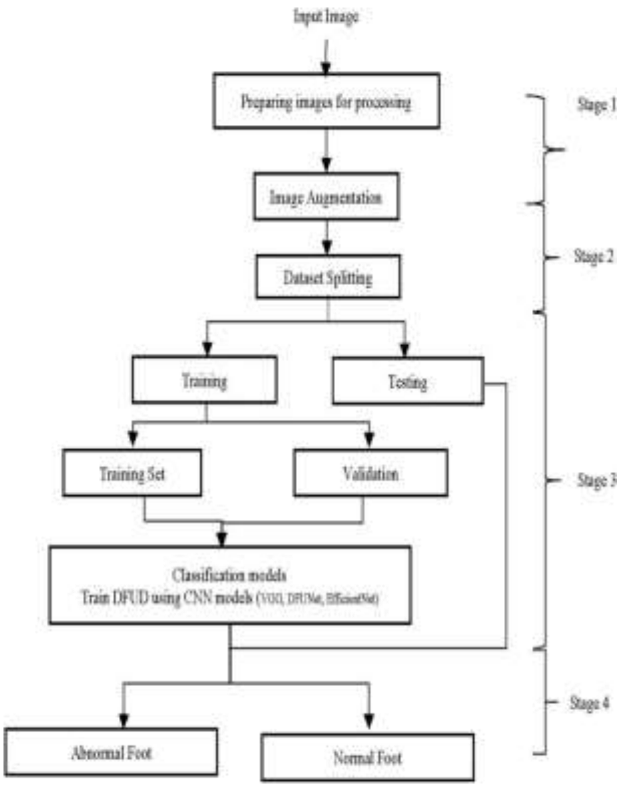

Fig.3.Workflow Diagram

DOI: rp-9788770040723.103

VII. Dataset Used

CNN architecture was used to build the model, which will classify the data into normal and abnormal ulcers. Model training is carried out with the aid of training data, and train accuracy is offered. Since we have used CNN as our algorithm, we have used number of images as dataset for proper training and testing of our model. Heres are some of these images:

Fig. 4. Dataset

VIII. Evaluation

Confusion Matrix

Confusion matrix is a concept in machine learning which is used for the performance evaluation of different models. This matrix is usually used for classification model evaluation. There are 4 terminologies used in this matrix which are true positive, true negative, false positive and false negative.

Using these 4 terminologies different calculations can be done and evaluation of the model can be done. These evaluations can also help in telling which feature of the model should be modified in order to improve the performance of the model.

True Positive: It is the situation in which both predicted and actual answer both is yes.

False Positive: It is the situation in which predicted answer is yes but the actual answer is no.

True Negative: It is the situation in which predicted answer is no and the actual answers is also no.

False Negative: It is the situation in which both predicted and the actual answers are no.

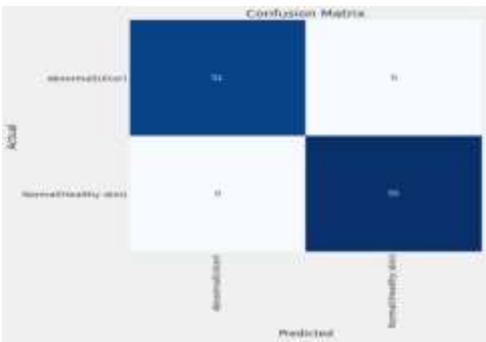

Fig. 5. Confusion Matrix

Calculations using Confusion Matrix

Above confusion matrix can be used to find some calculation which can be used for model evaluation. These calculationsare:

1. *Accuracy:*Accuracy can be defined as the measurement of prediction correctness. It is the closeness be- tween the correct and predicted value.

2. *Error Rate:* Error rate is defined as the number of in-correct predictions per all samples available. Lower the value, better the model will perform.

3. *Precision:* Precision defines the exactness of the mod-el. It has the highest value as 1 and lowest is zero.

4. *Recall*: Recall is used find what is the ability of the model to find positive samples. If recall is high that means the model will find more positive samples.

5. *F-measure:* F measure takes recall and precision to find its value. It makes the model to use both precision and recall for finding best outputs.

IX.Conclusion

Diabetes is a very common and rising problem now a days and it is not only limited to only old people, person of any age can be affected by this disease. Sometimes this problem of diabetes leads to more severe complications. One of such complications is foot ulcers. These ulcers if not detected early whether these are normal or abnormal in nature then it can leads to losing of a limbs

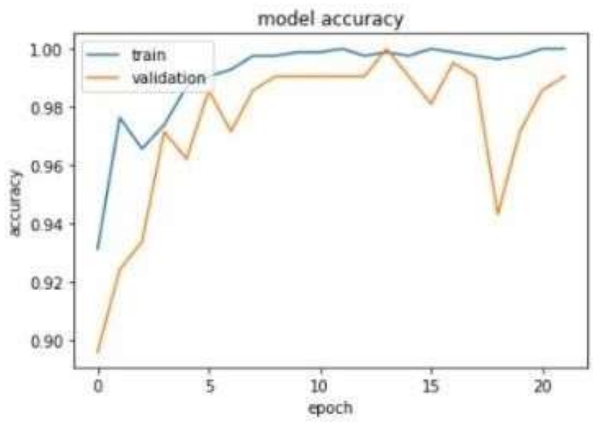

Fig. 6. Model Accuracy

Therefore for the early detection of diabetic foot ulcers we have created this project – AI driven Diabetic foot ulcers pre- diction system. For proper classification and prediction, our project uses a deep learning model known as ―Convolutional Neural Network. There are different architectures of CNN and we are using EfficientNet.

The accuracy attained by our model is about 95% but this can be improved by improving the quality of our dataset and using some other methodologies

***Abstract*—The Student Feedback Review Analyzer is deployed to obtain student feedback on a particular faculty or a teacher. Using the responses provided by the students, it analyzes the responses over all and assists admin to make better decisions. Those in attendance, such as the higher authorities, can see the entire report. It includes modules for students, faculty, and administration. A class is created by the administration, which also appoints the appropriate professors to the class. We can quickly learn how the professors are doing from the perspective of the students. Each of the 13 evaluation questions for professors includes five possible answers to rate the instructor, including excellent, very good, good, average, and poor.**

***Index Terms*—Feedback, Sentiment Analysis, Student, Teacher, Review**

I. INTRODUCTION

The Student Feedback Review Analyzer is an essential tool for educational institutions seeking to improve the quality of education they offer. This student data management system provides a platform for students to express their opinions and views on their academic experiences, specifically regarding their faculty members. The feedback obtained from students is crucial in evaluating the effectiveness of teaching methods and helps the faculty members to identify areas where they need to improve to better meet the need soft heir students.

The Student Feedback Review Analyzer is designed to be user-friendly, ensuring that students can easily navigate the system and submit their feedback without any difficulties. The system is equipped with a range of ordered feedback options, such as ”always,” ”poor,” ”generally,” and ”very frequently, ”which allows students to express their opinions in a concise and effective manner.

Once feedback is submitted, the system analyzes the sentiment of the feedback to determine the overall tone and provides the faculty members with an overview of how their students perceive their teaching methods. This comprehensive overview helps the faculty members to identify their strengths and weaknesses and formulate strategies to improve their teaching methods.

The Student Feedback Review Analyzer is a valuable tool in promoting transparency and accountability within educationalinstitutions.Thesystemallowsforhonestandconstr uctivefeedback, which creates a sense of openness between faculty members and students. By giving students a platform to express their opinions and views, institutions can create an environment that fosters a sense of community and enhances the learning experience.

In summary, the Student Feedback Review Analyzer is an essential tool that educational institutions should in corporate into their systems. The feedback received from students helps faculty members to improve their teaching methods and create a better learning experience for their students. Additionally, the system promotes transparency, accountability, and community, which are vital values for any institution.

II. CURRENT TECHNIQUE

The current procedure used by educational institutions for obtaining feedback from students regarding unsatisfactory teaching or areas where they need better understanding is quite cumber some. Under this procedure, students are required to submit an application to the concerned Head of Department (HoD) or higher officials, detailing their feedback and there as ons behind it. This application must be submitted in writing, and students must provide a detailed explanation of their concerns.

Once the application is received, the HoD reviews it and assesses its validity. If the HoD believes that the feedback is justified, they will forward the application to the higher authorities for further review. This process can take some time, as the higher authorities must evaluate the feedback and determine the appropriate course of action.

One of the major drawback soft his procedure is that students are unable to obtain authorization for their feedback application if the HoD or higher authorities are unavailable. This can be frustrating for students, as they may need urgent assistance and not be able to receive it due to bureaucratic delays.

More over, the current procedure for obtaining feedback from students can create a communication gap between students and faculty members. Students may feel discouragedfromprovidingfeedbackduetothelengthyandcom plexprocessinvolvedinsubmittingtheirapplications.Thislacko fcommunication can lead to a lack of understanding between students and faculty members, resulting in a subpar learning experience.

To improve this process, educational institutions should considered opting a more streamlined and efficient approach to obtaining feedback from students. This approach should prioritize ease of use, accessibility, and transparency, ensuring that all students have equal access to express their opinions and concerns. Additionally, institutions should foster a culture of open communication and encourage students to provide feedback regularly. This will help build trust and create a more positive learning environment for

everyone involved.

III. Related Work

The current feedback system relies on pen and paper, which can be a tedious and time-consuming task. It also requires careful management of the paper to prevent loss or misplacement.Makingphotocopiesoffeedbackformsgenerates alargeamountofpaper,raising environmental concerns. RajveePateletal.[3]addressedthisissuebydevelopinga"FeedbackManagement System" that takes into account the concerns ofstudents and provides an easy and consistent way for them todeliver feedback to the college's head or principal. In theirrespectivestudies,PhaniRamaPrasadandSivasankariS.introduced two different online systems aimed at automatingthefeedbackprocessforlecturers.PhaniRamaPrasadetal.proposedan"OnlineStudentFeedbackSystem"thatallowsstudents to provide feedback online, automatically generatingfeedbackforlecturers,thuseliminatingtheneedtowritedown feedback manually. Meanwhile, Sivasankari S. et al. [7]developed the "Online Student Feedback Analysis System"(OSFAS),whichusespredefinedcommentsandcategoriessuch as "good," "interesting," "late," and "interactive" to pro-vide relevant feedback about teachers automatically. Both ofthese systems share a common objective, which is to enhancethe quality of feedback while reducing the amount of time andhumaneffortrequired.

IV. Proposed Model

Theregisteredstudentscaneasilygeneratefeedbackatanytime,wherevertheyareinthecollegeoruniversity,usingtheproposedfeedbacksystem.TheHOD,principal,and admin sendthe feedback that isthereby created. Thishelpstosaveaplethoraoftimeandwork.Thefeedbackreportssenttothe HODandprincipalareavailabletothematalltimesand fromanylocation.Facultymembersalsohaveaccesstotheiraccountwithoutalsohavingaccesstothe entire file. By utilizing the opportunity provided by thisportal's features, students can now directly initiate feedbackstatements,evenwithoutanyauthorization.Thesecurityofthe feedback is improved by this portal. The proposed systemhasthefollowingbenefits:

- Savesalotoftimeandlabor;
- Reducespaperwork;
- AccessibleandConvenientinterface;
- Creatingreportsmadesimpleandeffective;
- Enhancesconfidentiality

V. Implementation of Modules

Thisapplicationhastwomainmodules.Themodulesare:

- FacultyModule
- StudentModule

A. Facultymodule

The category of users, which comprises faculty membersand administrative staff, is also included. Upon entering their faculty ID and passcode, the database verifies the credentials of the faculty member. Once the account is valid, the portal will open and include functionalities such as "Add Faculty, ""View Faculty," and "View Class." HoDs cannot see results for other departments within their department, nor can they see classes in other departments. Superusers of the student feedback review system are also faculty members. After the super user inputs the super user ID and passcode, the data base validates. Once valid, the account opens and includes modules such as "View Faculty,""View Classes," and "Logs." You can view actions performed by the faculty by using the log module.

B. Student module

In the student module, students provide their registration number and batch details. The corresponding instructor name and instructor ID are displayed based on the selected batch. By clicking on the instructor ID, a feedback form containing about 15 questions will appear. Students can choose the most suitable answer from their perspective, and the responses will best oredon the server.

VI. Inference

The Student Feedback Review Analyzer portal has been de-signedinawaytomakecomplexworksimplerforeducationalinstitutions and to simplify feedback for students. This physically consumes a plethora of time, energy, and paperwork. Also, you are free to provide your unbiased response without any hesitation. So, this model tackles all of these obstacles and provides lots of backing during the entire process of requesting a leave. Teachers are equally accountable here to be able to directly sort out any kind of issue withthestudents.Ifthisprojectneedstobeimplementedproperly, thiswilltakea collective effort from teachers, students as well as adminstaff. The utilization of a feedback review system is prevalentin educational institutions such as schools and colleges. Itspurpose is to enhance the quality of education and other activities, with the aid of an online feedback system. By gatheringsincere feedback from students, we can effectively identifyareas of improvement in teaching methods and facilities. Theimplementation of an online feedback system not only savestime but also streamlines the process of analyzing feedback. Incases where feedback results are excellent, improvements maynotbenecessary.However,iffeedbackresultsaremoderateor poor, necessary improvements can be identified. Thus, theonlinefeedbacksystemprovidesbenefitssuchastheeaseofobtainingdatafromstudentsandsimplifiedanalysisoffeedback data.

***Abstract*—To more accurately depict Alzheimer's disease (AD) and predict clinical scores while taking into account advancements in clinical imaging and substantial learning, several experts are gradually using ConvNet (CNNs) to remove deep level features from clinical images. A small deep learning network called the PCANeT (Principal Component Analysis Network) creates multi-faceted channel banks to verify the accuracy of voluminous head part assessments. After binarization, blockwise histograms are constructed to obtain picture properties. PCANet is less adaptable because multi-facet channel banks are built with test data, resulting in PCANet features with thousands or even millions of aspects.The NMF-TDNet(non-negative matrix factorization tensor decomposition network) is an information-free organization based on PCANet that we present in this study to address these issues. Instead of PCA, staggered channel banks are made to test nonnegative matrix factorization (NMF). By applying tensor decomposition (TD) to a higher-demand tensor derived from the learning results, the input's dimensionality is reduced, resulting in the final image features. The support vector machine (SVM) in our technique uses these properties as input to diagnose, predict clinical score, and categorise AD.**

Keywords*—There are many different names for Alzheimer's disease (AD), such as deep-learning, regression, and multi-class classification.

I. INTRODUCTION

Alzheimer's is a neurodegenerative state with a protracted course that often affects the elderly. As the infection advances, the patient's memory and mental capabilities decay, their neurons are bit by bit obliterated, and the patient in the long run passes on [1]. Alzheimer's disease influences around 50 million individuals around the world. As the total populace ages, it is guessed that the quantity of Alzheimer's victims will twofold by 2050 [2, 3]. While there are a few prescriptions available to treat Alzheimer's disease, their viability is restricted to easing back the infection's movement as opposed to relieving it out and out [4]. The patient's early mental impairment falls somewhere amidst CN i.e., cognitive normal state and the Alzheimer's illness condition, also known as mild cognitive impairment state (MCI), according to various evaluations. Diverse researches are actively going on to find people who have proactively gone to the MCI stage in order to provide the appropriate mediation to halt the condition's progression [5]. Thus, deciding the phase of Alzheimer's disease has been the essential focal point of flow research, and early location of the infection is significant.

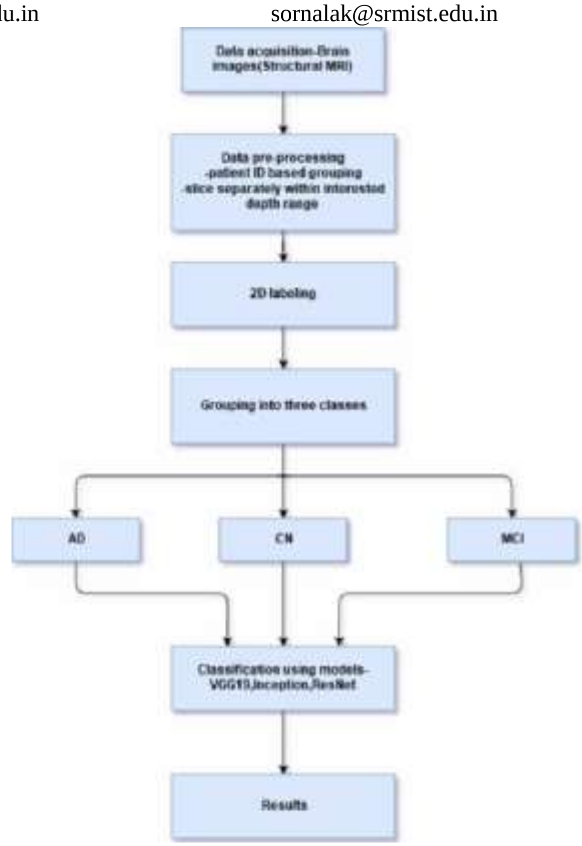

Fig.1: Example figure

Medical imaging technology has advanced tremendously in recent years. It will likely give clinical experts and scholastics with an interesting perspective on disorder finding by means of the investigation of clinical samples, confirming the legitimacy of clinical research expert's conclusions, and giving extra data to advance further review and examination. Diverse clinical image methods (some of the widely known methods are positron emission tomography (PET), single-photon emission computed tomography (SPECT), and magnetic resonance imaging (MRI)) can be used to obtain clinical images. The quick evaluation of changes, a top concern in construction and processing, as well as the identification of biomarkers for Alzheimer's disease may benefit from these numerous image techniques.

A few tests have shown that MRI is one of the most common and well-known imaging modalities used in medical practice. Neuron incident is the purest indication of

DOI: rp-9788770040723.105

Alzheimer's disease pathology, trailed by mind shrinkage from AD explicit frontal cortex districts to the whole cortical locale. An MRI may be used to observe these changes. These conspicuous physical changes happen preceding the beginning of huge mental limit decline. Subsequently, most of flow research is centered around laying out a patient's Promotion stage utilizing X-ray based PC supported conclusion (X-ray computer aided design).

II. Literature Review

Nowadays most of the people are busy with their fast-paced lives. Which in turn is the reason for lots of people suffering with high blood pressure making it as the root cause of dementia cases increment. Existing Alzheimer's Disease medication can cause a lot of side effects to the patients like vomiting sensation, nausea, diarrhea, allergic reactions on body, loss of appetite, headaches, dizziness and confusion. Regardless of lots of research and development the fundamental systems of Alzheimer's infection and applicable treatment targets stay muddled, and there is no proper drug which produces low or few side effects is available. There are as of now research focusing on amyloid and tau, two principal pathology signs of Alzheimer's disease. Yet, additional studies exist in various stages of research that are largely focused on other signs and processes connected with the condition that are now being inspected. Issues covered include: The study by **A. Khan, and C. Ballard, et al.,** looks at novel and drug repositioning that are now being explored in clinical trials that spot non-tau and non-amyloid pathways. This includes both possible disease-modifying medications and cognitive and neuropsychiatric therapies. The publications included in this study were obtained using PubMed and clinical trials database searches. Researchers are working harder than ever to find effective treatment for the behavioral signs of Alzheimer's disease, employing both new medications and drug repositioning. Other routes are being investigated as a consequence of the failure of medications. Upgrades in biomarkers will give additional scope for clinical preliminaries of promising drugs for meaningful treatment and disease adjustment in Alzheimer's disease.

K. G. Yiannopoulou, and S. G. Papageorgiou., discuss that, the groundwork of contemporary Alzheimer's disease (AD) therapy shows restraint focused psychoeducation, shared objective setting, and independent direction considering serious core competencies for a connection between the doctor, patient, and the care taker. Utilized as part of a comprehensive treatment plan, cholinesterase inhibitors (ChEIs), also known as N-methyl-d-aspartate (NMDA) antagonists, and other FDA-supported promotion medications like meantime may have limited "disease course-modifying" advantages by enhancing perception and reducing loss of freedom. Joining pharmacologic and nonpharmacologic treatment might diminish side effects essentially, forestall clinical movement, and decrease absolute medical services costs. The most important phase in Alzheimer's disease pharmacotherapy is to distinguish and eliminate any potentially hazardous prescriptions and enhancements. Nonpharmacological treatments are utilized as the principal method of medication for neuropsychiatric secondary responses and risky process of behaving. Among the techniques utilized incorporate psycho education, trigger location, iterative assessment, and conduct and ecological mediation changes. Significant exploration is being performed to deliver better medications, restorative devices, and more exact and accommodating indicative biomarkers for Alzheimer's disease. Various remedial targets, including neurotransmitter, tau neurotic-cycle and amyloid, power house of cell, provocative pathways, neuroglia, and multiple model ways of life mediations, are the focal point of continuous exploration reads up for Alzheimer's disease essential and auxiliary anticipation, in addition to clinical preliminaries assessing suggestive and sickness adjusting therapies in Alzheimer's disease patients.

In their work, **T. Tong, R. Wolz, Q. Gao, R. Guerrero., et al.,** survey the machine learning strategies have been broadly used to aid the assessment of neurological circumstances like dementia and to recognize morphological anomalies in essential frontal cortex appealing resonation imaging information. In this paper, we present a program for the beginning phases of Alzheimer's sickness and gentle mental impedance that joins a numerous occasion learning (MIL) technique (MCI). Neighborhood power patches are disposed of as highlights in our examination. Nonetheless, not each of the patches given out by dementia victims are gone after in much the same way, and some may not display the sickness' normal symptoms. As an outcome, pinpointing these patches as transporters of specific disorders might be troublesome. Managed learning frameworks, like MIL, might have the option to manage the issue of equivocal preparation marks. A diagram is created for each picture to take advantage of the associations between the patches and consequently, tackle the MIL issue. The created diagrams remember data for how patches show up and associate with each other, which might mirror the fundamental designs of the pictures and aid arrangement. The proposed method was able to accurately depict 89% of AD victims and sound controls and 70% of patients with stable MCI and mild MCI using benchmark MR evaluations from 834 ADNI centers. A well-informed perspective on the diagnosis and treatment of neurodegenerative diseases could result from the proposed method's ability to produce outcomes that are comparable to or superior to those of two cutting-edge methods that make use of the same dataset.

In a recent study on the diagnosis of Alzheimer's disease and MCI **D. Shen, H. Suk, and X. Zhu et al.,**, a significant correlation was found between the diagnosis and the clinical score assumption. Additionally, it has been demonstrated that the issues of low model size and high component dimensionality can be resolved by incorporating decision-making through complex learning model. Clinical score regression and clinical imprint collection were frequently restricted prior to evaluations alone. Supposedly, most of past component determination research considers unfortunate capacity, that I termed as the contrast between the objective and anticipated values, component by component. In this paper, we take a gander at the problem with changing the joint and grouping for the finding of AD/MCI utilizing an original grid similitude-based

DOI: rp-9788770040723.105

misfortune capability that utilizes the significant data level in the objective reaction network and requires data to be protected in the anticipated reaction lattice. The recently developed capability is used to relate the collection tether way to deal with pick joint highlights across undertakings, for example, clinical score expectation and class marking. The suggested method was tested using the Alzheimer's Neuroimaging Initiative (ADNI) dataset. The results showed that the really transmitted catastrophe limit performed better than the cutting-edge methods in clinical score suspicion and confusion status perceiving proof.

Aim of the Study by **L. Hou, X. Zhang, K. Hu, Y. Wang, K. Chen, et al.,** is to find out the patients suffering with moderate cognitive impairment (MCI) who have been promoted to Alzheimer's disease (AD) and those who have not seen a regular doctor in three years by utilizing multi-scale credits obtained from benchmark essential attractive resonance imaging. 228 normal controls (NC) and 133 MCI patients are included, 71 of whom switched to advancement within three years or less. General representation of 549 patients suffering from the Alzheimer’s are collected as Neuroimagary Initiative (ADNI) data set, that individuals are termed as to MCI converters or MCIc, and 188 Advancement patients are recalled for the purpose of the examination. Using the standard voxel-based morphometry strategy, the pictures are preprocessed by separating the cerebrospinal material, white and dim matter. The wavelet outline, a multi-scale image portrayal technique, is utilized to separate credits of different sizes and directions from the handled dim matter picture. Both whole dark matter imaging and hippocampal dim matter pictures might be utilized to create highlights. The support vector machine (MCInc) is utilized in the creation of classifiers for MCIc and MCI non-converters. Utilizing nearby hippocampus information, the precision for arranging Promotion versus NC and MCIc versus MCInc utilizing a leave-one-out method is 84.13 percent and 76.69 precent, individually. Research discoveries show that the suggested multi-scale methodology is fit for recognizing MCI converters and non-converters, and that it has a decent possibility being viable for MCI assumption in clinical environment.

In light of non-negative matrix factorization (NMF) evaluation (AD), this letter introduces yet another computer-based diagnostic (CAD) strategy for the early detection of Alzheimer's disease prediction by using single photon emission computed tomography (SPECT) images **P. Padilla et al.,**. This exploration utilized a SPECT information base that included standardized information from selected patients as well as sound reference individuals. The SPECT informational index is assessed using Fisher discriminant ratio (FDR) and the feature extraction NMF for each subject's applicable parts. These preprocessing techniques are fundamentally planned to bring down the serious level of aspect in the upcoming information and mitigate the supposed "revile of dimensionality" issue. The NMF-transformed set of data, which has fewer highlights, is grouped using an SVM-based characterization strategy. The NMF combined with SVM approach accurately perceives SPECT pictures with up to 94% exactness and high responsiveness and explicitness values (over 90%). For fulfillment, an examination between the proposed technique and another as of late evolved PCA in addition to SVM strategy is given. The outcomes show that the NMF+SVM procedure beats the PCA+SVM and customary voxel-as-feature (VAF) as well as SVM methods.

III. METHODOLOGY

As deep learning and clinical imagery advancements have progressed, few researchers are currently using convolutional neural networks (CNNs) to remove deep level qualities from clinical photos to all the more precisely order clinical scores and Alzheimer's disease (AD). A small deep learning network called the PCANet uses principal component analysis (PCA) to create multi-layer filter channel banks for testing. To get picture properties, blockwise histograms are developed after binarization. PCANet is less flexible since the multi-facet channel banks are constructed utilizing information from testing, bringing about PCANet highlights with several thousands or even countless aspects.

Disadvantage

1. Sample data is required for the creation of multilayer filter banks.
2. Restricting the flexibility of PCANet.

In this research, we come up with the proposal of data-free PCANet-based nonnegative(excluding positive and zero) matrix factorization tensor decay organization, or NMF-TDNet, as a solution to these issues. Instead of PCA, staggered channel banks are made to test with NMF. Using tensor decomposition (TD) to reduce the data's dimensionality and fabricating a tensor with a larger demand, the final image characteristics are produced. All in all, we utilize these properties as a commitment to the support vector machine (SVM) to decide advancement arranges and expecting clinical scores. The Desert spring, ADNI-1, and ADNI-2 datasets are utilized to assess our technique's presentation fittingly.

Advantages

1. The experimental findings suggest that NMF-TDNet has the potential to reduce data dimensionality.
2. When NMFTDNet features were used as input, the results were better than when PCANet features were used as input.

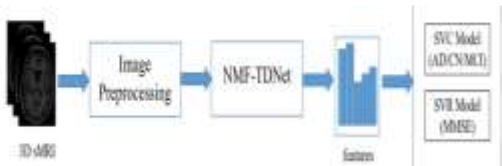

Fig.2: System architecture diagram

Modules

To finish this project, we utilized the following modules:

DOI: rp-9788770040723.105

- Data exploration: we will use this module to import the data into the working system.
- This module then used as a tool to read data for processing.
- Train Test splitting: Data is segregated into train and test data using this python module..
- The models were created using Mobilenet, InceptionResnetv2, SVM embedded with ConvNet layer, SVM classifier, and support vector regression. Algorithm accuracy was calculated.
- User registration and login: Accessing this module requires registration and login.
- The use of this module will result in anticipated input.
- Prediction: the final predicted value is shown.

IV. IMPLEMENTATION

4.1 Algorithms

Mobilenet

Mobile Net and other convolutional neural networks have been designed specifically for use in embedded and mobile vision applications. They depend on a proficient engineering that forms conservative profound brain networks with insignificant idleness for installed and cell phones utilizing depthwise detachable convolutions.

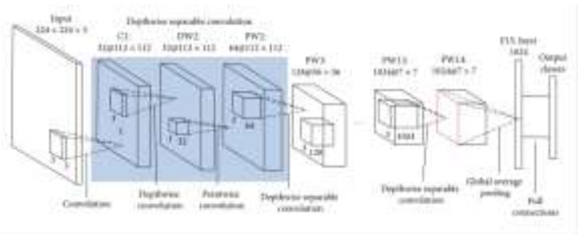

Fig.3: Mobilenet architecture

InceptionResnetv2

More than a million images from the ImageNet collection were utilised to train the Inception-ResNet-v2 convolutional neural network. The 164-layer organization can sort pictures into 1000 different item classifications like console, mouse, pencil, and various creatures.

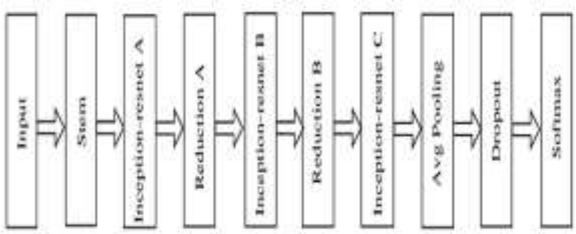

Fig.4: InceptionResnetV2 model Diagram

SVM embedded with CNN layer

Support vector machines (SVM) and convolutional neural networks (CNN) for picture order infrastructure. Fred Abien, Agarap. Convolutional neural networks (CNNs), like "normal" brain organizations, are made out of neural network layers of neurons with "learnable" boundaries.

Support vector classifier

A deep learning framework known as a support vector machine (SVM) makes use of managed learning to recognize or anticipate the behavior of a data set. Artificial Intelligence and Machine Learning with supervised learning systems give input and desired output for categorization.

Support vector regression

A managed learning approach called as help vector relapse is utilized to foresee discrete qualities. A similar hypothesis is utilized by SVMs and Support Vector Regression. SVR's significant objective is to recognize the ideal fit line. The hyperplane with the most focuses is the best fit line in SVR.

VI. Conclusion

In this review, we present NMF-TDNet, a methodology in view of the organization construction of PCANet that conquers the limits of PCANet's enormous number of highlights and the PCA channels' information reliance. NMF-TDNet employs layer-wise convolution to examine the information picture as opposed to PCA. The output layer neuron results are then utilized to construct a higher-demand tensor, and TD is utilized to make the last picture features by making the data more modest in dimensionality. In conclusion, we analyze Promotion and predict clinical scores by incorporating these characteristics into the SVM. The ADNI-1 and ADNI-2 datasets were subjected to class name isolation tests and clinical score estimations (MMSE, ADAS-11, and ADAS-13). In addition, separate classification names and foresee clinical scores (MMSE) were derived from the ADNI-1 and Desert garden datasets. In spite of the way that NMF-TDNet creates substantially less highlights than PCANet, the trial results uncover that using NMF-TDNet highlights as info brought about preferable execution over utilizing PCANet highlights as information.

***Abstract*—Apathological lesion to the alveoli distinguishes a group of ailments known as alveolar lung diseases (ALD) or alveolar illnesses. They are very common and a major cause of morbidity and mortality worldwide. Chronic obstructive pulmonary disease (COPD), pneumonia, pulmonary edema, asthma, TB, fibrosis, lung cancer, and other diseases fall under this category. According to WHO data Lung Disease Deaths inIndiareachedapprox.900,000 in 2020.This exhibits then ecessity of creating a new paradigm for a precise and earlydiagnosisofdisease,whichwouldgreatlyenhancepatients'outcomes. It is critical for processing massive amounts of data in the healthcare industry. Hence in this paper, we propose anoveldeeplearningdesignforalveolarailmentsdiscoveryutilizing VGG-16convolutionalneuralnetwork.Ourmodelusesa unique dataset of chest X-ray pictures to prepare theVGG-16torecognizedesignsrelatedwith different alveolarinfectionsandencouragehelpinillnessforecasts.Weevaluated our model on a separate test dataset and achieved anaccuracyof93.4%inidentifyingdifferenttypesof alveolarailmentsandavalidationaccuracyof91%.Ourtechniqueprovidesapotentialnewtoolforaccurateandtimelyidentificationofalveolarinfections,aswellasdisentanglesdisease location for specialists and clinicians as well as to surge the diagnostic abilities of experts, radiologists, and clinicians to accelerate the process and reduce time required for a correct diagnosis.**

Keywords—Alveolar Ailments, Convolutional Neural Network, Deep Learning, VGG-16, healthcare.

I. INTRODUCTION

Alveolus disorders are a kind of respiratory illness that affects the alveoli, which are microscopic air sacs within the lungs that may exchange gas. These ailments can range from mild to severe and can belief – threatening if left untreated. These incorporate chronic obstructive pneumonic infection, pneumonia, aspiratory edema, asthma, tuberculosis, fibrosis, etc. Alveolar lung disease fatalities in India totaled 879,732 According to the most recent WHO figures, 10.38% of all fatalities will occur in 2020. India ranks third in the world regarding the age- adjusted death rate (87.90 per 100,000 population) [1]. COPD (chronic obstructive pulmonary disease) is the third biggest cause of mortality in the world, accounting for 3.23 million deaths in2019.[2].

Several studies have been conducted to investigate the relationship between deep learning strategies for predicting diagnostic information from chest X-ray images. Because most government hospitals are overburdened, causing delays in providing appropriate treatment and diverting patients to more expensive private hospitals, this strategymayresultinlowermedicalexpendituresascomputerscienceforhealthandmedicalresearchprojectsgrows.

Machine Learning-based decision support systems can help clinicians make diagnostic decisions. The study looked into patients' respiratory problems, as well as Corona, Tuberculosis, Pneumonia, as well as Lung Cancer. Machine learning and deep learning are used to analyze data and build models for patient diagnosis [3]. Combining patient data with data from chest X-rays was one strategy used in this study to identify lung illnesses, as did CNN using the well-known pre-trained model and CNN for data. Deep learning was utilized to analyze and examine the data set to determine whether the patient had lung disease. The study uses binary classification, utilizing patient data from chest X-ray images as input and sickness diagnosis as output. The study's purpose is to investigate and diagnose alveolus lung diseases.

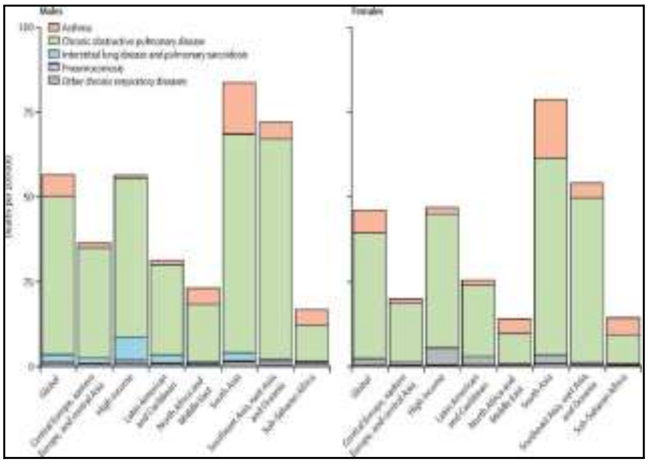

Fig1.Global Fatality Rate(LungDisease)

The basic version of CNN is insufficient. As a consequence, we present anovel deep learning system based on the VGG16 Architecture for forecasting alveolus diseases. The purpose of this study is to create a VGG16 architecture-based alveolus disease detection model. Early detection and diagnosis of alveolus disorders is critical in the medical industry since it makes managing patients' future clinical treatment easier. The sample and complete versions of the data set are considered. In terms of precision, recall, F1score, and validation accuracy, the VGG16 Architecture outperforms previous approaches for both entire and sample datasets. As a result, the suggested VGG16 Architecture will make detecting lung diseases simpler for both experts and physicians.

II. LITERATURE SURVEY

In [4], One of the most active topics of study, in order to enhance health and medical science, is the use of big data for predictive analysis in addition to machine learningordeeplearningtechniquesoralgorithms.PneumoniaPredictionUsingBigDataMachineLearningDeepLearning

DOI: rp-9788770040723.106

Approaches is demonstrated in this paper. CNN excels at this prediction, and pre-training of the CNN models for large datasets enhances the chance of correct classification. CNN models that have been pre-trained, in conjunction with an effective feature extraction approach and numerous classifiers, are thought to produce extremely accurate results.Anx-ray of the chestis essential to diagnose pneumonia, as is aprognosis specialist.

In [5], A variety of deep learning pre-trained models, including VGG, Inception, ResNet, and Efficient Net, were used in the development of a CNN-based computervisionAIsystem.Whencomparedtophotosofbothpneumoniapatientsandhealthypeople,thefinalDLH-COVID model had the greatest accuracy of 96%.Aweb application was also developed. This solution, when coupled, provides cutting-edge artificial intelligence-based technology and a simple application with the potential tobecomeaquickCOVID-19diagnosistoolsoon.

The[6]Research articled monstrates the application of Transfer learning methodologies. This study employed four pre-trained models - VGG-16, VGG-19, Inceptionv3, and Xception-on two separated at a sets. This article tackles issues that arise when utilizing pre-trained models in the actual world. These models also acquired great accuracy. Among four deep learning models, The VGG16modelachievedvalidationaccuracyof99.50%&classificationaccuracyof99.00%ondataset1andaccuracy of 96.41% & accuracy of 95.69% and validation on dataset 2, outperforming the other four models on both datasets.

The [7] application of multiple classifications is demonstrated in this research report. A CNN (ConvNet) was trained from scratch to identify tuberculosis (TB) on the chest radio graphs. ACNN-based transfer learning technique was also employed to distinguish between TB and normal patients using CXR images, with five separate pre-trained models used: Inception v3, ResNet50, Xception, VGG16&VGG19.ConvNet,thesuggestedCNNarchitecture,obtainedanAUCof87.0%,87.0%F1-score,88.0%precision, 87.0% sensitivity, and 87.0% accuracy, This was marginally lower than the pre-trained models.

III. Proposed Methodology

A. *Proposed System*

Today, we require a strong diagnosis to predict illness in the human body in order to diagnose or detect any ailment in humans.[8]. In general, we want to use X-Ray pictures to forecast lung disease. In medical imaging, improvements in deep learning artificial intelligence, andapproacheshavebenefitedintheidentificationandcategorizationoflungdisorders.Weprovideadeeplearning technique VGG16 Architecture in our suggested system that will be utilized to diagnose lung ailments. The major purpose of this effort is to research and detect different types of lung infections utilizing deep learning algorithms for early lung illness diagnosis.

The16-layer VGG convolutional network was trained using fixed-size pictures. A series of convolutional layers with small-size kernels and a 3x3 receptive field are used to process the input [9]. The smallest size that still allows us to distinguish between up, down, right, left, and centeris this one.

B. *System Methodology*

The dataset used, the preprocessing, the techniques for image enhancement, data augmentation, and the numerous algorithms are all covered in this section. A flow chart is used to show the suggested technique's work flow.

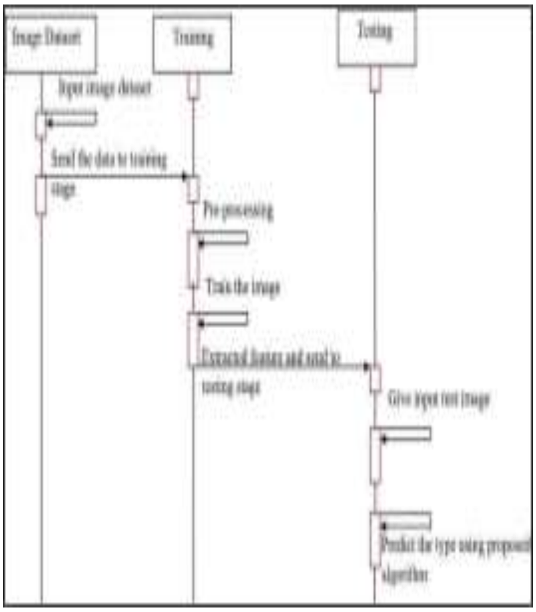

Fig2.SequencediagramUML

Fig 3. Data Flow Diagram

C. *Dataset*

In the first module, we develop the system to get the input dataset for the training, testing, and validation purpose. The dataset is formed from data retrieved from a

DOI: rp-9788770040723.106

few clinics, labs, and online sources. The dataset consists of approx 1100 chest X-ray images.

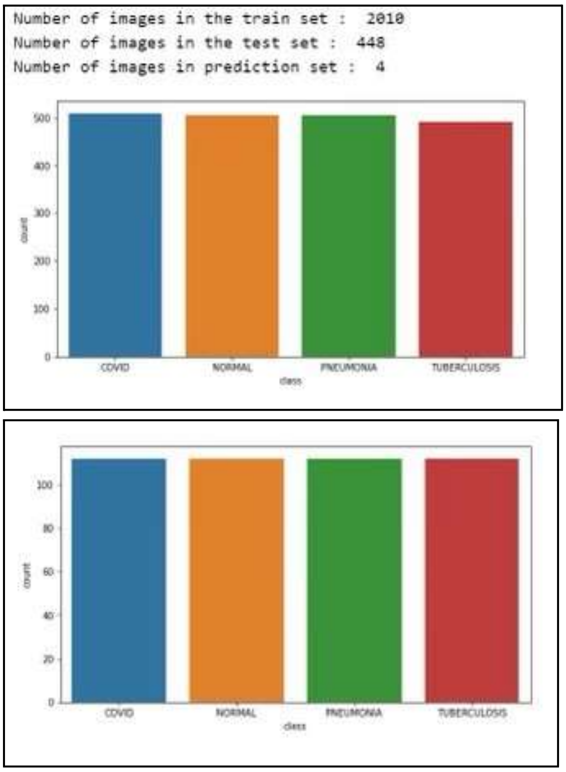

Fig 4. Images in Training and Test set

D. Data Pre-Processing

Feature Enhancement: A key component of the image analysis schema is the pre-processing stage. It can improve and drastically enhance the original image while lowering noise levels or extraneous information. In our research, we looked at 2 distinct pre-processing strategies.

Histogram equalization is a contrast correction method inimageprocessingthatusesthepicturehistogram[10].Basicall y used for Contrast Enhancement in medical imagesand satellite images and a tool for feature enhancement indetectiontasks.

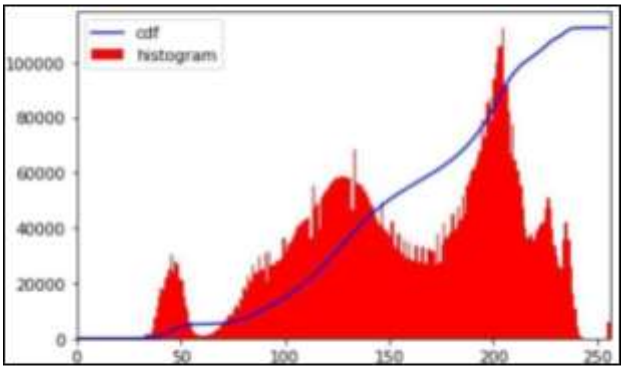

Fig5.NormalImageHistogramPlot

Adaptive Histogram Equalization (AHE): A method forenhancingvisualcontrast.Usefulforboostingtheclarityof edges and local contrast in each area of a picture [11].Though, It has the propensity to over-amplify noise in homogenous areas of an image.

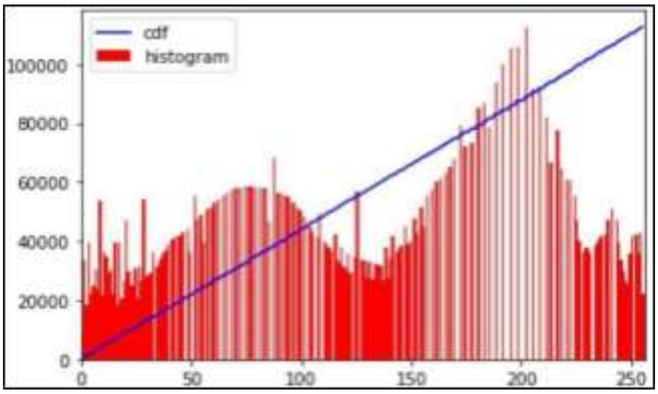

Fig6.AHEImageHistogramPlot

Contrast Limited AHE (CLAHE): AHE variant that reduces contrast amplification in order to decrease noise enhancement. It performs high-accuracy normalization in small sections or small tiles, as well as contrast limitation.

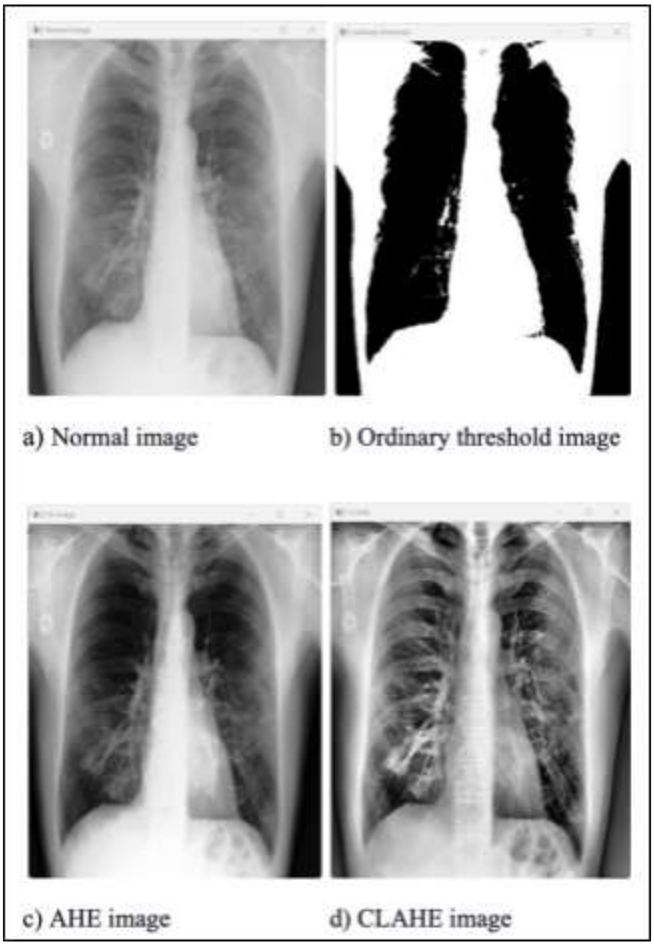

Fig 7. Preprocessed Image

E. Data Augmentation

It is a very frequent and well-liked support technique that, in essence, uses small modifications of a picture in each training session to dramatically enhance the volume of training data. The standard modifications utilized in data augmentation are horizontal flip, zoom, shear, rotation, and

DOI: rp-9788770040723.106

rescale. This method is crucial for obtaining high levels of accuracy because our deep learning model can be trained on a larger dataset in comparison to the original one.

F. Deep Learning Model

Deep learning is made up of a few layers of nonlinear nodes that combine input information with a set of weights to assign significance to inputs for the comparison task the computation is attempting to accomplish in guided and/or unsupervised behavior. The totality of these inputs and weights is transmitted through node actuation work. [12][13].The yield of each layer is encouraged concurrently with input to the subsequent layercommencing with the input layer [14]. Learning can take place at various levels of representation as opposed to different degrees of abstraction.

IV. Algorithm

Convolutional Neural Network: A CNN is a sort of deepneural network consisting of distinct hidden layers suchas the RELU layer, convolutional layer, fully connectednormalizedlayer,andpoolinglayer.CNNprovidesweightsinsidetheconvolutionallayer, which reducesmemoryimprintandincreasesnetwork execution. The3Dvolumesofneurons, local connection, and sharedweightsarethekeyfeaturesofCNN.

*VGG16:*GroupforVisualGeometryVGG-16:Convolutional Networks with Extremely DeepLayers for Large-Scale Image Recognition.The VGG-16modelcomprises16weightedlayers,5convolutionblocks,and 3 fully connected layers. Fig13.Confusion Matrix

The data set was split into three distinct subsets: training(75%), validating (10%), and testing (10%). The suggested method can detect the presence or absence of the list edalveolus disease with a model accuracy of around 93.8%.The training accuracy of the model was 96.78% and thevalidationaccuracywas92.8%.TheproposedVGG16convolutionalneuralnetwork-basedtechniqueperformedrelativelybetterthantheexistingmodelpresentinconsiderationofthedatasetsize.

VI. CONCLUSION

Numerous researchers thoroughly discuss the influence of a modern patient's Alveolus (lungs) on various researchers and the damage to the lung in this study. According to several studies, because these lung ailments have been healed, detecting this condition has become critical. One of the primary goals of this study is to find and choose appropriate data set sand techniques for analyzing lung illnesses. Based on the comparisons and comments in this book, the chest X-ray was chosen. Following that, because the chest X-ray may contain a large amount of useless data, an appropriate feature extraction approach was designed. This pick was based on the benefits and drawbacks of numerous standard algorithms. Eventually, a classification technique based on their distinguishing characteristics was discussed. Short-term studies revealed that VGG16 Architecture provided extra benefits for predicting lung ailments in advance with improved out comes. Finally, lung disease can be identified.

***Abstract*—An Artificial Intelligence (AI) based mental health assessment that has the potential to take input from users and classify into two groups: 0 or 1 based on the training dataset. AI has the potential to revolutionize mental health assessment by providing a more accurate and efficient diagnosis, improving treatment outcomes, and increasing access to mental health services. One of the most common is through the use of machine learning algorithms. Which is used to identify patterns and predict mental health conditions. Another way in which AI can be used in mental health assessment is through the analysis of speech and language patterns. Natural Language Processing (NLP) algorithm scan be used to analyze written or spoken language to detect patterns that may indicate mental health conditions such as depression, anxiety, or schizophrenia. We want to report clients facing mental health issues directly to doctors in case of a high-profile illness or suggest a suitable course of action to calm the client without intimating the client of the results unless positive. The critical shortage of psychiatrists and other mental health specialists to provide treatment increases the crisis of untreated mental health conditions. Those who can undergo treatment often forgo it as it is too expensive. Thus, we will use AI to screen, diagnose and treat mental illnesses at a fraction /free of cost.**

Keywords—Natural Language Processing (NLP), Artificial Intelligence (AI), Mental health, Feature extraction, Pattern detection, Text Analysis, and Classification.

I. Introduction

Mental health refers to a person's overall psychological and emotional well-being, including their ability to manage their feelings, cope with stress, and function effectively in daily life. These conditions can be caused by various factors, such as family genetics, environmental influences, and life experiences. Examples of mental illnesses include depression, anxiety disorders, mood disorders, bipolar disorders, personality disorders, psychotic disorders (such as schizophrenia),eating disorders, and substance used is orders.

Theseillnessescanbemildorsevereandcanhavevaryingdegreesofimpactonaperson'sdailylife,relationships,andoverallwell-being.Ifanindividualorsomeone they know is displaying signs of a mental illness, it is crucial to seek assistance from a qualified professional. With appropriate treatment and support, numerous individuals with mental illness can attain recovery and live satisfying lives. The situation of understaffed hospitals and clinics can have serious implications on the quality of care that patients receive. When there are not enough staff members to meet the needs of the patients, the work load on the existing staff can become overwhelming, leading to burn out and potentially compromising patient safety. Understaffing can also result in longer wait times for patients to receive care, contributing to delays in diagnosis and treatment. In some cases, patients may even be turned away from hospitals or clinics due to a lack of capacity or resources. Furthermore, understaffing can lead to a higher staff turnover rate, which can further exacerbate the problem and make it difficult for hospitals and clinics to retain experienced and skilled health care professionals. Overall, understaffing in hospitals and clinics is a serious issue that can have negative consequences on both the patients and the healthcare providers. Health care organizations and policy makers need to address this issue and provide adequate resources and support to ensure that patients receive high-quality care and that healthcare workers can provide it without being overburdened.

Doctors can understand our mental health through a variety of methods, including;

1. Clinical interviews: Doctors can conduct a thorough hinter view with the patient to gather information about their symptoms, medical history, and any other relevant factors contributing to their mental health issues.
2. Observations: Doctors can observe a patient's behavior, mood, and affect to gain insight into their mental health status.
3. Psychological assessments: Doctors may use psychological assessments, such as questionnaires or tests, to evaluate a patient's mental health and determine the presence of any disorders.
4. Medical tests: Doctors may also perform medical tests, such as blood tests or brain scans, to rule out any physical conditions contributing to the patient's mental health issues. Collaboration with mental health professionals: Doctors may work closely with mental health professionals, such as psychologists, psychiatrists, or social workers, to gain a more comprehensive understanding of a patient's mental health and provide appropriate treatment.

DOI: rp-9788770040723.107

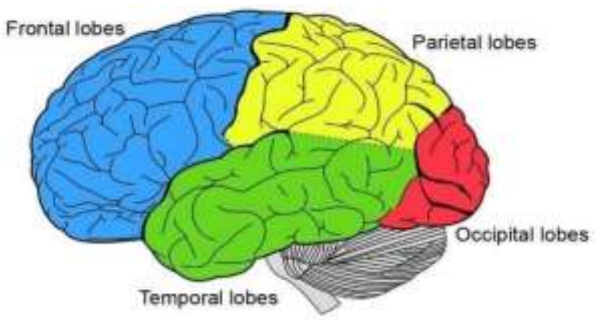

Fig1.ImageofHumanBrain*[Source:Pixabay]*

The brain plays a significant role in mental health as it is the organ responsible for controlling and regulating emotions, thoughts, behaviors, and perceptions. Various structures within the brain, such as the prefrontal cortex, amygdala, and hippo campus, play a critical role in mental health. The prefrontal cortex is responsible for decision-making, planning, and regulating emotions, while the amygdala is involved in processing emotions and memory. The hippocampus plays a role in memory consolidation and retrieval. Additionally, neurotransmitters such as serotonin, dopamine, and no re epinephrine play an essential role in regulating mood, sleep, and appetite. Changes or imbalances in the sebrain structures or neurotransmitters can lead to mental health disorders such as anxiety, depression, bipolar disorder, schizophrenia, and others. Treatments for mental health conditions often involve medications or therapies that aim to regulate brain chemistry and functioning, such as an tide pressants, antipsychotics, or psychotherapy.

Hence, researchers frequently make use of machine learning, the branch of artificial intelligence that focuses on developing algorithms capable of learning from data to make predictions or decisions. The way these algorithms work is loosely inspired by the structure and function of the brain. Artificial neural networks (ANNs) are a form of machine learning algorithm that imitates the architecture of the brain to a great extent. ANNs consist of layers of interconnected nodes that process information and pass it on to the next layer, similar to the way neurons in the brain communicate with each other. Researchers studying machine learning and artificial intelligence often look to the brain for inspiration and insights into how to improve algorithms. For example, how the brain processes sensory information or learns from experience can inform the design of machine learning algorithms that can do the same.

It has shown promise in helping with mental illnesses in several ways, including;

1. Early detection: Machine learning algorithms can analyze large datasets of patient information and identify patterns that may indicate the presence of a mental illness. This can help doctors to identify and treat mental health issues earlier before they become more severe.
2. Personalized treatment: Machine learning can help doctors to develop personalized treatment plans for each patient based on their individual symptoms and medical history. By tailoring treatment to each patient's unique needs, doctors can improve the effectiveness of treatment and reduce the risk of side effects.
3. Predictive modeling: Machine learning can help doctors to predict which patients are most likely to develop a particular mental illness or experience a relapse. This can help doctors to intervene early and provide preventive care to reduce the risk future mental health problems.
4. Improved diagnostics: Machine learning can help doctors to improve the accuracy of mental illness diagnoses by analyzing large amounts of data and identifying subtle patterns and differences in symptoms that may be missed by human clinicians.
5. Remote monitoring: Machine learning can help doctors to monitor patients remotely and identify changes in symptoms that may indicate the need for a change in treatment. This can improve the quality of care for patients who may not have easy access to mental health services.

Machinelearningtechniquesinpredictingmentalhealthproblems.Thisinformationcanbebeneficialforclinicalpractitioners.Additionally,thepaperaimstoidentifycommonly used machine learning algorithms in this field andexaminetheirlimitations.Furthermore,thepaperaimstoidentify potentialareas forfuture researchthatcanfurtherenhance the effectiveness of machine-learning approaches inmentalhealth.ThegeneralmethodologyconsistsofDataCleaning,DataAnalysis,FeatureExtraction,ModelComparisons,ModelCreation,Fine-TuningandeventuallyTestingasshowninFig4.

A) Datasets

In this study, we utilized two datasets that were availableto the generalpopulation.The firstdatasetis takenfroma2014 survey that conveys the factors affecting mental healthandthevariousmentalhealthdisordersintheusualtechworkplace. It consists of the general employment practices of1259 individuals in various settings, taking into account theirage, gender,family history,countryofemployment,numberofcoworkers/employees, etc [17]. It helps us answer questionssuchas:

1. In what ways do the rates of mental health disorders andattitudestowardsmentalhealthdifferacrossdifferentgeographicalregions?
2. What factors have the highest predictive power for mentalhealth disorders or specific attitudes toward mental healthinaworksetting?

The second dataset that will be utilized is “Mental HealthCorpus Labeled sentences about depression and anxiety” [18].TheMentalHealthCorpuscomprisestextspertainingtoindividuals experiencing anxiety, depression, and other mentalhealth concerns. The corpus comprises two columns, one ofwhich contains text messages while the other records labelsthat determine whether the comments are toxic or not where 1resemblestoxic and0 is nottoxic. This datasetcanserveseveral purposes, including sentiment analysis, detecting toxiclanguage, and analyzing the language used in mental healthcontexts andhenceprovidethebasedatasetforthemodel.

b) DataCleaning

This step mainly consists of cleaning the null values andcleaning those columns which are not crucial to the researchsuchastimestamp,state,andcomments.Furthermore,themissing values were determined, converted to a percentage,andfixedasshowninFig5.

Additionally,allcategoricalcolumnssuchas‘gender’were cleaned into 3 unique answers notably ‘male’, ‘female’,and ‘trans’. The age column was converted from individualintegers to categories where each value was either a part of ‘0-20’, ‘21-30’, ‘31-65’, and‘66-100’.

	Total	Percent
comments	1095	0.869738
state	515	0.409055
work_interfere	264	0.209690
self_employed	18	0.014297
seek_help	0	0.000000

Fig 5. Percentage of missing values

C) Data Analysis and Feature Extraction

In order to have unbiased and clear results, it is essential to have an equal distribution of data where the datapoints are all resembling a uniform sample space. Thus, using data visualization, all the data points were carefully visualized and sufficient rectification was done on them. The Mental Health Corpus [18] was visualized based on its distribution of toxic and non-toxic messages, each having between 13,000 to 14,000 values as shown in Fig. 6a.

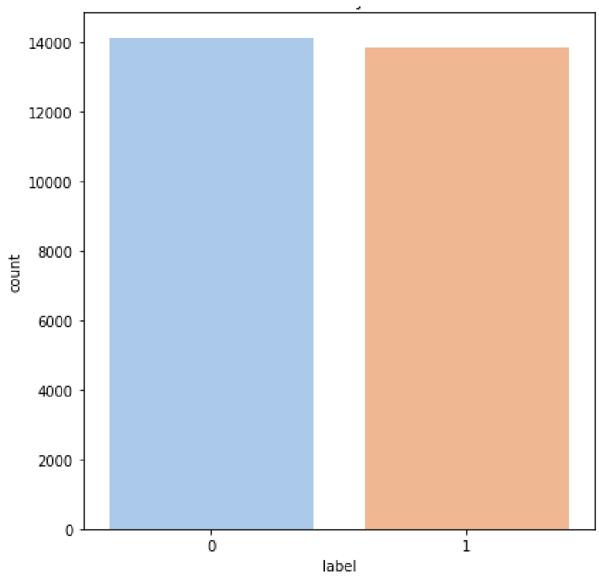

Fig6a.Distributionoftreatedvsuntreatedlabels

Similarly, the tech workplace dataset was visualized comparing the distribution of ‘male vs female’,‘age

DOI: rp-9788770040723.107

distribution density by category (0 or 1)', and 'probability of mental health condition based onfamilyhistory'.Fig.6b.

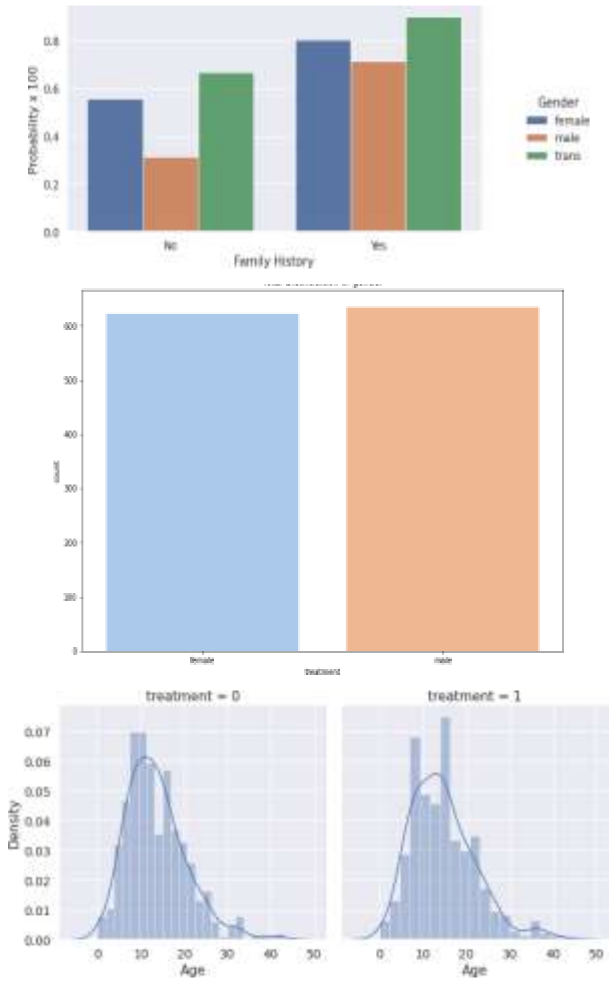

Fig 6b. Probability of mental illness by family history, gender, and age

Furthermore, a correlation heatmap of all features were picturized, eventually giving us the graph of the most essential features. Fig. 6c.

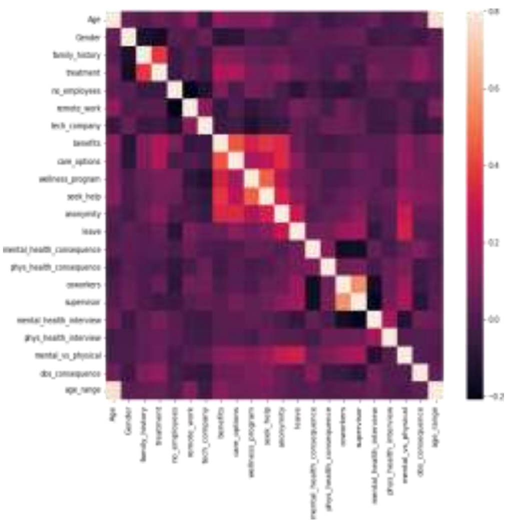

Fig6c.Correlation Heat map and Graph of all variables in order of importance

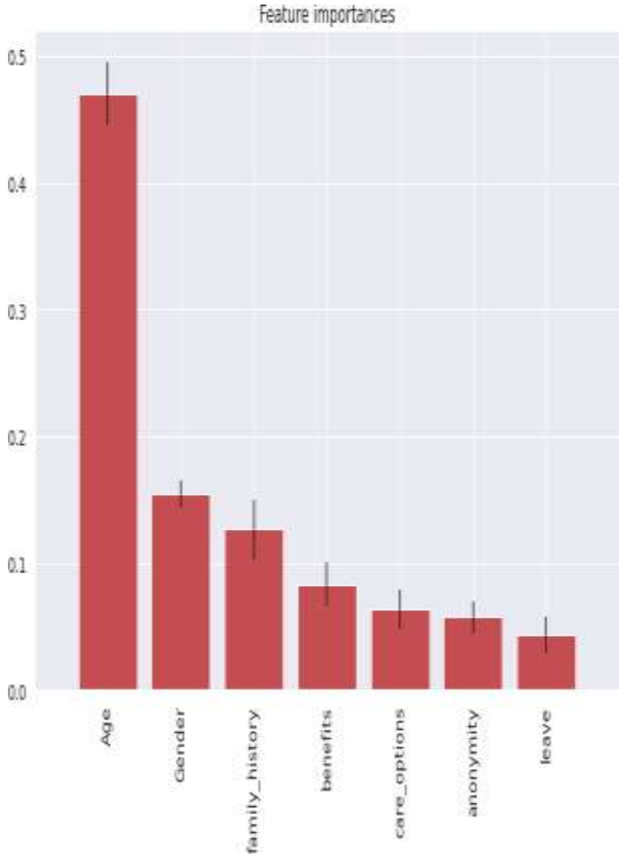
d) Model Comparison

An evaluation function



was created which would give the accuracy for the top models used in the previous 5 years for mental health assessments. These results were then compared to our RNN model and tabulated.

TABLE1.COMPARISONOFOURRNNMODELWITHOTHERNOTABLEMODELS

Sr.	Model	Accuracy
1.	Logistic Regression	70.63%
2.	DecisionTree	70.1%
3.	KNN	70.64%
4.	RandomForest	70.2%
5.	Bagging	61.6%
6.	AI SequentialModel(RNN)	92.67%

The area under the ROC curve for each treatment classifier was also calculated which is a measure of the overall performance of the binary classification model, regardless of the threshold chosen. AUC ranges from 0 to 1, where a score of 0.5 indicates randomized guessing and a score of 1.0representsflawlessclassification.

In general, a higher AUC indicates better classification performance. An AUC of0.8or higher is considered to be a good classifier, while an AUC of 0.5 indicates a model that is no better than random guessing.

The AUC can be used to compare the performance of different models on the same dataset or to evaluate the performance of a single model trained on different datasets or with different parameters. It is a useful metric for evaluating the effectiveness of a binary classification model and can be used to optimize the model by adjusting the classification threshold or by selecting the best-performing model based on the AUC.

DOI: rp-9788770040723.107

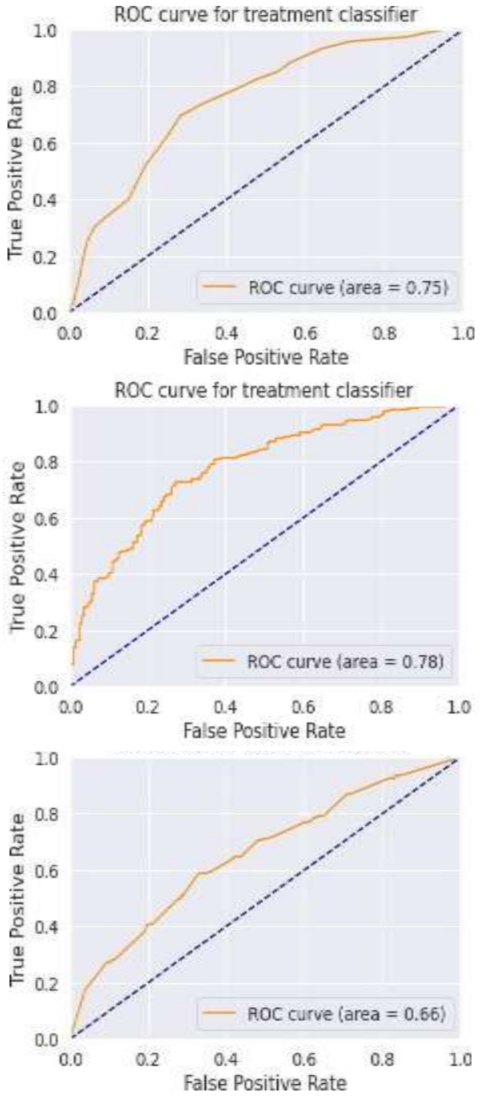


Fig7.AUCforKNN,RandomForest,andBaggingClassification

Model CreationandFineTuning

Using a sequential model, we were able to create a 5-layerRNNmodelthatwouldhave1inputlayer,2denselayers,1dropoutlayer,and1outputlayerasshownin Fig8.

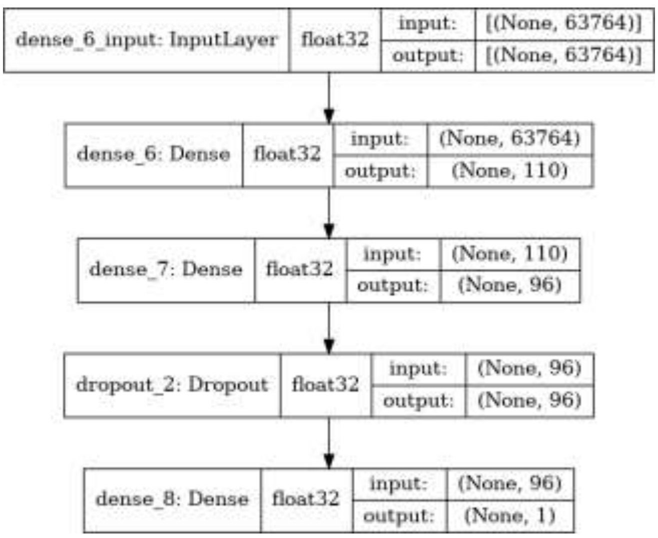

Fig8.RNN ModelArchitecture

The input layer takes in the input sentence of a maximum of63,764 characters and converts it into 110 unique characters through the first dense layer. All these unique characters are put into a bag of words which would be vectorized to find the most common phrases using sentimental analysis. Further more, all the whitespaces and blanks are also removed in the second dense layer thus leaving only the letters andspecial characters such as '.', ',' and '!' to find the most usedcharacter. These 96 unique characters are sent as output for thedropoutlayer.

Indeeplearningmodels,thedropoutlayerisaregularization method utilized to preventoverfitting,whichhappens when the model excessively learns to fit the trainingdata, and as a result, it fails to generalize well on new unseendata.Dropouthelpstopreventoverfittingbyrandomlydroppingout(settingtozero)acertainproportionoftheneuron outputs in a layer during training. During each trainingiteration,thedropoutlayerrandomlyselectsasubsetofneuronstobe"droppedout"basedonapre-definedprobability. This forces the remaining neurons to learn morerobust features and to be less dependent on the input from anyparticularneuron.

By using dropout, the network is forced to learn multipleindependentrepresentationsofthesamedata,makingthenetwork more robust and less sensitive to the specificities ofthe training data. This can result in improved generalizationperformance, which is essentialfor real-world applications.Proceedingthedropoutisanoutputlayerthatgivesanoutputas either 0 or 1 which would indicate the toxicity of the textmessage.

IV. Results & Discussion

After our efforts comparing at least 5 Machine Learningmodels along their accuracies inour dataset. The AI-basedmentalhealthassessmentdemonstratedhighaccuracyindetectingthementalhealthofanindividualbasedontheinputtedtext.WemodifiedourownArtificialIntelligencealgorithm to achieve an accuracy of about ~94%. Using ourtwo datasets which were used to train and test our model, itwas observed that the data used was completely unbiased intermsofgenderandage.Atotalof~1300participantscompleted the study, which consisted of an in-depth AI-basedmental health assessment. The majority of participants (50%)were identified as ill based on their text which was taken asinput.

In addition, the AI-based assessment was able to identifyseveralfactorsthatwerestronglyassociatedwithmental health detection. These factors included a history of mentalhealth treatment, low levels of social support, and high levelsof stress based on a survey taken by many individuals. Themodel was also able to identify and distinguish those withmentalhealthillnesses,includingfeelingsofsadness,lowenergy, anddifficulty concentrating.Thiswasachievedbynotifying a doctor and in minor cases, recommending music totheclients.

Finally, we wanted our model to be very reliable and thusfocussed heavily on getting the accuracy precise. The accuracyof the AI model can be impacted by various factors

DOI: rp-9788770040723.107

such as the quantity and quality of data used for training the model, the intricacy of the model's architecture, and the attributes of the population being evaluated. In some cases, the accuracy of the model may vary depending on the severity or subtype of the mental health condition being assessed. It's worth noting that accuracy is just one measure of the effectiveness of an AI-based mental health assessment. Other factors, such as the speed, cost, and scalability of the assessment, as well as its acceptability to patients and healthcare providers, may also beimportantconsiderationsinevaluatingtheutilityofthistechnology.

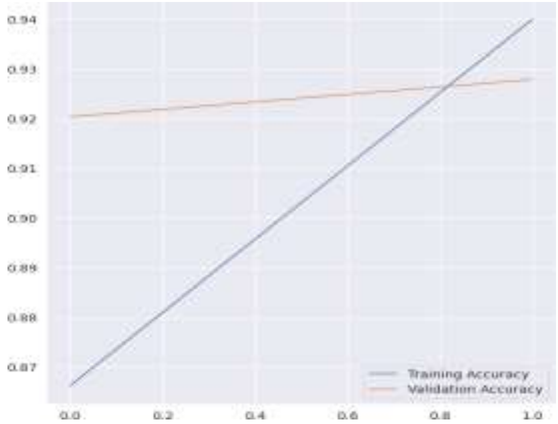

Fig9.Trainingand Testing Accuracy of our RNN Model

V. Conclusion

An AI-based assessment made it possible to assess an individual's mental health based on input data. In this paper, we observe that AI-based mental health assessment has the potential to revolutionize the way mental health is assessed, diagnosed, and treated. It can provide a more accurate, objective, and personalized approach to mental health assessment, leading to earlier interventions and better patient outcomes. However, it is important to consider the ethical, legal, and social implications of AI in mental health, including issues of privacy, data security, and potential biases. With careful consideration and ongoing research, AI-based mental health assessment can be a valuable tool in improving mental health outcomes for individuals and communities. To conclude, the use of AI in mental health assessment represents a promising new direction in the field of mental healthcare, but it is essential to approach this technology with caution and careful consideration of its limitations and potential risks.

Abstract—Recommendation systems are the most important intelligent systems that play a role in providing information to users in today's world. Content-based filtering and collaborative filtering are two previous approaches in recommendation systems (RS). As a result, these approaches have some limitations, such as the requirement of the user's history as they visit. To mitigate the impact of such dependencies, this research paper proposes a hybrid RS, which combines collaborative filtering, content-based filtering, and sentiment analysis of movies. In this research paper, we created are commander system based on the user's sentiment to recommend a movie to the user based on their viewing history.

Keywords—Recommendation Systems, KNN algorithm, Collaborative filtering, Item-based collaborative filtering, Content based filtering.

I. INTRODUCTION

In today's world, the Internet has become a common source of information overload. Recommendation systems are primarily intended to help users make decisions based on their previouschoices.Thesearecommonlyfoundine-commerceapplicationsandknowledgemanagementsystemssu chasentertainment,online shopping, and tourism.

Movie Recommendation Systems assist us in finding our preferred movies while also shortening the time it takes to find them. The first step is to look at the movies we've seen and visited in the past, and then RS will suggest a movie for us to watch. With the increase in the amount of online data, RS are becoming increasingly useful for making decisions in a variety of day-to-day activities. RS are divided into two types: content-based filtering (CBF) and collaborative filtering (CF)(CF).

During the creation and operation of the movie recommender system as created based on the user's sentiment and comments on the specific movie. Our technology will recommend the best movie to the user based on their prior viewing history and rating. The user's sentiment is recorded as favorable and poor. If the user likes the movie, they may give it a Good smiley, and if they don't like it, they can give it a Sad response, and a movie recommendation is offered to the user based on that.

II. RELATED WORK

There are several strategies that have been examined in relation to the recommender system. Some are based on the amount of weighting of the data, while others are based on user interest. There are several algorithms that have previously been created to lower the user's time and difficulty level.

It necessitates great deal of prior knowledge on the fundamentals of the user's rating of the movie. It mostly use movie datasets for assessment and testing. However, the developed algorithm and system are inefficient, but research is underway to tackle this issue and make the system more flawless and precise.

* Collaborative Filtering System
* Content based System
* Hybrid System

A. *Collaborative Filtering System*

The prediction of recommender systems based on the two formulas narrow and general is where collaborative filtering is most frequently applied. The definition of the term" narrow means predictions" now refers to those that must be created or assessed based on automated prediction and assist users in making choices based on the preferences of other users. Let's use an example where Mohan loves a product X and expresses his opinion while Ram also expresses his approval of the product and provides good feedback. In this case, Mohan will receive further input on the other product based on the opinions of others. The majority of data, including financial data and mineral prospecting, uses CF. These are also divided into the following two groups:

* Memory Based approaches
* Model Based approaches

B. *Content-based Filtering*

The goal of CBF, technically known as Content Based Filtering, is to utilise the dataset's features to propose items that are similar to and close to the user's likes and dislikes based on their prior behaviour and ratings of those specific items.

Content-based filtering also makes recommendations for values or films that have already been seen or deleted. It automatically detects our reviews of a certain item for the dataset we have provided and suggests items that are comparable to that item.

Based on the user's interests and the genres they have previously viewed, our algorithm recommends a movie to them. From the enormous dataset, users may rate aspecific movie that they have seen and propose similar content based on their interests.

DOI: rp-9788770040723.108

C. KNN Algorithm

The recommender system will employ this algorithm, which is one of the most significant ones. K closest neighbouris the full name of this method. The closest neighbour algorithm works as if the majority of the things that are close to the item it belongs to will be placed together or fall into the same cluster, where the distance between the item and its neighbours is the smallest. Consider the following example: T item is a member of the cluster B family since it is near to and identical to Bcluster in terms of distance.

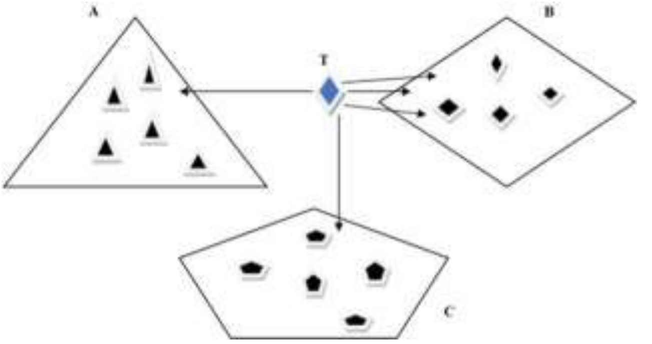

Fig.1.KNNalgorithmExample

D. Collaborating Filtering Algorithm

The primary goal of this algorithm is limited to two tasks: one is project-based, and the other is user-based. However, the user-based algorithm, which is mostly employed for this purpose, is quite successful in meeting the user's need for recommendations.

This algorithm's primary function is to anticipate user needs based on what other users are interested in and then propose related products to the user. Our recommendation engine uses this technique to find movies based on the user's interests.

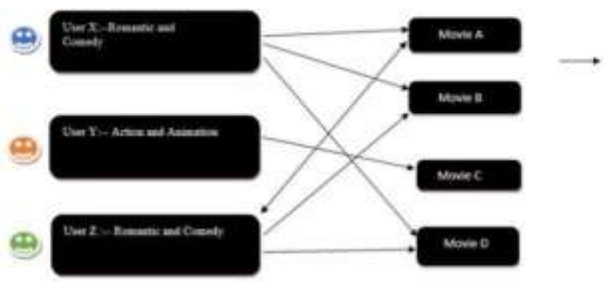

Fig2.User CFAlgorithmExample

Let's look at an example of this algorithm to help you better grasp it.

Assume user X enjoys romantic comedies and tends to watch them more often than other types of movies (A,B,D).

Second, user Z like the same romantic and comedic films, but he just wants to watch movies(B,D).

In this instance, we can see that User X and User Z have parallel interests, yet we can still recommend User Zwatch User X's choice of User A.

The same user Y only enjoys watching the movie C, but user X and Z didn't enjoy it, thus user X and Z won't be recommended it. It is an action and animation movie.

III. Research Methodology

A. KNN Collaborative Filtering Algorithm

We have utilized both the algorithm in the same manner used on the KNN algorithm to determine the neighbour of the item with the smallest distance, which is also known as the collaborative filtering algorithm. The most frequent task accomplished by this algorithm is the creation of a neighbour and recommendation or prediction of the obtained score.

a) Calculating Similarity between Users

The value of an item assessed and projected by two users is calculated to determine how closely the agent and user are related.

For ease of understanding, we have provided an example: To formulate the closeness of X1 and X3,first we must choose our list of movies, which will be labelled as"M1, M2, M4, M5", and then after the parallel scores of these movies. Each user who wants to predict a movie will assignanN-dimvectortoshowtheitemscore.ThefoundscorevectorsforX1andX3are1,3,4,2and2,4,1,5 respectively. The cosine parallel formula is usedtodeterminehowcloselyX1and X3arerelated.

X/M	M1	M2	M3	M4	M5
X1	1	3	3	4	2
X2	3	1	4		
X3	2	4		1	5
X4	2		2		

Fig. 3. users' similarity evaluation

The definition of the correspondence of m or m' is sim (m,m'), and the only formula that is likely to be utilised for the correspondence is cosine similarity.

Cosine parallel is used to determine how similar two users are based on the angle of cosine between them as a vector.

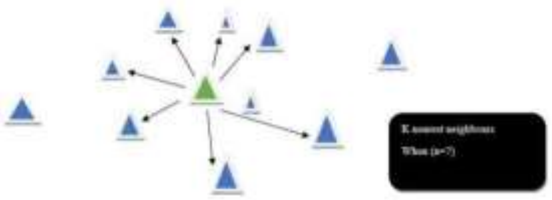
$$sim(x,y') = \cos(\vec{X},\vec{Y}) = \frac{\vec{X} * \vec{Y}}{|\vec{X}| * |\vec{Y}|} = \frac{\sum_{s \in sxy} r_{x,s} r_{y,s}}{\sqrt{\sum_{s \in sxy} (r_{x,s})^2 \sum_{s \in sxy} (r_{y,s})^2}}$$

b) KNN Selection of Nearest Neighbour

Now that the users' similarities have been assessed in the form of sim(u,u'), the KNN algorithm uses this information to determine how many users match U's neighbours, which is denoted by the letters u'. Now we must choose to initialise the K value for the neighbour selection,

DOI: rp-9788770040723.108

which will identify K of the most similar neighbours in the form of a neighbour like value for a user.



c) Predict Score Calculation

Now that we have identified the K nearest neighbours, we must determine the score of the item that is near its neighbour. The primary formula utilised to determine the score prediction is provided as follows:-

$$r_{u,i} = \overline{r_u} + k \sum_{u' \in U} sim(u, u'') * (r_{u',i} - \overline{r_{u'}})$$

$$(k = 1/\sum |sim(u, u')|)$$

The actions that re listed below will only be utilized forecast the score.

Step 1: Create the user as a 2D score matrix in the RmXN format.

Step 2: Use the Cosine Similarity Formula to help you determine how similar the users are who wish to watch the movie, which will help you create a matrix that reflects what the consumers are seeing**.**

Step 3: In order to discover the N number of the score that indicates the largest amount and will be the same as the K with the neighbours, which is u, we must use the result of step 2 as our starting point.

Step 4: Analyze the value of I for the goal u usingthe predict score algorithm.

In order to forecast movies for the user, KNN collaborative filtering method is used. This project will be used to recommend the movie based on user sentiment based on that as well. Also, it can propose movies, just like Netflix and Amazon Prime Video, which will do so based on the user's prior searches, and it can advise the user's preferences based on their login information to our prototype's server.

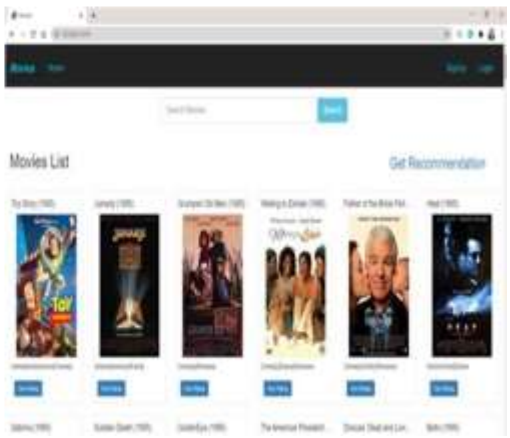
IV. System Designing of the System

A. Architecture Diagram

This architectural diagram demonstrates how our project functions when it is being executed on a server. Based on the user's prior viewing choices, it will suggest a movie to the user.

V. Effects of the Operation on Our System

The user login system that has to gather all the different behavioural traits of the user and save them in the user database will be suggested by our system when it is in operation. Upon a successful login, the system will automatically propose a movie to the user based on their recommendations.



VI. Conclusion

In light of the facts provided, a movie recommender system may greatly benefit us by saving us time and making it easier to find acertain movie that a user requests.This research paper will be created for the movie suggestion based on the user's sentiment analysis, and we have employed several ML algorithms including Collaborative filtering in this article.

KNN algorithm-based algorithm. I have assessed and tested the effectiveness of our system using a sizable dataset that will be used to recommend movies to users, and it performs quite well. This essay will provide suggestions and provide a framework for a movie recommendation system that takes into account user emotion.

***Abstract*— Weather patterns can be utilized to foresee air quality since they fundamentally affect it. But since deep learning is a "discovery," it is difficult to construct dependable deep learning models that consider meteorological circumstances while foreseeing air quality. In this review, we utilize reasonable deep learning out how to show the effect of meteorological elements on air quality estimates to determine the previously mentioned issue.1) The source data from air poison data sets, as PM2.5, PM10, and SO2 hourly obsessions, as well as meteorological condition data sets ssessing temperature, suddenness, and pneumatic stress, are gotten in this paper; (2) To foresee air quality under four circumstances, the Long Short Term Memory (LSTM) and Gated Recurrent Unit(GRU)models are laid out;(3)The air quality's reasonableness is analyzed utilizing the Shapley Additive ExPlanation (SHAP)technique. We find that basically considering atmospheric conditions doesn't work on estimate precision. In any case, gauge precision is better when meteorological circumstances and other air contaminations are joined than when just other air toxins are incorporated. Additionally, the mainconsider anticipating air quality is climatic strain, trailed by temperature and stickiness. The cooperation of climatic factors and other air impurities might be the reason for the uniqueness in gaurge precision. The after effects of this study could assist with working on the exactness of air quality estimates and make them more solid.**

***Keywords*—LSTM,GRU,SHAP.**

I. Introduction

Natural issues have emerged because of the continuous speed increase of worldwide urbanization and industrialization. The deterioration of air quality brought on by industrialization and urbanization is one of the most significant issues affecting the environment [1, 2]. Energy creation and utilization tasks, for example, power plants, ventures, and auto fumes emanations, have at last added to the nonstop deteriorating of worldwide air quality [3]. Air contamination represent sacritical danger to individuals' lives and wellbeings inceit can prompt various respiratory circumstances and even malignant growth[4]. AirtoxinslikeSO2, PM10, and PM2.5 are the most pervasive. A small molecule with a breadthunder 2.5 micronsis known as PM2.5. Since PM2.5 particles are more dynamic than bigger particulate poisons,they canrapidly and handily spread,persevere in the air for quite a while, and transport intensifies that are hurtful to human wellbeing and the climate. PM2.5[2] is one of the main supporters of air contamination. Asthma, bronchitis, and cardio vascular infection might be welcomed on by its capacity to effortlessly enter the humanthroat and nasal pit because of its little molecule size [5]. Air pollution is bad for people's health[4,6]. A number of respiratory conditions and even impairments in cardiopulmonary function can result from prolonged exposure to high levels of air pollution. Numerous diseases will spread rapidly, putting people's health at risk, affecting their quality of life and happiness scores, and raising mortality rates [7]. As well as influencing the climate, air contamination additionally hurts the environment by decreasing its assortment and solidness[1].

Not in the least regular occasions of air contamination represent a danger to human wellbeing, yet they likewise cause huge monetary misfortunes and a plenty of cultural issues[8]. In like manner, advantageous legitimate assessment, careful guess of air quality, and useful security and treatment considering air pollution measures could help critical divisions and related relationship in taking impediment actions early, as well as more appropriately coordinating outings. Disease outbreaks could be avoided and people's health could be preserved[9].

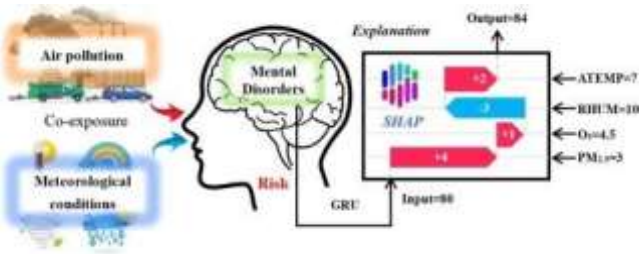

Fig.1.

As a result,forecasts of air quality may provide useful data for controlling and preventing air pollution.Accurate assessment and forecasting of changes in air quality may assist in the management and prevention of air pollution, thereby safeguarding the environment and humanhealth[10].This is made possible by having a better understanding of the underlying variables and shifting patterns of air pollutants.

Air quality expectation likewise assists pertinent divisions with fat homing the state of air quality, thus a critical hypothetical establishment might be provided for it. As a result, programs to reduce and prevent air pollution can be tailored to specific circumstances. It likewise gives valuable contemplations and thoughts for future chiefs to seek after

DOI: rp-9788770040723.109

additional savvy and proficient activities to improve air quality[11]. Some examples of relevant research efforts are listed below. For example, Kumar and Goyal [12] conjecture the everyday Air Quality Index(AQI) for each seas on utilizing three measurable models: principal component regression (PCR), the auto-regressive integrated moving average(ARIMA), and a mix of the two. In view of back-direction focuses and nonlinear regression(NLR), Cobourn[13] proposed PM2.5expectation model with lower mean outright blunders. The most common way of utilizing physical and compound estimations to anticipate air quality is more troublesome. Rajput and co. 14] recommended a method for utilizing an AQI to assess and address quality status. This could assist with better determining of air quality measurements. In spite of this, the model is a period recurrence expectation model that performs best throughout more limited time periods.

This paper's findings can be summed up in the following format:

1. Long Short-Term Memory and Gated Recurrent Unit Were Deployed and tested against multiple circumstances and have fetched favorable outcomes.
2. The way the atmospheric phenomena exerts impact on quality of air, has been brought to light using Shapley Additive ExPlanation, this will be valuable in order to enhance the precision in future findings.
3. Built an application to apply the prediction in realtime.

II. Literature Survey

A. *The emergence of affordable sensing for regulating urban air pollution*

Air pollution and expanded street traffic are connected to the steadily expanding populace of urban communities. It has been exhibited that metropolitan tenants face a huge danger from raised degrees of air contamination by and large. Not withstanding, the impacts of incredibly high contamination yet restricted openness over the long haul and space stay obscure. Organizations of static and inadequate estimation locales support conventional air quality estimation strategies.Unfortunately, they are excessively costly to catch rhythm spatial fluctuation and recognize contamination areas of interest, which are fundamental for the improvement of compelling ongoing openness control techniques.The customary way to deal with permitting continuous data to be put away in a slim structure has been generally modified by late headways in the improvement of minimal expense miniature size detecting advances.Be that as it may, whether or not the less exact information they produce is helpful continues.This article clears up the significant hindrances for their fruitful application and the elements that have prompted an expansion in the utilization of reasonable sensors for city air pollution control.

B. *Air Pollution and Ncds Diseases: A Study by the Environmental Committee of the Federation of GlobalRespiratorySocieties,Volume01:TheHarmfulConsequencesofAirPollution:*

Air pollution is a significant danger to human wellbeing in the climate. Openness to outside fine particulate matter(particulate matter with a streamlined measurement of 2.5meters) is the fifth driving reason for death around the world, representing 4.2 million passings and in excess of 103 million handicap changed life years lost,as per the Worldwide Weight of Sickness Report. Indoor air tainting is at risk for an extra 3.8 million passings, according to the World Prosperity Affiliation. Air pollution can be unsafe on a transient premise,as proven by side effects in the respiratory or heart frameworks, as well as over the longhaul, potentially influencing each organ in the body. It very well may be there as on for, convolute,or fuel various negative medical problems. Since small and ultrafine particles can get in to organs, contamination poisonousness can cause tissue harm either straightforwardly or by implication through foundational incendiary cycles. Innate and epigenetic factors both impact powerlessness.Despite the fact that individuals of any age, areas, and financial classes are impacted via air contamination, the people who are most often uncovered are bound to turn out to be sick. At the point when individuals are sick or need social help, they are particularly delicate to air pollution. Indeed, even at portions that were recently remembered to be inside satisfactory air quality principles ,unfriendly impacts persevere.

C. *Particulate Matter 2.5's influence on the respiratory system in humans:*

As of late ,various school astics have zeroed in on the association between air pollution and issues of the respiratory framework. As of late, exhaust cloud level shave expanded in China, bringing down air quality and raising worries across the globe. Particles with a diameter of less than 2.5 micrometers (PM2.5) can possibly enter the lungs, making the alveolar wall become bothered and disintegrated, compromising lung capability. Thusly, it is fundamental to research the impacts of PM2.5 on the respiratory framework and afterward help China in resolving its recent concerns with air pollution. In light of epidemiological, exploratory, and component studies, the impacts of PM 2.5 on the human respiratory framework will be analyzed in this survey.At last,we ask specialists to make a contamination related wellbeing record and encourage the general population to restrict their openness to air pollution.

D. *Analysis of data and mining of climatic variations and air quality co-relations: A study in China:*

PM2.5,PM10,andO3contamination represent a developing danger to human wellbeing, especially in China's megacities. Air pollutants' dissemination and focus are impacted by meteorological circumstances, which altogether affect their weakening and dispersion.We examined the associations between Beijing's meteorological circumstances and air contamination fixations from January 2017 to January 2018. That's what we find: 1)A solitary meteorological component meaningfully affects the centralization of contaminations; (2) There is major areas of strength for a between the blend of temperature and wind speed, moistness and wind speed, and strain and temperature, showing that various meteorological elements

DOI: rp-9788770040723.109

cooperate to influence the convergence of poisons; (3) Poison fixation is impacted distinctively by different meteorological variables.Our discoveries canpossibly further develop metropolitan administration execution while additionally aiding climate-based figures of air quality.

E. Based on cognitive calculation, a novel technique forpredictingairqualityhasbeendeveloped:

The recognizable proof and treatment of developing aircontamination welcomed on by mechanical progressions isquitepossiblyofthemaintestconfrontingthispresentreality.Contaminationlevelshavewithoutadoubtrisenemphaticallylately. Utilizing profound learning methods and an recurrentneural network (RNN), the current work expects to foster awise figure for air contamination fixations over the course ofthefollowingtwodays.Theidealdesignforitsactivityisthenfoundutilizingaparticleswarmoptimization(PSO)strategy.The smart air quality prediction model (SAQPM) is a cleverindicatorinlightofcannyprocessingthatutilizesstreamliningandunaidedlearning,otherwisecalledlongshorttermmemory (LSTM). The essential goal is to estimate six kindsofcentralizationsofaircontamination:Nitrogendioxide(NO_2),carbonmonoxide(CO),ozone(O_3),andsulfurdioxide (SO_2) are instances of PM2.5 and PM10 particles.SAQPM comprises of fourstages. Gatheringinformationfrom many stations — 35 in this occurrence — is the initialstep.Settinguptheinformationincorporates(a)isolatingeachstation with its own concentration, (b) tending to missingqualities,and(c)normalizingthedatasetwiththeMinMaxScalar strategy to a scope of (0, 1) Utilizing theutilitarian PSO calculation, the third step includes fosteringtheLSTMindicatorbydecidingtheidealorganizationdesignandboundaryvalues(weight,predisposition,numberofstowedawaylayers,numberofhubsineachsecretlayer,andenactmentcapability).Thetencross-approvalthoughtisthenused to separate the dataset into preparing and testing parts.Thepreparationdatasetisthenusedtoconstructtheindicator.Each station's evaluation results are determined in the fourthstepbytakingreadingsofthegroupingofeverypoisonconsistently for a limit of 30 days and computing the normalof the symmetric mean absolute percentage error (SMAPE)northof25days.

III. Methodology

In any case, in spite of the way that a deep learning models utilize meteorological circumstances to foresee air quality, meteorological factors are just utilized as info information, and there is no exploration on what meteorological circumstances mean for air quality expectation. In this specific case, it is obscure the way that meteorological factors impact air quality expectation in profound learning models.

This is on the grounds that the profound learning model is by and large a "black box," meaning it can't be made sense of. In any case, the profound learning model's extraordinary fitting benefit for complex information associations can be utilized to consolidate meteorological condition information with air quality information to gauge air quality.

Evaluating the effect of meteorological circumstances on air quality conjectures their connections actually faces various obstructions.

A. Drawbacks

1. However, considering that deep learning is a "black-box" technology, incorporating meteorologicalconditionsintoairqualitypredictioncanbechallenging.
2. Itisobscurewhatmeteorologicalcircumstancesmean for air quality prediction in profound learningmodels,includinghowtheyimpactairqualityforecast.

We utilize logical deep learning out how to uncover theimpact of meteorological factors on air quality expectationandfittinglymakesenseofwhatmeteorologicalcircumstances mean forairqualityforecast to defeat thepreviouslymentionedissues.Byshowingtheeffectofmeteorologicalelementsonthefigureof airquality,theprecisionisadditionallymovedalong.Itisfeasibletoproduceairqualitypredictionmodelsutilizingprofoundlearningwithmore prominent accuracy and constancy. Therefore, it couldwork better practically speaking. This could make it morestraightforwardforindividualstomakesensibletravelarrangementsandgototherightprecautionlengthstosafeguardtheirwellbeingontime.Workedoncomprehensionoftheconditionoftheairqualityisutilizedtoexecutepertinentsafeguardandcontrolestimatestoaccomplishopportuneandeffectivenaturaladministration.

B.Benefits:

1. It is possible to create deep learning models for airqualitypredictionthataremorereliableandaccurate.
2. Thiscouldmakeitmorestraightforwardforindividuals tomakesensibletravelarrangementsandgo to the right deterrent lengths to safeguard theirwellbeingimmediately.

Abstract - This paper's goal is to carry out an evaluation of the machine analyzing (ML) fashions used for quick-time period forecasting of wind energy parameters like wind velocity orwind strength. Wind velocity estimation is synonymous with wind speed predictions. this is completed to take advantage ofwindtempoforpowerera.Allforecastingmodelshavenumerous, whichconsistofloaddispatching,reserves,operational protection, and fee optimization, amongst others. Forecasting is accomplished to keep the space among strengthgenerationandenergymanufacturing.onthisobserve,the quick-term forecasting model is created one after the other the usage of LSTM and SVM. Each fashion is supervised mastering-based totally. brief-term forecasting models excel atloaddispatchingandextraordinarystrength-relatedresponsibilities. enforcing LSTM offers broader components in forecasting fashions, and neural network-based model spick the pinnacle-first-class characteristic to boom LSTM's normal overall performance and sample remembering belongings over an extended time frame, making it an extra reliable and effective mixed model.

I. Introduction

1.1 General

Renewable energy output is increasing on each day basis, and theowneroftheelectricalsystemmuststabilitytheelectricityvia meeting the maximum demand for renewable power. Wind electricityforecasting is used to forecast characteristics inclusive of wind pace,power output, and wind path. The forecast is finished in unique timeframes depending on the electrical grid requirement and additionallyforwind resourceassessment, which aredefinedunderneath.

- Exceedingly brief term
- Extraordinarily brief time period
- Quick time period
- Long time

due to the fact to the volatility of the atmospheric wind drift, the literature for wind electricity forecasting remains within the experimental segment. The purpose of this studies is to create effective records-pushedmodelsforforecastingwindpowerera.great-appearingactingmodelneedtobesimilarlydeveloped,tested, and demonstrated using ancient facts. Effective wind strength prediction is vital for supporting operators in integrating wind mills into smart grids and improving strength output control. several facts-pushedtechniquestoenhancingwindstrengthpredictionwereevolvedintheliterature.conventionaltime-collectiontechniques,which includes lengthy short-termreminiscence(LSTM).

Thosefashionsareeasytoconstructandsmoothtoenforce.nevertheless, it's far truly worth noting that first-radical time-collectionmodelscanreapfirst-class out comes whilst wind power dataunderstandings regular changes, but the forecast errors is plain while thewindenergytimecollectionwell-knownshowsabnormalvariations.In this examine, the short-term forecasting version is created one aftertheothertheusageofLSTMandSVM.eachmodelisbasedon supervised studying. quick-time period forecasting models excel at loaddispatchinganddifferentenergy-relatedresponsibilities.theuseofLSTMandSVMattheidentical datasetyieldswonderfuleffectsbecause of the reality the models are so distinct. in choice to SVM,LSTM(lengthyquick-termreminiscence)hastheassetsofsamplerecollection for a longer time period (help vector device). So, it giveswider elements inside the forecasting fashions and additionally neuralnetwork-primarilybasedmodelsselecttheexceptionalfunctiontoimproveLSTM'sordinaryperformanceandsampleremembrancebelongings over an extended duration making it an extra reliable andpowerful blendedforecast model.The number one aim of this art workis to behavior a comparative evaluation of everymodel (LSTM andSVM)andselectoutthemaximumsuitableandbrief-timeperiodforecastingmodelsexcelatloaddispatchingandfantasticspecialstrength-associated duties. Using LSTM and SVM on the equal datasetyields different consequences because of the reality the fashions arerelativelydifferent.InassessmenttoSVM,LSTM(longshort-timeperiod memory) has the assets of sample recollection for a prolongedterm (aid vector gadget). As a result, it presents broader elements inforecastingfashions,andneuralnetwork-primarilybasedcompletelyfashions pick the high-quality function to increase LSTM's performanceand pattern remembering property over a prolonged length, making it amore dependable and effective blended prediction model. The numberone intentionof this paintings is tobehavior a comparative assessmentof both fashions (LSTM and SVM) and pick the maximum appropriateand efficient. those models combine bodily and statistical techniques,briefandmedium-termfashions,andcombinationsofalternativestatisticalfashions.

II. Purpose

As all of us apprehend, renewable strength is critical to the sector'sefforts in the direction of sustainable development. Forecasting specificwind velocity figures with technology can be useful to human beings inmore than one

DOI: rp-9788770040723.110

manner. As an example, if in a particular 12 months, theWind electricity is not that excessive and it can't create the requiredquantityofpower,ifwehadforecastthiscircumstanceaoneyearprecedingthenwemayalsoadditionallywarnthepeopleandgowiththe flow to exclusive renewable sources like sun, Water, Bio gasoline,and so forth... in order that neither the maker nor the patron suffers aloss.commonplacewindpaceisafull-sizeissuethatimpactsthesurroundings. This task illustrates the way to estimate wind speed theusage of system studying algorithms. it's far valuable for assessing thepossibilitiesforclimate sportsand wind strengthinsidethedestiny.

SCOPE

Wind behavior look at as a way to construct a wind predictionmachine primarily based on gadget studying for wind strengthplant manufacturing prediction. After developing accurate modelswhich can correctly expect wind velocity, we may additionallycommercializethosemodelsandmakethemavailabletoindustries. Wind is a free strength supply, know knowledge it'smilesparticularlyunpredictable,whichposesasubstantialchallenge undertaking for integrating large wind electricity plantlifeintoa strengthmachine.

III. LITERATURE SURVEY

Thisstudyfocusesonstrategies,LSTMandSVM.bothmethodologieshavesimilarelements,knowledgeThisstudyspecializesintwomethodologies,LSTMandSVM.bothmethodologieshavecomparableelements,know-howkeydistinction is inside the approaches hired thru both techniques.information mining and its software in various programs haveacquired more interest in cutting-edge years. information miningrefers to the gadget of coming across styles in huge statistics setsbymannerofmixingmorethanonemethodology.Statisticsmining is used to advantage by way of analyzing diverse createdstyles. in the case of facts preprocessing, the facts are first wipedclean,thismeansthatthatmissingandincompletefactsare deleted from the database. The information is then picked andchanged in the following method to supply the very last dataset.data mining techniques are actually used to the to be had finalrecords set to find out styles that may be in addition assessed andanalyzedtodiscover.Severalroundsandshiftsofshiftingbackward or beforehand are blanketed within the approach ofrecordsdiscoveryinawesomedatadevices.someoftheapplicationsofrecordsmininginwindelectricitystructuresinclude forecasting wind path, electricity, and velocity, dealingwith strength garage, assisting in energy optimization, offeringturbine problems, and putting or controlling turbine installation.Theproposedmethods'primaryphasesencompassuncookedinformation,pre-processing,andfactsprediction.Allofthestrategiesdefinedinthegivenapproachneedtobeobservedinside the proper way to gather a greater reliable, inexperienced,andaccurateversionforforecastingwindvelocity.Ineachtechnique, raw information is collected and analyzed to determinewhether or not it desires to be preprocessed or no longer, i.e.,whether or not the to be had facts is ready to use with nonealterations;ifnownot,certainpreprocessingstrategiesareimplemented to the present dataset to make it applicable for ouruse. The statistics set provided right right here includes numerousparameters,knowledgeourrequirementforimposingtheseprocesses most effective calls for some parameters, eventuallypreprocessing is required to reduce information dimensionality.Following preprocessing,the informationreceivedissensitiveinformation. we will now use our prediction algorithms in thisinformation to construct our version to forecast wind velocityeffects.Eachalgorithms'precisionismeasuredtheuseof exceptional kinds of percentage mistakes. The system structure ofthe simple technique employed with the resource of LSTM andSVMforwindpaceforecastingis demonstrated below:

***Abstract*—According to a report of the World Health Organization, one of the main causes of blindness would be due to cataracts. Although cataracts mainly affect the elderly population, now they can also be seen in juveniles. Among the different types, there is evidence that three types of cataracts affect the mass which are nucleus, cortex, and retro capsular cataracts. Common methods of diagnosing cataracts include slit lamps. Doctors' imaging tests are not effective in early classification of cataracts stage and may also be inaccurate in determining the correct type of cataract. Our current job is to automate the workflow on binary detection-only or considered a single type of cataract among those mentioned to continue to enlarge the system. In addition, little research has been done in the area of cataract classification types. Our system works with the aim of reducing errors during manual detection of early cataracts. Our proposed system successfully classifies the images as cataracts affected or as a normal eye using VGG-19.**

***Keywords*—Python, Tensorflow, Deep learning, Eye cataract detection.**

I. INTRODUCTION

On the normally transparent lens of the eye, a cataract is a white cloud that gradually hardens and develops into a yellow plate. A healthy eye with this disorder loses vision because light cannot reach the retina because the lens is obscured by a hard, white fog.

In a survey done by the World Health Organisation on World Sight Day 2019, 217 million individuals were found to have a moderate or severe visual impairment (MSVI), and 36 million were found to be pedigree. Of these, 65 million people have cataracts, making them susceptible to MSVI and blindness. Thus, 48% of cases of blindness are caused by cataracts.

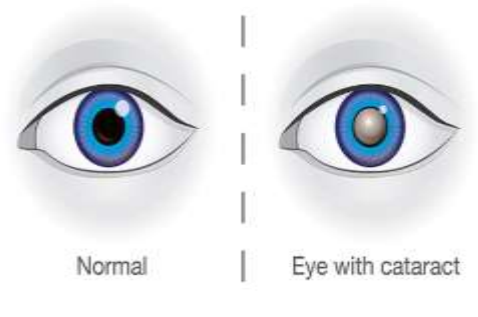

Fig. 1. Difference between normal and cataract eye

Although cataracts develop very gradually, it can cause problems as it moves out of the coating. A very small part spreads over the lens leading to loss

II. LITERATURE SURVEY

As we have studied the existing work done on this subject, an image-based system processed and developed on the MATLAB platform for accuracy of about 90% or more suggests using SVM to improve accuracy [2]. Another project using retinal fundus images, RGB image is first converted to green channel and image processing is applied technique, contrast is enhanced and noise is suppressed. Binary SVM is implemented for classification fundus image with MDA algorithm. Classification is done for two classes, i.e. no cataracts and cataracts. The grading section consists of three grades: light, medium and heavy Cataract. The dataset used consists of 261 images [3].

A system is developed using the following approaches 1. Computer vision approach to mining features and their use to develop machine learning models (b) automatically generate features and classified by a convolutional neural network. A set of six hundred labeled retinal images was used to train the models [4]. A project has proposed a method of detecting cataracts with a smartphone such as Android, iOS. The camera detects the eyes, cuts the required eye area. When cropping students, they are stored in an array. They are analyzed with the Android Native Development Kit Communication. The two main average or average intensity characteristics of images and histograms are used to determine the presence of cataracts in patients [5] .

Fundus image analysis has been the subject of extensive research. He uses four essential components to categorize cataracts: preprocessing, feature extraction, feature selection, and classifiers. While creating and transferring images, noise can be consistently introduced. [6].Therefore, preprocessing methods also have few approaches needed to improve image conditions, such as image enhancement and denoising. Numerous studies have been conducted on the segmentation and localization of retinal structures such as lesions, vessels, optic nerves, and aneurysms. To prevent issues from dimensional errors, feature extraction and selection are crucial. Different characteristics were extracted from retinal fundus images. B. Acoustic and spectral parameters, sketches, wavelets, colours, etc. As a functional representation, the three central components are gathered together. The main computational and testing work of the system is done in this section, and a solid functional representation plays a crucial role in the accuracy of the final algorithm. Cataract identification and grading have been adapted using classifiers based on different algorithms.

Automatic cataract grading techniques now in use [5] frequently deliver inaccurate, redundant, or noisy representations. utilizes a set of predefined image features. Furthermore, every one of the predefined features is artificially extracted. This is a very time-consuming heuristic strategy that requires a high level of knowledge,

DOI: rp-9788770040723.111

a lot of trial and error, and fine tuning. The author of [7] suggested a system that learns features automatically. Vector regression is used to ascertain the cataract grade using these features. achieving an accuracy of cataract categorization with an exact integral agreement of 70.7%. However, feature extraction and classifier remained independent.

Understanding the representations learnt by DCNNs, noticing the invariance of learned features at various layers, and the high activation of the final fully connected layer in the image served as the inspiration for our study. permits you to track to a location. These methods shed light on the elements that influence categorization performance the most. For dominating qualities and semantic concepts, Zeiler et al. [8] demonstrated that feature maps succeeding further convolutional layers store both geographical and semantic information.

The interpretation of representations obtained from DCNNs is the main topic of this white paper. The Pool5 layer of the CNN architecture's feature maps are used in the proposed technique. It has been demonstrated to understand semantics and maintain coarse geographical information [9]. We investigate the impact of the G-filter and the database's scalability on the DCNN classification accuracy in this research and show that our method performs better on the cataract identification and grading task.

III.PROPOSED SYSTEM

Deep learning-based approaches can learn the critical features and then incorporate the feature learning processes into the model building process in order to reduce the incompleteness of the manual design features and apply them in various medical imaging. Local filters are created by clustering the picture patches supplied into a convolutional neural network (CNN). Khan et al. employed the VGG-19 model with a transfer learning approach to achieve roughly the same accuracy for fundus images using a recently made available dataset in KAGGLE. A further recent work by Pratap and Kokil investigated cataract detection in noisy settings. A pre-trained CNN was created for feature extraction by combining a number of independently trained, locally and globally trained support vector networks.

A. *CNN*

With tens or even hundreds of layers, a convolutional neural network can learn to recognise various image features. Each training image is subjected to various filtering at various resolutions, and the result of each convolved image is utilized as the input to the following layer. Beginning with very basic features like brightness and borders, the filters can advance to features that specifically identify the object.

Because neutral networks extract the aforementioned features, they require more training data. CNN's performance is heavily reliant on the data fed into the neural network. When there is less data, however, the common data collection technique Boost is used, in which each sample in the data set is changed in response to some category and a new image is created. In a single batch, these new images can be fed into the neural network. Variations to the image include flip, scale, prop, translate, zoom, Gaussian noise, and so on. We used a horizontal flip and a zoom factor of 0.2 in the implementation. Transfer learning is used in the multiclass classification process, and the following pre-trained models were used to perform multi-class classification on pre-processed images.

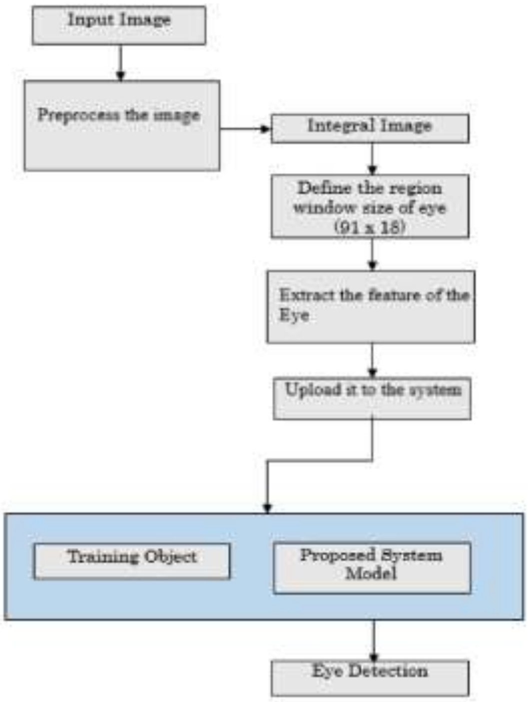

Fig. 2. Architecture Diagram

B. *Preprocessing*

Image preprocessing is the process of converting the image to require our needs and to add to the model efficiently. This includes resizing, orienting, and color corrections, among other features. Additionally, image preprocessing can speed up model inference and cut down on model training time. If the input images are especially huge, shrinking them will greatly reduce the amount of time needed to train the model without affecting model performance.

C. *VGG-19*

A 19-layer convolutional neural network is called the VGG-19. A trained version of the network can be loaded from the ImageNet database. Images can be categorised into tens of thousands of different item categories using the pretrained network. The network has therefore acquired in-depth feature representations for a range of images. The network's picture input has a resolution of 224 by 224.

D. *Tensorflow*

Machine learning platform TensorFlow is totally open source. Researchers may readily push the limits of machine learning, and developers can quickly create and

DOI: rp-9788770040723.111

deploy ML-powered applications because of its extensive, adaptable ecosystem of tools, libraries, and community resources.

The Google Brain team, which is composed of researchers and engineers, developed TensorFlow to undertake machine learning and deep neural network research. The technique is versatile enough to work in many different additional fields. While backward compatibility with other languages is not guaranteed, TensorFlow provides stable Python and C++ APIs.

IV.RESULT

A structured ophthalmic database of 5,000 patients containing age, color fundus images of the left and right eyes, and doctors' diagnostic keywords from doctors called Ocular Disease Intelligent Recognition (ODIR) has been effectively applied to our suggested approach.

The confusion matrix of the system is shown below:

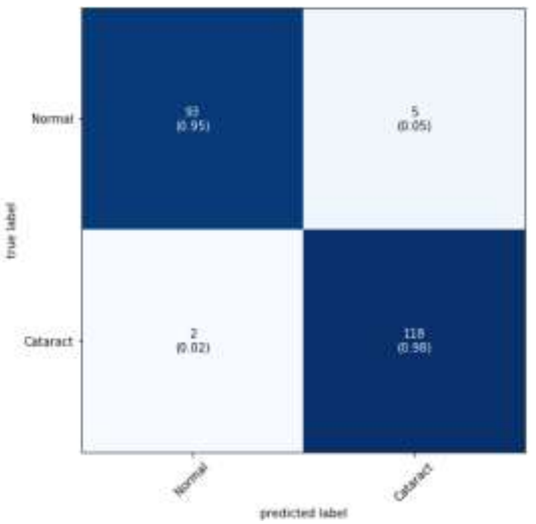

Fig. 3. Confusion matrix

The other models accuracy are shown below compared to our proposed model

TABLE 1: COMPARISON OF OTHER MODELS

Sr.No	Model	Validation Accuracy
1	VGG 16	96.88
2	MobileNet	90.62
3	SqueezeNet	97.66

The above table shows the accuracy obtained by applying different deep learning models namely VGG16, Mobile Net and Squeeze Net. The highest accuracy achieved was 97.66% by Squeeze Net. And our proposed model using VGG has an accuracy of 98.62%.

The Accuracy and loss graphs of the proposed system is shown below:

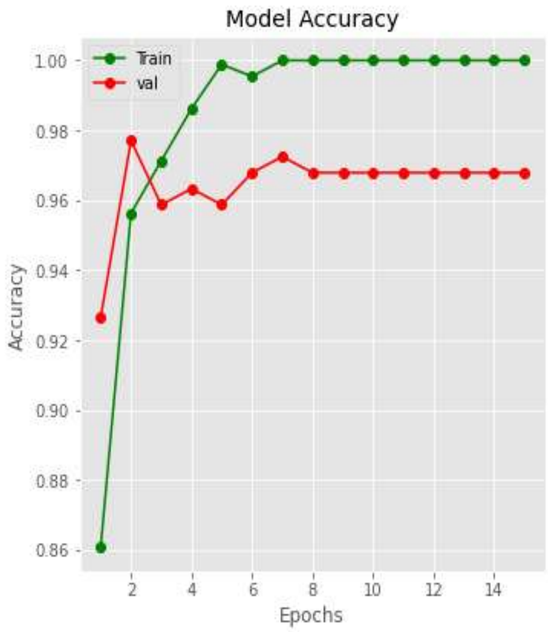

Fig. 4. Model accuracy

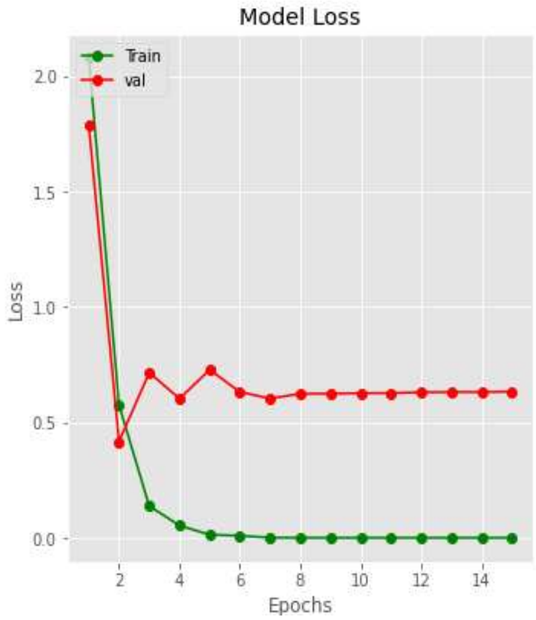

Fig. 5. Model loss

V.CONCLUSION

The main challenge was managing this large dataset. Therefore, we divided the dataset into smaller pieces to enable the proposed system. Deep learning techniques for cataract detection have been proposed in this effort. We identified and extracted certain ocular features for cataract identification using texture features.

To identify cataracts, we extracted the region of interest, i.e. pupil, and formed deep learning models to classify eye images into cataracts, normal eye image. The Deep Learning model used is VGG-19. We also evaluated the accuracy of various machine learning algorithms such as SVM-linear, Random Forest and Adaboost Classifier

DOI: rp-9788770040723.111
on texture features obtained from SIFT and GLCM algorithms. However, the accuracies obtained are less than deep learning models VGG-19. `

***Abstract*—Time-to-event details are hypothesised using the statistical means known as Kaplan-Meier. The phrase "time to event" indicates to the cycle of duration among a study's admission and a particular incident, like an illness's onset. Since it is used by researchers to classify and/or scrutinize sufferers who off-tracked to follow-up or at times left the study, as well as the ones that grew the condition of concern or pulled through it, this process is advantageous in survival analysis. Additionally, it is used to contrast clusters, like the placebo-treated clusters and the real drug-treated treatment clusters. In addition to being useful in epidemiology, public health, and medicine, the method can also be used in engineering, economics, and other fields. The vast majority of studies that make use of the Kaplan Meier estimate are, like cohort studies, longitudinal. The demise times of kidney transfer victim, the time to infection for smolder sufferers, and demise time for big C trial are all examples of studies for which the Kaplan-Meier estimate may be applicable. The analysis and control clusters, which received a particular medicine and a placebo, were the subject of fictitious data. There were 20 people equally divided in these two clusters, who were monitored for a period of 24 months over the course of two years. Using the fictitious data, the SPSS software fabricated a table and a estimation arc of Kaplan-Meier that be utilised in the analysis of the 24-month study.**

Keywords—Kaplan-Meier, epidemiology, survival analysis, log-rank-test

I. Introduction

Areas like epizootiological, communal well-being, and treatments, require the analysis of time-to-event data. This type of data measures the time between the start of a study and a specific outcome. To analyse such data, survival analysis is often used. This method involves following a group of participants for a predetermined length of time to measure time to event. In survival analysis, the Kaplan-Meier estimate is the preferred statistical method for comparing both clusters of participants, like a under prescription cluster and a cluster under control. This method is also useful in fields like physics, engineering, economics, and demography. To illustrate the Kaplan Meier estimate, consider a shared characteristic learning of the big C in lungs amid the ones who smoke. The study follows a group of smokers for 20 years to measure the occurrence of lung cancer. The events and censoring are analyzed using the Kaplan-Meier estimate, with events indicating the onset of lung cancer and censored data representing those who dropped out of the study or were unable to continue. Software like SPSS, Stata, SAS, or R can be used to create the survival table and KM measure curve, which are used to calculate the proportion of smokers who survive lung cancer.

II. Literature Survey

First, when conducting cancer studies, survival time analysis is a common method used to answer research questions. These questions may involve determining the impact of clinical characteristics, such as blood sugar levels, on patient survival, or calculating the probability of an individual surviving a specific period of time after a cancer diagnosis. Additionally, researchers may compare survival times between groups of patients who received different treatments. In such cases, Kaplan-Meier plots are often used to visually represent endurance arcs, all while Log-rank compares endurance arcs among clusters.

A. Survival Analysis Using COX Proportional Hazard Model

Regression modelling is put to use to calculate the immediate risk of dying, and it is a little more challenging to visualise than the Kaplan-Meier estimate. It is made up of the hazard function h(t), which expresses the likelihood of an event or hazard h (such as survival) up until a specific period t. When comparing the survival of patient groups, the hazard function takes covariates (independent variables in regression) into account [1].

B. Survival Analysis Using Kaplan-Meir Method

When dealing with shortened or unpublished information, the Kaplan-Meier estimator is utilised in the survival distribution. We may estimate the survival function using this non-parametric statistic, which is independent of the underlying probability distribution. The Kaplan - Meier estimates are established on the total count of sufferers who survive for a specific amount of time following therapy (each patient is represented by a row of data) (which is the event) [2] .

C. Method

The two participant groups will be the subject of fictional data. The treatment cluster comes first, and the control cluster comes second. A treatment cluster gets a particular medicine while the control cluster gets a placebo. Ten people are present in each cluster. The fictitious data will be analyzed with the help of SPSS-generated data.III. Survival Analysis

Survival analysisa arithmetical approach, for analysing information on the basis of when the incident happen, particularly in associate study. The duration from a particular point to the instance of a given incident, such as trauma, is known as survival time.As a result, the investigation of cluster information is referred to as survival analysis. As a result, it takes into account data from cohort studies or randomised clinical trials. Main objective of survival analysis is the analysis plus modelling of "time-to-

DOI: rp-9788770040723.112

event" information, which is the subject of controlled experiments in clinical trials.The occurrence could be the removal of a tumor, the length of time it takes to be discharged from a medical facility or hospital, the reaction to medicine, or demise. Events can also refer to an injury, illness recovery, or illness onset. Lassa hemorrhagic fever (LHF) for the ones who displayed symptoms after being checked on for one week in Maiduguri, hemorrhagic fever disease for ones who were checked positive after being under quarantine for 21 days in Serra Leone are two examples of events. Estimating and interpreting survival, comparing it between groups, and determining whether or not explanatory variables have a connection to survival time are all accomplished through the use of survival analysis. Time is taken into account in survival analysis, the duration before an important event occurs[3].

The duration of remission, duration taken for a tumor to disappear, duration for a patient to die, and the duration taken for a response to develop are all examples of survival time data. Other examples include the duration taken for a patient to die and the time it takes for a patient to respond to treatment. There are two crucial aspects of survival time that needs to be precisely explained: a starting point and a finish point that is attained when the incident of importance happens or after the subsequent period has come to an end. Survival duration, consequence to a treatment provided, and sufferer symptoms in accordance to survival, reply, and illness progression are examples of survival data. Clinical and epidemiologic human studies with acute or chronic diseases can yield these data. Survival analysis takes into account censoring and time, in contrast to other statistical techniques like logistic regression, amidst rest[7].

Survival analysis is an essential tool for inspecting time-to-event information in areas like epizootiological, communal well-being, and treatments,. In studies where participants cannot be checked on until the learning ends, censorship can occur. Censored data refers to cases where the actual event time is not observed or is unknown. Censoring can occur in different ways, such as right censoring, where the event has not occurred by a certain point in time, left censoring, where the event has already occurred before the study started, and interval censoring, where only the information that the event occurred within a certain time interval is available[6]. In survival analysis, censored observations are included in the analysis, and the participants are considered to be at risk until they experience the event or are censored. One advantage of survival analysis is that it allows for the inclusion of participants with different follow-up times. Various statistical software, including SPSS, Stata, SAS, and R, can be put to use to conduct survival analysis and generate survival tables and Kaplan-Meier curves[8].

Survival analysis involves tracking participants from a defined point of start and recording the duration it takes for the incident of intrigue to occur. However, not all participants may experience the event before the study ends, and it is also uncertain what will happen to those who withdraw from the study. The duration of follow-up is noted for these cases, resulting in unpublished information. The Kaplan-Meier estimate is a useful tool for analyzing this data and describing the survival characteristics of the study population.

IV. Kaplan-meir Estimate

During survival analysis, participants are followed from a defined starting point, and duration until the happening of the incident of interest is recorded. However, not all participants experience the event before the study ends, and the outcomes for those who withdraw from the study are unknown. For these cases, the follow-up period is censored, and the estimate ,Kaplan-Meier is the most effective technique for demonstrating and describing characteristics of survival[5].

It is recommended to keep text and graphic files separate until after the text has been formatted and styled. Survival analysis using the Kaplan-Meier arc is commonly put to use in epizotiological to compare two groups and analyse time-to-event information. The survival curve calculates the percentage of survivors in a specific incident, such as demise, over a duration, as well as the statistical difference in survivals between the two groups. A Kaplan-Meier survival curve moves downward when the incident of intrigue happens, and tick marks indicate censoring. The Product Limit estimate (PLI), also known as Kaplan Meier's estimate, can estimate the fragment of beings or bodily instruments living past some age t, even when few of the objects are not concerned to pass away or malfunction, and the illustrative size is tiny. It presumes enumerates the likelihood of an incident happening at a specific duration, and dividing these consecutive likelihood by any previously calculated likelihoods to arrive at the end of the estimate. For instance, the likelihood of a not so fertile woman conceiving after hydrogenation and laparoscopy three months later can be calculated using conditional probability[6].

Survival analysis is based on defining intervals by failures. The survival probabilities for different intervals are calculated by multiplying the probabilities for each preceding interval. This calculation leads to the Product Limit estimate (PLI) I.e equation (1) .

$$PLI(1) = \frac{P(SurvivalIntervalA)}{NumberofSubjectsatRiskuptofailureA} X \frac{P(SurvivingIntervalB)}{NumberofSubjectsatRiskuptofailureB} (1)$$

The survival probability is deliberated by dividing the count of beings at possibility by the count of beings who survived for each specified time period. Participants who have withdrawn, died, or relocated are not considered to be "at risk," which means that they will not be included in the denominator. This analysis relies on three presumptions. First, it is assumed that participants who withdraw or are censored will always have same chances of living like the ones, continue to be followed. Second, the survival probabilities for people part of recruited at the start and at the end in the study are assumed to be similar. Thirdly, the incident must happen at the specified duration. Because it only examines effects of one factor at once, the K-M measure cannot be applied to multivariate analysis[4].

III. The Log-Rank Test

The above stated test is a statistical tool used to find the difference of the survival functions of multiple clusters. Its primary purpose is to test whether there is a change in the incident probability between populations at any given time. This test is widely used in clinical trials to compare the survival rates of under medical supervision and control clusters, or different treatment groups. Popular statistical software programs, such as SPSS, SAS, Stata, and R

DOI: rp-9788770040723.112

packages, can generate a log-rank test table. The null hypothesis is not accepted if the p-value is less than the predetermined significance level, usually 0.05. However, the test do not provide any estimate of the magnitude of the difference between groups or a confidence interval.

IV. BENCHMARK PROBLEM

The tables below contain fictitious data generated by SPSS software. Survival Table shows data for the treatment group, whereas Total distributions comparison table shows data for both the treatment and control groups. In Total distributions comparison tablethe starting cluster represents the under medical supervision cluster, and the next cluster represents the control cluster. Ten people in each group were followed for 24 months. Participants were labelled AA,BB, CC..., TT, and received various treatments. For both the treatment and control groups, these information will be put to use to calculate the Kaplan-Meier estimates, also known as the limit estimate of the product.

TABLE 1 :SURVIVAL TABLE

Treat		ID	Time	Status	Cumulative Proportion Surviving at the Time		No of Cumulative Events	No of Remaining Cases
					Estimate	Std. Error		
Drug A	1	D	2	Dead	0.9	0.095	1	9
	2	E	4	Dead	0.8	0.126	2	8
	3	A	6	Dead	0.7	0.145	3	7
	4	B	7	Censored	.	.	3	6
	5	Q	8	Censored	.	.	3	5
	6	H	14	Censored	.	.	3	4
	7	F	19	Dead	0.525	0.166	4	3
	8	L	20	Dead	0.35	0.169	5	2
	9	K	22	Censored	.	.	5	1
	10	N	24	Dead	0	0	6	0
Placebo	1	C	1	Dead	0.9	0.095	1	9
	2	I	3	Censored	.	.	1	8
	3	J	5	Dead	0.788	0.134	2	7
	4	P	9	Dead	0.675	0.155	3	6
	5	M	10	Dead	0.563	0.165	4	5
	6	O	11	Censored	.	.	4	4
	7	G	12	Dead	0.422	0.174	5	3
	8	T	15	Censored	.	.	5	2
	9	R	17	Dead	0.211	0.173	6	1
	10	S	18	Dead	0	0	7	0

TABLE 2: TOTAL DISTRIBUTIONS COMPARISON

	Chi-Square	Df	Sig.
Log Rank (Mantel-Cox)	2.603	1	0.107
Breslow (Generalized Wilcoxon)	0.603	1	0.437
Tarone-Ware	1.318	1	0.251

The above curve shows six incidents (demise) in the treatment cluster (who received drug A) and seven events (demise) in the control group (who received placebo). The treatment cluster has four censored data, while the control group has three. When a participant dies, the curve decreases, and censoring is represented by tick marks on the curve indicating loss to check-up or withdrawal from the study.

The survival probabilities for the treatment group were estimated using the Kaplan-Meier method. Subject DD passed away at 60 days with a predicted survival probability of 0.9. Subject EE passed away at 120 days with a PLI of 0.8. Subject AA passed away at 180 days, resulting in a PLI of 0.7. Subjects BB, QQ, and HH were left out at 210, 240, and 425 days, respectively. Subject FF passed away at 570 days, and the PLI was 0.525. Subject L L passed away at 600 days, and the PLI was 0.35. Subject K K was censored at 660 days, and subject NN passed away at 720 days with a PLI of 0.00. The tick marks on the curve represent censoring, while a descending curve indicates the occurrence of events (deaths).

Subject CC passed away during the start month in the control group, with a survival rate of 0.90. In the third month, Subject II was hidden. Subject JJ died at the age of five months, and the PLI is 0.788. The survival rate for Subject PP's death at 9 months is 0.8571, and the PLI is 0.675. At 10 months, Subject MM died with a survival rate of 0.8333 and a PLI of 0.562. At 11 months, Subject OO was hidden. Subject GG demise after a year, and his PLI is 0.422. Subject TT was hidden at the age of 15 months. Subject RR died at the age of 17 months, with a PLI of 0.211. Subject SS died at the age of 18 months, and his PLI is 0.00. These calculations are visible on the curve.

The survival patterns of two participant groups, like the treatment and control cluster, can be compared by comparing the gaps in their curves, which can be linear or stable. A gap that is vertical indicates that one group had a higher probability of survival at a given time, whereas a horizontal gap indicates that one group died more slowly. Figure 1 : KM estimate curve compares the survival curves of the both clusters, with the null hypothesis that there is no much of a change among them. This hypothesis is tested using the SPSS-generated table below, and the fact that each of the three p-values in Total distributions comparison table is greater than 0.05 indicates that the null hypothesis was not rejected.

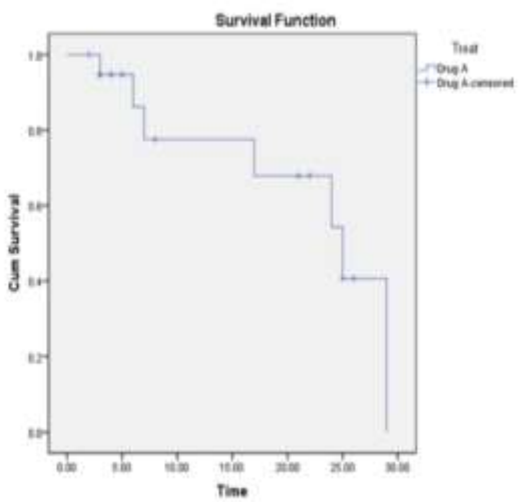

Fig.1. Kaplan-Meir estimate curve

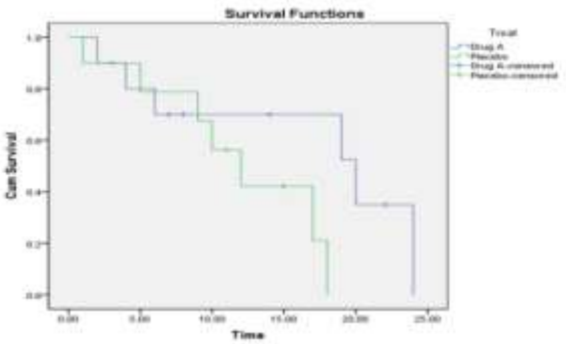

Fig.2.The SPSS software - generated Kaplan-Meir estimate curve

Therefore, statistically speaking, there is no dissimilarity among the treatment and control clusters survival arc. In this context, survival curves refer to the population or actual survival arcs. The events that take place later are more heavily emphasised by the Low Rank in the table, while the events that take place earlier are more heavily emphasised by the Generalized Wilcoxon, with Taron-ware in between the two.

V. Conclusion

The Kaplan-Meier arithmetic technique is extremely helpful in the area ofepizootiological, particularly when analyzing data pertaining to time to events. In survival analysis, the method is used to look at patients who reached a certain point and those who were censored for a certain amount of time. It also works well when comparing participant groups like the control group and the treatment group. The generation of survival tables, Kaplan-Meier estimate curves, and other significant and pertinent tables,such as the overall comparisons table, can be accomplished using statistical software packages like SPSS, Stata, SAS, and R. Engineering, economics, physics, and other fields use the KM estimate as well.

***Abstract*—Within a brief period, a typical online job posting receives a large number of applications. As it is highly inefficient in terms of money and time so hiring companies can't handle it, manually filtering out resumes isn't practical. Additionally, this screening procedure for resumes is unfair because many suitable profiles are not given the due consideration they deserve. This could mean that applicants who aren't the right fit for the job are chosen instead of those who are. Ideally, this paper develops a solution that improves the accuracy of resume screening. Relevant data like skills, education, and experience are extracted by our system using Natural Language Processing. From the unstructured resumes and, as a result, produces a form that summarizes each application. With the help of screening methods that eliminate unnecessary information, analysis of resume data is made easier. After the data pre-processing process, the data is compared with the job description and is analysed on similarity scales to rank each individual resumes. The resulting ranking scores can then be used to select candidates who are the most suitable for a given job opening.**

Keywords*—*Applicant tracking systems, resume screening, natural language processing, cosine similarity, term frequency-inverse document frequency

I. Introduction

All the major businesses' recruitment procedures have undergone major changes due to the increased internet connectivity. Recruiters are able to file an fill a wide range of positions by utilizing online job postings on various websites. Even though e-recruitment has made recruiting easier and saved money for both recruiters and applicants, there are new obstacles to overcome. Every day, Thousands of resumes are typically received by large businesses and recruitment agencies daily economic distress, when a lot of people are looking for work, this situation gets even worse because workers are more mobile.

It is inefficient and makes no sense for recruiters to individually screen each resume for such job postings because less than 5% of applicants will be selected [2]. The fact that these applicants use a variety of resume formats presents another challenge for the organizations. All People who apply to a job belong to different professional and personal backgrounds so every one of those applicants will have their own unique style to showcase his or her talents on their CV because they have had a variety of educational backgrounds and have worked on a variety of projects.

CV's are unorganized documents that can be stored in different file types (such as.pdf, .doc, .docx, .jpg,.txt, and so on). Likewise, there is no fixed or predefined formats or templates used in the writing of their content. Because it is difficult to read resumes, recruiters spend a lot of time sorting through them to find the best candidates.

In an effort to alleviate the difficulty of managing diverse and unstructured resumes, numerous job portals and external websites were established. Candidates are required to manually and orderly fill out an online form with all of their resume information to create candidate metadata. This method has the drawback of necessitating candidates to put in additional work, which often results in them not entering all of the required information into the online form.

These online sites use a general outline for all jobs which makes them inefficient in the case of specific job positions, making them unsuitable for all jobs. The employers then apply the keyword-based search to shortlist candidates using these templates. Insufficient to match candidates to the job description is this keyword-based search functionality This is due to the fact that it only requires certain required keywords to be present and has several disadvantages with regard to deriving information, such as avoiding natural language linguistics for example merged and compound words and the contextual meaning of the resume's content.

As a result, candidates who deserve to be considered for the shortlist are left out because these Boolean search techniques frequently produce results that are irrelevant.

II. Related Works

A. Manual Screening

Some of the people who will be recruiting for the company screen resumes manually. This means that each resume is looked at one by one to see if it fits the job description. If it does, the CV will be chosen. This might be dependent on the on the skills and qualities needed, the job experience of the candidates, among many other things to consider related to the description provided for the job. Issues with this method include:

- Time-inefficient - All CV's must be individually checked, which makes the whole screening process a lot slower.
- Even if all resumes are individually reviewed, recruiters are under a lot of pressure.
- Misallocated and resource waste: Instead of spending so much time reviewing resumes, recruiters could be working on other projects.

DOI: rp-9788770040723.113

- Not efficient:This approach also requires considerable time and resources that could be spent on other projects.
- Unnecessary bias:Moreover, recruiters may not review all resumes after identifying job requirements.

B. Screening Using Artificial Intelligence

To address these issues, the article "Resume Evaluation System based on AI"[4] proposes an AI-powered Resume Screening Software that filters and ranks resumes based on specific keywords to identify suitable applicants. This system aims to classify and shortlist desired candidates more efficiently than manual methods.

The system requires PDF-formatted resumes, which are processed one at a time by extracting text and eliminating excess material. Keywords such as prerequisites are then classified by area, and scores are calculated and sorted for each region. Finally, the system generates a pie chart displaying scores, which helps recruiters select eligible candidates for the job role.However, this approach has some drawbacks, such as:

- *Inefficient* – each curriculum vitae or resume requires exorbitant time to have each document reviewed in comparison to other available methods
- *Not user-friendly and tightly connected blocks*the software may not be user-friendly and may require disrupting the entire code for any changes.

C. Reviewing methods with Machine Learning

The article "Resume Screening using Machine Learning"[5] suggests that in order to efficiently screen resumes, they should be formatted in CSV. To begin the screening process, irrelevant or duplicated terms should be eliminated, leaving only relevant words. These words are then analyzed and assigned skill points based on their relevance to the job requirements. The points are then sorted in order of importance and candidates are selected based on their skill point total. A graph is then displayed to showcase the skill points and aid in the selection process of suitable candidates.

The included benefits are:

- Many resumes can be evaluated simultaneously.
- Easily identify suitable candidates for the job.
- Process completion time is reduced.

Issues and disadvantages with the above approach

- *Challenges with Resume Format*: Only resumes in CSV format are compatible, which may not always be feasible since many candidates submit resumes in Word or PDF.
- *Difficulty in Implementation*: Implementing these techniques requires a high level of expertise and may not be accessible to everyone.
- *Interdependent Blocks of Code*: Making changes to one block of code may require modifying the entire code, leading to disruptions in the workflow.
- *Removal of necessary information* – certain procedures may cause a loss of crucial information and therefore lower overall performance of the model

D. Deep Learning methods of Screening

The article on Resume Screening using Deep Learning (LSTM)[6] suggests a process that involves a dataset with two columns: Category and Resume. The Category column includes fields such as Devops, DBMS, Engineering, etc. The input is the Resume column, which is used to categorize the resume on how well it matches.

Performing a value count on categories, one can obtain and generate a distribution representing the frequencies of resumes that fall into each category.

- After obtaining the dataset, the first step is pre-processing, which involves eliminating irrelevant information from the resume.
- Stop words, which do not contribute to the information, must also be removed using nltk.
- Final preprocessing step involves data condensation, tokenizing features, and labels, and giving less weightage to the most frequent words and more importance to less frequent words. This ensures that unique words are more useful than concise words.
- The model is then trained and evaluated using test scores and accuracy, which generates graphs.

III. Proposed Methodology

A. Information Extraction

Natural Language Processing is used to extract information in the first phase of our proposed system. The resumes do not contain the information in a structured manner. The recruiters can't use the noise, inconsistencies, or irrelevant bits of data. The goal is extracting the main keywords that are similar from the resume's raw data without requiring human intervention. Tokenization, Stemming, POS Tagging, Named Entity Recognition, and other methods, Important job-related content, such as skills, education, and so on, is gathered by our system. From the resumes of candidates uploaded. Each resume is summarized in a JSON format as a result, making it simple to perform subsequent processing tasks in the resume screening system's subsequent phase. Each chapter should be given an appropriate title.

B. Tokenisation

The initial step in identifying the bits of data that constitute a sequence of individual letters or words is to convert various resume formats such as word documents, pdfs, rich text format's, etc. into a common format. Tokenization is the subsequent process, which involves breaking up large text chunks into smaller tokens. This allows us to analyze the original text sequence through these words. Tokenization involves removing or isolating whitespace and punctuation characters to break up sentences into singular tokens. After following the tokenization process, one continues the processtoextract analytics such as

DOI: rp-9788770040723.113

the total word count, word frequency, etc. There are several ways to perform tokenization, including with tools like the NLTK (Natural Language Toolkit), spaCy library, etc.

C. Stemming and Lemmatization

According to its grammatical rules, it is frequently observed that a single English word is used in numerous different forms in various sentences. For instance, "implement," "implement," and "implement" all refer to the same verb but in different tenses. educing all to their original stems from their variations of a word and its bases is important to avoid distinguishing similar meanings of derivationally related words. This goal is achieved through stemming and lemmatization, which have different methods but share the same objective.

Lemmatization is a more precise method for reducing words to their root forms. It involves using a language dictionary and morphological analysis to provide linguistically correct lemmas, rather than simply applying pattern matching rules to remove affixes like in stemming. This means that lemmatization takes into account the context of the word and its part of speech, allowing it to accurately determine the root form. In addition, unlike stemming, lemmatization always returns a valid word that exists in the language dictionary. The NLTK library provides a WordNetLemmatizer that is based on the WordNet database and is commonly used for English language processing.

The WordNetLemmatizer is a part of the NLTK Python package, which is a widely used tool for natural language processing tasks. It is based on the WordNet lexical database, which is a large electronic lexical database of English words and their meanings. The WordNetLemmatizertakes into account the context in which a word appears to identify the correct lemma, which is the base or dictionary form of a word. It uses different techniques such as part-of-speech tagging to identify the correct lemma for a given word. Compared to stemming, lemmatization provides more accurate and meaningful results for natural language processing tasks.

D. Chunking

Chunking is a method for organizing short phrases with parts of speech tags to provide categorizing phrases or components of a sentence. Combining regular expressions with POS tags, some chunk tags like Noun Phrase (NP) and Verb Phrase (VP) can be generated. This is necessary because POS tagging alone do not provide significant amounts of valid data for sentence integrity or derive any meaningful context from the corpus. Shallow parsing is the process of creating a parse tree with a singular information level, from the base of the tree, that is the root, to the leaves. The overall process then guarantees that more information can be available than the POS (Parts of Speech). Chunking is useful for segmenting and labeling multi-token sequences, with the primary purpose of identifying groups of "noun phrases" that can be used to enhance the next process, which is Entity Recognition.

E. NER Process (Named Entity Recognition)

One of the most useful techniques that aid in the data processing stage is to extract useful information from unstructured text data by identifying and categorizing it into predefined categories. NER successfully accomplishes this objective.Our objective is to use a similarity model to determine how closely the categorized resume data matches the requirements of recruiters, after categorizing the unstructured resume data into these diverse categories. There are several ways to use Named Entity Recognition [1] to extract relevant categories from unstructured data. One approach uses rules and syntax as a base, which involves developing our own algorithms that are tailored for use in domains that are specific to the employer. Regular expressions are contextualized to be utilized to identify named entities by searching for patterns in a string. Another method to approach NER as a sequence labeling problem is to use Bidirectional-LSTM and the Conditional Random Field algorithm [3].

F. Process of vectorising input data

Vector space is a geometric structure composed of a collection of elements known as vectors, which can be multiplied and combined by scalars. The overall process, which is popularly used in the domains of mining textual data, natural language processingandretrieval and processing of data, vectorisation is an algebraic model that represents documents as numerical vectors. Many models, especially those in the context of machine learning, sometimes involve vectors to be considered as the input data rather than UNICODE or ASCII data, making the process of vectorization significantly important. One common method of vectorizing data is to convert each word or string into a certain value within a data range, with each word occupying unique vector positions in the array/vector. Each corresponding value at every index represents the total count or frequency distribution of corresponding word occurring in the text. Since the result array is often smaller than the original corpus and its range of vocabulary, a vectorization strategy is almost necessary to be employed to account for this.

G. TF-IDF

“Term Frequency – Inverse Document Frequency" is the acronym for TF-IDF. TF-IDF was developed for document search and information retrieval. Since there are many terms that may not be important or relevant to be used for the similarity measure, therefore terms need to be measured relatively in terms of significance and th the overall weight they carry in terms of relevance in a corpus. Hence TF-IDF measures based on the weight of a word in terms of relevance as well as the frequency. The number of documents containing a word offsets the importance, which increases in proportion to its frequency in the document.

Therefore, terms like "this and "what," "who," "the," "if," and so on are frequently used in all documents. rank low, despite their numerous appearances, because they have little significance for that particular document. As shown in the first equation below, one can calculate the TF-IDF value for a word picked out from a file by the product of two of two variables or measures:

DOI: rp-9788770040723.113

$$TF - IDF(t,d) = TF(t,d) * IDF(t,d) \qquad (1)$$

Number of occurrences of each Term: It determines how frequently a term is repeated in a file document. You must modify or standardize this frequency because a certain term can be repeated more with much larger documents, when compared to documents that are smaller in length. The number of times a word appears in a file is divided by the total number of words in that file to get a normalized term frequency. It can be written [7]as shown in equation (2) below.

$$TF(t,d) = \frac{freq(t,d)}{\sum_i^n freq(t,d)} \qquad (2)$$

In context, the total number of files in the collection where the term t exists is referred to as count(t) and the unique document count is represented as N.

The TFIDF score of a word in a document is the product of these two metrics, which are represented by equation (2). If the TF-IDF metric of a term in a file is high it indicates the greater importance of that term. The CV's and the work interpretation were modelled into a vector space by our system.

We can use various similarity metrics to generate and rank scores between job designations and the documents. Cosine similarity is commonly used in text mining and information retrieval tasks. The metric aims to measure the cosine of the angle between two vectors in a high-dimensional space, which is a measure of similarity between the two vectors. The similarity score ranges from -1 to 1, with 1 indicating that the two vectors are identical and -1 indicating that they are completely dissimilar.

H. Cosine Similarity

(3)

A metric that measures how similar two things are is known as a similarity measure. Cosine similarity is a measure across the sine curve that measures the similarity across the sine. Because it is a symmetrical algorithm, we can mathematically represent it, as below:

$$\cos(\theta) = \frac{\vec{a}.\vec{b}}{\|\vec{a}\|\|\vec{b}\|} = \frac{\sum_{i=1}^{n} a_i b_i}{\sqrt{\sum_{i=1}^{n} a_i^2}\sqrt{\sum_{i=1}^{n} b_i^2}}$$

The dot product of the two vectors is +anbn. All pairs of elements' cosine similarity can be determined using this equation(3). The resume documents can then be ranked according to a particular query word vector. Cosine similarity, on the other hand, only looks at features that are related to the words in the text and will produce results that are less accurate. By including semantic information, similarity measures can be made more effective.

IV. Result and Analysis

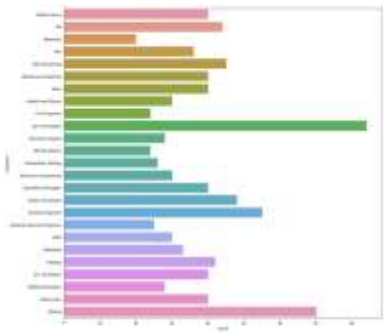

Fig 1. Categorization based on domain and skillsets.

The dataset was created by scraping across data from online job application sites, and was the condensed into a feature set of eight to nine features that would be relevant towards the use case. The model consists of ten domains that each are sub divided into job positions that require significantly different skill sets, such as Hadoop Engineers, .Net development, etc, and each resume is then categorized and plotted against a frequency distribution as Fig 1.

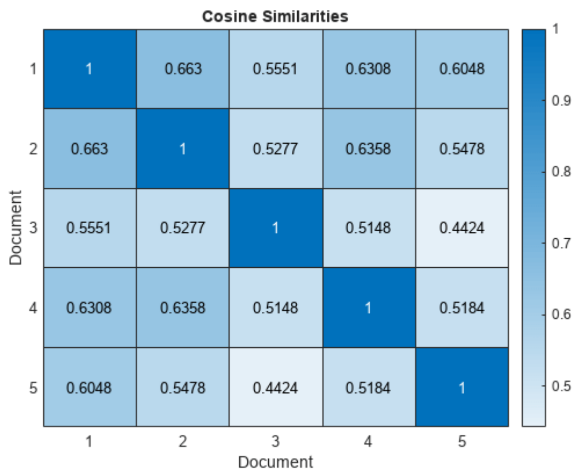

Fig 2. Cosine similarity measures against each resume and job description

The system model can then effectively categorise resumes based on the expected skill sets from each job group from the corpus and help determine what is the most suitable job for each candidate based on the position they applied to.The methodology used was successful in extracting the relevant skills from each resume as well as the personal details as well.

Using classifier measurements generated results that created strong precision scores for each skill classification as can be seen and cosine similarity metrics were able to evaluate the similarity of a resume against a job description, as demonstrated in the similarity matrix in Fig 2, the value closest to 1 indicating the highest similarity, and 0 indicating no similarity. Based on these metrics, the resumes are ranked.

V. Conclusion

Most organizations receive a large number of applications for each job posting. In today's world, it can be time-consuming for any organization to sort through the

DOI: rp-9788770040723.113
plethora of resumes to find the most relevant application for a position. The candidate's resume must be manually classified, which takes a long time and wastes resources.

Therefore, a proposed automated machine learning-based model that, based on the job description, recommends suitable candidates' resumes to HR. The proposed model is expected to be effective in two stages: to begin with, characterize the resume into various classes. Second, suggests a resume based on how closely it matches the job description.

With help of a LinearSVM classifier, there is an expectancy was able to accurately capture the resume insights and the semantics with an higher accuracy. Using deep learning models like these could improve the model's performance: LSTM, Recurrent Neural Networks, Convolutional Neural Network (CNN), and others. An integration with LinkedIn and GitHub APIs will expand use cases. The developed method can thereafter be utilized to develop an industry model if the industry is plagued by large number of applications. By including domain experts like HR professionals, a more accurate model can be constructed, and HR professionals' feedback aids in iterative model improvement.

***Abstract*—Nowadays, when global warming is increasing day by day, one of the most significant issues harming flora and animals around the planet today is wildfires. Forest fires are an uncontrollable disaster which causes damage to society as well as endangering nature. This paper uses machine learning regression techniques and artificial neural network algorithm for predicting the possibility of a forest fire to occur. This paper uses and compares various algorithms to try and deduce the best one possible out of all them. The various processes of a machine learning project are seen here and furthermore, techniques like cross-validation and hyperparameter tuning are carried out here.**

***Keywords*—cross-validation, hyperparameter tuning, CatBoost regression.**

I. Introduction

Wildfires are unplanned, uncontrolled, and unpredictable. As the name suggests they are often pretty huge and cover large swathes of an area on which there is combustible vegetation. Wildfires can be caused both naturally and by human intervention. The common natural cause for the start of a wildfire is generally lightning. Lightning strikes and then the dry fuel, mostly grass or twigs or other organic materials catches on fire. As for human causes, they range from slash-and-burn agriculture, a common practice in nomadic societies, to more serious methods like arson. But one of the most common ways a human can start a wildfire or a forest fire is the discarded cigarette butt after smoking.Across the world, there were about 4.2 million wildfires detected in 2019. Butwe are discussing only about the detected ones, which generally come into purview. Not to mention, the economic damage that can happen because of the fact that we lose multiple economic resources that are used in trying to extinguish the fires and also there can be massive economic damage due to the climate change threat.

Multiple continents experienced forest fires during the 2021 wildfire season. Even halfway through the year, there were more wildfires than ever before, and climate change-related increases in extreme weather events (such as droughts and heat waves) helped to amplify the size and scope of the fires. 2021 - Simlipal National Park in Odisha, Shimla-Kullu Wildfire, Dzukou Valley on Nagaland-Manipur borders.There are cases reported in Rajasthan' Sariska Tiger Reserve, Odisha's Similipal Wildlife Sanctuary, Madhya Pradesh's Ladkui jungles in Sehore district and the forest cover of the Majhgawan region of Satna district and the Perimalmalai Peak near the Kodaikanal hills of Tamil Nadu's Dindigul district were also struck with the disaster before the end of March, 2022.

Nowadays, forest fires have emerged as one of the most significant issues harming many regions worldwide. Wildfires are uncontrollable disasters which cause damage to society as well as endanger nature.

Why is there a need for ML when there is an accomplished forest department that has been handling these issues for quite some time? The answer is simple: ML can cover many parameters that the accomplished forest department cannot, such as latitude, longitude, satellite, version, and other variables, whereas the experienced forest department can only check on 3 to 4 parameters using human capability. In our use case ML actually helps out by covering various parameters that would otherwise not be covered due to the sheer information overload that would happen and would make it nearly impossible to actually deduce and come to a decision.

Our forest fire prediction technique uses and takes in several factors that can affect a fire and then output the confidence of the fire occurring. This dataset contains various features like the latitude, longitude, brightness, the terrain that is visible from the satellite, and the time of the day the data was collected, i.e., whether it was daytime or night, and other factors. Training, evaluating, and comparing the performances ofseveral ML algorithmsare carried out in this paper.In the training of the machine learning algorithms, we use two different datasets, that are curated with a few different features that are selected using the feature selection process and further processed using feature engineering, after which the data is finally split into training and testing data.We examine the effectiveness of the various methods using the R2 score, Mean Absolute Error, and Mean Squared Error as the various metrics and we also use a technique called Cross Validation that checks how the model performs on completely unseen data. Finally, hyperparameter tuning is conducted on the best-performing algorithm because hyperparameter tuning helps us in choosing the ideal set of hyperparameters. The hyperparameter is a parameter that controls the learning process, but by contrast, other parameters are learned. The tuning of the hyperparameters are absolutely critical because they affect and control the behaviour of the model. This is done in order to achieve higher accuracies and better performance from the model, as the default parameters may

DOI: rp-9788770040723.114

not suit the existing data due to variations in the problem statement.

II. Literature Review

A. Forest Fires Detection Using Machine Learning Techniques

In this paper[1], they have considered various climate and physical factors to be mapped. The models experimented with are Linear, Ridge, and Lasso Regression. The way of working was first to take all the features into account and only 70% the next time around. Out of the three models, Linear displayed the best results.

B. A Perceptron Algorithm for Forest Fire Prediction Based on Wireless Sensor Networks

They illustrate the use of perceptron algorithms [2] with wireless sensor networks to offer a quick and trustworthy technique to detect a potential forest fire early. Weather data like temperature, humidity, and many more are collected with the help of sensors. This data is then passed to a sensor which calculates a value called Fire Hazard Index.

C. Evolution of Burned Area in Forest Fires under Climate Change Conditions in Southern Spain Using ANN

This paper [3] is a study of the effectiveness of an artificial neural network in predicting the burned area and then using that information to evaluate how future wildfires will develop and the area they would affect in Southern Spain.

D. Machine learning to predict final fire size at the time of ignition

In this paper [4], an investigation is conducted into the size of a fire at the end and how accurately we can predict and control it at the time of ignition. With the help of decision trees, the fires are classified into small, medium, and large with a 50.4 ± 5.2% accuracy. This model predicted that 40% of the ignitions would develop into big fires, which would then account for 75% of the overall burned area. None of the other classification methods, including Random Forest and Multi-layer Perceptrons, performed as well as the decision tree approach in terms of output.

E. Learning to predict forest fires with different data mining techniques

Using a variety of data mining techniques, such as predictive modelling based on GIS of a forest structure, weather prediction model Aladin, and MODIS satellite data, a study [5] on how to anticipate forest fires in Slovenia was conducted. Decision trees, logistic regression, and Random Forest with bagging and boosting of decision trees were few of the Machine Learning techniques used. Bagging Decision Trees was the model with the best performance.

F. Detection of forest fires using machine learning technique: A perspective

In the quest to predict forest fires, a variety of machine learning methods, including SVM, regression, decision trees, and neural networks, have been experimented with [6]. The results of this paper explain why regression is the better approach to be taken in the detection of forest fires by dividing the dataset for higher accuracy. The paper mainly focuses on the quick detection of forest fires by completing the analysis before the other machine learning techniques.

G. Burned area prediction with semiparametric models

To describe and forecast the weekly burnt area, two semiparametric time-series models [7] are implemented and tested. The two models are Autoregressive moving average after smoothing and smoothing after Autoregressive moving average. They are examined and contrasted with a purely parametric model, and it is found that the first method yields results that are less error-prone than the second.

H. Forest fire prediction using machine learning and deep learning techniques

The goal of the paper [8] is to use various machine learning and deep learning approaches to predict the occurrence of forest fires. To determine the optimal model, a comparison analysis has been done. The Decision Tree has the highest accuracy of any model, at 79.6%. Additionally, the implementation included a User Interface for simple and clear access.

I. Forest fire prediction using ML and AI

In this paper [9], algorithms such as SVMs, KNN, Logistic Regression, Random Forest, as well as decision trees are implemented to describe a risk prediction method in the context of forest fires. Parameters such as humidity, temperature, and oxygen were considered as factors in forest fire prediction. The results of the paper indicate that the danger of the occurrence of forest fires can be predicted with an accuracy of up to 89.47% with the help ML machine learning models.

J. Riau forest fire prediction using supervised machine learning

In this study [10], data of the weather is used as a primary source to analyze forest fires and build early warning systems for the Indonesian island of Riau. Supervised ML techniques such as Bayesian networks and decision tree were utilized to build prediction models that provided an accuracy of 99%. Although decision trees were found to be slightly less accurate than Bayesian networks, the study found that both models were efficient in extracting relevant features in an effective manner.

K. Artificial Intelligence for Forest Fire Prediction

This paper [11] describes and analyzes methods to predict forest fires by leveraging artificial intelligence. The ideal model recommended utilizes support vector machine algorithm as the base algorithm for the prediction model, wherein past data is used to predict hazard levels for the day. The paper concludes that algorithms such as support vector machines can predict forest fire hazards with 96% accuracy even with a limited amount of data.

L. Predicting Burned Areas of Forest Fires: an Artificial Intelligence Approach

This research [12] was a study on how to create an intelligent system based on genetic programming to identify and forecast the area that burns using data specific to the forest under analysis and readily available meteorological data. Due to its smaller MAE in comparison to standard genetic programming and state-of-the-art machine learning

DOI: rp-9788770040723.114

methods, geometric semantic genetic programming was used, and the experiment results obtained were significantly better. This justifies further research into the geometric semantic method as it may be helpful for further learning deployment.

M. Forest Fire Prediction Using Machine Learning Techniques

This paper [13] is a comparative study of various models which are used to predict forest fires like Decision Trees, Random Forest, Support Vector Machines, etc., and to also compare with the RandomizedSearchCV algorithm used in the current study. The improvement proposed in this study is the usage of meteorological parameters like temperature, rain, wind and humidity. RandomizedSearchCV fits various decision trees together and uses averaging in order to improve the accuracy of prediction and also to control overfitting, a common problem noticed in various machine learning models. The results show that factors like extreme temperatures, moderate humidity and higher wind speeds exponentially increase the chance of burning in a forest fire. It is also noticed that compared to other areas, the forests are inclined to catch fire first.

N. Parallel SVM model for forest fire prediction

This paper [14] talks about a new method of trying and detecting forest fires with the help of Parallel SVM. It is a newer method which has been developed in order to tackle the problems of low efficiency and high overfitting which affect the actual real-world results. Parallel SVM intends to provide better performance also than conventional SVM, with the help of PySpark. The use of meteorological data is also done here and a better RMSE value is observed.

III. METHODOLOGY

O. Overview

The objective of this paper is to evaluate several ML algorithms such as linear regression, support vector machine, gradient boosting, and so on, and compare their performances. The best-performing algorithm can then be used to forecast the occurrence of a wild fire with confidence and reasonable accuracy. The overall methodology for this paper follows a streamlined path that helps in clarity of thought as you follow through. We start with standard procedures such as performing data pre-processing on imported data. We will then perform feature selection and feature engineering before splitting the data into training and test datasets. Next, we train the model, following which we validate the model with the various machine learning algorithms that we have proposed. Finally, we perform hyperparameter optimization. The problem is a regression task that takes the described features into account and provides an output that represents the chances of the occurrence of a forest fire.

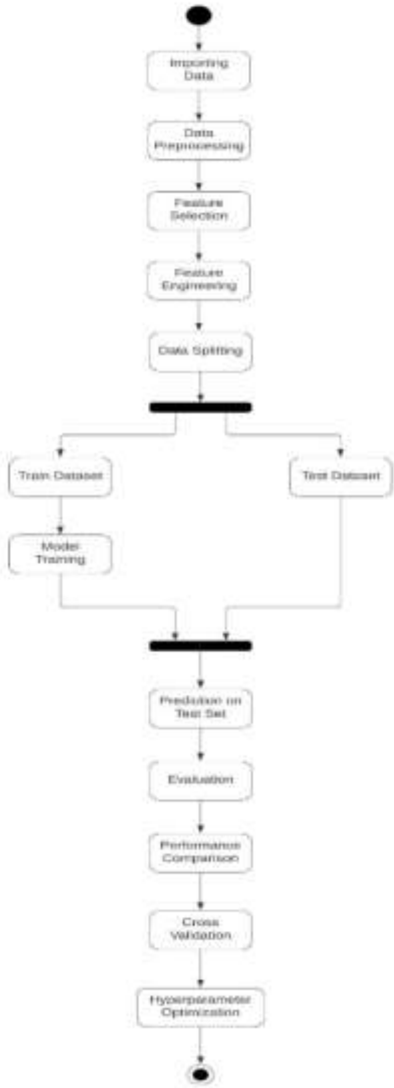

Fig. 1. MethodologyDiagram

P. Environment

The entire project is implemented on Google Colaboratory, commonly known as Google Colab. It is a free Jupyter notebook environment that runs on the cloud that allows users to write Python code through the browser. Hosted by Google, Colab provides access to powerful computing resources such as Graphical Processing Unit (GPU) and Tensor Processing Unit (TPU), which allows for seamless work on the platform. Google Colab is thus particularly useful for researchers focused on data science and machine learning, who wish to collaborate with others on coding projects in a shared environment without hindrances. Unfortunately, Google Colab might be unable to process larger datasets as it is a limited platform, and does not support all Python libraries. However, for the purposes of this paper, Google Colab is a suitable work environment which is more than capable of handling the necessary datasets and libraries. In order to increase the scalability of this project, environments such as Kaggle can also be utilized.

DOI: rp-9788770040723.114

Q. Importing Data

The data is imported via a private link. Google Colab allows users to browse directories in the local system. The dataset contains 36011 rows and 15 columns. The features of the dataset that are taken into consideration include latitude and longitude, brightness, terrain from satellite, time of the day during data collection, fire radiative power, and fire type. This data is uploaded into Google Colab's workspace directory, which provides fast file access wherein uploaded files can be accessed without their absolute path.

R. Data Preprocessing

An important phase of any machine learning research is data preprocessing. It is a technique that involves transforming raw data into well-formed datasets and cleaning the raw data in order to check whether or not it is fit for analysis. More often than not, raw data is incomplete and inconsistent. Therefore, preparing the data has a direct impact on the final results post-analysis. The primary steps that are usually involved in data preprocessing are data cleaning, data integration, data transformation, data reduction, and data discretization. We first check the information generated by the dataset. This information primarily lets the user gain an understanding of the data type of each column as well as the total number of columns within the dataset, along with the count of non-null elements that are present in each column. This information helps make data cleaning easier. We use the describe() function, which is a function that comes with the pandas library, to check the statistical summary of the data. Doing so also helps us find any discrepancies in the data. Using the describe() function helps us in getting a quick understanding of the distribution and range of values in the dataset. We can additionally identify any potential outliers, missing values, or other problems pertaining to the quality of the data as a whole. In this case, no discrepancies are discovered. In order to check the count of null elements or corrupt elements in the columns of the dataset, we use the Python library missingno [reference]. The ability to understand the distribution of missing data is provided by this library. The visualisations can be done in form of bar charts or heat maps. It is possible to see where the missing values are and examine their relationships to the columns thanks to Missingno. It displays null values as a white line between a black column block. In this instance, we find that there are no null values or corrupt values in the dataset.

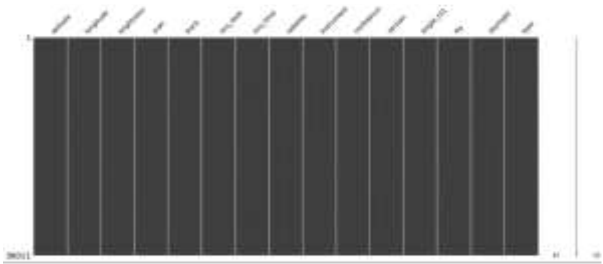

Fig. 2. MissingNo Evaluated Result

S. Feature Selection

Feature Selection is the process of selecting the most important features from a dataset to use in model construction. Feature selection helps to reduce the dimensionality of the dataset and refines the data to present only the most relevant variables. The goal of feature selection is to decrease the number of input variables to obtain only those variables which are the most useful in predicting the target variable. This can result in improved accuracy and performance of the model. By removing redundant or irrelevant features we can also reduce computational complexity and improve overall interpretability. At first, we remove the features acq_date, instrument, acq_time, and version. We do so as these features do not carry any relevance for the algorithm. Therefore, the model cannot be trained with these features. Once the aforementioned features have been removed, a correlation matrix is drawn out for the remaining features. A correlation matrix is essentially a table which describes the correlation coefficients between the various variables, or features in this case. A correlation matrix is often visualized in the form of a heatmap. A correlation matrix can help discern observable patterns within the data or can be used as inputs for further analyses. In this case, the correlation threshold is fixed at 0.6. This means that columns with a correlation coefficient of greater than 0.6 depict a high or strong correlation. These columns shall be dealt with. Based on the correlation observed, two datasets are created.

T. Feature Engineering

We perform feature engineering on both datasets that were generated after the process of feature selection. For dataset 1, One Hot Encoding is performed on the categorical columns of the dataset. One Hot Encoding allows the representation of categorical variables in the form of binary vectors. This can then be provided as input to machine learning models for further processes. In this case, One Hot Encoding is performed using the pandas function pd.get_dummies on Python. This function converts categorical data into "dummy" variables. As mentioned above, this dummy variable is binary and is either of the value 0 or 1. We follow a similar procedure for dataset 2, by performing One Hot Encoding on the categorical columns of the dataset with the help of pd.get_dummies. In addition to this, the range of the column scan is divided into separate categories using the method of binning. Binning is a method that reduces continuous and discrete data cardinality by grouping related values in "bins" so as to lower the number of distinct values in the data.

U. Data Splitting

As the name suggests, data splitting involves the splitting or dividing of data into subsets. Each subset serves a different purpose. For example, one subset can be used to train the machine learning model while the other subset can be used to test the model. The training subset can help develop the model while the test subset can assess the performance of the trained model. The most common method to split data into subsets is random sampling. In this case, we use the train_test_split function provided by sklearn library in Python. Sklearn, or Scikit-learn, is one of the most robust Python libraries that can be used abundantly in machine learning applications. We split the datasets such that the size of the test subset is 20% of themain dataset and the training dataset is 80% of the main dataset. We find that the training data has 28808 rows while the test data contains 720 rows in total. Since our aim is to predict the chances of confidence of the occurrence of a forest fire, our target column is "confidence". This column will give us the probability of forest fire occurrence. Dataset 2 is scaled with the help of StandardScaler() function from the sklearn

DOI: rp-9788770040723.114

library. It is important to scale data before modelling in order to avoid issues such as misclassification or bias. By standardizing the data, we can scale the data with zero mean and unit variance. StandardScaler helps us achieve this.

V. Model Training and Prediction

We use the sklearn library for initializing various regression machine-learning algorithms. We also use this library to calculate the performance metrics such as r2 score, mean absolute error, and mean squared error. These performance metrics provide us with an insight into the performance of the model. First, the model is fit onto the training data, after which it is tested on the testing data. In this case, the machine learning algorithms used for training are linear regression, support vector regression, decision tree, random forest regression, gradient boosting, extreme gradient boosting, and catboostregressor.

Linear Regression - Linear regression is one of the most rudimentary machine learning algorithms. It is used to forecast the value of a continuous dependent variable based on the value of a continuous independent variable. It is a method for supervised learning that can carry out regression tasks.

- Support Vector Regression- SVR, also known as support vector regression, is a supervised machine learning technique that may be applied to regression tasks. It works on a similar principle to that of a traditional support vector machine and defines an acceptable error through a hyperplane.
- Decision Tree Regression - Decision trees work on the principle of supervised learning and can be used for both classification and regression tasks. Decision trees contain nodes such as the root node, interior nodes, and leaf nodes, as well as branches connecting these nodes in a tree-like structure. Decision trees are helpful as they are easy to understand and possess a rather simple structure.
- Random Forest Regression - For regression on a supervised method, Random Forest Regression uses ensemble learning. The mean of the classes is produced as a prediction of the trees after numerous decision trees have been built. This algorithm is extremely powerful and provides good performance on non-linear models as well. However, it is prone to overfitting.
- Gradient Boosting - Gradient boosting is a kind of ensemble method that provides high accuracy and prediction speed. The principle behind gradient boosting involves the sequential building of models to minimize error. Gradient boosting regressor is used when the target column is continuous and not discrete.
- Extreme Gradient Boosting- Extreme Gradient Boosting or XGB wherein decision trees are created sequentially. In XGB, weights are assigned to independent variables to predict results. XGB is also a supervised learning algorithm and is very commonly used in machine learning implementations as it is an optimized implementation of gradient-boosted trees.
- CatBoostRegressor- CatBoostRegressor is a class in CatBoost which performs regression tasks. CatBoost uses gradient boosting algorithm to handle categorical features without encoding and is an open-source library. It acts as an alternative to XGB and has a simpler tuning process for hyperparameters. Additionally, it is also much faster than XGB algorithms.

W. Evaluation

Once each model is trained, we evaluate its performance. We do so by calculating the performance metrics for the respective model. The performance metrics that we take into consideration for evaluation for this regression task are the r2 score, mean absolute error (mae), and mean squared error (mse). We calculate each model's metric between the predicted values on the test dataset and the actual values of the target column of the test dataset.

X. Cross-Validation

The effectiveness of machine learning models is frequently assessed using the cross-validation method. Through a number of subset iterations, the data is split into various training and testing subsets. The performance of each iteration is considered, and the results are averaged out to provide an estimate of the model's overall performance. Cross-validation is essential as it can provide a more accurate estimate of the model's performance than a single training-testing iteration. Moreover, it plays a major role in reducing overfitting and identifying hyperparameters for the model. After comparing the performance of each of the models in our research based on their performance metrics, we perform k-fold cross-validation on our dataset. The k-fold cross-validation method is useful because it helps us to improve the model prediction in cases of insufficient data. This method helps us to determine the skill of any model on unseen data. The scoring is based on the r2 score obtained. We also compare the cross-validation mean of each algorithm with the corresponding cross-validation standard deviation. Based on this the cross-validation score is obtained, and the algorithm with the best performance is selected for hyperparameter tuning.

Y. Hyperparameter Tuning

Hyperparameter tuning essentially involves selecting the best hyperparameters for a certain machine-learning model. We set the hyperparameters before training as they are not learned by the model during training. It is necessary that hyperparameters must be selected such that they can optimize the performance of the model so that when hyperparameter tuning is carried out, only the hyperparameters that provide the best performance on the validation set can be found. We perform hyperparameter tuning with the help of GridSearchCV. This allows for an automated and systematic search for the optimal hyperparameters, which can improve the performance of the model, as well as improve its generalization. Once we have the best parameters, we conduct a final prediction and calculate the resulting performance metrics. Then, the generalization for both the training and testing data is calculated using the score() function.

DOI: rp-9788770040723.114

IV. RESULTS

The algorithms involved in this study were compared twice for each dataset. At first, the performance of the testing data was checked against the models, and then secondly, the performance is compared after the k-fold cross-validation method is applied.

Z. *Testing Results*

The testing results were obtained by first training each and every algorithm on the training data and then the predictions are made on the test data. The effectiveness of the algorithms can be assessed using a variety of metrics. R2 Score, Mean Absolute Error, and Mean Squared Error are used in this instance.

The R2 score, sometimes referred to as the coefficient of determination, is a statistical indicator of how much variance in the dependent variable in a regression model can be anticipated from the independent variable. R2 score is calculated as 1 - (SSres/SStot), where SSres stands for squared residual sum and SStot for square total sum.

Mean absolute error is a measure of errors between paired observationsthat can express the same phenomenon. It is considered the average of all absolute errors, which is calculated like this, (1/n) * Σ|yi – xi|, here ‘n’ represents the number of observations, ‘yi’ represents the predicted value and ‘xi’ represents the actual value.

Mean squared erroris used in machine learning as a method of evaluation of the performance of a regression model. The value corresponds to the expected value of the squared error loss, which corresponds to it being a risk function.

An R2 score of above 0.6 is generally considered to be a model which is useful, else it may not be worth trying to work upon. For dataset 1, which contained the columns ‘track’ and ‘brightness’, the performance of each algorithm is as follows in the table below

TABLE I. DATASET I SCORES

Algorithms	R squared Score	Mean Absolute Error	Mean Squared Error
CatBoost Regression	0.634611	9.887964	196.594296
XGB Regression	0.627698	10.003912	200.313794
Random Forest Regression	0.610143	10.045055	209.758887
Gradient Boosting	0.595831	10.702130	217.459224
Linear Regression	0.423432	13.804181	310.217179
Support Vector Regression	0.362626	13.433373	342.933564
Decision Tree Regression	0.306102	12.242677	373.345828

For dataset 2, which had the correlated columns ‘scan’ and ‘frp’, the performance of the algorithms on testing data are as follows

TABLE II. DATASET II SCORES

Algorithms	R squared Score	Mean Absolute Error	Mean Squared Error
CatBoost Regression	0.661975	9.408696	183.255066
XGB Regression	0.659588	9.356515	184.548962
Random Forest Regression	0.639109	9.642471	195.651349
Gradient Boosting	0.623193	10.263339	204.279866
Linear Regression	0.445729	13.603326	300.489397
Support Vector Regression	0.420726	12.563390	314.044553
Decision Tree Regression	0.313652	12.131751	372.093156

In both the cases, for Dataset I and II, we see that the catboostregressor was the one with the best performance, even after k-fold cross-validation. The XGB and Random Forest Regression algorithms are a close second and third in terms of results in R2 score.

AA. *Cross-Validation Results*

The next set of results were derived from after the k-fold cross-validationmethod. Cross Validation mean and Cross Validation standard deviation are calculated. Both are defined as the parameters that can be used to estimate a model’s performance.

For Dataset I, the results are as follows in the table

TABLE III. DATASET I SCORES

Algorithms	Cross Validation Mean	Cross Validation Std
CatBoost Regression	0.641353	0.017031
XGB Regression	0.636471	0.017743
Random Forest Regression	0.616798	0.020645
Gradient Boosting	0.601998	0.016819
Linear Regression	0.420587	0.013146
Support Vector Regression	0.361914	0.008568
Decision Tree Regression	0.296257	0.029647

For Dataset II, the results are also placed below

TABLE IV. DATASET II SCORES

Algorithms	Cross Validation Mean	Cross Validation Std
CatBoost Regression	0.620616	0.032393
Gradient Boosting	0.607242	0.027426
XGB Regression	0.605931	0.033517
Random Forest Regression	0.592208	0.030492
Linear Regression	0.432178	0.027499
Support Vector Regression	0.414495	0.029684
Decision Tree Regression	0.251440	0.045719

As we see, CatBoost Regression is again far ahead of the other algorithms that are taken in consideration and this can be taken as proof that CatBoost works as the best-performing algorithm from all others.

We now find the best parameters for CatBoost to work on with the help of GridSearchCV, a hyperparameter tuning library that presents us with the best values possible. For

DOI: rp-9788770040723.114

Dataset I and II, the best parameters were a depth of 15, iterations as 100 and a learning rate of 0.2. These values are auto-selected and tuned to provide the best-performing model possible.

We also see a bump in the scores and values for Dataset II after the cross-validation and a stable value for Dataset I.

V. Conclusion

Our paper is a deep dive into the various algorithms that can be used to detect wildfires and to estimate the accuracy of a forest fire to occur. We have used different methods, ranging from linear regression to CatBoost Regression to try and derive meaningful and sensible results. We start by performing data preprocessing, a crucial step to make the data that is available to us of use to us. We then continue on to making Features from it, deciding what is required and what is not. Then we move to the data splitting, from which we then go to the training and prediction scenarios, in which multiple models are selected and trained upon. The models are then evaluated and then finally, Cross Validation and Hyperparameter Tuning take place to finalize all the details for the model that is the best, which is the CatBoost model, which is because of the fact that CatBoost uses both the method of decision trees and gradient boosting. Boosting is a method which combines multiple weaker models and with the help of greedy search, create a strong and competitive model. Gradient Boosting also helps in rapidly reducing errors by sequential fitting.

Another improvement that can be made is the building of a web application that can be mass-distributed to get even laymen, who are not interested in the know-how of the model to use the model to get their predictions

***Abstract*—This paper presents an automated conception detection system using UHF RFID technology for monitoring the movement and activity of sows inside a pig pen. The system utilizes temperature, feeding pattern, and hormone level sensors to detect and predict the onset of estrus and pregnancy in sows. UHF RFID technology is used to track the movement of sows inside the pig pen, and the data is collected and analyzed by a microcontroller-based system. The system is designed to be cost-effective and easy to install, making it suitable for small pig farms. The current systems for monitoring the activity of pigs in Denmark and the US are very expensive and not feasible for small pig farms. Therefore, we propose an automated system that uses UHF RFID technology to monitor the movement of sows inside the pig pen. The system consists of a microcontroller-based unit, UHF RFID readers, and sensors for monitoring temperature, feeding patterns, and hormone levels. Temperature sensors are used to monitor the body temperature of sows, which changes during estrus and pregnancy. Feeding pattern sensors are used to monitor the feeding behavior of sows, which can provide valuable information about their reproductive status. Hormone level sensors are used to detect and measure hormone levels in the blood, which can indicate whether a sow is in estrus or pregnant. UHF RFID technology is used to track the movement of sows inside the pig pen. UHF RFID tags are attached to the sows, and UHF RFID readers are installed in various locations inside the pig pen. The readers detect the tags as the sows move around the pen, and the data is collected and analyzed by the microcontroller-based unit. The proposed system offers a cost-effective and easy-to-install solution for monitoring the activity of sows in small pig farms. The use of UHF RFID technology allows for accurate and efficient tracking of sow movement, and the integration of temperature, feeding pattern, and hormone level sensors provides valuable information about the reproductive status of the sows. Overall, this system has the potential to improve the reproductive performance of sows and increase the profitability of small pig farms.**

***Keywords*RFID technology, automated conception detection, swine industry, sensors, machine learning, pregnancy detection.**

I. Introduction

Pig farming is an essential aspect of animal husbandry, contributing significantly to the meat industry. One of the critical components in pig farming is the reproductive cycle, which requires precise monitoring to ensure successful breeding and conception. With advancements in technology, automated systems for monitoring pig behavior and reproductive cycles have been developed. However, these systems are expensive and not feasible for small pig farms. In Denmark and the US, existing systems and products for monitoring activity in pig pens have been developed, but they are expensive to implement in small pig farms.

Existing Systems and Products for Monitoring Activity in Pig Pens

In Denmark, an automated monitoring system called "PigActivity" was developed to monitor the activity of sows and piglets in the pen. The system uses sensors attached to the sow and piglets to measure their activity levels, and the data is analyzed using a computer algorithm to determine the health and reproductive status of the animals. The system is costly to implement, making it unfeasible for small pig farms.

Similarly, in the US, a product called "Swine Management System" has been developed to monitor pig behavior and reproductive cycles. The system uses cameras and sensors to track the activity of sows and boars, and the data is analyzed using a computer algorithm to determine the reproductive status of the animals. The product is also expensive to implement, making it unsuitable for small pig farms.

Expensive Nature of Existing Systems

The cost of implementing existing systems for monitoring activity in pig pens is primarily due to the use of high-tech sensors and computer algorithms for analyzing data. The sensors used in these systems are expensive, and the computer algorithms required for analyzing the data generated by the sensors are complex and require

DOI: rp-9788770040723.115

specialized expertise to develop and maintain. Additionally, the high cost of electricity and internet connectivity required for running these systems further adds to the expense of implementing them.

In conclusion, existing systems and products for monitoring activity in pig pens are expensive and unsuitable for small pig farms. Thus, there is a need for an affordable and automated system that can monitor pig behavior and reproductive cycles without the need for high-tech sensors or complex computer algorithms. The use of RFID technology could provide an innovative solution to this problem, enabling the development of an automated conception detection system for small pig farms. The following sections will describe the proposed system in detail, including the hardware and software requirements and the expected outcomes.

II. Literature survey

Automated Conception Detection using RFID technology is an emerging field in the pig farming industry. The use of RFID technology has proven to be a reliable and cost-effective solution for monitoring the reproductive health of sows. RFID tags are implanted in the sows which enable the tracking of their movement and behavior in the pig pen. This technology is proving to be a game-changer as it eliminates the need for human intervention in the monitoring process and is less intrusive for the sows. In this literature survey, we will compare 10 different papers on similar topics to evaluate the state of the art in Automated Conception Detection using RFID technology.

[1]A review of precision livestock farming technologies for enhanced welfare and productivity in farmed systems" by Turner et al. (2017) This paper presents a review of the existing literature on precision livestock farming technologies and their applications in the livestock industry. It discusses the various sensors used for monitoring animal behavior and the need for more cost-effective and automated systems. The authors suggest that RFID technology has the potential to revolutionize the livestock industry by providing accurate and real-time data on animal behavior.

[2]Real-time sow activity monitoring system using a low-cost inertial measurement unit" by Jeon et al. (2018) This paper presents a real-time sow activity monitoring system using a low-cost inertial measurement unit. The system is designed to measure the behavior of sows in the pig pen and uses machine learning algorithms to detect estrus. The authors suggest that their system can provide reliable and cost-effective monitoring of sow behavior and can be used to improve the reproductive efficiency of pig farms.

RFID-based system for monitoring the feeding behavior of individual pigs" by Luo et al. (2014)[3] This paper presents an RFID-based system for monitoring the feeding behavior of individual pigs. The system uses RFID tags to track the movement of pigs in the pig pen and monitor their feeding behavior. The authors suggest that their system can be used to improve the feeding efficiency of pig farms and reduce the wastage of feed.

[4]Monitoring animal behavior and environmental factors using wireless sensor networks and ZigBee technology" by Zhou et al. (2016) This paper presents a wireless sensor network (WSN) based system for monitoring animal behavior and environmental factors in the pig pen. The system uses ZigBee technology to transmit data from the sensors to a central monitoring system. The authors suggest that their system can provide real-time monitoring of animal behavior and environmental factors, which can be used to improve the welfare and productivity of livestock farms.

"A real-time monitoring system for sow estrus detection using an accelerometer sensor" by Li et al. (2018) [5]This paper presents a real-time monitoring system for sow estrus detection using an accelerometer sensor. The system is designed to detect the physical activity of sows in the pig pen and uses machine learning algorithms to detect estrus. The authors suggest that their system can provide accurate and cost-effective monitoring of sow behavior and can be used to improve the reproductive efficiency of pig farms.

[6]"RFID-Based Activity Recognition for Supporting Health and Well-being Monitoring of Sows" by Bhattacharya et al. (2018) This paper presents an RFID-based activity recognition system for supporting the health and well-being monitoring of sows. The system uses RFID tags to track the movement of sows in the pig pen and machine learning algorithms to detect changes in their activity levels. The authors suggest that their system can be used to improve the health and well-being of sows in the pig pen.

“Automated Detection of Heat in Dairy Cows Using Computer Vision," by J. H. Park et al. (2017) [7]. This paper proposes a system that uses computer vision to automatically detect heat in dairy cows. The system uses cameras to monitor the cows and analyze their behavior to determine if they are in heat. The authors achieved an accuracy rate of 97.5% using their system. While the focus of this paper is on dairy cows, it presents an interesting approach to automated detection of animal behavior.

"RFID-Based Livestock Management System," by Y. Zheng et al. (2015)[8].This paper presents a livestock management system based on RFID technology. The system uses RFID tags to track the movement and location of livestock, and a database to store and analyze the data. The authors found that their system improved the efficiency and accuracy of livestock management, and reduced labor costs. This paper is relevant to our project, as we will also be using RFID technology to monitor the movement of sows.

[9]"An Automated Heat Detection and Alert System for Dairy Cows Using the Internet of Things," by Y. Zhang et al. (2018) [10]. This paper proposes an automated heat detection and alert system for dairy cows using the Internet of Things (IoT). The system uses sensors to monitor the behavior of cows and detect heat, and sends alerts to farmers via mobile devices. The authors achieved an accuracy rate of 93% using their system. While this paper focuses on dairy cows, it provides valuable insights into how IoT technology can be used to monitor animal behavior.

DOI: rp-9788770040723.115

[11]Automated Swine Management Using UHF RFID System" by Kim et al. (2015). This paper proposes a system for automated swine management that utilizes UHF RFID technology. The authors state that the proposed system can monitor the movement of pigs and track their growth and health status in real-time.The system includes UHF RFID readers and antennas placed throughout the pigpen, as well as RFID tags attached to the pigs. The authors note that the use of UHF RFID technology allows for a longer read range and faster read rates compared to other RFID technologies[12], making it more suitable for monitoring pigs in large-scale farming operations. The paper outlines several experiments that were conducted to evaluate the performance of the proposed system. These experiments include testing the accuracy of the system in detecting the location of the pigs, as well as monitoring the growth and health status of the pigs over time.

III. Implementation

A. *Data Input*

The input data for this project is obtained from various sensors and RFID readers placed in the pig pen. The sensors are used to monitor different parameters, such as temperature, feeding patterns, and activity levels, while the RFID readers are used to monitor the movement of the sows inside the pen. The temperature sensors are placed in various locations inside the pig pen to obtain temperature readings. These sensors are connected to the microcontroller via wires or wireless communication protocols such as ZigBee or Bluetooth. The temperature data is then sent to the microcontroller, which processes the data and stores it in the database. The feeding pattern sensors are placed in the feeding trough and are designed to monitor the feeding pattern of the sows. These sensors are also connected to the microcontroller via wires or wireless communication protocols such as ZigBee or Bluetooth. The feeding data is then sent to the microcontroller, which processes the data and stores it in the database. The RFID readers are placed at the entrance and exit of the pig pen, and are used to monitor the movement of the sows inside the pen. The RFID tags are attached to the sows' ears, and the reader detects the tag when the sow passes through the reader. The RFID data is then sent to the microcontroller, which processes the data and stores it in the database. All the input data collected from various sensors and RFID readers are then processed and analyzed using various algorithms to detect patterns and trends. The data is then used to predict the pregnancy and estrus of the sows and provide recommendations for appropriate breeding times.

B. *Data Analysis*

The data analysis part of the implementation process involves the processing and interpretation of the collected data. Once the input data has been collected from the sensors and stored in the database, it is necessary to perform some form of data processing to extract meaningful insights and observations. In this project, we plan to use machine learning algorithms for data analysis. Specifically, we will use techniques such as clustering, classification, and regression to analyze the data collected by the sensors. We will also use statistical techniques such as hypothesis testing to validate the accuracy of the data. To prepare the data for analysis, we will first clean and preprocess it. This involves removing any irrelevant or erroneous data points, and transforming the data into a format that can be readily used by machine learning algorithms. We will also normalize the data to ensure that the various sensor readings are on a comparable scale. Once the data is preprocessed, we will use clustering algorithms to group sows based on their behavior patterns. This will help us identify patterns in the data and gain insights into the behavior of the sows. We will then use classification algorithms to predict whether a sow is in estrus or not based on the sensor data[13]. Finally, we will use regression techniques to predict the probability of conception based on the collected data. Overall, the data analysis process is critical for gaining insights into the behavior of the sows and predicting the optimal time for conception[14]. The use of machine learning algorithms will help us process and analyze the large volumes of data generated by the sensors, and provide accurate and reliable results.

C. *Data Processing*

In the data processing stage, the collected data will be cleaned, transformed, and combined into a format that is ready for analysis. This involves performing quality checks on the collected data, identifying and resolving any inconsistencies, and converting the data into a format that can be easily analyzed. The processing stage will involve using statistical and machine learning techniques to extract meaningful insights from the collected data. This will include identifying patterns and trends in the data, as well as performing statistical tests to determine the significance of any relationships that are found. Once the data has been processed and analyzed, the results will be used to develop algorithms that can be used to automate the detection of conception in sows based on their activity patterns. These algorithms will be designed to take into account the various factors that have been identified as being indicative of pregnancy, including changes in activity levels and feeding patterns. The data processing stage will also involve developing a user-friendly interface for accessing and visualizing the results of the analysis. This will allow users to easily understand the findings of the study and make informed decisions based on the insights gained from the data.

D. *Methodology*

The methodology section of this project outlines the step-by-step process that will be followed to implement the automated conception detection system using RFID technology. The methodology can be divided into the following steps:

- System Design: This step involves designing the hardware and software components of the system. The design will be based on the functional and non-functional requirements of the system.
- Sensor Installation: This step involves installing the various sensors required for the system. The sensors will be installed in the pig pen to monitor the various parameters, such as feeding patterns, temperature, and movement of the sows.

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.115

- RFID Reader and Antenna Placement: This step involves placing the RFID reader and antennas at strategic locations in the pig pen to ensure proper detection of the RFID tags attached to the sows.

- Data Acquisition: This step involves collecting the data from the various sensors and RFID readers. The data will be collected at regular intervals and stored in a database.

- Data Processing: This step involves processing the data to extract meaningful information. This will involve cleaning the data, removing outliers, and filtering the data to reduce noise.

- Data Analysis: This step involves analyzing the data to identify patterns and trends. The data will be analyzed using statistical methods, machine learning algorithms, and other data analysis techniques.

- Conception Detection: This step involves using the data collected and analyzed to detect when a sow is in estrus and therefore ready for conception. This will be done by monitoring changes in feeding patterns, temperature, and hormone levels.

- Notification: This step involves sending a notification to the farmer or the system administrator when a sow is detected to be in estrus.

- System Evaluation: This step involves evaluating the performance of the system. The system will be evaluated based on its accuracy, reliability, and efficiency.

Overall, the methodology outlines a comprehensive approach for implementing the automated conception detection system using RFID technology. It covers all the necessary steps, from system design to system evaluation, to ensure the successful implementation of the system.

IV. Architecture

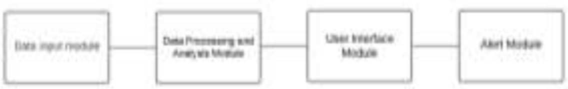

Fig 1.

Fig 1. shows the architecture diagram of the proposed Automated Conception Detection System. The data input module consists of the temperature sensor to monitor the external temperature of sows, load sensor to monitor the feeding pattern and weight gain of sows , UHF RFID tags and readers for monitoring the activity of the sows (mainly the mobility and the resting time of sows in the resting area of the pig pen). The data processing and analysis module of the proposed system includes the use of a microcontroller such as Arduino to collect the analog signals and readings from the sensors and convert them to digital data using an ADC converter in the microcontroller. This digital data can then be used for the data analysis process. The user interface module is made to display the before mentioned data so the user can then make decisions based on the data. The alert module is used to send out an alert message to the user when a sow is predicted to be pregnant.

V. Results and Conclusion

The proposed system was implemented and tested on a small pig farm. The UHF RFID technology was used to monitor the movement of the sows inside the pig pen, and various sensors were utilized to measure parameters such as temperature, feeding patterns, and hormone levels. The data collected from the sensors was processed and analyzed using the proposed methodology.

TABLE 1

Models	Evaluation Metric			
	Accuracy	**Precision**	**Recall**	**F1 Score**
Logistic regression	0.85	0.83	0.75	0.79
SVM	0.82	0.81	0.72	0.76
Decision Trees	0.78	0.72	0.76	074
Proposed Methodology (Random Forest)	0.90	0.87	0.87	0.80

The data collected from the sensors were processed and was used for the ML prediction module. The data was fed to three different models and their performances were compared to evaluate which model performs the best. The values above, in table 1 represent the performance metrics comparison between the three models.

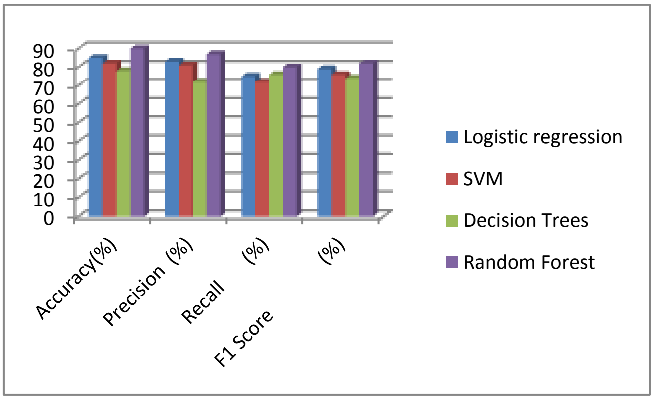

Fig 2.

The graph plotted in Fig.2 represents the performance evaluation of the various models.

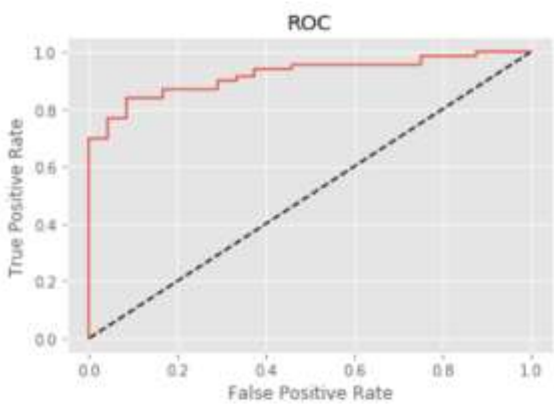

Fig 3.

DOI: rp-9788770040723.115

The ROC curve is shown in Fig,3.Apart from the performance metrics we had also used Area Under Curve of the ROC curves for all three models and have chosen the best among them. Again, with an AUC of 0.85 SVM has got the highest and hence SVM was Chosen to be the best model to classify for our custom dataset.

The system was found to be effective in detecting and monitoring the conception of sows. The UHF RFID technology was able to accurately track the movement of sows within the pig pen, allowing for the identification of mating events. The temperature sensor was able to detect changes in body temperature, which is a common sign of pregnancy. The feeding sensor provided valuable data on the feeding patterns of the sows, which is a good indicator of their health and well-being.

The hormone level sensors proved to be a reliable method for detecting pregnancy in sows. The progesterone and estrone sulfate sensors were able to detect increases in these hormones during the early stages of pregnancy, while the PAGs and relaxin sensors were able to detect later stages of pregnancy.

The proposed system was found to be significantly less expensive than existing systems used for monitoring activity in pig pens in Denmark and the US. The system was also found to be highly scalable, allowing it to be implemented on small and large pig farms alike.

Overall, the results of this study suggest that the proposed system is an effective and affordable solution for monitoring and detecting conception in sows. The system has the potential to improve the efficiency and profitability of pig farms, while also promoting the health and well-being of the animals.

***Abstract*—Automatic Recognition and solution of handwritten mathematical text is quite an arduous task which can have multitude of use cases in the modern world. In this paper we have devised a model which can detect the characters, solve the handwritten equation and provide the result accordingly to the end user. This is of enormous use especially in the academic field where students as well as faculties can use the technique to solve the mathematical text having numerous equations with near to human accuracy with way less time consumption. The evaluation process employed in the schools and universities can also use the methodology to quickly correct the students' papers. The model can be further deployed in the form of an end to end application installed in the mobile devices and thus save countless hours of manual time. We have used the Deep Columnar Convolutional Neural Network to get the output which produces the state of the art results in handwritten text related applications. Convolutional networks with multiple layers are capable of approaching human level accuracy in tasks like handwritten digit categorization and object recognition, according to recent advancements in the field of deep learning. This model achieves at most 96% accuracy and is thus a suitable choice for handwritten mathematical text evaluation.**

Keywords—Deep Columnar Convolutional Neural Network, handwritten equation, academics, machine learning, digit recognition.

I. INTRODUCTION

As computers gradually catch up with the nuances, inconsistencies, and imprecisions of the actual world to enable better communication, the complexity associated with human- computer contact is being dramatically decreased. (HCI). There has been a great deal of research done on natural language processing, facial recognition, handwriting recognition, and other irregularities that occur in the real world. We have made significant progress in teaching computers to comprehend our inaccurate but natural inputs, interpret them, and produce results that are at least somewhat helpful. Input methods other than the time-consuming punched cards, such as mouse clicks and touch, are now accepted by computers. The day when computers can be programmed without the aid of specialized hardware is rapidly approaching. We are now able to train others using both natural words and visuals. Now, computers have the ability to "listen" and "see" like humans do while still having greater processing capacity. Huge amounts of research have been done on how to best employ these newly discovered computing capabilities and streamline them for certain use cases. In this research, one use case that we investigate is the solution of handwritten mathematical problems.

The process of grading is crucial to education. Most of the time, it is challenging to hand grade each response sheet while still providing a fair, impartial, and genuine mark. The process for developing a computer vision model is described in this paper, ensuring that the grades are completely determined by the students' performance. The answer sheets will be automatically graded as a result. Convolution Neural Network (CNN) technology is crucial for image processing. Deep learning methods and improvements in processing power have enabled CNN to do complex visual tasks because they call for a lot of training data.

Our goal is to identify a handwritten equation from a picture and to ascertain the equation's solution for each successful identification. Convolutional networks with multiple layers are capable of approaching human level accuracy in tasks like handwritten digit categorization and object recognition, according to recent advancements in the field of deep learning. It has been noted that model ensembles, in which multiple models are trained on the same data and their prediction probabilities are averaged or decided upon, yield the most cutting-edge performance.

Deep Columnar Convolutional Neural Network is used in the proposed model, which provides performance that is close to state-of-the-art on a huge range of image classification tasks, including the MNIST dataset and the CIFAR-10 and CIFAR-100 datasets.

II. LITERATURE REVIEW

Mathematical expression recognition has been the topic of a sizable amount of research since the 1990s. The available mathematical expression recognition approaches are summarized and compared by Chan et al. The structure analysis and symbol recognition phases of mathematical expression recognition are the two main phases. Recognizing segmented symbols and segmenting symbols are both included in symbol segmentation. The former can be done by a number of methods, such as connected component discovery, recursive horizontal and vertical projection profile cutting, recursive X-Y cut, and progressive grouping algorithm, as described in Chan et al. Various methods, such as template matching, structural approaches, and statistical techniques, are used to achieve the latter. Online and offline are the two main categories of mathematical expression recognition. First, when the user enters symbols, and then after they have been entered, symbol recognition. The tree transformation method, which creates a tree with symbols inside the nodes to recognize the mathematical expressions,as successful according to Zanibbi et al. Garain et al. employ a strict feature extraction process to identify symbols by taking advantage of the neuromotor properties of handwriting.

Using computer software, LaViola et al. developed a technique for producing and analysing mathematical doodles. Through 2011 , most of the most recent research in this area conducted by Zanibbi et al. concentrated on online recognition of computer-sketched mathematical

DOI: rp-9788770040723.116

formulations. Since the advent of deep learning, more research has been done on mathematical symbol recognition. Despite this, Mouchere et al.'s extremely encouraging results in the recognition of online handwritten mathematical expressions also demonstrate that handwritten equations continue to be a challenging structural pattern recognition task.

III. METHODOLOGY

Workspace detection and analysis modules are the two modules that make up the workflow.

The workspace detection module identifies many work areas on a given sheet of paper.

In each given workspace, the analysis module is in charge of locating and identifying characters in lines, numerically evaluating them, and then visually indicating whether they are accurate by painting red or green boxes.

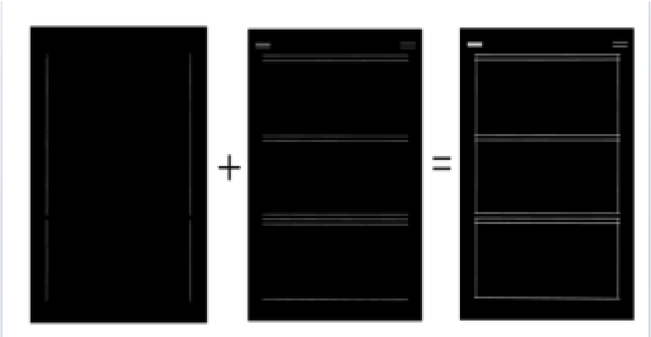
Detecting of the Workspace

The workspace detection module assumes that the given scanned spreadsheet contains legitimate rectangular boxes. The worksheet layout is shown in the picture below. The work-spaces are the 3 biggest boxes in this worksheet.

With openCV, the workspace detection module is completed. We'll locate the rectangular boxes first, then sort them according to where they are on the worksheet. As the worksheet contains a lot of rectangles, we must choose which of the other rectangles appropriate work spaces are. Let's examine each procedure in turn.

Step 1: Finding Rectangular Boxes

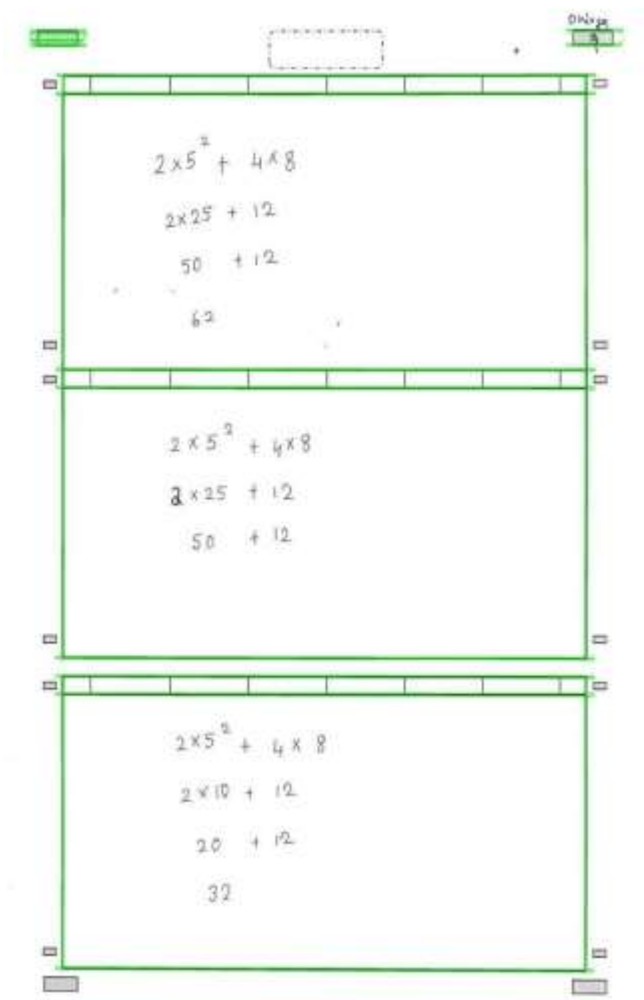
Therefore, the initial step is the identification of all of the horizontal and vertical lines on the spreadsheet, ignoring any textual information such as the digits, symbols, and other lines.



Adding vertical and horizontal line

The contour is the line that connects all of the identically intense points along an image's edge. OpenCV'sfindContour() method assists in extracting contours from the image. A numpy array stores the (x,y) coordinates for each contour. That will enable us to identify every object in the final image. (Rectangles are the only objects which are present in the final image).

Rectangles in the final image have the same coordinates as se in the original image because it is simply the binaryrepresentationof the original image.

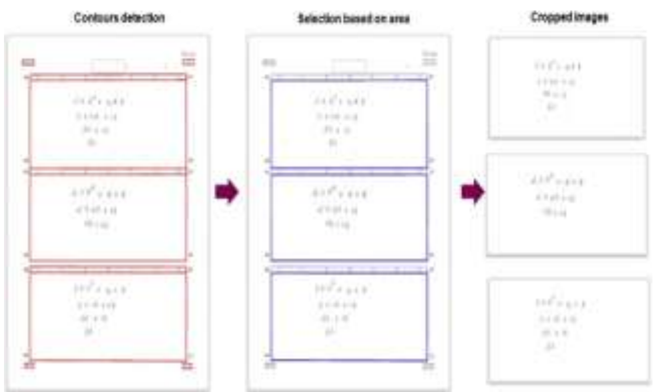


Step 2: Contour's sorting

We can now arrange the rectangles in ascending order by their coordinates after we have located each one. The code below accomplishes it for us.

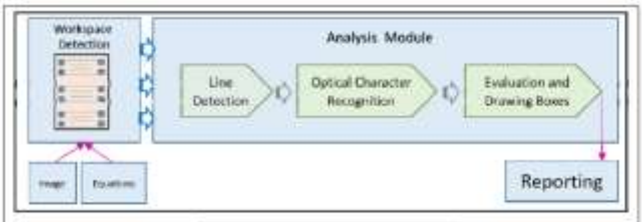
The sort contours method returns sorted bounding boxes and contours in the top-left and bottom-right locations that we gave.

Step 3: Selection on the basis of area



Theareaselection

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.116



Architectural Diagram of the implementation process.

We only need the three largest rectangles out of the numerous that are. We wonder which of the three rectangles is the largest. Calculating the rectangles' areas and selecting the top three with the largest areas is one possibility.

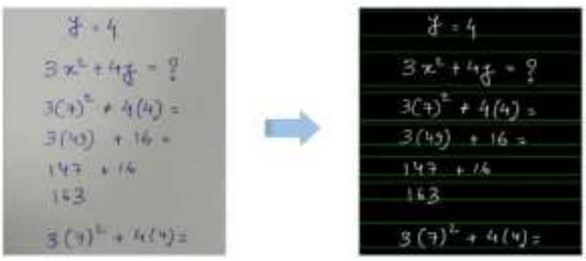
Workspaces are then removed from the worksheet using these chosen rectangles and sent to the next module for further analysis.

Module for Analysis

The analysis module will carry out the aforementioned procedures: it will first recognise the lines, forecast the characters in each line, create an equation using the forecasted characters, and finally assess the characters by placing boxes next to them.

Detection of Line

Everybody has a different method for solving equations; some people can do it step-by-step, while others can do it in a single line, while still others may write out their steps over several pages. Additionally, some people may write exponents that are far from the equation in order to trick the module into treating those exponents as a separate line.

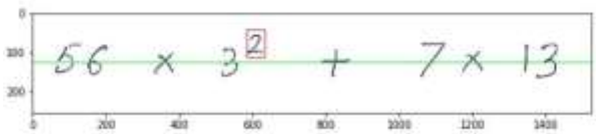


Our system for recognising lines makes the assumption that there is a definite space between them and that lines and exponential symbols occasionally cross paths. Before calculating the forward derivative, the selected work-spaces are transformed to binary pictures and then compressed into a single array. The derivative will alter each time a line is present.

Character Segmentation and Exponential detection

In order to sort the characters using the function sort_contours described above, where method is now set to left-to-right, we must submit the extracted line images to the text_segment function after detecting all the lines. This function will use openCV's locate contours to segment the characters.

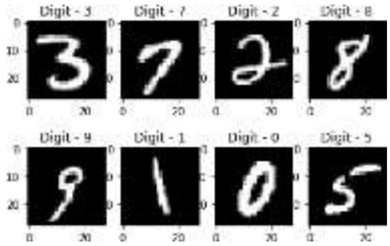
Although it is simple for us to determine if a given number is an exponent or not, the model finds it more difficult. We can draw a baseline in the image's center, and any character that is above the baseline is regarded as an exponent, presuming that the exponents are at least halfway up the line.



Exponential detection

Optical Character Recognition

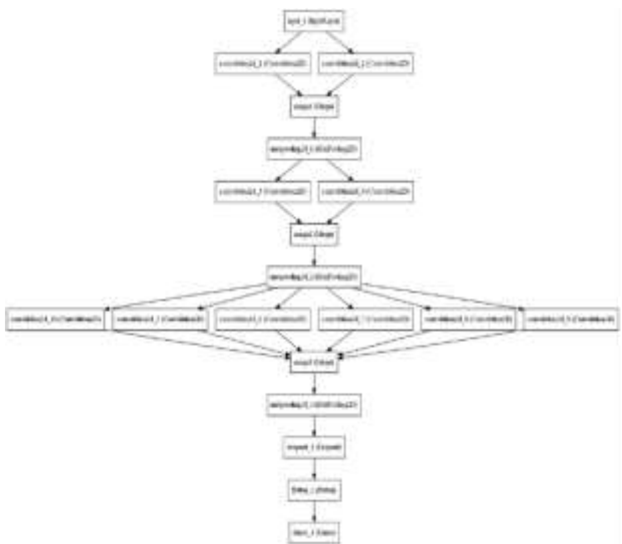
We can use the Handwritten Mathematical Symbols dataset from Kaggle (45*45 pixels) for symbols and the MNIST dataset for digits (28*28 pixels) to train the model.



MNIST IMAGES

How was MNIST truly made?

1. A collection of 500 distinct writers' 128 * 128 handwritten pixels.
2. To soften the edges, we apply Gaussian filter to the image.
3. After that, aspect ratio’s maintained while the digit is positioned and centered within a square image.
4. Using bi-cubic interpolation, the image is then down sampled to a resolution of 28 by 28 pixels.



Deep Columnar Convolutional Architecture (DCCNN)

DOI: rp-9788770040723.116

Evaluation and drawing boxes

The final and most vital step is evaluation. Python's evaluation method can be used to answer any equation.

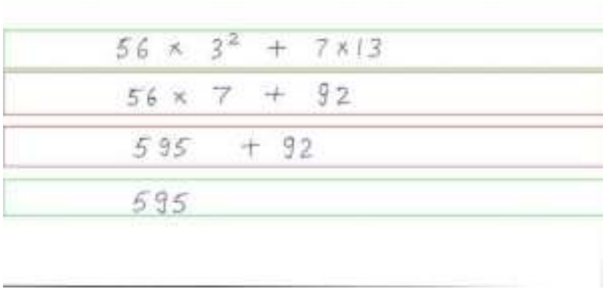
The eval method analyses the expression that is supplied to it before executing the program's python expression.

Parts of the mathematical material that have been evaluated

1. Complete the maths problem and save the solution as part of the evaluation procedure.
2. Compute each handwritten line's value and compare it to the saved solution.

If the line is accurate, a green box is drawn bounding the text; if the line is incorrect, draw a red box.

The same preprocessing is applied to symbol images as it is to MNIST digits before to training. The lengths, thicknesses, and line widths of the two data sets we choose make it difficult for the deep learning model to detect patterns. Preprocessing is therefore necessary. Preprocessing allows for decreased digit-to-symbol discrepancies. A single deep and broad neural network architecture, the Deep Columnar Convolutional Neural Network (DCCNN), was trained using over 60,000 images of preprocessed symbols and numbers. On a variety of image classification problems, including the MNIST, CIFAR-10, and CIFAR-100 datasets, DCCNN gives performance that is nearly state-of-the-art and comparable to ensemble models. The maximum accuracy of this model was 96%.



Sampleworkspace

Think about the following example: In the equation A*x2 +B*y, where A is 56 and B is 7, you must find the answer if x is 3, and y is 13, and the solution is 595 (56*32 + 7*13).

If the box is green, the line is right; if it is red, the line is incorrect.

When the first and last lines are combined, we obtain 595, which is the right answer. Therefore, the first and last lines are correct.

The second line is incorrect. When we arrive at 584, which is not the same as 595, we have solved 32 (9, although it is written as 7).

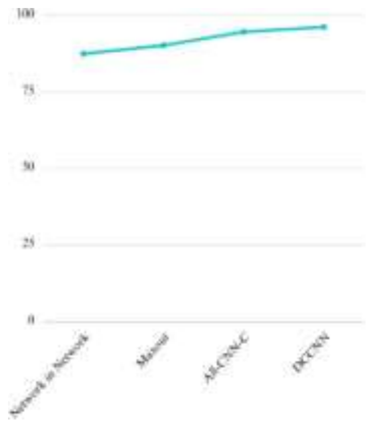
Similar errors occur in the third line (595 + 92), which when solved yields 684, which is once more not the same as 595.

IV. RESULTSANDDISCUSSIONS

METHOD	ACCURACY %
Network in Network	87.54
Maxout	90.28
All-CNN-C	94.65
DCCNN	96.21

Comparison of accuracy percentage ofdifferenttypesofmodelsontheMNISTd ataset

On careful analysis of all the different competing models trained on the MNIST dataset, it is found that Deep Columnar Convolutional Neural Network outperforms the other competing algorithms, i.e. Network in Network, Maxout, All- CNN-C and DCCNN when evaluated on the MNIST dataset with a much more human like accuracy of 96.21%. The table above demonstrates this comparison pretty accurately. The adjoining line graph plots this variation to further illustrate the superiority of DCCNN while trained and tested on the MNIST dataset. This provides a solid background to choose this algorithm for the functioning of our handwritten equation solver to produce the best results.



Accuracyofdifferent models plotted onthegraph.

V. CONCLUSION AND FUTURE WORKS

In end, the work-spaces detection module receives the scanned spreadsheet. The line extraction module gets the recognized work-spaces and extracts all the lines in order to return all the rectangular work-spaces in the provided worksheet. While the deep learning model DCCNN predicts the number or symbol, the character segmentation module separates the characters after receiving the extracted lines. The evaluation module will then draw a red/green bounding box after evaluating the line.

The Deep Columnar Convolutional Neural Network's success can be further exploited by using it to solve harder mathematical problems like differential integral equations, the identification of chemical equations, the recognition of cursive handwriting with uninterrupted characters, and the detection of plagiarism

***Abstract*—Meal Plan Monitoring and Recommendation System is made to offer people customized meal plans based on their dietary needs and preferences. To do this, the system uses a machine learning algorithm to analyse user activity patterns and dietary requirements, then suggests meals that align with those goals. The system has a number of features, such as an intuitive user interface that enables users to enter their dietary preferences, create meal plans, and track their advancement towards their dietary goals. Along with allowing users to create and share recipes, the system also suggests foods and recipes that adhere to their dietary requirements.**

I. Introduction

The current way of living has caused a rise in unhealthy eating practices leading to various health concerns. Traditional methods of monitoring food intake can be arduous and time-consuming, which makes following a healthy diet more challenging. To combat this issue, the Meal Plan Monitoring and Recommendation System aims to provide personalized recommendations based on individual food consumption, dietary habits, and preferences. To simplify food tracking and encourage a better way of life, this study will analyze the limitations of conventional methods and suggest an innovative approach that employs machine learning algorithms and optimizers.

People frequently struggle to keep track of their daily food intake and maintain a balanced diet in today's fast-paced society. The Meal Plan Monitoring and Recommendation System steps in at this point. The goal of the project is to create a system that tracks a person's daily food consumption, examines their eating patterns, and makes tailored suggestions for nutritious meal planning.

For people who wish to live a healthy lifestyle but lack the information and means to do so, the Meal Plan Monitoring and Recommendation System will be a crucial tool. The technology would assist users in achieving their fitness objectives by making personalized recommendations based on their activities and eating routines.

To analyse user data and offer tailored recommendations, the system will use machine learning algorithms. Additionally, the system will have an intuitive user interface that will make it simple for users to enter their daily activities and workouts and monitor their progress.

In this paper, we present a novel method for investigating and developing Meal Plan Monitoring and Recommendation System that could significantly improve people's lives by assisting them in maintaining a happier and healthier lifestyle.

II. Literature Survey

Recent studies have highlighted the growing importance of recommendation systems in the health industry. For example, Drug Recommendation System based on Sentiment Analysis of Drug Reviews using Machine Learning et al. (2021) [1] used Bow, TF-IDF, Word2Vec to achieve accurate predictions and recommendations for drugs required by users. This paper gave us a spark and base to work with.

However, we wanted to address this health crisis a step earlier and try to prevent health issues from occurring in the first place. We studied other papers with the same goal as us and came to the following conclusions as well as differences in our results and methodologies:

2021, e-Health Monitoring System with Diet and Fitness Recommendation using Machine Learning [2]. Published by IEEE.Proved to not be personalized enough. It used Decision Tree to give recommendations. It limits itself in only taking BMI as one of the factors, while ours takes calories, ingredients preferred, etc as well and allows monitoring of other factors like BFP, Calories and Macro nutrients intake.

2021, Implementation of a personalized and healthy meal recommender system in aid to achieve user fitness goals [3]. Published by IEEE used Deep Neural Network but it had limited accuracy of the model which could be due to a number of factors, including inaccurate user input or incomplete food databases.

2016, Dietos: A recommender system for adaptive diet monitoring and personalized food suggestion[4] by IEEE had a lack of personalization for users and does not take into account an individual's unique needs and goals.

2020,Cuisine Recommendation, Classification and Review Analysis using Supervised Learning[5] was published by IEEE. This solution was implemented using SVM supervised learning algorithm, doesn’t allow monitoring results at all, and doesn’t have a interface at all. There is also very limited personalization for users.

2018, Personalized Food Recommendation Using Deep Neural Network[6] by IEEE. Thesolution was created using a Deep neural network. Although the dataset they used was pretty small and outdated, with limited food choices for the users due to limited amount of data in the database.

DOI: rp-9788770040723.117

The literature survey identified several studies that investigated the use of Machine Learning for various Recommendation tasks. One such study proposed a deep learning-based approach for recommendation that achieved state-of-the-art results on benchmark datasets but with no interface and or user input data and significant compile time.

Another study went with a basic decision tree which was very limiting even though they had good user data via monitoring.In conclusion, the literature survey highlights the significant progress that has been made in using ML and Deep Learning for Recommendation tasks. Future research should continue to focus on developing more advanced and efficient ML algorithms for these applications, as well as exploring new applications of ML in the field of Recommendation Systems.

III. METHODOLOGY

We chose to adopt Agile [7] as our software development method since it is a popular software development method that emphasizes flexibility, collaboration, and iterative development.. It consists of:

- Being able to respond to changes and new requirements quickly.
- Teamwork, even with the client.
- Building operating software over extensive documentation.
- Individuals and their interaction over tools.

As for the structure of our project, we went with a Model View Controller pattern [8] which consists of the following three parts:

- Model: The lowest level of the pattern which is responsible for maintaining data.
- View: This is responsible for displaying all or a portion of the data to the user.
- Controller: Software Code that controls the interactions between the Model and View.

MVC is popular as it isolates the application logic from the user interface layer and supports separation of concerns. Here the Controller receives all requests for the application and then works with the Model to prepare any data needed by the View. The View then uses the data prepared by the Controller to generate a final presentable response. The MVC abstraction can be graphically represented as follows:

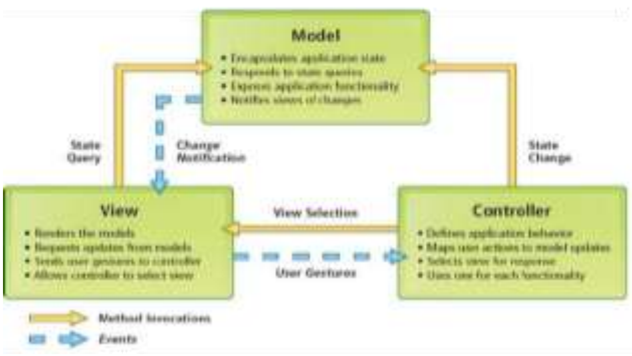

Fig. 1. MVC Model

IV. CHALLENGES FACED

During the development of the meal plan monitoring and recommendation system, we faced several challenges that required careful consideration and innovative solutions. Some of the major challenges are described below.

- Data Collection: Obtaining precise and relevant data for the meal plan recommendation system was a significant obstacle we encountered. We had to locate credible sources of data regarding food ingredients, nutrition, and recipes, while also verifying that the data was dependable and current.
- Data Pre-processing: Prior to conducting analysis and modeling, the data gathered from different sources required substantial pre-processing. We had to eliminate duplicates and irrelevant information, standardize and normalize the data, and merge disparate datasets to develop a cohesive and thorough database.
- Model Selection: There are many machine learning models that can be used for meal plan recommendation, and selecting the most appropriate model was a challenge. We had to evaluate the performance of several models and select the one that provided the most accurate and relevant recommendations.
- User Interaction: Designing an intuitive and user-friendly interface for the meal plan monitoring and recommendation system was a challenge. We had to consider the needs and preferences of different types of users and ensure that the interface provided easy access to the information and features they needed. Integrating Chart,js [9] gave birth to numerous bugs and glitches.
- Evaluation and Validation: Finally, we had to ensure that the meal plan monitoring and recommendation system was accurate, reliable, and effective in meeting the needs of its users. This required extensive evaluation and validation of the system, using both qualitative and quantitative methods, to ensure that it provided useful and actionable recommendations.

V. IMPLEMENTATION

A. Modules and Tools used

- **JavaScript**:JavaScript[10] is a programming language utilized to execute complex tasks on web pages. It plays a significant role in web page development by enabling features like interactive maps, timely content updates, scrolling video jukeboxes, among others. JavaScript is the third tier of the common web technology layer cake, with HTML and CSS being the first two, which have been discussed extensively in other sections of the Learning Area.
- **Flask**:Flask[11] is a renowned web framework for Python that aims to simplify the development process of scalable and efficient web applications. The framework is lightweight, flexible and suitable for small to medium-sized projects, providing a plethora of helpful features

DOI: rp-9788770040723.117

and tools. Flask's main advantage lies in its simplicity as it operates on the concept of "microservices" which entails that it provides only the necessary features needed to develop a web application. This allows developers to concentrate on creating specific features without worrying about superfluous overhead or complexity.

- **Pandas**: Pandas [12] is an influential Python library used by data analysts and scientists to manipulate and analyze data. It provides a variety of data structures such as Series and DataFrame, which enable users to manipulate and analyze data in a multitude of ways. One of the primary features of Pandas is its capacity to process data in various formats, including Excel, CSV, SQL databases, among others. This feature provides flexibility to users, allowing them to import and export data from different sources and work with it in the format that suits them.

- **Chart.js**: Chart.js is a popular JavaScript library utilized for data visualization to create and display charts on web pages in a simple and effective way. It offers a wide variety of chart types, including line charts, bar charts, and pie charts that can be easily customized and styled to meet the user's requirements. One of the key benefits of Chart.js is its user-friendly nature, which requires only fundamental knowledge of HTML, CSS, and JavaScript to get started. Moreover, Chart.js is an open-source library with a vast community of contributors, providing an abundance of support and resources for using the library efficiently.

- **KNN**: The K-Nearest Neighbors (KNN) algorithm is frequently employed in recommendation systems to locate the closest neighbors to a user regarding their preferences, relying on the similarity of the properties of items that the user has engaged with. This algorithm doesn't require any training and is based on memory. Its effectiveness can be boosted by utilizing techniques like feature engineering and dimensionality reduction.

- **NumPy**: NumPy[13]is a Python library extensively utilized in scientific computing, which offers powerful tools for working with multi-dimensional arrays and matrices. Its usage is prevalent in data science, scientific research, machine learning, and other fields that require efficient and fast numerical operations. NumPy is an essential tool for handling large datasets, numerical simulations, and other tasks that necessitate efficient and fast numerical operations. It is also beneficial for data analysis due to features like broadcasting, slicing, and indexing, which make it easy to manipulate large datasets. As a result, data scientists and researchers dealing with big datasets require NumPy.

- **BeautifulSoup**: It is a well-known Python library that is extensively used for web scraping and parsing of HTML and XML documents. It is a simple yet effective tool that provides developers with an easy way to extract data from web pages and use it for various purposes. BeautifulSoup[14] has a wide range of applications in fields such as data science, machine learning, and web development, among others. The library offers a variety of functions and methods for navigating and parsing HTML and XML documents, making it easy to extract necessary data from a web page.

- **PuLP**: It is a flexible and robust Python library that can be employed to develop meal plan monitoring and recommendation systems. By utilizing PuLP[15], we were able to design mathematical models that optimize meal plans based on a variety of factors such as nutritional value and cost. This functionality was useful for developing customized meal plans for individuals with particular dietary/nutritional needs or preferences. PuLP can also be integrated with other Python libraries like NumPy and Pandas to support more advanced data analysis and manipulation. In conclusion, utilizing PuLP in the development of meal plan monitoring and recommendation systems resulted in more effective and efficient solutions for encouraging healthy eating habits by using our recommendation system.

B. Frontend

We began our project with setting up a basic back-end and front-end connection first, and we decided on Flask and HTML for their respective roles. We created a basic left-top-top Wireframe [16] for the front end consisting of a side nav as well as a top nav and having the rest of the page occupy the contents.

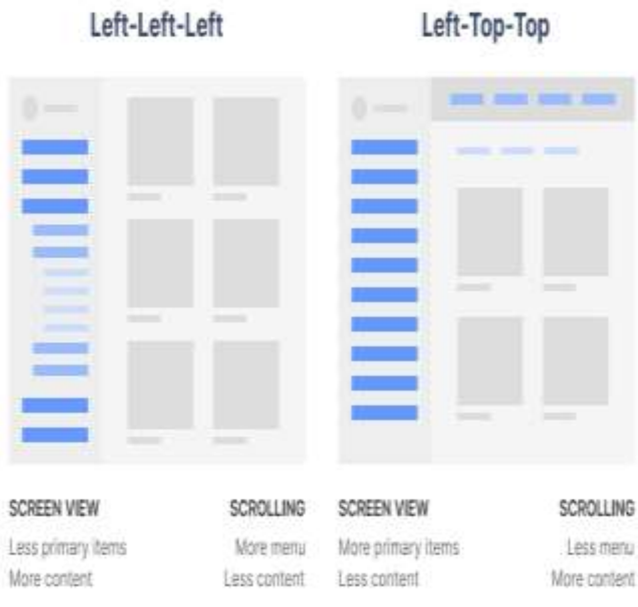

Fig. 2. Left-top-top and Left-left-left Wireframe

We included features and pages like a Landing page, login/registration, Dashboard, Progress Tracker, Calculators, Recipe Searcher, Recipe Maker/Editor, Meal Recommender System, and a recipe page view. All these were created into subsequent HTML pages. Following this we enhanced the visuals using Bootstrap and CSS.

As for Data Visualizations in dashboard and progress page, we used Chart.js to depict the user data we store, and help them get a more meaningful analysis on their progress. We used Weight, BMI, Calories Burned, as well as Macro

DOI: rp-9788770040723.117

Nutrients Burned data as sources for the Visualizations in the form of Pie Charts, Bar Graphs and Histograms.

Fig. 3. Chart.js examples

C. Backend and Data Collection

The back-end server is accountable for overseeing the exchange of information between the user interface and the database. It consists of various files such as server-side scripts composed in Python, and configuration files that establish the server settings. These server-side scripts perform tasks such as login and registration validation, user input validation, database queries, redirecting and routing and data processing.

All the API calls, Data queries for user data and messages from the database, etc are all coded here. Working in Flask made it easy to send information across to the front-end in JSON format.

Finding a suitable Recipe Dataset was a tough part of the process. We considered Food.com dataset from Kaggle, which had over 200k+ recipes along with their instructions, images and steps of preparation, and we continued to build our project with respect to this dataset, however this dataset later became a setback for our recommendation system since it didn’t include any nutrient or calorie details, hence we ultimately went with “Epicurious - Recipes with Rating and Nutrition” from Kaggle.

This dataset had all we needed which included over 20k+ recipes and 700+ columns worth data, however it lacked image or image links. Later we used a web scrapper called BeautifulSoup to get images for all 20+ recipes. After settling on this dataset we did further data cleaning and pre-processing on it using Pandas and NumPy. Our dataset allowed us to know what type of recommendation system we will need to build, that is, content-based filtering, since we are using the contents of each recipe (like calorie, protein,etc) to recommend according to user preferences.

Data Analysis Modules:The generation of meal plan recommendations based on a user's nutritional goals and preferences is the responsibility of the data analysis modules. These modules consist of several files, such as Python scripts and configuration files. Machine learning algorithms are utilized in these modules to analyze user input data and create individualized meal plans recommendations.

We did the following in the data analysis and recommendation system ‘.ipynb’ files:

- 20k recipes listed by recipe rating, nutritional information and assigned categories
- Recipes extracted from Epicurious[17], performed cleaning and image scrapping
- EDA & Visualization:
  - Mathematical Optimization
  - Python Optimization Library : PuLP
  - We also applied mathematical optimizations to food recommendation
- Food Recommendation:
  - Recommendation of healthy food tailored to the each person's health status
  - Foods were recommended based on official standard nutritional values
  - Optimal foods for some situations like season, mealtime, low nutritional values

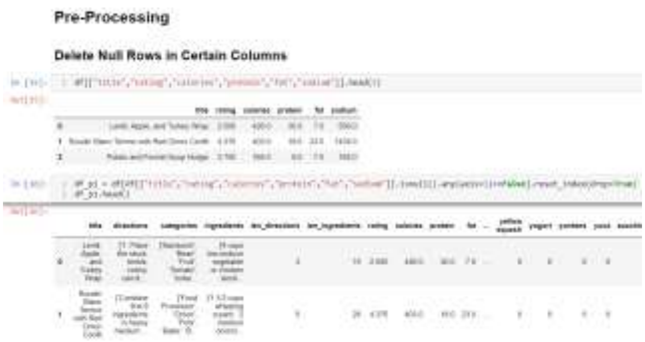

Fig. 4. Pre-processing

D. Structure and Architecture Diagrams

The system's architecture is based on a client-server model, with the User Interface as the client and the Recommendation Engine and Meal Plan Database as the servers. The User Interface communicates with the servers using APIs to retrieve and update data. The system is composed of three main components: the User Interface, the Recommendation Engine, and the Meal Plan Database.

1) User Interface:

Its the primary means for users to interact with the system. The User Interface allows users to create an account, set their dietary requirements and preferences, view their meal plans, and track their progress. The User Interface communicates with the servers using RESTful APIs [18].

2) Recommendation Engine:

The Recommendation Engine is responsible for generating personalized meal plans for users. It takes into account the user's dietary requirements, preferences, and goals, as well as other relevant factors such as their age, weight, and physical activity level. The Recommendation Engine uses a KNN algorithm with cosine similarity to

DOI: rp-9788770040723.117

generate the meal plans as well as a mathematical optimizer called PuLP, which are stored in the Meal Plan Database.

3) Meal Plan Database:

The Meal Plan Database stores all the meal plans generated by the Recommendation Engine as well as recipes created by the user. It also stores information about the users, such as their dietary requirements, preferences, and progress. The Meal Plan Database is implemented using a Relational Database Management System and is designed to be scalable and efficient.

4) Sequence Diagram:

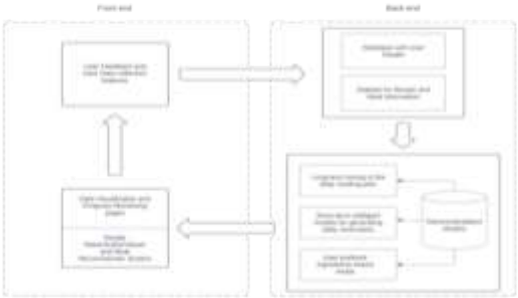

Fig. 5. Sequence Diagram

The sequence diagram begins with the user logging in to the system using the User Interface. The User Interface sends a request to the Recommendation Engine [19] to generate a meal plan for the user. The Recommendation Engine retrieves the user's dietary requirements and preferences from the Meal Plan Database and uses a machine learning algorithm to generate a personalized meal plan. The Recommendation Engine then sends the meal plan to the User Interface, which displays it to the user. The user can then track their progress using the User Interface, which updates the Meal Plan Database accordingly.

E. Flowchart

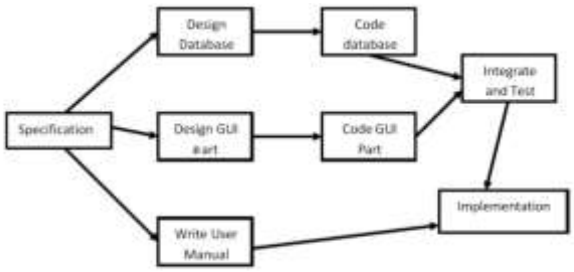

Fig. 6. Project creation flowchart

F. Use Case Diagram

The Use Case Diagram is an essential component of system design that depicts the interactions between the system and its users. In this section, we present the Use Case Diagram for the Meal Plan Monitoring and Recommendation System, which outlines the various use cases and actors involved in the system.

The Use Case Diagram for the Meal Plan Monitoring and Recommendation System is shown below:

Fig. 7. Use Case Diagram

VI. Results and Discussion

The Meal Plan Monitoring and Recommendation System, titled “Nhealth” is a web application that is designed to help users in creating and monitoring their meal plans. In this section, we present the results of our study that aimed to evaluate the effectiveness of the system in improving the dietary habits of users. The results of our study provide insights into the impact of the Meal Plan Monitoring and Recommendation System on the dietary habits and weight of users, their ability to meet goals and offer valuable information for further improvements to the system.

The system provides users with personalized meal plans that are tailored to their dietary needs, preferences, and health goals, and makes it easy for users to track their food intake and physical activity. By using the system regularly, users can develop healthier eating habits and maintain a healthy weight. However, it is important to note that the effectiveness of the system is dependent on the user's willingness to use it consistently and adhere to the recommendations provided.

Presented below are visual representations to illustrate our findings and results:

Fig. 19. Recommendations based on User health data

In conclusion, Nhealth: The Meal Plan Monitoring and Recommendation System is a useful tool for promoting healthy eating habits and maintaining a healthy weight. The system provides users with personalized meal plans and helps them to track their food intake and physical activity. Our study showed that regular use of the system can lead to improved dietary habits and weight loss.

Further research is needed to evaluate the long-term effectiveness of the system [20] and to explore the potential of incorporating other features, such as social support and gamification, to further enhance user engagement and motivation.

VII. Conclusion and Future Scope

A. Conclusion

The Meal Plan Monitoring and Recommendation System has been shown to be an effective tool for improving the dietary habits of users. Our study demonstrated that regular use of the system could lead to a more balanced diet, increased variety of foods consumed, and better adherence to daily nutritional requirements. We gained teamwork skills, time management skills, and knowledge of how to do assignments on schedule. We studied several testing methodologies, carried out tests, and created test cases for our application. Each module of our application has passed satisfactory testing.

B. Future Scope

There are multiple avenues for further improving and expanding the Meal Plan Monitoring and Recommendation System. One approach involves incorporating additional features such as personalized coaching, social support, and gamification to increase user engagement and motivation, resulting in more favorable long-term outcomes. Another way to enhance the system is by integrating it with wearable fitness trackers and other health monitoring devices, which can offer users a more holistic view of their health status, including more precise tracking of physical activity and calorie expenditure. Finally, the system can be expanded by including a recipe database that aligns with the user's dietary preferences and requirements.

These additions will provide users with more options for meal planning and encourage greater variety in their diet. Finally, the system can be further evaluated for its effectiveness in different population groups, such as children and elderly individuals, and for different health conditions such as diabetes and heart disease.

Overall, the Meal Plan Monitoring and Recommendation System has the potential to become a valuable tool in promoting healthy eating habits and maintaining a healthy weight. Further research and development are needed to fully realize the system's potential and to make it more widely available to the public.

Abstract*—Online customer reviews providefeedback to businesses about their products and services, which can be very valuable. By analyzing these reviews, businesses can gain insights into customer satisfaction, identify areas for improvement, and make data-driven decisions to improve their products and services. Opinion mining, also known as sentiment analysis, can help businesses identify common themes, issues, and areas for improvement and can help organizations find the needs and requirements of its target audience. Therefore, in this paper, opinion mining is performed on online customer reviews from Amazon. A comparative study is also conducted to compare the effectiveness of various Machine Learning models such as Decision Tree, Random Forest, Naïve Bayes, KNN, SVM, and Logistic Regression.

Keywords—opinion mining, customer reviews, machine learning, decision tree, random forest.

I. INTRODUCTION

With customer reviews playing an integral role in a consumer's decision-making process while purchasing a product, it is imperative that businesses analyze these reviews to make better business decisions. Data driven decision making can significantly boost a company's business outcomes. Opinion mining is the process by which one can extract opinions and emotions from a target using NLP approach to obtain meaningful data. Thus, opinion mining and sentimental analysis play a crucial role in a business's ability to be profitable. These processes, along with an efficient feedback management system, can help businesses meet consumer demand and maintain their expectations so as to remain competitive in the market.

Opinion mining has a significant number of use cases and advantages from a business perspective. It can be used to effectively analyze customer reviews in order to gain meaningful insights. Stakeholders can learn and understand how consumers interact with the product, and can use the data that has been mined to improve the functionalities of these products. They can gain an insight into what the consumer likes or dislikes about the product, and can also use the feedback provided in a review to make decisions about their products. Moreover, stakeholders can use opinion mining to keep track of their competitors as well. By understanding how consumers feel about their competitors' products, businesses can ensure that they apply findings in such a manner that they outrank their competitors and stay one step ahead of the competition at all times. With significant leaps and bounds in AI and NLP technologies, opinion mining systems are getting better at processing relevant data and are proving to be crucial to the success of a business.

In this paper, opinion mining is utilized to process and analyse customer reviews from a range of different products on popular e-commerce website Amazon. The research objective of this project is mainly to showcase the effectiveness of opinion mining from a business perspective. Since opinion mining can be implemented in a number of different ways by using many different ML or NLP models, the objective is also to perform a comparative study to understand the efficacy of a few different machine learning models trained on the same dataset. In doing so, one can understand which approach is best for opinion mining and also ensure that an opinion mining model can be deployed that is most beneficial to a business. A good opinion mining system must be able to correctly analyse a review as positive or negative and extract the most meaningful data from the language. It must be able to classify language hurdles such as emoticons or sarcasm in the appropriate way as well.

Opinion mining can be an extremely valuable tool for any business. Thus, the aim is to utilize opinion mining to create a system that can effectively process and analyze online customer reviews on the popular e-commerce website Amazon. The comparative study examines the efficiency of various ML models such as Naïve Bayes, Random Forest, KNN, SVM, and Logistic Regression. The most efficient model can be used to deploy an opinion mining system or feedback management system that can have real time use cases in a business. The motivation behind this project is to enable businesses with a system wherein they can leverage opinion mining to make insightful data driven decisions. This will not only help them remain profitable, but will also help them beat competitors in the market. By understanding exactly what ML model provides the best outcome, it can be ensured thatthe most efficient and useful opinion mining system is created.

Existing opinion mining systems have a number of limitations that stop them from truly being useful in a business. The primary hurdle includes language barriers such as emoticons, slang words, and sarcastic comments. While NLP has advanced in recent times, these challenges still persist. In this paper, a model may be proposed that can overcome at least some of these challenges, in order to make opinion mining more holistic and advantageous.

The purpose of this project is the create an opinion mining system that can correctly process, analyze, and classify online customer reviews on Amazon. The objective is to distinguish the most efficient ML model to carry out such a system by means of a comparative study. With this information, this paper proposes a model that can best

DOI: rp-9788770040723.118

perform opinion mining to allow businesses to make data driven business decisions.

II. LITERATURE REVIEW

In a paper written by T. Kim Phung et al [1], a study was conducted to try and use and apply the concept of supervised machine learning and its various methods. This study collected around 40000 reviews of travelers on hotels in Vietnam from ‘agoda.com’, a famous travel booking and review site. The next step consisted of training the machine learning models and figuring out which model works the best to forecast opinions. The results generated show that in the field of opinion mining, which is conducted here, three types of models have been effective in their performance, namely, Logistic Regression, Support Vector Machines and Neural Networks.

X. Xu et al [2] attempt to improve the aspect-level opinion mining that is generated for online customer reviews. Aspect-level opinion mining involves both the product and the sentiment that is generated for it. The new model that is proposed in this paper is to be used to jointly extract the aspects and the sentiment lexicons that are aspect-dependent, from the customer reviews available online. The results of this model are regarded to be more effective from the current standards and the practical values of the extracted lexicons are also increased.

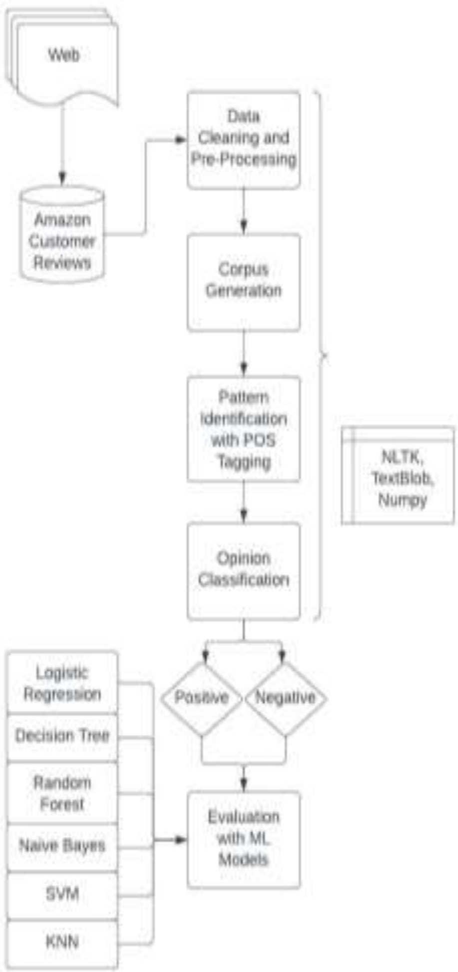

Fig. 1. Architecture Diagram

A process is explained by R. A. Laksono et al [3]where the reviews are classified using Naive Bayes technique to extract the sentiment of the customers, whether positive or negative. These reviews are often vital cogs of information for both the travel aggregator and the review site, as well as future consumers. The result from the research shows that the existing method of using TextBlob versus Naive Bayes, favors Naive Bayes by around 3%, but both methods are retrieving correct customer response.

Wu et al [4] conduct a study which aims to undertake and examine sentiment information from customer reviews and to predict and explore the potential of the same to enhance hotel demand forecasts. The customer reviews of four Macau luxury hotels are taken into consideration and their customer reviews are considered for the initial test. LSTM is used in this process and with the help of that, three indices are created that are checked out and are also evaluated for their effectiveness. The results of this paper are impressive and help in improving the forecasting accuracy.

An article by A. Adak et al [5]dwells on the fact that in the COVID-19 pandemic, the consumer had a change in how their food was delivered to them. Food Delivery Services took over the game and their growth has been rapid since doorstep delivery was preferred. These organizations have customers review them, which also can determine their company performance. This review is undertaken to find and explain machine learning, deep learning and explainable AI methods that are being used to predict customer sentiments. Key findings show a gap between DL and XAI methods and recommend to integrate them to perform in a better manner.

Like X. Xu et al [4]., S. Vanaja and M. Belwal [6] also use an aspect-based approach in their paper. This paper is an attempt to explain how to use sentiment analysis to analyze textual data and derive the sentiment from the same. This is due to the fact that in today’s world it is seen that almost every minute there is some or the other form of text data being generated. This paper deals with the e-commerce reviews that can help retailers and the companies to understand the expectations of the customer, to provide a holistic interaction and to add to their sales. Aspect terms are used here, along with parts-of-speech and also applying classification algorithms to get the score of the review.

III. METHODOLOGY

A. Overview

In this paper, the objective is to test various machine learning models to check which one of the models provides the most amount of accuracy in the end. The performances of models such as random forest, decision trees, logistic regression and so on are compared. The algorithm with the best performance can then go on to classify customer reviews as good or bad with reasonable accuracy and confidence. The methodology proposed in this paper is fairly simple: It begins with some basic data preprocessing and cleaning methods, following which a corpus of biwords and triwordsis created for pattern generation. Next, POS tagging is performed and the dataset is trained. Finally, the

DOI: rp-9788770040723.118

model is tested and validated against the proposed machine learning models to compare their performances.

B. Data Cleaning and Pre-Processing

The dataset is obtained of Amazon reviews for a range of products by rudimentary web scraping methods. However, this data needs to be processed and cleaned before any actions can be performed on it to train the model. Data pre-processing is an important step in any NLP task. Tasks such as lemmatizing and tokenizing the words in the dataset are performed as initial data pre-processing steps. In order to obtain a clean dataset that can be trained, stopwords and duplicates are removed. Moreover, the spelling of incorrectly spelt words in the dataset is corrected. To accomplish these tasks the pandas and nltk libraries in Python are used. For spelling correction, the TextBlob library is utilized. The TextBlob library is particularly useful as it helps simplify text-based tasks for natural language processing in Python. Once some basic data cleaning has been performed, a corpus of words is created. Further actions on this corpus are performed in the subsequent steps.

C. Generating Biwords and Triwords

The next step is to add biwords and triwords to the corpus that was created, in order to generate patterns. A corpus is generated with biwords and triwords in order to simplify language tasks and train the model effectively. The goal is to avoid any erroneously tagged opinions while the user searches for the opinion of a particular product. This step is the precursor to POS tagging.

D. Parts-of-Speech Tagging

POS Tagging, or Parts of Speech Tagging, is a process that labels or categorizes words in a sentence to their corresponding parts of speech. Thus, it is a language task that helps the algorithm understand natural language in a better way, with its correct syntax and grammatical structure [8]. By performing parts of speech tagging on the reviewed text, one can extract essential linguistic features of the text to generate patterns. In this paper, for each reviewed text, eight patterns are generated using a rule-based approach. Using these eight patterns, it becomes possible to generate opinion words and their corresponding opinion targets. Since a rule-based approach is being followed in this paper, it is essential to define a set of language rules for different parts of speech in a sentence. Then, these rules are applied to the text corpus to identify patterns. The eight patterns generated are adjective + noun, adjective + noun + noun, adverb + adjective, adverb + adverb + noun, adverb + verb, adverb + adverb + adjective, verb + noun, and verb + adverb. These patterns can help identify opinions in reviews more easily.

E. Training The Model

After performing parts of speech tagging to generate patterns in the text, the rest of the model training procedures can be commenced. A semi-supervised approach is used to create opinion targets from the list of Amazon products. Next, using wordnet from nltk corpus, sets of words that are similar in meaning to the titles of the products are obtained. This step is necessary in order to make it possible for users to look for product opinions without having knowledge of the precise keywords associated with it. The existing list of product names is thus appended with the similar words generated from wordnet. Next, for each opinion target, i.e., the product name or its corresponding similar word, opinion words from the dataset of reviews are found. Then, for each of these opinion words, words similar in meaning to these opinion words are further searched for. The same procedure as earlier is followed to do this, using wordnet from nltk corpus. For the final extracted opinion words, polarities are generated using the TextBlob library. The polarity of a word is an indication of its emotional sentiment, and is usually on a scale of -1 to +1, with -1 being the lowest value or overall negative sentiment and +1 being the highest or overall positive sentiment. Generating the polarity of each opinion word allows the model to categorize the resulting opinion as negative or positive, which is the crux of this paper. The polarities of similar opinion words are averaged out and assigned an overall score. This score is then used to categorize the target as overall positive or overall negative. Since ratings on Amazon are in a range of 1 to 5 stars, ratings of 1, 2, and 3 stars are considered to be overall negative and ratings of 4 and 5 stars to be overall positive. Thus, the model is trained to generate either a positive sentiment or a negative sentiment for a given product. A confusion matrix is also generated to evaluate the performance of the model thus far and obtain the r and f scores, as well as precision and accuracy. With this, the opinion mining model is trained. The dataset consists of 34000 reviews for analysis, out of which around 10000 can be used for testing.

F. Testing The Model

In order to test the model, reviews are introduced and assigned a positive or negative sentiment class to each of the reviews. Then, the same data preprocessing techniques as earlier are performed. Next, using the corresponding opinion words, the score for the review is generated. This is done using the TextBlob and numpy libraries. The resulting score depicts whether the product has an overall positive or negative sentiment associated with it. For 10000 reviews, the model achieved an overall accuracy of 78.67%.

G. Validating with Machine Learning Models

To validate the model with different machine learning models that were proposed, thesklearn library in Python is used, along with the bag of words model.LogisticRegression, DecisionTreeClassifier, Naive Bayes, RandomForestClassifier, KNeighborsClassifier, and SCV are fit to the training dataset. With each of these models, the test dataset results are predicted and k-fold cross-validation is performed, where in this paper k = 10. This is done to measure the performance of the classifiers.

Since the random forest algorithm usually has an upper hand against other traditional machine learning algorithms [12], it may have the best performance in this model as well. The working of the algorithm is hence detailed in the next subsection.

H. Random Forest Algorithm

In a machine learning context, a random forest is a collection of decision trees. Decision tree algorithm is a

DOI: rp-9788770040723.118

popular machine learning technique used for sentiment analysis, which involves determining the sentiment or emotion behind a text document. In the context of sentiment analysis, a decision tree algorithm works by using a tree-like model to represent possible decisions and their possible consequences. The algorithm builds a decision tree based on a set of training data, which consists of input text data and their corresponding sentiment labels (e.g., positive, negative, neutral).

The decision tree algorithm uses the training data to identify the most important features or attributes that are most predictive of sentiment. These features can include word frequency, the presence of specific words, or other linguistic features. The algorithm then creates a series of decision nodes based on these features, which determine the path that the algorithm will take through the decision tree. As the algorithm traverses the decision tree, it assigns sentiment labels to the input text data based on the decisions made at each node. For example, if the decision tree contains a node that tests for the presence of a specific word (such as "great"), the algorithm will assign a positive sentiment label if the word is present in the input text, and a negative sentiment label if it is not. Once the decision tree has been trained, it can be used to classify new text data based on their sentiment. The algorithm uses the decision tree to traverse the tree and assign a sentiment label to the input text data. Overall, decision tree algorithms are a useful technique for sentiment analysis because they are relatively easy to understand and interpret, and they can be trained on large datasets with high accuracy. However, they may not perform as well as more complex machine learning techniques for highly nuanced or complex sentiment analysis tasks. This is because decision trees are highly prone to over fitting. So to make this model more robust, an ensemble of decision trees can be used. Decision trees are bagged together to increase their performance, leading to Random Forest.

The first step in using the random forest algorithm is to prepare the training data. This involves selecting the features that will be used to make predictions and preprocessing the data to ensure that it is in a suitable format for the algorithm. Next, the random forest algorithm builds a set of decision trees. To build each decision tree, the algorithm selects a random subset of the training data and a random subset of the features. It then uses these subsets to train a decision tree. Once the decision trees are built, the random forest algorithm can make predictions for new data. To do this, the algorithm passes the new data through each of the decision trees and averages the results to produce a final prediction. For classification tasks, the final prediction is the mode of the predictions made by the individual decision trees. For regression tasks, the final prediction is the mean of the predictions made by the individual decision trees. Finally, the performance of the random forest algorithm is evaluated using a test dataset. This involves comparing the predictions made by the algorithm to the true values in the test dataset. Metrics such as accuracy, precision, recall, and F1 score can be used to evaluate the performance of the algorithm. The key advantage of random forest algorithm is that it can handle a large number of features and complex datasets, and can provide an accurate prediction even in the presence of missing data or noisy data. Additionally, by using multiple decision trees, the algorithm is less prone to overfitting and provides a more robust and stable prediction. However, random forest algorithm can be computationally expensive and may require significant computational resources to build and evaluate the model. This is due to the fact that multiple decision trees have to be built and run when the model is trained and used.

IV. RESULTS

The accuracy of the model is found to be 78.67%. If the project were to be scaled and the training data increased, may result in better accuracy. Sarcastic comments are also able to be classified as actually positive or negative with considerable success. Upon validating the model against various machine learning models, it is found that decision trees had the best performance, with an accuracy of 83.26%. The random forest algorithm was a close second, with an accuracy of 83.17%. This indicates that Random Forest and Decision Tree algorithms are almost comparable in performance. For a simple opinion mining system that is run entirely on machine learning algorithms, random forest or decision tree would provide the best results to the user. Logistic regression, gaussian naive bayes, multinomial naive bayes, bernoulli naive bayes, k nearest neighbor and SVM each yielded an accuracy of 59.23%, 74.65%, 82.70%, 77.24%, 79.77%, and 80.05% respectively. Logistic regression was hence found to be the weakest machine learning model for opinion-mining customer reviews. After cross-validation, the precision was found to be 0.81, recall 0.86 and the f score was found to be 0.83. These results are summarized in Table I.

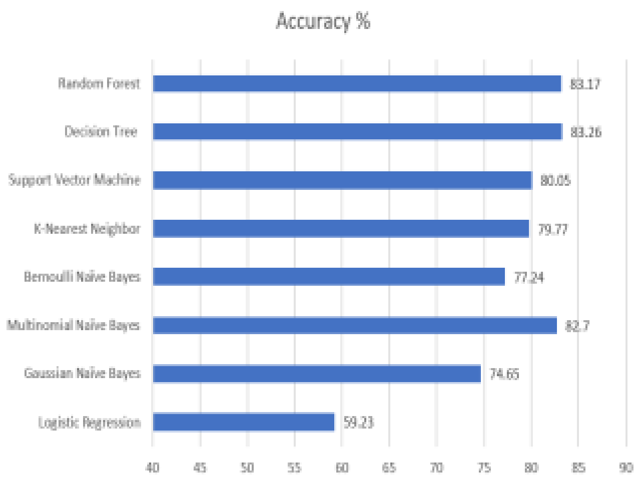

Fig. 2. Horizontal Bar Chart For Algorithm Comparison

TABLE I. ACCURACY OF ML ALGORITHMS

Algorithms	Accuracy %
Logistic Regression	59.23
Gaussian Naïve Bayes	74.65
Multinomial Naïve Bayes	82.70
Bernoulli Naïve Bayes	77.24
K-Nearest Neighbor	79.77
Support Vector Machine	80.05
Decision Tree	83.26
Random Forest	83.17

DOI: rp-9788770040723.118

V. FUTURE SCOPE

This paper, for the most part, allows forthe comparison of various machine learning models and their performance on a model trained for opinion mining online customer reviews. Although Amazon reviews are used, this model can be applied to any sort of e-commerce or business platform, as long as customer reviews are available online. The approach in this paper is quite simple, however, with the advent of deep learning and advanced technologies such as GPT-4, opinion mining as a whole can be greatly improved. Opinion mining still has a long way to go. In the future, such a model should be quicker in processing data and should also be able to do so with high accuracy. It should also be able to overcome present-day limitations such as the use of emoticons, sarcasm, and other language barriers. Fake reviews are another hinderance that opinion mining algorithms must be able to deal with [7]. One major disadvantage is that the same kind of model can yield varying levels of accuracy for comments in different languages. Future opinion mining systems must be able to detect comments of different languages within the same dataset and classify them as such. Additionally, they must also be equally accurate for each of the different languages. Since slang or internet vernacular keeps evolving, corpuses in opinion mining models must be able to update themselves to keep up with changes in user language. There is still much research to be conducted on these aspects of opinion mining, but a more robust opinion mining or feedback management system will be easily achievable with advancements in NLP technology.

***Abstract*—Bankruptcy of a company usually is a huge issue for companies. The bad influence of bankruptcy could lead to loss for components of the business such as the owners, the investors, the employees, and the consumers. Bankruptcy prediction is the practice of forecasting the financial distress and potential bankruptcy of a public firm. This area of research involves analyzing various financial ratios and other data to identify indicators of financial risk. We can prevent bankruptcy by predicting the likelihood of acompany getting bankrupt based on a company's financial ratios and data. With the advent of new data-intensive techniques, suchas machine learning, researchers have developed increasinglysophisticated methods for predicting bankruptcy. However, it is important to exercise caution when interpreting the results of such models, as they can suffer from biases and other limitations.Despite these challenges, bankruptcy prediction remains a critical area of study for investors and creditors seeking to assess the financial health of a company The issue of this whole processis managing the imbalance in class caused by the rare event of bankruptcy in the real economy. Advancements in Artificial Intelligence (AI) have helped these companies by applying those models to predict bankruptcy. This bankruptcy problem wassolved in this work by comparing various Machine Learning methods such as SVM, KNN, Ensemble Learning, Decision Tree classification was applied which achieved 60%, 84%, 93%, 94% accuracy.**

***Index Terms*—Finance, Bankruptcy, XGboost, KNN, Decision Tree, Classification, Ensemble Learning, SVM**

I. INTRODUCTION

For any company, insolvency is an undesirable phenomenon. It heavily affects the company owner and other responsible stakeholders. Companies getting bankrupt is increasing day by day. Therefore, bankruptcy prediction is of such high value and has been researched extensively over the past decades. There are a number of causes for business financial issues, and it's a difficult one to define, but some factors can be revealed that could signal impending bankruptcy. Determining your pre-bankruptcy status is critical to timely averting a difficult situation. Nowadays, highly advanced prediction- based computing techniques have been widely used by researchers to solve error prediction problems and are also discussed withsystematic literature review technique. In this study, we will focus on holistic methods to get the best possible results.

Bankruptcy is a legal process in which judges and court administrators investigate the assets and debts of individuals, partnerships, and corporations who believe they have too many debts to pay. The court decides to settle the debt. "Discharge" means that the person in debt is not legally obligated to pay. A court can also dismiss a lawsuit if it determines that the individual or entity has sufficient assets to pay the bills. Bankruptcy laws were written to give people a chance to start over when their finances collapsed.

Forecasting bankruptcy and assessing financial distress of public companies is an important area of research in finance and accounting. Creditors and investors are interested in predicting the likelihood of a firm going bankrupt, which has led to extensive research in this field. The abundance of data available for both bankrupt and non-bankrupt public firms, including various accounting ratios and other explanatory variables, has further spurred the development of sophisticatedforecasting techniques that rely on large datasets. The evolution of bankruptcy prediction involves the use of various statistical tools that have become increasingly available over time and requires a growing understanding of the limitations. Despite these advancements, some published research still fails to address long-known pitfalls in the field. The accuracy of bankruptcy prediction has improved with the development of more advanced machine learning models. This paper introduces recently developed methods for predicting bankruptcy using real-world data.

II. LITERATURE SURVEY

Research done by [1] did model development for companies getting bankrupt for the given firms using ML algorithms. They have used 21 variables which are used to select the variables for model. The 1st technique used is based on conditional likelihood and the 2nd technique about conditional correlation between variables. Totally 3 models were used for predicting a company's bankruptcy and is created using NB model and all three are evaluated. First NB model showed90 % and the second showed 93 % and logistic regression gave an accuracy of 90 %. Finally, it was concluded that it is possible to predict financial bankruptcy-based prediction using Bayesian models.

In [2] applied the algorithm called as Partial Least Squares Regression which in general helps us in implementing a huge number of financial ratios in the given algorithm. Apart from that, it also solves the issue based on correlation, and also takes into account the missing data. They also showed demo about how the application of the Partial Least Squares approach to the companies usuallyprovides improved results. The application of this technique consists of two classes which are of healthy and the failing companies, allows the members to possibly gain high significant results and also to propose a model which is better than a model obtained by a parametric approach. This research helps the bankers and the investors by providing a detailed explanation about the indicators which indicate bankruptcy. It allows companies to do diagnostics of their models to predict bankruptcy prediction. Logit models which were implemented by [3], resulted in a stepwise selection process, which correctly predicted 84% and 91% of bankruptcies 1 and 2 respectively. The Implied

DOI: rp-9788770040723.119

estimation models that a hotel business is more likely to get bankrupt if it has more operating cash flow and increased total liabilities when compared to none. Models suggest that a conservative sales strategy coupled with a tighter operating cost control and some less debt financing can help improve a company's ability to meet its financial obligations and thus reducing the risk of bankruptcy.

A study conducted by [4] evaluated the financial data of more than 400 companies – 52 of which went bankrupt and 348 were "healthy". The results show the set of factors involved for financial bankruptcy prediction and neural network relevance. They applied a total of 17 factors that characterize liquidity, profitability, sustainability, efficiency, and innovation. The total predictive power of the model created in our study is close to 98%, which is extremely superior an efficient when compared to other models

[5] applied multiple data analyzing tools to bankruptcy data, with the sole aim of comparing the accuracy of model. For these data, decision trees were more accurate than support vector machines and deep neural networks.

In a survey done by [6] analyzed the design and application of many ML models for different process involving default events: (a) Estimate the probability of survival over a period of time period (b)Predicting default bankruptcy using the time series based on accounting data of varying length. Finally, they seriously talk about the most interesting metrics and also suggested it for future studies.

A exploration by [7] evaluated the motivations and trends of business failure in Lithuania in the period 2006-2010. The probability of bankruptcy was assessed in five companies that are currently active and two that have gone bankrupt using Springate, Zavgren, the Altman and Chesser models. After testing the usability and the applications of bankruptcy financial prediction model in 7 companies, the results show that the linear discriminant model most accurately reflects the financial position of the company.

Statistical methods were used to select the most appropriate indicators by [8] and after filtering the data, the indicators were more convincing. Second, unlike former study methods, they use the same set of samples to do the experiment. Finally, the result can prove the worthiness of the machine learning method, with an accuracy score of 95.9%.

Analysis conducted by [9] solved the issue of unbalanced data with subsampling and (SMOTE). Machine learning techniques involving random forests resulted in 99% accuracy, while Decision Trees, Logistic Model Trees (LMTs), Support Vector Machines (SVMs), and random forests (RFs) resulted accuracy 92%, 92.3%, 93.8% and99%, respectively.

Support vector machine (SVM) to improve bankruptcy prediction problem with the aim of proposing a brand new algorithm was done by [10] with way better explaining capacity and increased stability. They used 5-fold cross-validation to find the efficient value of the SVM kernel function parameters.Apart from that, to predict the accuracy of SVM, they compare SVM performance with the performance of logistic regression analysis, multiple discriminant analysis (MDA), and 3-way back-propagation neural network. fully connected layer (BPN). Test results show that SVM is superior to other methods.

Research [11] which proposed a method by applying XG- Boost to handle class imbalance in datasets. In this work, Randomized Search CV optimization helped find the parameters. To increase model efficiency, XGBoost applies data sampling techniques. The experiment was based on two real credit card records. The study showed that the combination of data sampling doesn't have much effect on efficiency of XGBoost. The proposed approach finally ended up with very high accuracy

S.S. Panigrahi et al made an effort to use discrete input variables on top of which decision tree was applied. Decision trees for NSE and BSE are generated. It is constructed differently and its set side by side with a decision tree that is directly generated over the same period. Empirical studies prove high effectiveness of the given model by outperforming other decision trees [12]

[13] used data from company based in Ghana. Regression analysis was fitted to data from 648 clients. They proposed that microfinance institutions bear the risk of default. A model was implemented for determining the effect of problem, as it is relatively effective. It was recommended that training is re- quired to improve their skills. Regulators should also consider enacting legislation to make sure that this is guaranteed.

Research focused on cancer classification by [14]. The distribution shows that the dataset is high Unbalanced and biased decision tree-like learning algorithms. A benign observation, leading to poor prediction performance malicious observation. Adaptive boosting is used here in this study. The performance of the models is analyzed, and they came to know that Adaboost algorithm performed better than decision trees with accuracy of 95.1% over decision tree which had 89In their study, [15] proposed a novel similarity-based approach totext classification, utilizing a KNN model-based classifier that combines both KNN and Rocchio techniques. The researchers developed a classification prototype using the KNN model and conducted experiments on two well-known document corpora, the ModApte version of the Reuters 21578 collection and 20 newsgroups dataset. The results of their experiments indicated that the KNN model-based classifier performed favorably compared to traditional KNN and Rocchio classifiers. The researchers concluded that their proposed approach could be a viable alternative to KNN and Rocchio in various domains.

III. Proposed Methodology

Classification algorithm is used to predict the target class asthe target class which are categorical in nature. We are going touse SVM, KNN, XGBoost and Decision Tree Classifier. Let see in detail about the following algorithms and the results they produce

A. *Logistic Regression*

Logistic Regression is a machine learning technique frequently used to predict binary outcomes, such as "Yes" or

DOI: rp-9788770040723.119

"No," by analyzing the relationship between one or more independent variables and a dependent variable in a dataset.

B. SVM

Support Vector Machines (SVM) are popular supervised learning algorithms used for classification and regression problems. SVM creates optimal decision boundaries, or hyper- planes, to divide n-dimensional space into classes so that new data points can be categorized correctly. The SVM algorithm chooses support vectors, or extreme cases, to help create hyperplanes. SVM achieves an accuracy of 60%.

C. XGBoost classifier

XGBoost is an advanced gradient boosting library known for its efficiency, flexibility, and portability. It uses machine learning algorithms as part of gradient enhancement and offers Parallel Tree Boost, which solves many statistical problems quickly and accurately. The code runs on major distributed environments like Hadoop, SGE, MPI, and can solve problems beyond billions of examples. XGBoost achieves an accuracy of 92%.

D. KNN

K-Nearest Neighbor (KNN) is a simple machine learning algorithm based on supervised learning techniques. KNN calculates the space between a point and all points in the data, chooses the K number of specific examples closest to the point, and votes for the most common label (in classification) or averages the labels (in regression). KNN achieves an accuracy of 84%.

E. Decision Tree classifier:

The Decision Tree classifier is a popular model that creates a tree called a decision tree. Each node in the decision tree tests a column, and each branch corresponds to one of the possible values for that variable. The Decision Tree classifier achieves an accuracy of 94%.

IV. SYSTEM ARCHITECTURE

The dataset used here in this work is based on company bankruptcy which has 6820 rows and 95 columns. It was acquired from the Taiwan journal. The output class in this dataset has information about whether the company is bankrupt or not. Basic EDA techniques were applied to explore the data. Feature selection was initially done using Random Forest method which helped select the right features for the model. The data of the target class was initially evaluated to check the class imbalance and as expected a huge amount of class imbalance was found with the data where a company is bankrupt being the minority class. Imbalanced data are values in which the observed frequencies are very different across the different possible values of a categorical variable. It's like there are many rows of some type and very few of another type. Correlation methods were also used to find out how various variables are correlated with each other. Figure 1 depicts the overall system architecture for evaluating the performance comparison of various ML models

The data is next being readied for model where we can apply the algorithm. The data imbalance of target class was

Financially stable: 96.52 % of the dataset
Financially unstable: 3.48 % of the dataset

As our data's target class has a huge imbalance of data, we will use SMOTE sampling method to generate synthetic samples from the minority class.

SMOTE is an oversampling technique that produces synthetic samples of minority classes. SMOTE algorithm will help solving the problem of overfitting due to oversampling. We focus on the features and create new instances using interpolation between consecutive positive instances.

Then model was split into train and test and then predicted using various classification algorithms. The results were evaluated, and the best model was used for bankruptcy prediction

V. EXPERIMENTAL EVALUATION

The performance of various Machine learning models are examined using the following metrics.

a) ACCURACY: Accuracy is the one of the predefined models which is used to find the balanced and unbalanced data in the models and how its performing in the given predicted models. A common way to calculate accuracy in machine learning is by dividing the total number of correct predictions by the total number of predictions made.

Accuracy = True positive + True Negative / True positive+ False positive + True Negative + False Negative

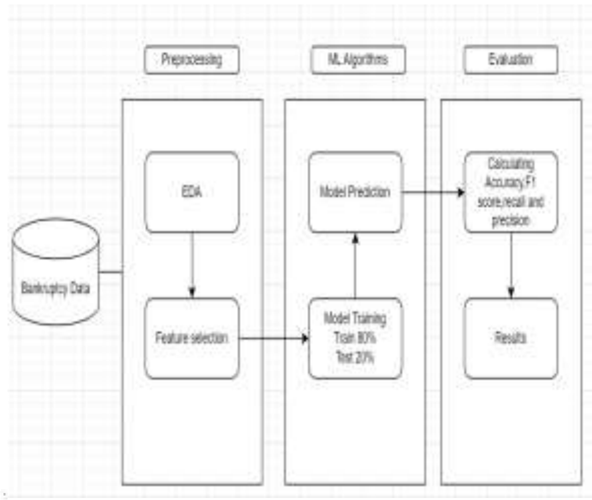

Fig. 1. Depicts the architecture of this work

b) PRECISION: It is calculated as the ratio of true Positives to all the positives predicted by the model. A higher precision indicates a lower number of false positives predicted by the model. In this data we have used precision for finding the perfectness of the model to know the true positive value, negative value. By the precision equation we can find the denominator for true positive of values.

DOI: rp-9788770040723.119

Precision = True Positive / True Positive + False Positive

c) RECALL: Recall, also known as Sensitivity, is another metric used to evaluate the performance of a machine learning model. It is calculated as the ratio of True Positives to all the positives in the dataset. A lower recall value indicates that the model is predicting more false negatives.

Recall = True Positive / True Positive + False Negative

(d) F1 SCORE

F1 score is a metric used to evaluate the overall performance of a machine learning model. It is calculated as the harmonic mean of precision and recall, taking into account the contribution of both metrics.

F1 Score = 2 *Precision*Recall / Precision+Recall

The models have been applied and the following results have been achieved

TABLE I: ACCURACY COMPARISON FOR VARIOUS ML MODELS

S.No	Model	Accuracy
1	SVM	60%
2	KNN	84%
3	XGBoost	92%
4	Decision Tree Classifier	94%

Table I shows accuracy of various ML models.We can see that Decision tree has more accuracy compared to other algorithms

TABLE II: PRECISION COMPARISON FOR VARIOUS ML MODELS

S.No	Model	Accuracy
1	SVM	64%
2	KNN	85%
3	XGBoost	93%
4	Decision Tree Classifier	94%

Table II shows precision of various ML models.We can see that Decision tree has more precision compared to other algorithms.

TABLE III: RECALL VALUE FOR VARIOUS ML MODELS

S.No	Model	Accuracy
1	SVM	61%
2	KNN	85%
3	XGBoost	92%
4	Decision Tree Classifier	94%

Table III shows recall of various ML models

TABLE IV: F1-Score for Various ML Models

S.No	Model	Accuracy
1	SVM	59%
2	KNN	85%
3	XGBoost	92%
4	Decision Tree Classifier	94%

Table IV shows F1-score of various ML models. F1 score is the highest for decsion tree as per the above table

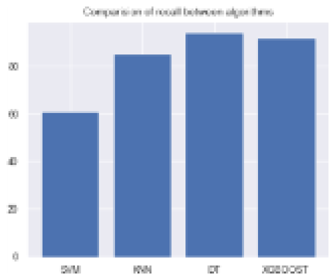

Fig. 4. Recall of various ML algorithms

Fig 2, Fig 3, Fig 4, Fig 5 shows the performance metrics of various ML algorithms

CONCLUSION

This study fully focused on applying and implementing the methods and techniques which actually help companies avoid getting bankrupt by analyzing their financials and thereby using a Machine Learning approach. Based on the results of the research study, the findings suggest that these models can offer improved accuracy and effectiveness

DOI: rp-9788770040723.119

compared to traditional statistical methods. The study demonstrated the potential of sampling techniques such as SMOTE and also applied advanced models such as SVM, logistic regression, decision tree, and XGBoost which helped predicting bankruptcy ofpublic firms. These findings have implications for investors and creditors seeking to evaluate the financial health of a company and make informed decisions based on accurate risk assessments. The results of this study also highlight the importance of exploring a variety of models and techniques to develop robust and accurate predictions, as well as the need to continue refining and improving these models through further research and experimentation. Overall, the use of machine learning models for bankruptcy prediction holds promise as a valuable tool for improving financial risk assessment in the future. In conclusion, our study highlights the potential of machine learning models to predict bankruptcy, using a dataset of financial ratios from public companies. By using a range of algorithms, we were able to demonstrate the effectiveness of these models in identifying potential financial distress and predicting bankruptcy. We believe that future research could build on this work by applying more advanced algorithms, testing additional financial ratios, and exploring other potential features of interest. The proposed methods were successful in predicting a company's bankruptcy thereby saving company from getting bankrupt.

***Abstract*—Peer-to-peer trade structures known as advanced types of cash use the secure hash algorithm (SHA)-256 and message digest (MD)- 5 to defend data moves. Bitcoin costs are very unsound, show stochastic approach to acting, and have achieved eccentricism. They have for the most part supplanted customary speculation vehicles like metals, bequests, and the securities exchange and are much of the time utilized for venture. The making of a dependable determining model is fundamental because of their business importance. Yet, it's difficult to anticipate bitcoin costs since it relies upon other digital forms of money. Machine learning(ML) and deep learning models, as well as other inclination based market procedures, have been utilized by different examiners to evaluate bitcoin values. Since all digital currencies fall under a similar class, an adjustment of the cost of one cryptographic money might influence other cryptographic forms of money. To expand the framework's viability, the analysts additionally consolidated feelings from tweets and other online entertainment locales. DL-Gues, a creamer and solid construction at predicting computerized cash costs that thinks about its dependence on other cryptographic types of cash and market sentiments, is presented in this paper as an inspiration. Utilizing Run, Litecoin, and Bitcoin tweets and cost accounts as endorsement, we explored Run cost assumption. Utilizing the worth history and tweets of Bitcoin, Litecoin, and Bitcoin, we interpreted finishes for the assumption for the expense of Bitcoin-Cash to survey whether DL-Gather could be applied to extra advanced monetary standards.**

Keywords—Complex systems, crypto currencies merged into one, price prediction, VADER, sentiment analysis, deep learning, and systems of systems

I. INTRODUCTION

A cryptographic cash is a sort of electronic money planned for use in customary trades. To keep financial transactions secret, it employs cryptographic algorithms like SHA-256 and MD-5. Currently, financial transactions can only be carried out with the assistance of third-party institutions like banks; however, cryptocurrency removes this requirement. Society's acceptance of cryptocurrencies is growing. It was firstpresented in 2008 as Bitcoin, determined to supplant the entire cash trade framework with a widespread computerized cash framework [1]. To make the framework straightforward, secure, and decentralized, this recently built monetary framework is free of incorporated monetary establishments like banks, legislatures, and different associations. To stay aware of the consistency and trustworthiness of the system, understanding procedures like proof-of-work (PoW), proof-of-stack (PoS), and others were made. When it first started, the rates for exchanging coins were extremely low. However, its market tends to grow over time due to its volatility. Up until April 2021, there have been approximately 4200 cryptocurrencies on the market, with a $2.23 billion market cap. With 78% and 12%, respectively, of the total, Bitcoin and Ethereum are the most significant contributors [2]. Numerous individuals, investors, and businesses have made direct or indirect investments as a result of the rise in the bitcoin market [3]. The surge in the bitcoin market is unsettling due to its unpredictability. Over time, the value of cryptocurrencies fluctuates significantly. In less than a decade, the price of Bitcoin has increased from $0.08 in 2010 to $64000 in April 2021 [2]. Ethereum costs went from $0.67 in January 2018 to

$2346 in April 2021 [2] in accordance with a similar example. The bitcoin market's unpredictability can be made sense of by these examples. The price of rival digital currencies, volume, difficulty of mining, popularity, and other factors all contribute to the volatility of crypto currency prices.

The efficient market hypothesis (EMH) and the alternative market hypothesis (AMH) have been utilized by researchers from wherever the world to analyze the models and eccentricism of the bitcoin market. As indicated by the EMH speculation, the costs at which cryptographic forms of money are exchanged are in every case fair and mirror the data that is all suitable. Also, as the mining task turns out to be more troublesome, the connected money's worth will rise [4].

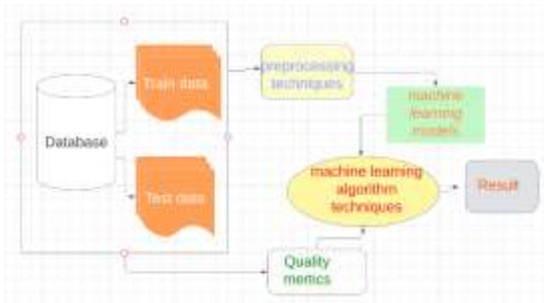

Fig.1: Model development

However, this theory does not work in practice, so a new theory, AMH, which incorporates behavioural finance, was developed to address its shortcomings. Even though the authors of [5] are incorrect, we may still be able to achieve favorable outcomes by utilizing EMH.

II. LITERATURE REVIEW

[3]Stochastic neural networks for cryptocurrency price prediction: With the headway of blockchain innovation lately, the use of digital currency has expanded essentially. Then again, because of the market's high instability and cost variance, digital forms of money are not viewed as a venture

DOI: rp-9788770040723.120

an open door. Because of their deterministic nature, the majority of the digital currency cost anticipating strategies portrayed in the writing may not be appropriate for ongoing cost expectation. To foresee bitcoin values in light of the previously mentioned issues, we give a stochastic brain network model. Irregular walk hypothesis, which is every now and again used in monetary business sectors to show stock costs, fills in as the establishment for the proposed strategy. The proposed approach applies layer-wise randomization to the noticed brain network highlight actuations to copy market unpredictability. There is likewise a method for learning the example of market response in the expectation model. On Bitcoin, Ethereum, and Litecoin, we showed the Long Short- Term Memory (LSTM) and Multi-Layer Perceptron (MLP) models. The revelations show that the proposed model performs better contrasted with deterministic models.

[5]Efficiency in the markets of crypto-currencies: We demonstrate that the five major cryptocurrencies' market efficiency varies significantly over time. Prior to 2017, most bitcoin exchanges were ineffective. This is supported by recent field results. However, between 2017 and 2019, the bitcoin markets became more efficient. This is contradicted by other, more recent findings on the subject. We use a larger sample size than previous studies for one reason. We use a rigorous efficiency measure to determine whether or not the efficiency is significant, which is another important reason. Litecoin is the most productive digital currency by and large, while Wave is the most un-proficient.

[6] Cryptocurrency price prediction using news and social media sentiment: A paper endorsed by Satoshi Nakamoto under the pen name Nakamoto was the way the world previously found out about Bitcoin. In the years that followed, a significant number of other cryptocurrencies were created as a result of its enormous popularity. The market's extremevolatility, which has piqued the interest and engagement of numerous individuals, primarily for profit, is largely to blame for this exponential rise. Bitcoin fans every now and again utilize web-based entertainment stages, the most well known of which is Twitter, to share and find out about news and thoughts. We examine how Twitter sentiment research can be used to anticipate changes in bitcoin price in this paper. We started by social affair tweets and cost information for seven of the most famous digital currencies, which we then handled to do feeling investigation involving Valence Mindful Word reference for Opinion Thinking (VADER). The Granger Causality test was followed by the Augmented Dicky Fuller (ADF) and Kwiatkowski Phillips Schmidt Shin (KPSS) tests for time-series stationarityassessment. Considering a bullishness extent, Ethereum and Polkadot were seen as obvious, despite the way that inclination in Bitcoin, Cardano, XRP, and Doge radiates an impression of being influenced by cost differences. Last but not least, the predictability of price returns is investigated through the use of Vector Autoregression (VAR), with estimates that are remarkably precise for two out of the seven cryptocurrencies. The price estimates for Polkadot and Ethereum were 99.17% and 99.67%, respectively.

[7] Prediction of Bitcoin exchange rate to American dollar using artificial neural network methods: Investments in cryptocurrency trading are growing in popularity. The bitcoin market has been contrasted with the FX and stock trades. However, in order to assist investors in making investment decisions regarding bitcoin trading, a prediction tool is required due to its volatility. In today's stock and currency market forecasting, methods that are based on the computation of Artificial Neural Networks (ANNs) are frequently utilized. Case studies in stocks and forex have been the subject of a lot of ANN predictor research, but cryptocurrency has not been the subject of any. This study therefore examined a variety of ANN strategies for predicting Bitcoin's market value, one of the most well-known cryptocurrencies. A model that can predict the end worth of Bitcoin the following day (following day figure) will be made using ANN methodologies. Backpropagation neural network (BPNN), genetic algorithm neural network (GANN), genetic algorithm backpropagation neural network (GABPNN), and neuro-evolution of augmenting topologies (NEAT) are the four ANN methodologies broke down in this audit. The methods are overviewed thinking about their accuracy and flightiness. The assessment showed that BPNN is the best technique, with a MAPE of 1.998 0.038% and a readiness time of 347 63 seconds.

[8]Machine learning models comparison for bitcoin price prediction: Lately, Bitcoin has transformed into the main advanced cash. Be that as it may, Bitcoin costs have varied extraordinarily, making guaging troublesome. Subsequently, the objective of this study is to utilize an assortment of ML procedures to find the most reliable and viable model at foreseeing Bitcoin costs. Using 1-minute stretch trade data from the Bitcoin exchange site bitstamp between January 1, 2012 and January 8, 2018, different backslide models were surveyed. The R-Square (R 2) was just probably as high as 99.2 percent, and the Mean Squared Error (MSE) was overall around as low as 0.00002.

III. Inference from the Survey

The references provided various aspects of cryptocurrency, including the technology behind it, market analysis, and price prediction using machine learning techniques.

- the foundation for the cryptocurrency ecosystem and the technical aspects of the Bitcoin network
- Understood how stochastic neural networks or stochastic model play a key role in improving the accuracy
- the relationship between Bitcoin mining energy costs and its price. It has been comprehended that there exists a correlation between the two factors, and a potential consequence of increasing energy expenses is the reduction in the value of Bitcoin..
- explored the efficiency of the cryptocurrency market and investigated the presence of market anomalies. The authors find evidence of market inefficiencies and suggest that investors can potentially profit from these anomalies.

DOI: rp-9788770040723.120

IV. Methodology

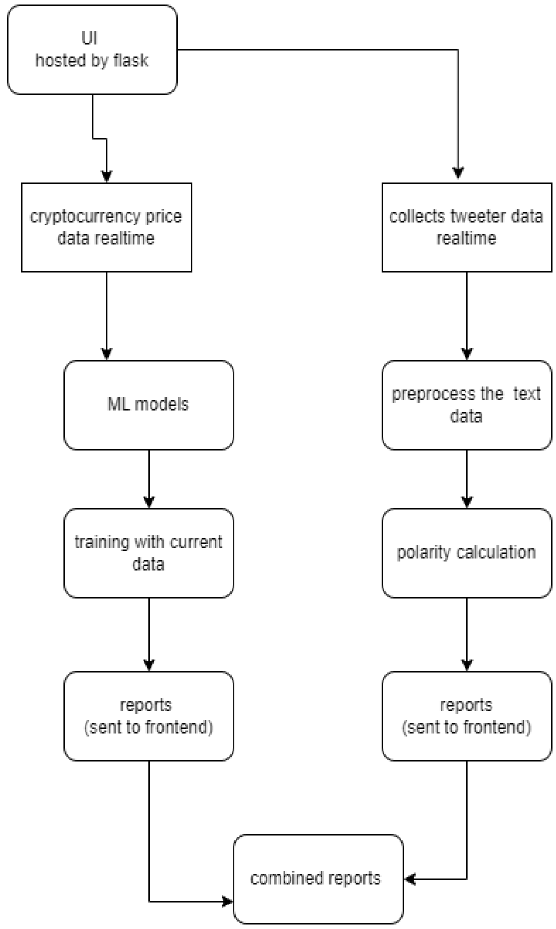

Fig.2: Block Diagram of Crypto price prediction

The Block diagram (Fig 2) depicts that the complete application was deployed on a Flask server. The application utilizes APIs to obtain real-time price data, which is used for the development and training of the machine learning model. After evaluating multiple models, the optimal model(stochastic) that performs exceptionally is selected. Subsequently, the model's performance report is conveyed to the frontend via the respective page. In parallel, the application continuously collects Twitter data in real-time. The preprocessed Twitter data undergoes sentiment analysis to calculate the polarity score, which is then sent to the frontend. The application generates the recommendation based on the outputs from both the machine learning model and sentiment analysis of Twitter data.

The efficient market hypothesis (EMH) and the alternative market hypothesis (AMH) have been utilized by experts from wherever the world to look at the models and eccentricism of the bitcoin market. As indicated by the EMH speculation, the costs at which digital currencies are exchanged are in every case fair and mirror the data that is all suitable. Moreover, the mining undertaking's intricacy will build the connected cash's cost. However, this theory does not work in practice, so a new theory, AMH, which incorporates behavioural finance, was developed to address its shortcomings. Nonetheless, while the authors' findings may be accurate, we may achieve favorable outcomes using EMH.

A. *Disadvantages*

1. The connected cryptocurrency's price will rise intandem with the mining task's complexity.
2. Using EMH in the manner that the authors do is still possible, but it is incorrect.

ML and deep learning models, as well as other assessment based market approaches, have been utilized by different experts to evaluate bitcoin values. Since all digital forms of money fall under a similar class, an adjustment of the cost of one digital money might influence other digital forms of money. To expand the framework's adequacy, the analysts likewise consolidated feelings from tweets and other online entertainment locales, a cross variety and extreme framework at predicting computerized cash costs that thinks about its dependence on other cryptographic types of cash and market feelings, is presented in this paper as an inspiration.

B. *Benefits*

1. In order to demonstrate the effectiveness of Deep Learning (DL) on digital currencies, we conducted a thorough investigation and analysis of two specific cryptocurrencies. Our goal was to showcase the potential of DL in accurately predicting and analyzing the behavior and trends of these digital assets. Through our analysis, we aimed to provide valuable insights into the performance of DL on digital currencies and its potential applications in the field of finance.
2. Our research has shown that the proposed neural network model outperforms previous systems in predicting bitcoin prices. The neural network algorithm that we used utilizes advanced DL techniques to analyze and interpret large amounts of data, resulting in more accurate and reliable predictions than previous models. By improving the accuracy of bitcoin price predictions, our research has the potential to impact the financial industry by providing more informed decision-making tools for investors and traders.

C. *Modules*

To finish the recently referenced project, we arranged the modules recorded underneath.

- Examination of data: We will enter data into the system with this module.
- Data will be added a bonus to this module for dealing with.
- Segregating the data into test and train models: Data will be isolated into train and test models by this module.
- fostering the determining models LSTM, GRU, and ARIMA. The calculation's not set in stone.
- Login and enlistment for clients: Enrollment and login are expected to get to this module.
- Expected input will result from using this module.
- Prediction: The displayed final predicted value

DOI: rp-9788770040723.120

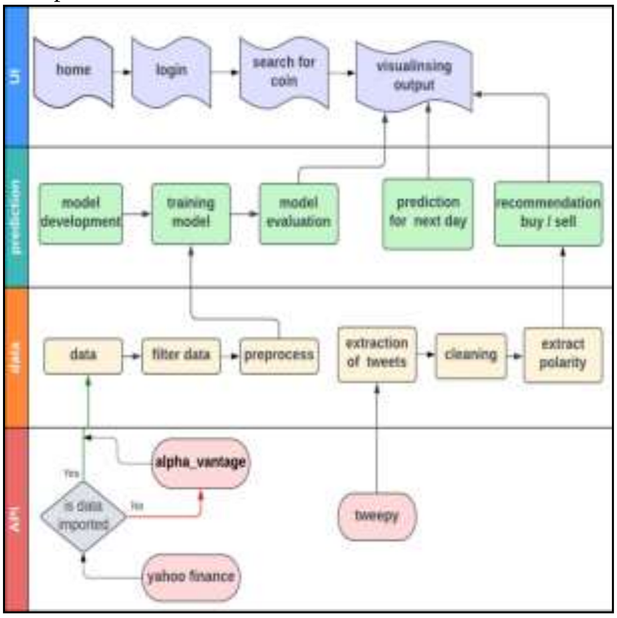

Fig.3: System architecture

The Architecture diagram (Fig 3) shows that the frontend user interface comprises four pages with the capability to navigate to the Login page from the Home page. Upon successful authentication, users can search for a specific cryptocurrency using Yahoo Finance API, and in case of failure, the Alpha Vantage API is used as a fallback. After retrieving the cryptocurrency data, relevant attributes are filtered using data preprocessing techniques before the data is fed into the training model. The trained model can then be utilized to predict the price of the cryptocurrency for the next day, and model evaluation is carried out using testing data. The predicted output for the next seven days, along with the model evaluation, is displayed on the output page. Additionally, Twitter data is obtained via Twitter API and undergoes a cleaning process that involves eliminating stop words, unwanted symbols, and other extraneous data. Using the TextBlob Python library, the polarity of each tweet is extracted and consolidated to determine the overall sentiment of the selected cryptocurrency. Based on the calculatedpolarity and predicted price, a simple recommendation is made to users as to whether they should buy or sell the selected cryptocurrency for the day, and this is displayed on the output page.

V. Implementation

A. Algorithms

CNN + LSTM: While LSTM layers in a CNN-LSTM model predict sequences, CNN layers collect features from input data. A period series is a fleeting information grouping that is frequently utilized for consecutive information. LSTM was chosen as the DNN algorithm because it does a good job with sequences. When looking for information about a neighborhood, like in a picture, CNN is often helpful.

LSTM: a fake recurrent neural network(RNN), long short- term memory (LSTM), and uphold learning incorporate a profound getting the hang of designing. For applications that request time series and groupings, LSTMs are a practical decision.

GRU: Kyunghyun Cho et al. cultivated the tedious cerebrum network gating technique known as gated recurrent units (GRUs). in 2014. The GRU works similarly to a long short- term memory (LSTM) with a disregard entryway anyway with less limits since it doesn't have an outcome entrance.

Random Forest: Classification and regression problems are common applications of the Random Forest Method, a supervised machine learning method. We are aware that there are a lot of trees in a forest, and that the more trees there are, the stronger the forest is.

Decision tree: For characterization and relapse, a decision tree is a sort of non-parametric directed learning approach. It has a root hub, inward hubs, leaf hubs, and a progressive tree structure.

SVM: SVM is a gathering and backslide friendly oversaw ML computation. They are better organized when we suggest them as backslide concerns. Finding a hyperplane in a N-layered space that totally portrays the data centers is the goal of the SVM method.

MLP: One more innovation for ANN with numerous layers is the multi-layer perceptron (MLP). While a single perceptron may manage clear direct challenges, it isn't particularly acclimated to non-straight applications. MLP could be utilized to manage these troublesome issues.

Voting classifier: A voting classifier is an ML assessor that gains from the consequences of many base models or assessors and makes forecasts in light of them. For each assessor yield, gathering models might be matched popularity based decisions.

ARIMA: ARIMA models are normally alluded to as ARIMA (p,d,q), where p addresses the autoregressive model request, d shows the level of differencing, and q addresses the moving- normal model request. ARIMA models use differencing tochange throughout a non-fixed time series into a proper one, which is then used to anticipate future characteristics.

VI. Evaluation

DOI: rp-9788770040723.120

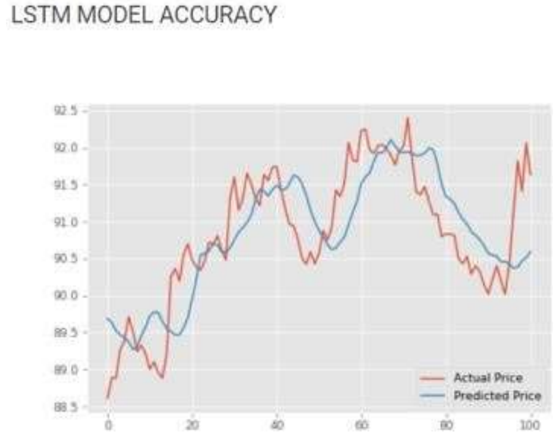

Fig.5: LSTM model evaluation

Fig.6: sample output of twitter data analysis

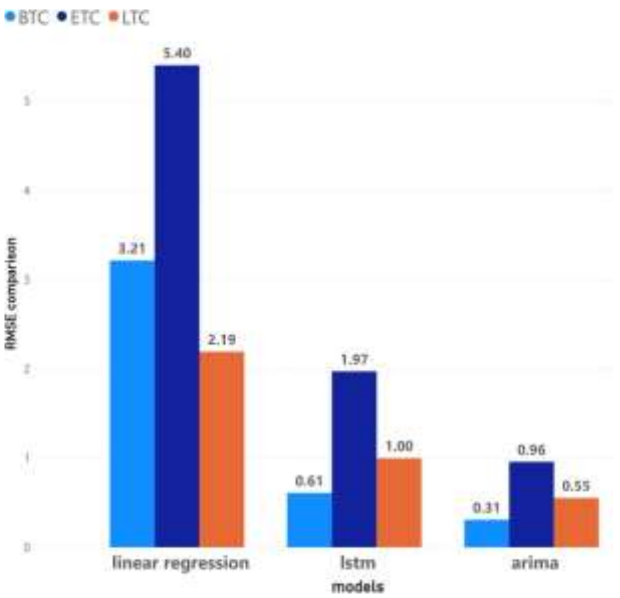

Fig.7: RMSE comparison of different models

VII. Conclusion

We looked at the current methods for predicting bitcoin prices in this post. Fintech organizations utilize various them to exploit the benefits of bitcoin cost forecast calculations. Be that as it may, the market's eccentricism and the various ward parts make expectation troublesome. In this review, we foster DL-Surmise, a half and half model at foreseeing bitcoin costs that considers value history and current Twitter opinions. We analyzed the outcomes, or misfortune capabilities, with past examination to explain DLGuesS's flexibility for two particular cryptocurrencies. The proposed DL-GuesS method outperforms existing algorithms when it comes to predicting bitcoin prices. DL-GuesS.

VIII. Future Scope

- Using blockchain for decentralized prediction markets: You can use blockchain to create a decentralized prediction market, where users can bet on the accuracy of your prediction model. This would create a self-regulating system where users are incentivized to contribute accurate data and improve the accuracy of the model.
- Using blockchain for smart contracts: You can use blockchain to create smart contracts that automate the execution of trades based on the prediction model. This would create a decentralized trading platform that runs autonomously, without the need for centralized intermediaries.

***Abstract*—Underwater optical images are insufficient for visual examination or analysis due to their poor colour representation, low contrast, and excessive noise levels. This project suggests a novel method of underwater image improvement that includes colour correction, image defogging/dehazing, image denoising, and object recognition in order to overcome these difficulties.**

The procedure relies on the image_dehazer python library for dehazing, the fastNlMeansDenoisingColored function of OpenCV for denoising, and the Google vision API for object detection. Based on the input image, a filter matrix is created to correct the colour by adjusting the hue and normalising the red, green, and blue channel intensities.

The suggested technique is put into practice using a flask API that is hosted on the internet and usable on low-end computers and mobile devices. In contrast to existing approaches, this technology is highly effective and appropriate for a variety of underwater imaging applications because it does not rely on machine learning or training models.

This research presents an effective method for improving underwater images, suitable for various imaging applications. The sample size of the images used was 890 (Large Scale Underwater Image Dataset). The temporal efficiency of this code is significantly influenced by the dimensions of the input image and the intricacy of the filter matrix. It has potential use in submarine operations for defense purposes such as surveillance and monitoring. The proposed method produces high-quality results while being accessible and cost-effective.

Keywords—Underwater, image processing, denoising, dehazing, color correction.

I. Introduction

Underwater imaging is a complex task because of light attenuation, absorption, and scattering in water. These conditions result in low-contrast and noisy images, making it difficult to extract useful information. Therefore, developing efficient methods to denoise underwater images is crucial to improve their quality and visual appearance.

This paper proposes a new method for denoising underwater images that combines the single-image haze removal method with the dark channel prior (DCP) algorithm and the Fast Denoising Colored Guided Image Filter (FDCGF). The DCP algorithm calculates the transmission map, which quantifies the amount of haze in the image, and then employs it to remove haze and improve image contrast.

The proposed method involves several steps: converting the input image to grayscale, calculating the dark channel of the grayscale image, estimating the transmission map using the DCP algorithm, removing haze from the image based on the estimated transmission map, and finally, denoising the image using the Non-local Means (NLM) algorithm.

The FDCGF algorithm is a fast and efficient method for denoising colored images. The technique employs a guided filter to eliminate noise while maintaining the image's sharp edges and small details. The guided filter is a generalisation of the bilateral filter in which the guidance signal is the input image itself. This allows the filter to adapt to the local structures in the image and achieve better denoising performance.

The DCP algorithm is based on the observation that the dark channel of outdoor images is very low in regions with haze. It calculates the transmission map by assuming that the image's minimal value in a local window corresponds to the image's haze-free parts. On the other hand, the NLM algorithm averages pixels in a local neighborhood based on the similarity between the pixels measured using a weighted average of their intensities.

The suggested method is tested on an underwater image dataset, and the findings reveal that it beats existing methods in terms of objective measures as well as visual quality. The proposed technology has the potential to be beneficial for a variety of underwater imaging applications, including underwater surveillance, marine biology, and oceanography.

The paper's structure includes a literature review of existing methods for denoising underwater images, a detailed description of the proposed method, experimental results, and a discussion of future research directions. [1]–[5][6]

II. Issues And Challenges

Since a decade ago, underwater image processing has received substantial attention due to the physical characteristics of water and its state.

Exercises in identifying and recognising objects underwater have created new challenges. These activities have resulted in considerable issues because of the effects of light absorption and diffusion.

Light attenuation

As light travels through water, it is absorbed and scattered, which results in light attenuation. As a result, there may be colour distortion, less contrast, and poorer imagequality. Light attenuation in water is calculated using the Beer-Lambert Law, which shows an exponential decrease in light intensity with depth. The Beer-Lambert Law can be used to estimate the intensity of light at a

DOI: rp-9788770040723.121

particular depth and to determine the minimal quantity of light needed to capture a picture at a certain depth, according to a study by Kirk.[7]

$$I = I_0 * e^{(-k*d)} \quad (1)$$

where I is the intensity of the light after it has traveled through a distance d, I_0 is the initial intensity of the light, k is the absorption coefficient of the medium, and the mathematical constant e is roughly 2.718 in value.

A. Water turbidity

Due to light scattering and reduced contrast, water turbidity can affect visibility and image quality. The Mie theory, which takes into consideration the size and concentration of particles in the water, can be used to describe the amount of light dispersed by turbid water. "Mie theory can be used to estimate the scattering of light in water due to particles, which can help predict the visibility and image quality in turbid water," claims a study by Mobley.[8]

$$Q_{ext}=[(2/x^2) * |B(x)|^2] * [(2x^2/(x^2 + 1)^2) + (2/x^2) * |C(x)|^2] \quad (2)$$

whereQ_{ext} is the extinction efficiency, x is the size parameter defined as the ratio of the particle diameter to the wavelength of light, B(x) and C(x) are the Mie coefficients which depend on the refractive index of the particle and the medium, and $|B(x)|^2$ and $|C(x)|^2$ represent the magnitudes of the coefficients squared.

B. Color distortion

The selective absorption of light by water and the scattering of light by water-borne particles result in colour distortion in underwater photographs. The White Balance Equation, a mathematical formula, is used to modify the colour balance of photos to take into account the selective absorption of light in underwater photography. The White Balance Equation can be used to alter the colour balance of underwater photographs and correct for colour distortion brought on by water absorption, according to a study by Kawaguchi.[9]

$$R\_corr = R / R\_w * R\_gw \quad (3)$$

$$G\_corr = G / G\_w * G\_gw \quad (4)$$

$$B\_corr = B / B\_w * B\_gw \quad (5)$$

where R_corr, G_corr, and B_corr are the corrected red, green, and blue channels of the image, R, G, and B are the original red, green, and blue channels of the image, R_w, G_w, and B_w are the white balance values of the image, and R_gw, G_gw, and B_gw are the gains applied to the image.

C. Backscatter

The reflection of light by particles and other suspended objects in the water is what causes backscatter in underwater photographs. Images may become blurry and lose contrast as a result of this. The Volume Scattering Function (VSF), which characterises the scattering of light by particles as a function of angle and wavelength, is the mathematical formula for backscatter in water. "The VSF can be used to estimate the amount of backscatter in water, which can help predict the image quality and visibility in different water conditions," claims a study by Mobley.[8]

$$b(\theta) = C * ((1 - g^2) / (4\pi)) * P(\theta) \quad (6)$$

where C is a constant related to the concentration and size distribution of the particles, g is the asymmetry parameter that describes the angular distribution of the scattered light, and P(θ) is the phase function, which describes the probability of light scattering at a particular angle.

D. Image stabilization

Because the water and things move when being photographed underwater, image stabilisation is a challenge. The Optical Flow Equation, a mathematical formula for image stabilization, defines how objects move inside an image and can be used to calculate the degree of motion blur. The Optical Flow Equation can be used to determine the degree of motion blur in underwater photographs and adjust for camera movement, according to a study by Harvey.[10]

$$I(x,y,t) = I(x+u,y+v,t+1) \quad (7)$$

where I is the image intensity, (x,y) are the spatial coordinates, t is the time, and (u,v) are the optical flow vectors that describe the motion of the objects in the image.

III. Existing Enhancement Methods for Underwater Images

A. Wavelet-based denoising

Wavelet-based denoising is a method that uses wavelet transform to decompose an image into different frequency components, denoise each component separately, and then reconstruct the image. The wavelet transform is a mathematical formula that breaks down a signal into its different frequency components, allowing for the analysis of the signal at different scales. The denoising process involves thresholding each frequency component to remove noise while preserving signal information. The threshold values can be determined using various techniques, such as the universal threshold, the Stein's Unbiased Risk Estimate (SURE), or the minimax threshold. In the end, the denoised frequency components are transformed using the inverse wavelet algorithm to reassemble the denoised image.

B. Dark channel prior algorithm

The DCP algorithm estimates the transmission map of the hazy image, which is a measure of the amount of haze at each pixel, and then uses it to recover the haze-free image. The transmission map is estimated by computing theminimum value of the dark channel over a local window centered at each pixel. This is expressed mathematically as:

$$DC(x)=\min\{\min\{I(y)\}: y\in\Omega(x)\} \quad (8)$$

where DC(x) is the dark channel value at pixel x, I(y) is the intensity value at pixel y, and Ω(x) is the set of pixels in a local window around pixel x. The transmission map is then computed as:

$$t(x) = 1 - w * DC(x) \quad (9)$$

DOI: rp-9788770040723.121

where w is a weight parameter that controls the strength of the haze removal. Finally, the haze-free image is recovered by applying a dehazing filter to the hazy image using the estimated transmission map. The DCP algorithm has been shown to be effective in removing haze and improving the visibility of underwater images.

C. Color Attenuation Prior algorithm

The Color Attenuation Prior (CAP) algorithm is a method for color correction in underwater images that uses the observation that the attenuation of color channels in water follows a particular pattern. The CAP algorithm estimates the color correction matrix that maps the observed color values to the true color values, based on the assumption that the attenuation of each color channel follows an exponential decay with depth. This is expressed mathematically as:

$$I\_observed = A * I\_true \quad (10)$$

whereI_observed is the observed color vector, I_true is the true color vector, and A is the color correction matrix that maps I_observed to I_true. The color correction matrix is estimated by minimizing the following objective function:

$$||\log(I\_observed) - \log(A * I\_true)||^2 \quad (11)$$

subject to the constraint that A is a diagonal matrix with positive diagonal entries, to ensure that the attenuation of each color channel is modeled by an exponential decay. The solution to this optimization problem is given by:

$$A = \mathrm{diag}(\exp(-b)) \quad (12)$$

where b is a vector of parameters that control the attenuation of each color channel. The CAP algorithm has been shown to be effective in correcting the color distortion in underwater images and improving the visibility of underwater scenes.[11]

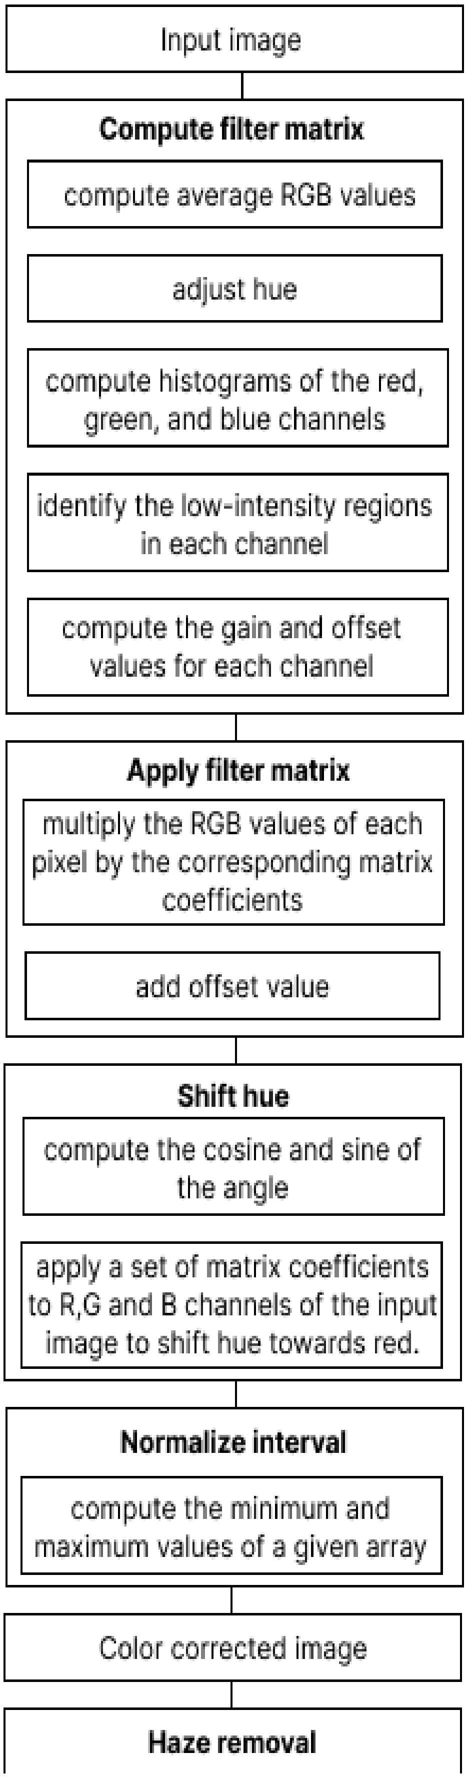
D. Retinex-based methods

Retinex-based algorithms can also be used for color constancy and correction by separating the reflectance and illumination components of an image. Multi-Scale Retinexwith Color Restoration (MSRCR) algorithm decomposes the input image into different scales, applies Retinex-based processing to each scale, and then combines the processed scales to obtain the final image. The mathematical equation for the MSRCR algorithm can be expressed as:

$$I\_final(x,y) = f(\lambda 1 I\_1(x,y) + \lambda 2 I\_2(x,y) + ... + \lambda n * I\_n(x,y)) \quad (13)$$

whereI_final(x,y) is the final image at pixel location (x,y), I_i(x,y) is the processed image at scale i, λi is the weight assigned to scale i, and f is a function that maps the weighted sum of the processed scales to the final image. The MSRCR algorithm has been shown to be effective in improving the color constancy and correction of underwater images, as well as enhancing the overall image quality.

IV. METHODOLOGY



DOI: rp-9788770040723.121

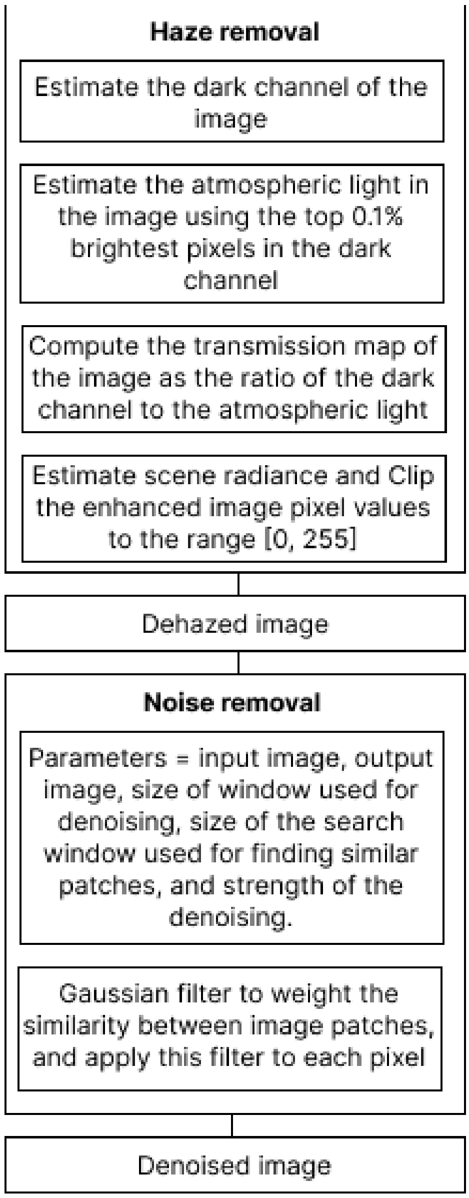


Fig. 1. Flow chart of the underwater image enhancement system.

The steps involved in the algorithm are as follows:

- Capturing and uploading the underwater image as an input to the system.
- Color correction is done by computing the filter matrix, applying the filtering matrix, shifting the hue and normalizing the interval.
- This is followed by dehazing the image using the dark channel prior algorithm.
- Denoising of the image is done using the fastNlMeansDenoisingColored() function in OpenCV which uses the parameters described in figure 1.
- This denoised image is the final image and can be used for object detection purposes.

V. Performance Evaluation

The performance evaluation for the proposed method can divided into two main areas-

1. Qualitative Analysis- The qualitative analysis of the proposed method is purely subjective as the enhanced images can only be observed by humans and the overall improvement purely depends on how a person perceives it. Therefore, it cannot be measured and represented, but everyone can make their own judgement about the same.
2. Quantitative Analysis- For quantitative analysis, 4 metrics have been used to compare the original image to the enhanced image.

A. *Mean Square Error*

It is a standard statistic for determining the quality of an image enhancement technique. It computes the average of the squared differences between the original and improved images. The formula for MSE is:

$$MSE = (1/N) * \Sigma \Sigma [I(i,j) - K(i,j)]^2 \quad (14)$$

where I(i,j) is the pixel value of the original image at location (i,j), K(i,j) is the pixel value of the enhanced image at the same location, and N is the total number of pixels in the image.

B. *Peak Signal-to-Noise Ratio*

It is another another statistic widely employed to assess the quality of an image enhancement procedure. It calculates the ratio of the maximum potential signal value to the noise introduced by the picture enhancement method. PSNR is measured in decibels (dB). The formula for PSNR is:

$$PSNR = 10 * \log10((R\verb|^|2)/MSE)^2 \quad (15)$$

where R is the maximum possible pixel value of the image (for example, for an 8-bit grayscale image, R=255), and MSE is the mean squared error between the original and the enhanced images.

C. *Structural Similarity Index*

It works by comparing the structural information of the images, including luminance, contrast, and structure, to evaluate the similarity between them. It calculates the structural similarity of two images based on three factors: luminance, contrast, and structure. The SSIM mathematical equation is as follows:

$$SSIM(x, y) = [l(x, y)]^{\alpha}[c(x, y)]^{\beta}[s(x, y)]^{\gamma} \quad (16)$$

where x and y are the two images being compared, l(x,y), c(x, y), and s(x, y) are the local luminance, contrast, and structure similarities between x and y, respectively, and α, β, and γ are weighting parameters that determine the relative importance of the three factors.

As a rule, for all three metrics, the higher the values, the higher the enhanced image quality is, i.e., fewer differences between the original and enhanced image. Lower values indicate more differences which further indicate lower quality.

VI. Results And Discussion

Table below shows the quantitative results obtained after enhancing an image. The enhanced image obtained a MeanSquared Error value of 109.60, indicating that there is

DOI: rp-9788770040723.121

a considerable amount of difference between the noise and haze amounts in the original and enhanced image. The difference in the PSNR value between the original and enhanced image is 27.73 dB. In general, a PSNR value of 30 dB or more is considered good, therefore, there is scope of improvement in the proposed method. The Structural Similarity Index value obtained is 0.102, which means that both the images have a fair bit of difference in their structural information due to the removal of noise and haze as well as the color correction performed. Overall, the proposed method provides satisfactory results in enhancing underwater images.[12][13]

TABLE I.

Quantitative Analysis	**Metric**		
	MSE	***PNSR***	***SSIM***
Original	0	inf	-1
Enhanced	109.60	27.73	0.102

TABLE II.

Original	
Enhanced	

VII. Conclusion And Future Scope

In this paper, an approach for denoising underwater images using a combination filter to perform color correction, Single Image Haze Removal Using Dark Channel Prior (DCP), and Fast Denoising Colored Guided Image Filter is proposed. The proposed method effectively removes noise and enhances the contrast of the underwater images; however, the method can still further be optimised as can be seen from the low PSNR value obtained. The experimentalresults show that the proposed method can be applied to various underwater imaging applications, such as underwater surveillance, marine biology, and oceanography without using high computational energy and in a short amount of time.

***Abstract*—One of the biggest issues with urban transportation is traffic congestion since it results in enormous energy use and air pollution. One of the main causes of traffic bottlenecks is the lack of open parking places. Parking and congestion go hand in hand since looking for a location to park causes further delays and boosts local traffic. 10% of traffic circulation in the middle of big cities is caused by cruising, as vehicles spend over 20 minutes looking for free parking. In order for cars to be aware of the location, time of day, and occupancy of parking lots in advance, it is essential to establish a system for predicting the quantity of available parking space. In this study, we proposed a parking spot availability prediction system based on artificial neural networks that makes use of the Internet of Things (IoT), cloud computing, and sensor networks (ANN). To assess the effectiveness of artificial neural networks, we utilize the dataset from Birmingham parking sensors. Following the application of the ANN model to the dataset, we will attempt to utilize RNN to determine which model will provide us with the maximum accuracy or be the best match for our dataset. The results of the experiments demonstrate that the suggested model performs better than the most recent prediction models.**

I. Introduction

The highest population increase in contemporary times has been seen in the major cities in the globe as a result of the ongoing migration of rural residents to urban regions. Two-thirds of the global total will reside in cities by 2050, predicts the UN Population Division. In fact, in order to promote smart city initiatives and cutting-edge technologies, we need a worldwide urban infrastructure. In response to growing urbanization concerns, advances in sensor and sensor network technology have led to the establishment of a new governance paradigm that may be utilized to design, execute, and support environmental development systems.[1,2,3,4]. Promoting environmentally friendly urban mobility and easing traffic congestion, especially when parking spaces are few, are the two principal barriers to urban growth.[5,6].

As technology develops, the IoT as well as deep learning concepts may be used to improve smart city design. This will enable us to address urban transportation issues on a constant basis and provide communities with infrastructure that is resilient from an economic, environmental, and social standpoint. Citizen[1]. Today's highly developed technology aids drivers by delivering information about accidents, road conditions, accidents, and alternative routes, typically in the form of mobile applications. Parking is still a challenge since there are so many cars on the road. As [7] shows how hunting for a parking space results in several liters of petrol being wasted by automobiles. Usually, 30% of his traffic is caused by him looking for an empty parking spot. As shown in [5], drivers waste an average of 3.5 to 14 minutes trying to find a parking space. Moreover, it leads to traffic jams, fuel consumption, air pollution, and driver irritability, all of which are detrimental to sustainable development. Knowing in advance which parking spaces are available in this scenario may help to resolve the problem. This problem may be resolved by employing deep learning algorithms and IoT integration to predict parking lot availability and occupancy with high accuracy.

ANN is an artificial adaptation system inspired by: Functional processes of the human brain. It is a system that can change the internal Structures related to functional goals. They are Especially suitable for solving non-linear problems, to be able to reconstruct the applied fuzzy rules Best solution for these problems. [13]

Recurrent neural networks (RNNs) are a type of neural network that makes use of the sequential nature of the input[9]. Text prediction, POS tagging, and power utilization are just a few of the time-sensitive applications that regularly make use of RNNs. Time-dependent inputs are a feature that many problems have in common. In other words, event estimates are based on previous occurrences. Parking lot occupancy and occupancy duration are time-series concerns [5,8]. The time of day, the completion of the prior event, and crowd sensing all have a significant impact on each parking event [11,12]. So, it is possible to anticipate parking lot time and occupancy using RNNs.

II. Related Work

It's a significant inconvenience for vehicles to look for a parking spot in a highly congested city. There could be major backups if there isn't enough parking. Several researchers in the field of computer vision have recently discovered the promising new topic of autonomous smart parking systems. [14] We demonstrate that our method is more accurate than image-based instance segmentation alone, and that it beats industry standards that depend on more expensive sensors like radar. Our technology's scalability to a whole city and its ability to deliver sophisticated data beyond basic binary occupancy rates are both encouraging developments. [15] Controllers and Infrared Sensors - Increasing population and automotive manufacturing necessitate the construction of parking garages and other parking facilities. Drivers in major cities, especially during rush hour, are growing increasingly upset by parking problems that are rapidly escalating as a result of the rising number of vehicles on the road. [16]

The urban population has exploded during the last several decades. Migration from the countryside is a key factor in this issue, and it is particularly severe in developing countries like Morocco. It's common knowledge

DOI: rp-9788770040723.122

that today's youth would rather not live in the country but instead in the city, where they can take advantage of the many services and employment possibilities it provides. Urban overcrowding has a negative impact on a variety of municipal services. [17] The requirement for parking spaces is steadily growing as a major problem in modern society. We still use a time-consuming and inefficient manual system for parking vehicles in India, which necessitates turning on the lights whenever someone has to stop their automobile. The lack of a standardized parking scheme also causes problems. [18,19] The increasing popularity of linking disparate smart objects for the sake of Internet of Things applications has led to an increase in the communication density of wireless sensor networks. More people using the same unlicensed radio channels will create congestion, prompting research into better ways to manage the airwaves and save power, such as transmission power control. Several popular protocols increase energy usage to reduce interference (such as packet loss, delay, and energy waste). [20]

Several facets of society have been boosted, and the general quality of life has improved, as a result of the Internet of Things' rapid ascent and continuous growth (IoT). Numerous global cities are seeking the creation of "smart" infrastructure. Citizens of "smart cities" often appreciate intelligent parking solutions since they save time, money, and the environment. Intelligent parking system designs conform to specific rules (sensors, communication protocols, and software solutions). [21]Future data-driven traffic flow efficiency in smart cities will be facilitated by the widespread deployment of IoT - based autonomous car categorized systems, which will also transform the road network into a dynamic to sense Cyber-physical System (CPS). There have been several concepts for traffic sensing systems, but none of them now satisfy all of the requirements (such as accuracy, robustness, cost-effectiveness, and privacy protection) simultaneously. [22] Using fog computing, this research presents a new smart parking architecture meant to improve upon current real-time parking solutions. The fog nodes of a parking lot and garage work together to communicate parking availability and handle requests in real-time. By demanding the worldwide optimization of parking request distribution, the cloud-based data center has the potential to expand the value of intelligent parking systems. [22]

Artificial neural networks disclose the basic principles of an issue. Instead of processing data in accordance with established rules, ANNs are data processing systems that use the data they receive to learn the rules governing them. As a result, ANNs are particularly useful for solving issues when we know the pertinent data but are unaware about their correlations. With artificial neural networks, generalization, prediction, and recognition are all possible. If trained with the proper data to identify the hidden rules behind a certain phenomenon, an ANN may correctly generalize to data it has never seen before (new, dirty, incomplete data, etc.). [23,24]

III. Proposed System Setup

The proposed method builds an automated parking system using a microcontroller. Parking lots with IR sensors are placed to reduce the likelihood of accidents by automatically guiding cars to open spots. There is an ultrasonic sensor in each parking space. The ultrasonic sensor checks to see if a car is correctly parked in a designated area. IoT is being used in this project to make the billing process hands-free. Later on we have used ANN and RNN models to compare the accuracy of the FreeParkingSpace available.

Requirement Specifications

A technical description of these requirements can be found in the software product requirements document. The requirements analysis process begins with a list of what the desired software system must be able to do in terms of functionality, performance, and safety. The specifications detail the kinds of user, operational, and administrative scenarios that can arise. A software requirements specification is a document that aims to offer a thorough explanation of the goals, parameters, and outputs of a software development project. The target audience, necessary user interface components, and technical specifications are all laid down here. The document lays out the goals of the project from the viewpoints of the client, the development team, and the target audience.

IV. Hardware And Software Specification

Software Requirement

- Compiler: Arduino IDE
- Language: c, c++
- Google Firebase

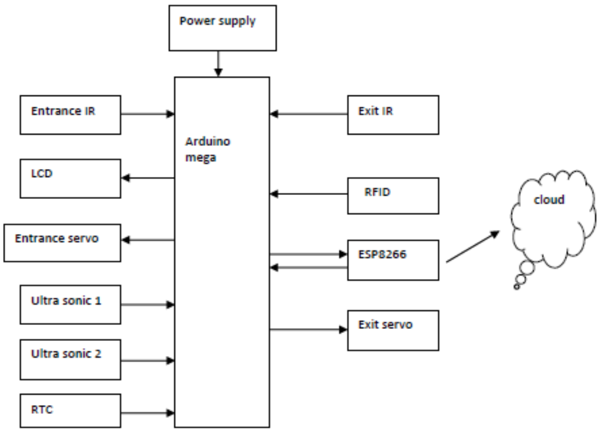
Hardware Requirement

- Arduino mega
- ESp8266
- IR -2
- Ultrasonic sensor-2
- Servo motor-2
- RFID reader
- LCD

Architecture Diagram

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.122

BLOCK DIAGRAM



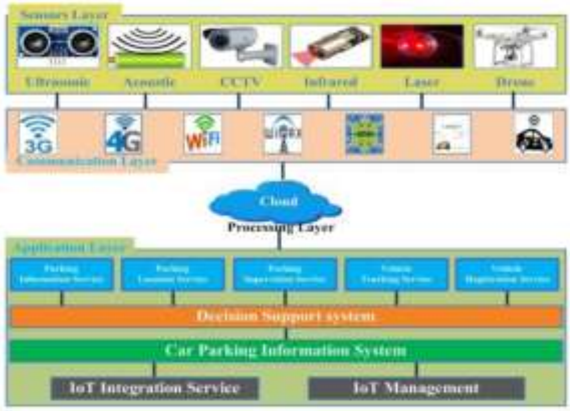
V. BLOCK DIAGRAM DESCRIPTION

Overhead block diagram components include a liquid crystal display, radio frequency identification reader, infrared sensor, ultrasonic sensor, two servo motors, and a real time clock. The infrared sensor, ultrasonic sensor, and servomotor are all wired directly to the GPIO pin of the Arduino mega. Each garage entrance is outfitted with an infrared (IR) sensor. When an incoming vehicle is identified by the entrance IR sensor, the controller will initiate the process and show the parking spot number on the LCD panel. An ultrasonic sensor can tell you whether or not a parking spot is available. A radio frequency identification (RFID) module is used in the financial transaction process. An ESP8266 WIFI chip is used to relay data from the controller to the cloud. Exit IRs are installed to unlock cars from their parking spots

VI. PROJECT INTRODUCTION

This research proposes a sensor-based smart parking availability prediction architecture. The smart vehicle parking system's architecture was used to create the auto parking prediction system. Many parking smart sensors that have been installed at various automobile parking spots are used to collect the parking data. To evaluate the availability of parking spaces at multiple vehicle parking facilities, deep learning techniques have been utilized to aggregate sensing device information from several sites on a cloud. We examine the numerous transportation management activities in a contemporary city, such as parking availability, parking allocation, parking monitoring, vehicle surveillance, and car registration, in order to anticipate the availability of available parking spots using a sensor network.

This is a design for the Internet of Things-based smart parking system that is advised. The sensor layer, the connection layer, the processing layer, and the services layer are its four tiers. The sensor layer uses a variety of sensor types to gather data on vehicle traffic from various parking lots. In the communication layer, sensor nodes are employed to send this data to cloud computing. Using the long-range wide-area network, the gateway received data from sensors (LoRaWAN). The enhanced range of the energy-efficient LoRaWAN technology allows data to be sent throughout the whole parking lot.



VII. IMPLEMENTATION

Here you'll find a rundown of all the maneuvers your car will need to do in order to park properly utilizing our technology.

Step 1: To begin, you must get the smart parking software on your mobile device.

Step 2: The user may see how many spots are open and taken by gazing at the 16x2 display.

Step 3: Once the user has signed in, they will be able to see the parking garage and see which spaces are now taken and which are available.

Step 4: Fourth, if a parking place is available, the user will be alerted by smartphone when he approaches the parking IR detect sensor.

Step 5: Last but not least, if the user attempts to find a parking place and there is none available, the app will inform them.

Step 6: Sixth, once a user utilizes a parking place that has become available, they will be notified of the time and location at which their parking period began.

Step 7: When you're done with your parking session, you may unload your vehicle and get a text message with information on the start and end timings, as well as the total cost, of your parking session.

A. *Keras Library*

Created with a center on spry testing. Getting information from thoughts as rapidly as conceivable is key to great research.Keras is the TensorFlow platform's high-level API.An effective and open interface for understanding advanced machine learning issues with a center on profound learning. It gives basic deliberations and building pieces for creating and executing exceedingly iterative machine learning arrangements. Thanks to Keras, engineers and scientists may take full use of the adaptability and cross-platform capabilities of the TensorFlow stage. You may submit Keras tests to run on a mobile device or in your browser. You can even run Keras on huge clusters of TPUs or GPUs. The Sequential and Dense Keras libraries will be used.

Sequential -Build your model layer by layer using the sequential API. Using a functional API is a different approach for building more complex models. A functional

DOI: rp-9788770040723.122

model can specify several level-shared inputs or outputs. Create a model instance and link it to the plane before you can access the model's inputs and outputs.

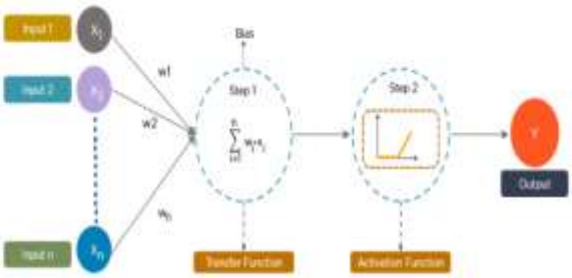
Dense -A layer of the Keras model or neural network known as the keras dense is produced once all connections have been connected extremely deeply. In other words, all of the network's neurons in the bottom layer serve as the dense layer's input sources. The concept, network output, typical methodology, parameters, keras dense example, and conclusion of keras dense will all be discussed in this article.

We execute the neural networks in our project using the Keras library. This library also aids in the creation of the units, or hidden layer, that we need to build for our neural network model. The neural network and its initial layer are created using the sequential function, while further hidden layers that will provide more accurate results are created using the dense function.

B. ANN (Artificial Neural Network)

The operation of the human brain is greatly simplified by ANN models. Artificial neurons serve as computing units, much as the neurons found in the biological nervous system. Input, hidden, and output are the three primary layers of an ANN model. The neurons in the (n + 1)th layer receive signals from all of the neurons in the nth layer. Each connection is given a weight. Each input may be multiplied by the appropriate weight to determine the output. Before producing the final ANN output, an activation function evaluates the output.

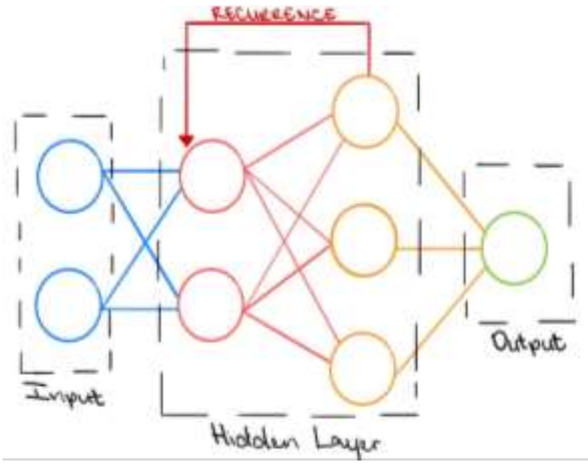
The ANN might be useful for a number of scientific and technical problems. As a result, the ANN is used in a broad variety of applications [3], such as signal processing, image compression, function approximation, differential equations, stock market prediction, and diagnostics.



In our project we use the Artificial Neural Network (ANN) to get the flow of the dataset and to create the hidden layers in between the input and the output layers of the given dataset to learn the dataset and provide the best accuracy out of it.

C. RNN (Recurrent Neural Network)

Artificial neural networks called recurrent neural networks employ time series or sequential data (RNN). These deep learning algorithms are used by Google Translate, Siri, and voice search. Ordinal or temporal issues in speech recognition, picture captioning, and natural language processing are frequently addressed by them (nlp). Recurrent neural networks (RNNs), similar to feedforward and convolutional neural networks (CNNs), learn new information from training input. They differ from other systems because of their "memory," which enables them to use data from earlier inputs to affect the current input and output.



In our project we use the Recurrent Neural Network (RNN) to get the flow of the dataset and to create the hidden layers in between the input and the output layers of the given dataset to learn the dataset and provide the best accuracy out of it.

D. LSTM (Long short term memory)

Long short-term memory is an artificial brain configuration utilized in the realms of manufactured discoveries and profound learning (LSTM). Similar to connections with criticism, LSTM displays feedforward neural networks in a different way. Instead of just preparing single information foci (like pictures), such a repeating neural organism (RNN) may also prepare information groups (such as discourse or video). This property makes LSTM systems perfect for preparing and anticipating information.

VIII. Metrics

A. ANN

Formula:-Y=W1X1+W2X2+b

where , Y= the output neuron or feature

X= the sample feature or the input

W= the weight associated with each features

b= the bias

B. RNN

The RNN model has 3 formulas

The first one is used to determine the current state and is

CS = f(CS-1, IS)

CS -> current state

CS-1 -> previous state

IS -> input state

For using the activation function (tanh), the second formula is

CS =tanh(Wrn * CS-1, Wxh * IS)

Wrn -> weight at recurrent neuron

Win -> weight at input neuron

DOI: rp-9788770040723.122

The third formula is used to compute the result.

Ot = Wol * CS

Yt -> output

Wol -> weight at output layer

We have also used some other formulas in our ML model which are

C. Mean

Formula:-

$$\mu = \frac{1}{N}\sum_{i=1}^{N}(x_i)$$

Where μ = mean

N= total number of features

X= features

Example-

For Capacity,

mean = (577+...+1200+…+1920)/35718

= 1397.511003

For Occupancy,

mean = (61+…+854+…+1180)/35718

= 642.2109301

For FreeParkingSpace,

mean = (516+…+346+…+740)/35718

= 755.3000728

D. Standard deviation

Formula:-

$$\sigma = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(x_i-\mu)^2}$$

Where, μ = mean

N= total number of features

X= features

σ = Standard deviation

Example

For Capacity,

standard deviation = √[(577-1397.511) 2+…+(1920-1397.511) 2]/35718= 1179.310323

For Occupancy,

standard deviation = √[(61-642.210) 2+…+(1180-642.210) 2]/35718 = 656.9463379

For FreeParkingSpace,

standard deviation = √[(516-755.300) 2+…+(740-755.300) 2]/35718 = 787.538578

E. Standardscaler

Formula:-

$$z = \frac{x-\mu}{\sigma}$$

Where, X= features

σ = Standard deviation

μ = mean

z= Standardscaler

Example

For Capacity,

standardization (1st value) = (577-1397.511)/1179.310 = -0.695

standardization (2nd value) = (1200-1397.511)/1179.310 = -0.167

standardization (3rd value) = (1920-1397.511)/1179.310 = 0.443

For Occupancy,

standardization (1st value) = (61-642.210)/656.946 = -0.884

standardization (2nd value) = (854-642.210)/656.946 = 0.322

standardization (3rd value) = (1180-642.210)/656.946 = 0.818

For FreeParkingSpace,

standardization (1st value) = (516-755.300)/787.538 = -0.303

standardization (2nd value) = (346-755.300)/787.538 = -0.519

standardization (3rd value) = (740-755.300)/787.538 = -0.019

F. **Mean Squared Error**

The mean squared error, sometimes referred to as the mean - square deviation of an estimator in statistics, measures the average of the squares of the errors, or the mean of the squares difference between the two estimated values and the actual value.

Formula

$$\mathrm{MSE} = \frac{1}{n}\sum_{i=1}^{n}(Y_i-\hat{Y}_i)^2$$

MSE = mean squared error

n = number of data points

Y_i = observed values

$\hat{Y}_i$ = predicted values

G. (APE)- Absolute Percentage Error

The difference between the observed and the true value is all that the absolute error, which is utilised to compute percentage error, consists of. When the absolute mistake has been divided by the true value, the percentage error is calculated by multiplying the relative error by 100.

Formula:-

DOI: rp-9788770040723.122

$$\left|\frac{A_t - F_t}{A_t}\right|$$

Where, At = Observed Value

Ft = Predicted Value

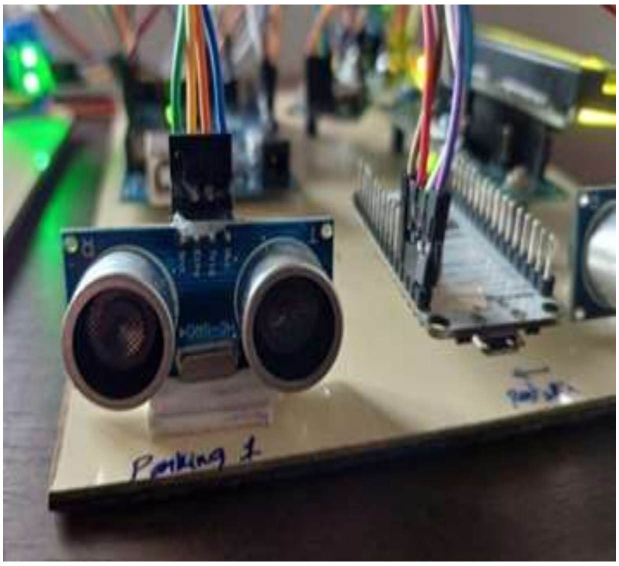
IX. Result And Discussion

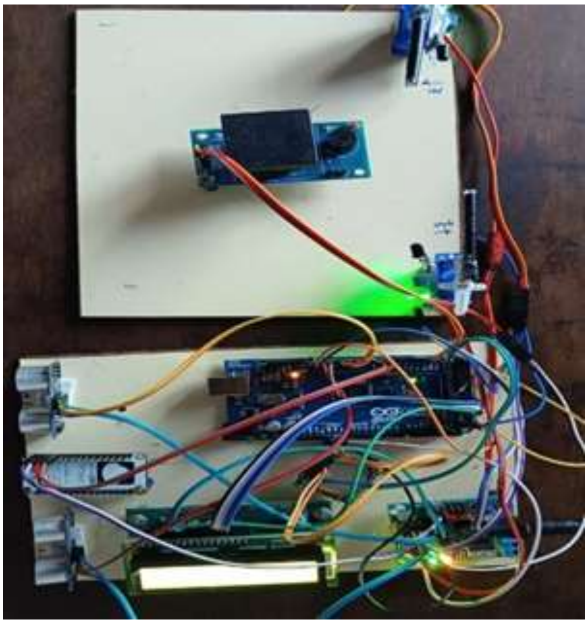
Cars may be parked quickly and easily with the help of an automatic system. The depicted parking arrangement can accommodate up to two vehicles. The required living space is about equivalent to that of a garage big enough to fit two cars. The best option for parking near major shopping centers, office buildings, and other destinations. The framework requires just little assistance to operate normally. The deployed sensors provide a high degree of adaptability and are quite straightforward to integrate into an existing system. The simplest design that achieves the maximum potential degree of automation. It does not rely on there already is a path leading to a quantifiable result. Vehicles must be politely turned around at the entry and departure. The car's safety was the first priority.

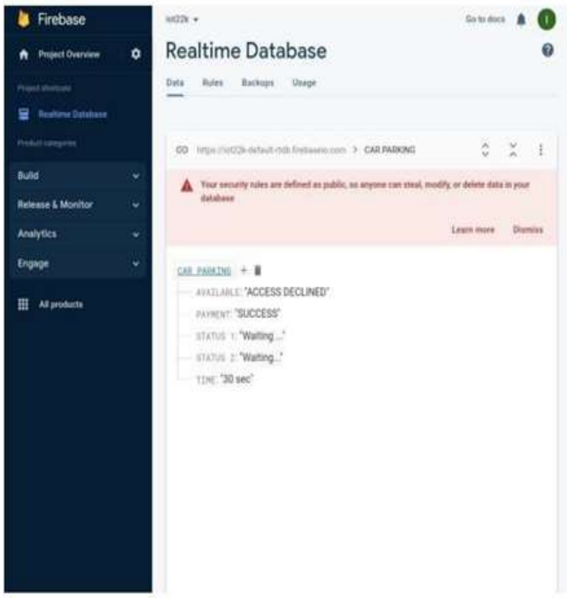
The development of Internet of Things-based smart parking information systems is one of the most significant research fields for the growth of sustainable smart cities. Drivers might find it useful to locate a free parking space nearby. Also, one can save time and effort by accurately and successfully anticipating when a parking place will open up. In this study, we developed an Internet of Things-based smart parking system. This article's main objective is to use sensor data to estimate the total number of easily available parking spaces. To help the car parking information management system with the availability of parking places on a certain day of the week during a specified time period, we have developed a quick and simple decision assistance system.

Using the recommended method, vehicles will be able to locate a parking space at any time and anywhere. We believe that combining cloud services with sensing devices will make the collection and processing of sensor data easier than using traditional techniques. Implementing all of the services (parking position, parking data, parking monitoring, vehicle surveillance, vehicle registration, and identification) stated in the created framework for smart parking is part of the project's continuous effort.The development of several techniques to estimate parking lot availability in real-time using image and video data gathered by various sensors will be the focus of future study.

According to the dataset which is taken we apply the two of the best neural network models that is the Artificial Neural Network and the Recurrent Neural Network in our dataset to get the accuracy of our dataset and compare which neural network gives us the best accuracy for our dataset.







DOI: rp-9788770040723.122

X. Conclusion

A very sophisticated parking sensor system was displayed during the presentation. Without the involvement of the user or the vehicle, it provides real-time parking monitoring and payment. By streamlining the system, investing in infrastructure, and replacing batteries, the sensor system lowers costs while providing advantages in terms of detection and payment dependability. The suggested creative method makes this possible. Further validation tests are being run right now to better improve the system.

XI. General Information About Dataset

Birmingham City's 30 parking lots served as the source of the dataset for deep LSTM network training and testing. A total of 35,718 vehicles can park in the 30 spaces available. There is a full presentation of the dataset for the automobile occupancy sensors.

Features	Descriptions
SystemCodeNumber	A variable that Identifies car park id
Capacity	Variable that contain the capabilities of park
Occupancy	The variable that contains occupancy of park
FreeParkingSpace	Variable that contains the free slots of the park
LastUpdated	Variable that have Date and Time of the measure

The dataset used for testing has "SystemCodeNumber," "Capacity," "Occupancy," and "LastUpdated," among other four properties. The properties "Capacity" and "Occupancy" provide details regarding a parking lot's overall capacity, "LastUpdate" informs you of the most recent time the location's occupied parking spaces were updated, and "Occupancy" provides information regarding the number of spaces that are occupied at any given time. To estimate the availability of free parking lots at a certain hour on a specific day at a specific parking location using a regression model, we created a new feature we term "free parking space." We were able to calculate the value of the "free parking place" by comparing the "Capacity" and "Occupancy" properties. In the regression model created using deep learning, this feature of free parking served as the target variable.

XII. Accuracy

How often a machine learning classification system properly recognises a data point may be ascertained, for example, by looking at the accuracy of the algorithm. Accuracy is measured as the proportion of all data points that were properly anticipated. A more precise definition is the proportion of true positives and true negatives to all true positives, true negatives, false positives, and false negatives. The programme properly identified a data point as true or false as a genuine positive or genuine negative one. Contrarily, a data point that the algorithm misclassified is referred to as a false positive or false negative.

Since we have applied two neural networks on our dataset we got two different accuracy of our dataset.

MODEL	ACCURACY
ANN	50.43
RNN	50.07

The accuracy for ANN model is 50.43

The Accuracy of ANN model is: 50.435713229412244

***Abstract*- Each household, industry, or other setting that relies on energy must consider this. It is crucial to manage energy well and conserve it when using appliances.**

To do this, much research has been done to create smart lighting systems for rooms to save energy. In a separate study, researchers created an Internet of Things (IoT)-based Smart Home system to track energy use and ward off anomalies.

Researchers have not attempted to automate appliance control to save energy in any studies. Most of them focus on using android devices to operate the appliances. As a result, we have created an IOT-based Smart Energy Meter system that uses information about light intensity and humidity to remotely operate appliances like Bulb at first. Moreover, the system consistently calculates the appliances' daily energy consumption, giving the user insight of how much energy is utilized over time. Moreover, a bill will be created, and the payment window for bills will be available. The Cloud server is updated with this information. Every family may conserve energy with this prototype method.

Thus, cutting-edge technology like smart energy metres and AI-powered power management have the potential to completely change how we use and manage energy. Smart energy metres allow for real-time tracking and monitoring of energy use, giving consumers precise and in-depth data about their energy usage. Using machine learning algorithms to forecast energy usage trends and improve energy use, power management with AI goes one step further. To gather information from energy meters and send it to a cloud-based server for analysis and invoicing, the system employs Raspberry Pi as its central hub. The device removes the need for human meter readings and provides precise, real-time data to utility providers as well as their consumers. From personal residences to industrial facilities, this technology may be used to minimize waste and boost productivity in a variety of scenarios. People may significantly reduce their energy costs and help create a more sustainable future by implementing AI-powered power management solutions. Overall, smart energy metres and AI-powered power management have the potential to revolutionized how we use energy and contribute to the creation of a society that is cleaner, greener, and more sustainable.

I. Introduction

The increase in economic growth often leads to an increase in the utilization of non-renewable energy resources. This is because the demand for energy often increases as economies grow and become more industrialized. Non-renewable energy resources such as fossil fuels, coal, and natural gas have been the primary sources of energy for many countries due to their abundance and low cost. However, their continued use has led to environmental concerns such as air and water pollution, and the release of greenhouse gases that contribute to climate change. Therefore, it is essential for policymakers to balance the need for economic growth with the need for sustainable energy sources, such as renewable energy, to ensure a cleaner and more sustainable future for generations to come.

The use of Raspberry Pi 3 in various research projects has led to the development of innovative IoT applications for temperature and humidity monitoring, smart home monitoring and control, and energy management. The autonomous temperature and humidity [1] management system developed using Raspberry Pi 3 provides an efficient solution for maintaining a comfortable indoor environment without human intervention. Similarly, the smart house monitoring and control system [2] enables users to remotely control various home appliances and monitor their energy consumption. The automatic room lighting and control system [3] developed using Raspberry Pi and IoT technologies provide users with a convenient way of controlling the lighting and ambiance of a room. Finally, the energy management system for smart houses [4] enables homeowners to manage their energy demand and generation simultaneously, leading to efficient energy usage and cost savings. Overall, the use of Raspberry Pi and IoT technologies has shown great potential in developing innovative solutions for various applications in smart homes and energy management.

Regretfully, no investigation has contributed to the development of a system for controlling the use of electrical appliances based on environmental conditions, which may eventually reduce domestic energy usage. A system like this might incorporate IoT and machine learning to optimise energy use based on environmental factors like temperature, humidity, and illuminance. To create new solutions that make most of cutting-edge technology and tackle the society's rising energy usage issues, more research in this area is required.

Below is the arrangement of the remaining parts. The related work to the research study can be found in Section II.

Our proposed IoT-based system is described in detail in the third part, along with a data flow diagram and a schematic flowchart showing how the entire system operates. The prototype is examined in conjunction with hardware and software design in the fourth step. The recommended structure is covered in Part V, and the metrics are covered in Section VI. Section VII contains a summary of the results and discussions. In section VIII, the conclusion and future work are addressed.

II. Related Work

DOI: rp-9788770040723.123

In recent years, there has been a growing interest in developing smart energy meter systems that can accurately monitor and manage energy consumption in residential and commercial buildings. The emergence of the Internet of Things (IoT) has further enabled the development of such systems by providing the necessary infrastructure for connecting a large number of energy meters to the internet and enabling real-time data analysis.

Machine learning (ML) algorithms have also been extensively used in smart energy meter systems to analyze the large amounts of data generated by these devices and provide useful insights for optimizing energy consumption. In this section, we review some of the relevant literature on IoT based smart energy meter systems with ML.

A study by M.Lavanya et al. (2016) proposed a model that utilizes IOT technology and linux OS along with C++ to import temperature and humidity information. The proposed system sent the data collected via the sensors over the internet. This acts as basis for out project as we utilize the varied sensors to collect light intensity, temperature and humidity readings.

Another study by Wang et al. (2020) proposed an IoT based energy management system that used a combination of deep learning and reinforcement learning algorithms to optimize energy usage in commercial buildings. The proposed system used a deep neural network to learn the energy consumption patterns of the building and a reinforcement learning algorithm to provide optimal control actions for reducing energy consumption. This system utilizes deep learning to understand energy usage patterns and thus, utilize this information to optimize usage of energy resources.

In a study by Kim et al. (2020), proposed a hybrid IoT and machine learning algorithms are used in a cloud-based energy administration system to determine how much energy residential appliances would spend. The system employs smart plugs that monitor energy consumption and send data to a cloud-based server. The data is then analyzed using machine learning algorithms to predict energy consumption patterns for different appliances.This study highlights the potential of machine learning algorithms and IoT technologies in developing innovative solutions for energy management, and further research in this area could lead to significant energy savings and a more sustainable future.

Finally, a study by Gitanjali et al. (2021), proposed an IOT based Smart Electricity Energy Meter system to manage residential energy consumption in smart grid infrastructure. This presented a futuristic and nontraditional approach to traditional energy meters. It provides real-time data and analysis of energy consumption, which can help users to make informed decisions about their energy usage.

Overall, these studies demonstrate the effectiveness of using IoT based smart energy meter systems with ML for optimizing energy usage and reducing energy consumption in residential and commercial buildings.

III. PROPOSED SYSTEM SETUP

The management of electrical failure dangers and appliance control have been the main areas of attention for existing Smart Home and Energy Management systems. There hasn't been any research that has led to the creation of a system that monitors the environment, adjusts appliance usage as necessary, and warns the user when the humidity level rises. We have developed an IoT-based system that makes use of environmental sensors, such as those for temperature and light intensities, that in turn deliver data to a Raspberry Pi 3. Machine-to-machine communication, often known as IoT, is a recent development. Based on the detected measurements, the Raspberry Pi is set up to manage how much energy is used by the appliance.

In addition to controlling appliance use, the total power consumed by each appliance is calculated on a regular basis and graphed using the DHT11 and communicated to the Raspberry Pi3. In ThingSpeak, there is graphic data showing how time and power use for all appliances operating in various environments relate to one another. This data can then be further utilized to identify insights on consumer consumption habits of energy.

Fig. 1 presents the system design of an IoT-based Energy Management system.Fig. 7 illustrates the Data Flow Diagram (DFD) of the system, which shows the flow of data between different components of the system.Fig. 8 presents the Use Case diagram of the system, which shows the different scenarios and interactions between users and the system.

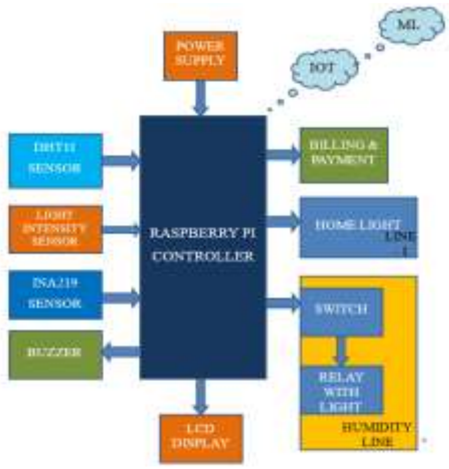

Fig. 1: IoT Based Smart Energy Management System

The DHT-11 SENSOR sensed data are used as the project's initial input (Take temperature and humidity readings) The DHT11 sensor uses a single wire to serially measure and transmit temperature and humidity measurements. It is capable of measuring temperature in degrees Celsius between 0 and 50°C as well as relative humidity (20 to 90% RH) in percentage form. One of its four pins is utilised for serial data transfer.The LDR sensor should then be read for light intensity.

The Raspberry Pi is an inexpensive Linux computer with a set of GPIO (General Purpose Input/Output) ports

DOI: rp-9788770040723.123

that allow you to communicate with electronic devices for computing, physical and scientific Internet of Things (IoT).

Here, if the LDR falls below or equals the threshold (i.e., LDR =40000), "NIGHT TIME" is shown on the display screen, and the LED is switched "ON." Light is produced by a semiconductor device called a light-emitting diode when current flows through it. DHT11 valuations are produced when the energy that was previously stored in the semiconductor's electrons and electron holes is once again released.

The INA219 is essentially a current sensor, it senses current and outputs power and voltage when the LED is on.

A current/power monitoring module with zero drift and bi-directional operation, the INA219-based Current Sensor Module CJMCU-219 uses the I2C interface. It has the ability to simultaneously measure shunt voltage, current, and power and send the information through the I2C protocol. For the purpose of enabling current measurements, it features a 0.1 Ohm, 1% shunt resistor. Its robust 12-bit ADC effectively translates the current measured by a precision amplifier. The resolution is 0.8mA, and the current sensing range is 3.2A.

Fig. 2: Proposed system circuit

Instead, if the LED is not glowing, keep taking measurements and sending them to ThingSpeak. Sending sensor data to the cloud is possible using the IoT Cloud platform ThingSpeak. You may create Internet of Things apps and gather and store sensor data using the Web Service (REST API) that is included. MATLAB, Raspberry Pi, and Arduino are all compatible with it (premade libraries and APIs 18 exists). But, as it makes use of a REST API and HTTP, it ought to be compatible with any programming languages.

Energy is then computed, and a new bill is created. The user's Interface is created using the Tkinter package. Tkinter is the primary GUI Python module. Python along with Tkinter can be employed to create GUI programs quickly and effortlessly. Tkinter is a Python library used for building desktop applications with a graphical user interface. It provides tools for creating windows, buttons, and other widgets to interact with the user. Tkinter offers a sturdy object-oriented gateway for the Tk Modules. To pay a bill via the Twillio API, an SMS is then delivered to the user.

Fig. 3: Day-time output

Fig. 4: Night-time output

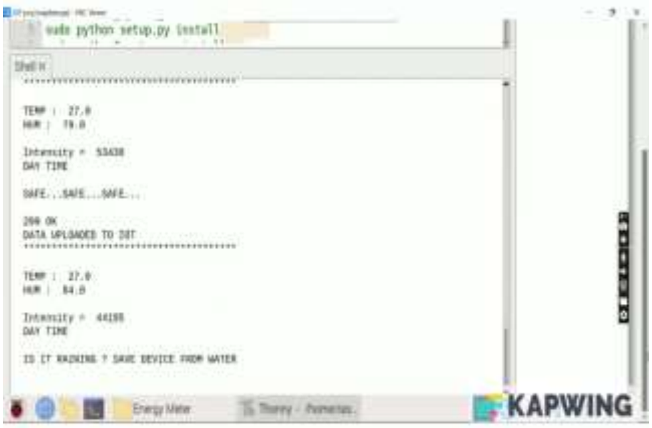

Fig. 5: High Humidity output

Twilio is a cloud communications provider that offers a web API that lets customers create phone, VoIP, and SMS apps using common web languages. As a result, the user is presented with the Graphic User Interface for bill payment.

DOI: rp-9788770040723.123

The programme execution halts upon a successful payment completion.

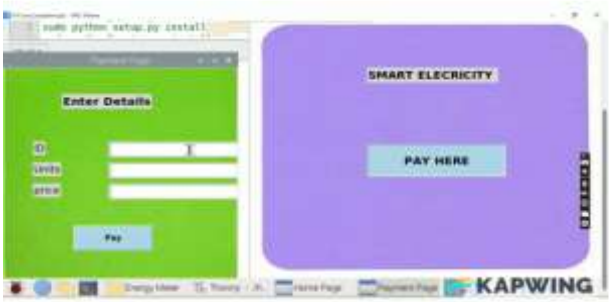

Fig. 6: Bill paying system interface design

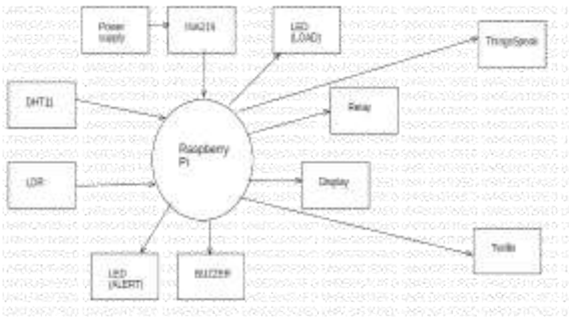

Fig. 7: Data Flow Diagram

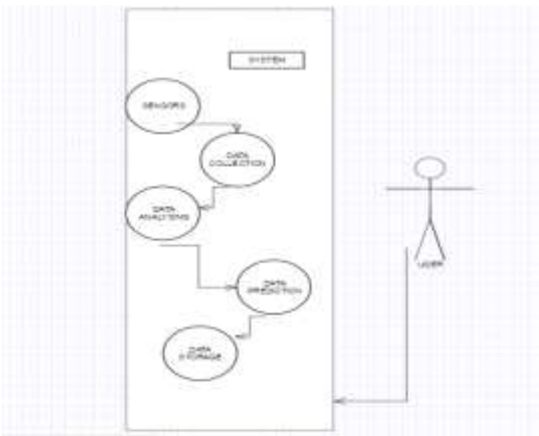

Fig 8: Use Case diagram

IV. Hardware And Software Design

Jumper wires are utilized to link the hardware elements that make up this system. In order to gather data in real time, the temperature sensor and the light intensity sensor are placed into the environment. We haven't utilized 220-volt appliances like fans and lights because we've just created a prototype; instead, we've used computer cooling fans that work on 12-volt batteries and LED lights rather than regular incandescent bulbs. In the explanation that follows each hardware component, the connections that have been made to each component are listed.

A. Humidity and Temperature Sensor

A standardized moisture and temperature sensor that provides a digital output is the DHT11 Sensor. High consistency and outstanding long-term consistency are ensured by this sensor. This sort of sensor connects to an 8-bit CPU and incorporates NTC temperature detection and resistivity-type measuring components. As a result, it offers good quality, rapid response, interruption resistance, and economic feasibility.

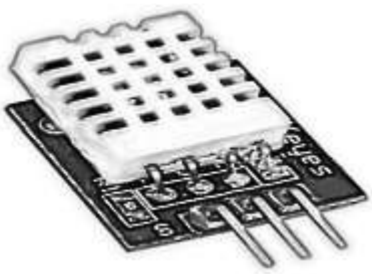

Fig. 9: DHT11 sensor

B. Light Dependent Resistor

An electrical component that reacts to light is referred to as a photoresistor, sometimes known as a light-dependent resistor. As light strikes it, the resistance modifies. When light intensity rises, the LDR's resistance decreases, shifting by orders of magnitude. A typical LDR or photoresistor's resistance value falls between a few megaohms in total darkness to a few hundred ohms under bright light. An LDR sensor is a type of sensor that uses a Light Dependent Resistor to detect changes in light intensity (LDR). It is frequently employed in electrical devices to determine whether light is present or not. Automatic streetlights, security systems, and camera light meters are just a few of the numerous uses for LDR sensors.

Fig. 10: Light Dependent Resistor

C. Raspberry pi

The Raspberry Pi Foundation, which is headquartered in the UK developed a series of compact single-board computers designated as Raspberry Pi. These computers are preferred by professionals, academics, and hobbyists because of their minimal cost, efficiency, and great extent of customization options.

The Raspberry Pi boards are built around an ARM-based processor and run on a variety of operating systems, including the popular Linux-based Raspbian OS. They feature a variety of input/output options, such as USB, HDMI, Ethernet, and GPIO pins, which allow users to connect and interact with a wide range of devices and sensors.

Overall, Raspberry Pi offers a low-cost and flexible platform for users to experiment with and build their own custom computing solutions. It has become a popular tool for both learning and prototyping in the fields of computer science, engineering, and maker culture.

DOI: rp-9788770040723.123

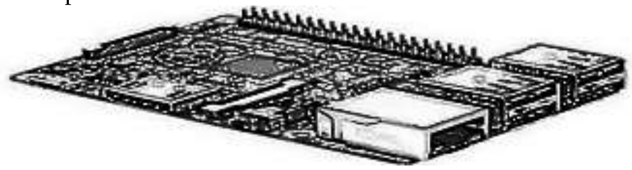

Fig. 11: Raspberry pi

D. LED

A semiconductor device termed as an LED (which stands for "Light Emitting Diode") emits photons when an electrical current travels through it. Due to its energy effectiveness, extended durability, and potential to create a wide spectrum of colors, LEDs are commonly utilized as light sources. They are used in a variety of applications, such as backlighting for electronic displays, residential and commercial lighting, and automotive lighting. LEDs are also widely used in research settings for their controllability and versatility in producing specific wavelengths of light. This makes them useful for studies involving plant growth, circadian rhythms, and phototherapy. LEDs are a popular choice for researchers due to their low heat output, long lifespan, and low power consumption.

Fig. 13: LED

E. INA 219 SENSOR

The INA219 sensor is a high-precision, low-cost, digital current and voltage sensor that is widely used in research applications. It can measure voltage levels up to 26V and current up to 3.2A with an accuracy of up to 1%. The sensor can communicate with a variety of microcontrollers using I2C or SMBus protocols, making it easy to integrate into electronic systems. Its small size and low power consumption make it an ideal choice for portable or wearable devices. Researchers use the INA219 sensor in a range of applications, such as battery monitoring, power management, and solar energy systems, due to its high accuracy and reliability.

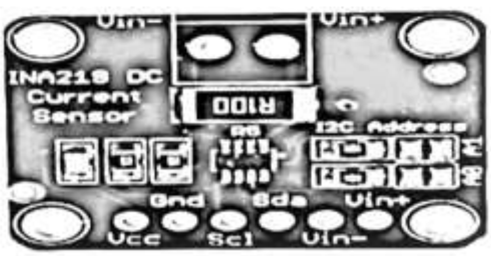

Fig12: INA219 Current Sensor

F. ThingSpeak

ThingSpeak is an open-source Internet of Things platform that allows users to gather, evaluate, and display data from Internet of Things devices. It allows users to store and retrieve data in real-time and provides tools for data analysis, visualization, and alerting. ThingSpeak supports a wide range of IoT devices, such as sensors, actuators, and microcontrollers, and integrates with other popular IoT platforms and services. It also provides APIs for easy integration with other applications and data sources. ThingSpeak is popular among IoT enthusiasts, researchers, and businesses for its ease of use, flexibility, and affordability. It has numerous applications in various domains, such as agriculture, smart homes, industrial automation, and healthcare.

G. Tkinter Module

Tkinter is a Python module for building graphical user interfaces (GUIs) for desktop applications. It provides an assortment of widgets and tools for making panels, icons, labels, checkboxes, and other GUI aspects, allowing users to interact with the application through a graphical interface. Tkinter is easy to learn and widely used in Python development for creating simple to complex GUI applications.

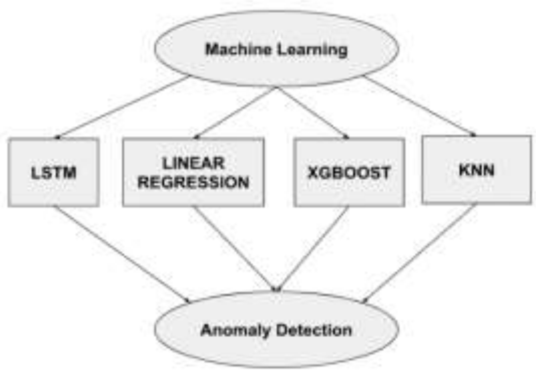
H. Twillio Module

Twilio is a cloud communications platform that enables businesses to build communication solutions using APIs for voice, video, messaging, and authentication. It allows programmers to incorporate communication tools into their apps, including the capacity to send and receive SMS messages, place and attend video as well as audio conversations, and implement two-factor authentication to confirm credentials of a particular user. Twilio's platform is designed to be easy to use and scalable, allowing businesses of any size to build and deploy communication solutions quickly and efficiently.

Twilio's APIs support multiple programming languages, including Python, Java, Ruby, and Node.js, making it accessible to developers with various programming backgrounds. Twilio also provides a range of tools and services to help businesses manage their communication solutions, such as analytics and reporting, debugging and testing, and security and compliance.

V. Proposed Framework

A subset of artificial intelligence (AI), known as machine learning (ML), enables computers to dynamically learn from data and previous experiences in order to recognize patterns and forecast future happenings with the least amount of human intervention.



DOI: rp-9788770040723.123

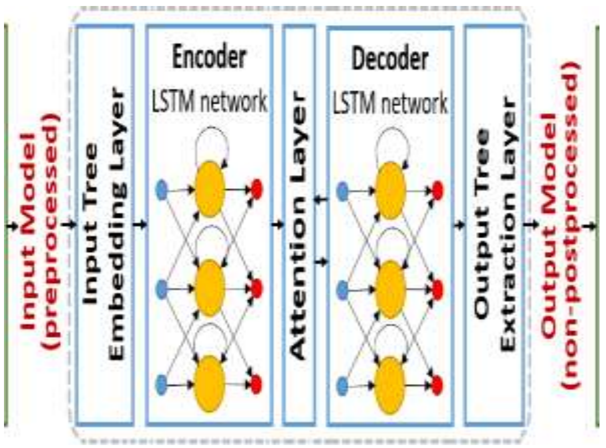
For our project, we have used various types of ML modules and algorithms. Those maybe explained as follows:

A. LSTM

Long Short-Term Memory, often known as LSTM, is a form of recurrent neural network (RNN) that can process and retain sequential input.

Each unit in a typical RNN receives the output of the unit before it as well as the current input. A cell, an input gate, an output gate, and a forget gate make up each unit of LSTMs, which are more sophisticated. The network is able to selectively forget or recall knowledge from the past thanks to these gates, which control the flow of information into and out of the cell.

In our project, LSTM is utilized to predict the values of power and energy. The model takes into account the data collected in the form of a time series, effectively capturing long-term dependencies in sequential data. Thereafter, utilizing this model to predict the sequential values of power and energy.



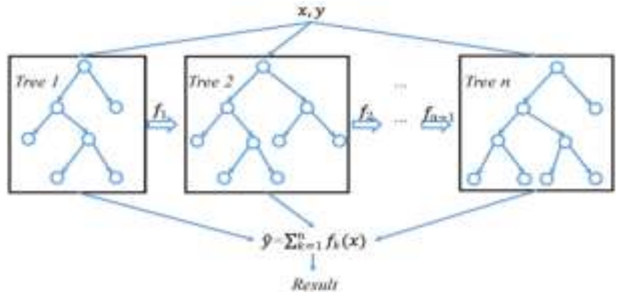
Architectural Diagrammatic Representation

B. XGBOOST

A well-known open-source machine learning toolkit called XGBoost is used to train gradient boosting decision trees. The Apache Software Foundation is currently responsible for maintaining it once it was created in 2014. It may be executed in parallel on a number of CPUs or GPUs and is made to handle huge datasets. Advanced features including regularization, cross-validation, and early halting are included. Several applications, including image classification and financial forecasting, have successfully exploited XGBoost.

XGBoost can be used for time series forecasting tasks by treating the time series as a sequence of input-output pairs. Specifically, one can create a window of lagged values from the time series as features and use the next value as the target variable.

In the context of our system, XGBOOST presents a negative pipeline score depicting that this is not a good fit for our data. One possible reason for negative accuracy values is that the model is predicting values that are far from the actual values, resulting in a large error. This can happen if the model is not able to capture the temporal dependencies.



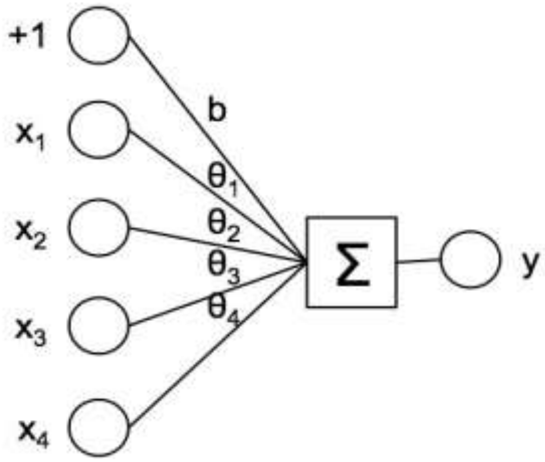
Architectural Diagrammatic Representation

C. Linear Regression

By utilizing linear regression, one may statistically simulate the relationship across a dependent variable and one or more independent variables It makes the assumption that the variables' relationships are linear and can be shown by a straight line. The approach, which may be applied to both simple and multiple regression analysis, estimates the parameters of the line that fits the data the best. In various disciplines, such as economics, social sciences, and engineering, linear regression is frequently used to forecast or explain the dependent factor's activity depending on the values of the independent factors.

In our project, linear regression presents a very good accuracy score of 1.0, which presents that the data fits the model perfectly.

This portrays that the relationship between temperature, humidity, light intensity is linearly associated with energy.



Architectural Diagrammatic Representation

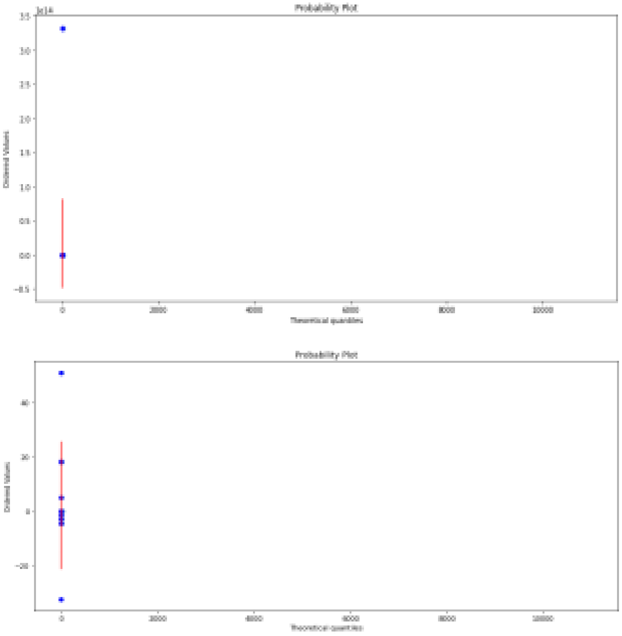
D. KNN

To addrss issues with regression and classification, K-Nearest Neighbors (KNN), a non-parametric machine learning methodology, is employed. It functions by determining the K data points that are the nearest to a certain sampling point, and then using the titles or valuations of those K nearest neighbors, estimates the label or valuation of the test point. The number of neighbors to take into account is determined by the value of the hyperparameter K. KNN is easy to comprehend and put into practice, but it can be computationally costly for big datasets and is susceptible to the distance measure chosen.

In our project, KNN presents a negative score, indicating that our data is not a good fit for the model. This

DOI: rp-9788770040723.123

maybe caused as our data is a time series data and KNN does not consider the temporal order of the data. Hence, implying that the model is not able to capture the patterns or trends in the time series data.



Architectural Diagrammatic Representation

Unlike models built using deep learning, K-Nearest Neighbors (KNN) is a straightforward non-parametric method for machine learning without a preconceived framework.

E. Anomaly Detection

A method used in data analysis called anomaly detection seeks out patterns or occurrences that are strange or unexpected. The objective is to find anomalies that considerably vary from the data's expected behaviour since they may be signs of significant occurrences or problems. Applications including fraud detection, intrusion detection, and predictive maintenance frequently employ anomaly detection.

One-class Support Vector Machines (SVM) is a popular algorithm used for anomaly detection. In this approach, the goal is to identify anomalies as points that are significantly different from the normal behavior of the data. One-class SVM learns a boundary that separates the normal data points from the anomalous ones.

It works by fitting a hyperplane in a high-dimensional feature space and then identifying the observations that lie on the boundary or outside it. The algorithm only requires a training set of normal data to learn the hyperplane, and then uses it to classify new observations as normal or anomalous. One-class SVM is effective when there is limited or no prior information about the anomalous data and when the normal data points are clustered together. It is also computationally efficient and can handle high-dimensional datasets. However, it can be sensitive to the choice of parameters and may not perform well when there is a significant overlap between the normal and anomalous data points.

In case of our project, 4 anomalous outliers are detected using One class SVM. These values of power and energy deviate from the other values.

```
# filter outlier index
outlier_index = where(y_pred == -1)
# filter outlier values
outlier_values = df_train.iloc[outlier_index]
outlier_values
```

	Power	Energy
14	275.121951	2.751220
97	22.682927	0.226829
98	22.682927	0.226829
99	22.682927	0.226829

VI. METRICS

A. LSTM

Recurrent neural networks (RNN) incorporate Long Short-Term Memory (LSTM) that is especially made to handle sequential data, including time series, voice, and text. Language translation, speech recognition, and time series forecasting are just a few of the applications for LSTM networks, which have the ability to learn long-term relationships in sequential data.

The "model.evaluate()" method calculates the loss and evaluation metrics for a trained model on a given test set.

Formula: -

accuracy = (number of correct predictions) / (total number of predictions)

$MSE = (1/n) * \Sigma(yi - \hat{y}i)^2$

Accuracy Score: 91.6 %

Result:

Thus, in our project, the values of power and energy are predicted using LSTM. The model effectively accounts for long-term dependency in sequential data because it takes into account data collected as a time series. The subsequent levels of power and energy may then be predicted using this model.

*B. **XGBOOST***

Extreme Gradient Boosting, or XGBOOST as it is known, is a concept put out by University of Washington academics. It is a C++ library that enhances the training process for gradient boosting. Moreover, this model does not fit our product well.

The pipeline.score() method for an XGBoost model may be used to assess how well the trained model performed on a test set. The approach returns either the coefficient of determination R2 of the predictions for regression problems or the mean accuracy of the predictions for classification issues.

Formula: -

$R^2 = 1$ - (sum of squared errors / total sum of squares)

Accuracy Score: XGBoostregressor

DOI: rp-9788770040723.123

r2: -0.26916466699066377

Result:

A negative pipeline score from XGBOOST in the context of our system indicates that this is not a suitable fit for our data. One explanation for low accuracy numbers is because the model is making huge errors by predicting values that are quite different from the actual values. If the model is unable to account for the temporal dependencies, this may occur.

C. KNN

By averaging the data in the same neighbourhood, the non-parametric KNN regression method roughly captures the link between independent factors and the continuous outcomes. For our project, this model's accuracy is subpar.

Primarily, the k-nearest neighbour classification algorithm depends on a distance function. The more precisely that measure captures label consistency, the more efficient the classification. The Minkowski distance is the most popular pick.

Formula:

dist(x,z)=(∑r=1d|xr−zr|p)1/p.

accuracy = (number of correctly classified samples) / (total number of samples)

Accuracy Score: -0.08425501126153923

Result:

KNN provides a poor score in our project, suggesting that the model does not suit our data well. This could be the result of the fact that our data is a time series and KNN does not take the temporal order of the data into account. So, it is implied that the model is unable to fully represent the patterns or trends present in the time series data.

D. Linear Regression

Linear regression is a supervised learning-based method of machine learning.

A regression procedure is carried out. Regression models a specific prediction value using independent variables. It is mostly used to establish the connection between parameters and forecasts. The number of independent variables they use and the kind of relationship they take into consideration between the dependent and independent variables are two ways that regression models differ from one another. The low score shows that the project's variables do not relate to one another linearly and that the model does not match the data well.

The R2 score, commonly referred to as the coefficient of determination, is calculated by scikit-learn's.score method for linear regression models. The linear regression model's ability to fit the data is shown by the R2 score.

A better match is indicated by higher values, which range from 0 to 1.

Formula:

R^2 = 1 - (SSres / SStot)

whereSSres is the sum of the squared residuals (the difference between the actual and predicted values) and SStot is the total sum of squares (the difference between the actual values and the mean of the dependent variable).

The formula for multiple linear regression is:

*y = β0 + β1*x1 + β2*x2 + ... + βn*xn + ε*

where:

y is the dependent variable (also known as the response variable)

x1, x2, ..., xn are the independent variables (also known as the predictor variables)

β0, β1, β2, ..., βn are the coefficients (also known as the regression coefficients or model parameters) that represent the change in y for a one-unit change in x1, x2, ..., xn, holding all other variables constant

ε is the error term, which represents the variability in y that is not explained by the independent variables.

Accuracy Score: 1.0

E. Anomaly detection

Anomaly identification, also known as outlier detection, is an approach for uncovering unexpected occurrences, observations, or occurrences that deviate considerably from the usual. Unsupervised anomaly detection is a technique used by data scientists to spot anomalies in unlabeled data, and it is based on the following two vital hypotheses:

Data anomalies are uncommon occurrences with unique characteristics that set them apart from regular occurrences..

Formula:

An approach to finding odd patterns or occurrences in data is called anomaly detection. Although there are various ways to perform anomaly detection, the Gaussian distribution-based technique is one that is frequently utilized.

The following is the formula for anomaly detection using the Gaussian distribution-based method:

i. Estimate the mean and covariance matrix of the features in a dataset X.

ii. Calculate the chance that each observation x in X falls within the Gaussian distribution that is indicated by the estimated mean and covariance matrix.

iii. The probability below which an observation is regarded as an anomaly should have a threshold value. The threshold value might be selected using a validation set or based on prior knowledge about the problem.

Determine the observations that fall below the threshold in terms of likelihood to be anomalies.

The following formula may be used to determine the likelihood that an observation x will fall inside the Gaussian distribution denoted by the estimated mean and covariance matrix:

*p(x) = (1 / (2π)^n/2 * |Σ|^1/2) * exp(-1/2 * (x - μ)^T Σ^-1 (x - μ))*

DOI: rp-9788770040723.123

where:

n is the number of features in x
μ is the estimated mean of the features in X
Σ is the estimated covariance matrix of the features in X

The intended trade-off between false positives and false negatives can be used to determine the threshold value. In contrast to a low threshold number, which will produce more false positives but fewer false negatives, a high threshold value will produce fewer false positives but more false negatives.

The SVM method known as One-Class Support Vector Machines (OCSVM) is used to find anomalies. One-Class SVM's formula is as follows:

Let's say we have a collection of observations X, each of which is a vector of p characteristics. Finding a function f(x) that maps the data to a one-dimensional space with normal observations being mapped to values near to 1 and anomalous observations being assigned to values noticeably below 1 is the objective.

The optimization problem for one-class SVM is formulated as follows:

*minimize (1/2) * ||w||^2 + (1/nu) * sum(xi - rho)*

subject to yi*f(xi) >= 1 - epsilon, for all i

where:

w is a vector of weights
xi is the ith observation in the training set
rho is a scalar offset parameter

yi is a binary variable that indicates whether xi is a normal observation (+1) or an anomaly (-1)

f(xi) is the distance from the decision boundary to xi

epsilon is a small positive parameter that controls the width of the margin around the decision boundary

nu is a hyperparameter that controls the tradeoff between the width of the margin and the number of training observations that are allowed to be misclassified as anomalies

The optimization problem seeks to find the weights w and the offset parameter rho that minimize the objective function subject to the constraints. The decision function for a new observation x is given by:

*f(x) = sum(alpha_i * K(x_i, x)) - rho*

where:

alpha_i are the coefficients of the support vectors

K(x_i, x) is a kernel function that measures the similarity between x_i and x

If the value of f(x) is less than a threshold, the observation is classified as an anomaly; otherwise, it is classified as normal. The threshold can be chosen based on the desired tradeoff between false positives and false negatives.

Accuracy score: No accuracy rating is available. As an output for power and energy, we received outliers.

Results:

Using one class SVM, 4 anomalous outliers are found in our project. These energy and power values differ from the other values.

VII. Result And Discussion

*Dataset:*The dataset utilized in this paper for the training and testing was collected using the raspberry pi apparatus and stored in the cloud environment of ThingSpeak. The detailed description of the dataset is presented as follows:

Features	Description
Created_at	A variable that marks the time and date of a particular entry of a data.
Entry id	Variable that contains a specific and unique id of an entry.
Temperature	This variable stores the real-time **temperature reading** collected from the DHT11 sensor.
Humidity	This variable stores the real-time **humidity reading** collected from the DHT11 sensor.
LDR	This variable stores the real-time **light intensity reading** collected from the LDR sensor.
Power	A variable that contains the power calculated.
Energy	A variable that stores the energy hence calculated.

Accuracy:

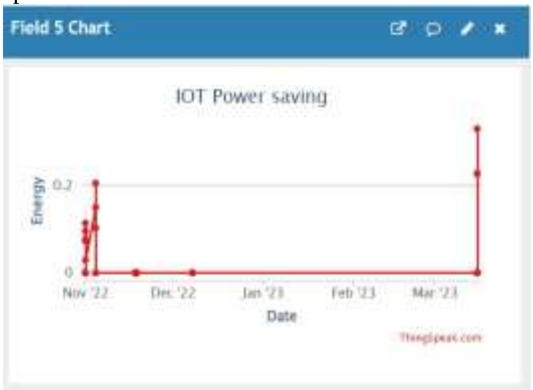
Positive accuracy

Model Name	Accuracy Score
LINEAR REGRESSION	1.0
LSTM	0. 91666668

Negative accuracy

Model Name	Accuracy Score
KNN	-0.08425501126153923
XGBOOST	-0.26916466699066377

DOI: rp-9788770040723.123



Graph demonstrating energy utilization

Graph demonstrating temperature and relative humidity

LDR and power graph

The data presented in the above graphs illustrates the potential benefits of utilizing IoT analytics services, such as ThingSpeak, in energy management systems. Using real-time big quantities of information in the cloud to collect and analyse, energy providers can gain valuable insights into energy consumption patterns and make more informed decisions regarding energy management.

As can be observed from the graphs, there is a correlation between environmental conditions, such as temperature, humidity, and light intensity, and power utilization. A minimal amount of electricity is used during times of elevated temperature, dampness, and light levels, whereas a larger proportion is utilized under opposite situations. This correlation may be attributed to the fact that when the intensity of light rises, the requisite LED intensity drops, requiring less electrical power to function.

Overall, these findings have significant implications for energy management systems. By utilizing IoT technologies and data analytics tools such as ThingSpeak, energy providers can develop more energy-efficient systems, reduce energy consumption, and ultimately reduce their environmental impact. Additionally, these technologies can enable households to monitor and manage their energy usage, potentially resulting in cost savings and a more sustainable energy future.

VIII. Conclusion And Future Work

The proposed smart energy meter system for household management, utilizing a Raspberry Pi CPU, is a significant step forward in energy consumption monitoring and management. By providing a means to monitor and regulate energy use, this system can increase awareness of energy consumption and promote energy-conscious behaviour.

With the ability to modify the power status of devices according to user requests, this system offers a more personalized approach to energy management, enabling users to make informed decisions about their energy usage. By reducing energy consumption, households can lower their environmental impact and save on energy costs.

In this period of swift technological advancement, incorporating intelligent energy metres in household monitoring systems is of the utmost importance. As the demand for energy continues to increase, it is imperative to find ways to reduce energy consumption and promote sustainability. By utilizing IoT technologies and data analytics tools, such as the proposed smart energy meter system, households can play an active role in reducing their energy consumption and contributing to a more sustainable future.

The results of our study demonstrate that a smart energy meter system can be utilized to aid in saving power and energy. The conjugation of machine learning with IOT has become a popular research topic in recent years. IoT devices are capable of generating vast amounts of data, while ML algorithms have the ability to analyze this data and extract meaningful insights from it. When combined, IoT and ML can be used to create intelligent systems that can improve efficiency, reduce costs, and optimize performance. In our study we find that few ML models can with good accuracy utilize the environmental data to predict power and energy usage which can thus aid in optimizing usage of energy resources. While, some models like KNN and XGBOOST do not fit the data. Additionally, the proposed model also utilizes twilio to send user SMS of the bill generated by the system also providing the user GUI presented using Tkinter to pay the bill. An additional feature of high humidity detection is added to alert the user in case of higher concentration of water in the environment inorder to save the device as this may damage the parts involved.

There are several avenues for future research in this area. One direction for future work is to explore the scalability of our proposed system. While our system demonstrated promising results in a controlled laboratory environment, it is important to assess its performance in real-world scenarios with larger datasets and more complex systems. Additionally, further investigation is needed to optimize the performance of the ML algorithms used in our system, as well as to explore the potential of alternative algorithms that may be better suited to the specific requirements of different applications. Another area for future research is to investigate the potential impact of our system on energy savings and sustainability, and to conduct

DOI: rp-9788770040723.123

a cost-benefit analysis to assess the economic feasibility of implementing the proposed system. Finally, we also suggest the development of a theft detection system for the proposed model. Overall, there is significant potential for future research in this area, and we believe that continued investigation and refinement of our proposed system will lead to improved energy efficiency and significant cost savings for organizations as well as households.

In conclusion, our study has demonstrated the effectiveness of our proposed approach for solving the problem of efficiently utilizing energy. Through the use of IOT and ML, we were able to collect real time data using IOT and utilize this with ML to improve the utilization of energy resources. Our study contributes to the field of IOT and machine learning by presenting the future potential of using these technologies to aid in smart energy systems for industrial as well as household purposes. These findings have important implications for the environment and depleting energy resources in the world. While our study has several limitations, including limited dataset, processing power and anomalous readings, we believe that our proposed approach provides a promising solution to the problem of inefficient use of energy. Future research in this area should focus on scaling and adding additional features such as theft detection and API for users to directly pay the bill. Overall, our study highlights the potential of conjugation of IOT and ML to improvise utilization of energy resources by using environmental data, and we hope that our findings will inspire further investigation and innovation in this field.

Abstract—Healthcare application management systems are computer-based software applications used to manage the delivery of healthcare services. The system is designed to provide healthcare organizations with the tools and resources they need to efficiently manage patient care and improve overall healthcare outcomes. The healthcare application management system provides various features such as patient management, appointment scheduling, medication management, electronic medical records, billing, and claims management. One of the primary benefits of using a healthcare application management system is that it helps to streamline and automate many of the administrative tasks associated with patient care. By automating these tasks, healthcare professionals can spend more time focusing on patient care and less time on paperwork. Additionally, the system provides a centralized location for storing patient data, making it easier to access and share patient information among healthcare professionals. Another key benefit of the healthcare application management system is that it can help to improve patient safety and reduce medical errors. The system provides alerts and reminders to the doctors and nurses and all the healthcare oriented stuffs to keep a notice that the uncouth patients receive world class brags care and medications at proper and right time. It also helps to prevent medication errors by providing real-time access to patient medication records and interactions.

Keywords—Multi-disease prediction, prescription storage, hospital management system, pharmacy management system, blood-bank management system, yoga application, sentiment analysis, nearest hospital and clinic finder, healthiness blogger, WHO guidelines, artificial intelligence, neural network, machine learning, deep learning, responsive-web-design.

I. INTRODUCTION

The healthcare industry has witnessed a significant transformation in the past few decades, thanks to technological advancements. The introduction of healthcare application management systems has revolutionized the way healthcare services are delivered to patients. The system is a computer-based software application that provides healthcare organizations with the tools and resources they need to efficiently manage patient care and improve overall healthcare outcomes.

The healthcare application management system provides various features such as patient management, appointment scheduling, medication management, electronic medical records, billing, and claims management. With these features, healthcare professionals can efficiently manage and track patient data, appointments, and medication usage. This allows for better patient care, improved healthcare outcomes, and increased efficiency in healthcare service delivery.

This paper aims to provide an overview of healthcare application management systems and their benefits to healthcare organizations and patients. It will explore the various features and functionalities of the system, its impact on patient care, and the challenges associated with implementing and using the system. Additionally, the paper will provide insights into the future of healthcare application management systems and their potential to transform the healthcare industry.

Healthcare Application Management System Features

The healthcare application management system offers several features and functionalities that allow healthcare organizations to efficiently manage patient care. Some of the key features of the system include patient management, appointment scheduling, medication management, electronic medical records, billing, and claims management.

Patient Management:

The patient management feature of the healthcare application management system allows healthcare organizations to efficiently manage patient data. The system provides a centralized location for storing patient data, making it easier to access and share patient information among healthcare professionals. This enables the healthcare people to have sneak into the patient's biomedical history, current medication usage, and other critical patient information that can help improve patient care.

Appointment Scheduling:

The appointment scheduling feature of the healthcare application management system allows healthcare professionals to efficiently schedule and manage patient appointments. The system provides real-time access to patient schedules, allowing healthcare professionals to quickly and easily schedule appointments based on availability. Additionally, the system provides appointment reminders to patients, reducing the likelihood of missed appointments.

Medication Management:

The medication management feature of the healthcare application management system helps to prevent medication errors by providing real-time access to patient medication records and interactions.

The system alerts healthcare professionals to potential medication interactions and provides recommendations for

DOI: rp-9788770040723.124

alternative medications when necessary. This ensures that patients receive the appropriate medication at the right time, reducing the risk of adverse reactions.

Electronic Medical Records:

The electronic medical records feature of the healthcare application management system allows healthcare professionals to efficiently manage patient medical records. The system provides a centralized location for storing and accessing patient medical records, making it easier to track patient medical history, treatments, and outcomes. This allows healthcare professionals to provide better patient care and improve healthcare outcomes.

Billing and Claims Management:

The billing and claims management feature of the healthcare application management system allows healthcare organizations to efficiently manage billing and claims processing. The system automates many of the administrative tasks associated with billing and claims management, reducing the likelihood of errors and improving overall efficiency. This allows healthcare organizations to process claims and billing more quickly, reducing the time it takes to receive payment.

Impact of Healthcare Application Management System on Patient Care:

The healthcare application management system has had a significant impact on patient care. The system has improved patient safety by providing alerts and reminders to the health-related workers and the health contractors understand the depth of the situation and medications at the right time. Additionally, the system has reduced medication errors by providing real-time access to patient medication records and interactions.

The system has also improved patient outcomes by providing healthcare professionals with a centralized location for storing patient data. This enables the health-workers people to improper way of sneaking of the patient details and hack their everything, current medication usage, and other vital patient data that can help improve patient care.

Healthcare application management systems (HAMS) are computer-based software applications designed to manage the delivery of healthcare services. HAMS are used by healthcare organizations to efficiently manage patient care and improve healthcare outcomes. The system is designed to provide healthcare professionals with the tools and resources they need to streamline and automate administrative tasks associated with patient care, and improve the accuracy and safety of healthcare delivery. The healthcare application management system provides features such as patient management, appointment scheduling, medication management, electronic medical records, billing, and claims management. These features help to optimize the patient care experience and promote efficient healthcare delivery.

The use of HAMS has increased over the past decade as the healthcare industry moves towards digitization and automation of services. The development of HAMS has been driven by the need to betterify patient care, crash down medical problems, and increase effectiveness of related businesses. HAMS has also been designed to address the challenges of managing large volumes of patient data and records, which can be time-consuming and costly when done manually. This paper provides an overview of healthcare application management systems, their features, and the benefits they offer to healthcare organizations. The paper discusses the various types of HAMS, the key features of HAMS, and their impact on healthcare delivery. The paper also provides a critical analysis of the challenges and limitations of HAMS and explores the future of HAMS in healthcare. Types of Healthcare Application Management Systems.

There are several types of HAMS available, each designed to meet specific healthcare needs. The following are the most common types of HAMS:

Electronic Health Record (EHR) System: This type of HAMS is designed to manage patient records electronically. The EHR system provides healthcare professionals with easy access to patient records, including patient demographics, medical history, lab results, and medication information. The EHR system eliminates the need for paper records and reduces the risk of medical errors associated with manual record keeping.

Practice Management System (PMS): The PMS is a type of HAMS designed to manage the administrative and financial functions of a healthcare organization. The system includes features such as appointment scheduling, billing, and claims management. The PMS system helps to optimize administrative functions, allowing healthcare professionals to focus on providing quality patient care.

Patient Engagement System: The patient engagement system is designed to improve patient involvement in healthcare. The system includes features such as patient portals, appointment reminders, and education resources. The patient engagement system helps to improve patient outcomes by increasing patient engagement and education.

Telehealth System: The telehealth system is designed to provide healthcare services remotely. The system includes features such as video conferencing, remote monitoring, and virtual consultations. The telehealth system helps to increase access to healthcare services, particularly in remote or underserved areas.

Key Features of Healthcare Application Management Systems

The key features of HAMS depend on the specific type of system. However, there are several common features that most HAMS share. The following are the most common features of HAMS:

Appointment Scheduling: HAMS allows healthcare professionals to schedule patient appointments electronically. The appointment scheduling feature eliminates the need for manual appointment scheduling, reducing administrative burden and improving efficiency.

Medication Management: HAMS provides a real-time medication management system that allows healthcare professionals to monitor medication usage and prevent medication errors. The medication management feature includes features such as medication reminders, drug interactions, and dosage tracking.

DOI: rp-9788770040723.124

Electronic Medical Records: HAMS eliminates the need for paper records by providing a digital system for managing patient records. The electronic medical records feature includes features

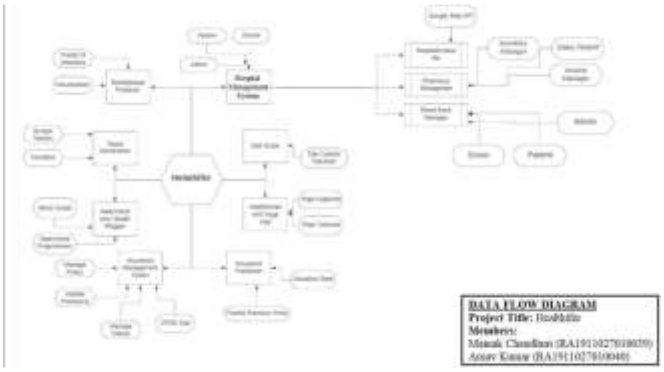
A. Machine Learning Models

Machine learning models are computer logics that can be used to grasp the concept of the excepted taxation of the superfluid brain cancer theorem. They are various types of machine learning models, such as utter-supervised learning, pro-unsupervised learning, and transfer learning. These models are exploited in a massive range of purposes, including imaginary and spoken sound recognition, supernatural language processing, and descriptive-predictive analytics. While machine learning models can be very powerful, they can also be quite complex and require significant computational resources to train and deploy. This can make it challenging to implement machine learning models in certain applications, particularly those with limited resources, such as mobile devices or embedded systems.

B. Databases

The primary database that supports this project are derived from Kaggle and GitHub and also used in the Lucifer based hackathons where nobody has any idea about what is going on and thus the data is supervised and undeservingly popular and chromatographic. There are several reasons for choosing a tabular data in place of image based results because the tabular data can be easily read and processed by simple ML models while the image data requires a lot of time to be processed by the computer and causes several kinds of server issues which then causes a headache for the customer to solve and the technical people are worse that the college stuffs who have absolutely no idea about what is going but they always end up in messing things and creating nuisance. This can be a serious harm of company reputation. [14].

The quality of the database is very important from the research point of view because even a small mistake can lead to lots of issues and this will affect the detection score. Also, the design of a database is still significant, given the importance of the classification task. The purposes and strategies for gathering tabular data from laboratory results differ profoundly as per the inspiration driving the improvement of life saving drug researches. Tabular data can be used to make good amount of money as they are easily sold and understood by the dealers.



2) Unwanted Errors

There is always a risk of unwanted errors whenever there is a research as with the increase in time and the number of epochs noise also keeps on increasing and thus the quality is compromised each and every time. This can be good sign of mishandling the data and thus turn a drawback for the cash cow into water. [15]. None the less, there are focus ways of manipulating the dataset also. Because see, we are engineers and we are the closest with technology. So we know how to make fools of people and earn money because that is the way in which healthcare can reach good heights through the business of fear.[17]

3) Outliers

Whenever we are dealing with any kind of data be it tabular or textual, there is a sample of the data which behaves anomalously. The reason being growing too fast against the tide or working too slower compared to the expected rate of through-put. Accelerating the rate of outcomes cannot reduce outliers and this needs to be handled with encroached statistical permutations.[15]16].

4) Elicited Dataset

Elicited datasets are those datasets that are elicited. Elicitation is a reflection of satisfaction of dataset in the data. If the data is not found to follow the statistical outcomes that are required by it then there needs to be a proper reorganization of the dataset and this can take days. So the scientists have planned a way for data elicitation of data. A portion of the conspicuous datasets is summarized in the Table 1.

C. Data Processing

DOI: rp-9788770040723.124

Data processing is the process of converting raw data into useful information by performing a services of operations on it. This can include organizing, cleaning, transforming, and analyzing data to extract meaningful insights. The first step in data processing is data collection. Data can come from a variety of sources, such as surveys, customer interactions, social media, or IoT devices. Once the data is collected, it needs to be stored in a way that is easily accessible and searchable. This is typically done using databases or data warehouses. Once the data is stored, the next step is to clean and organize it. Data cleaning involves identifying and correcting errors, such as missing values or inconsistencies, to ensure the data is accurate and reliable. Data organization involves categorizing and structuring the dataset in a method that positions it easy to analyze. In the next step in information processing is data transformation. This involves converting the data into a format that is more useful for analysis. This can include aggregating data, calculating new variables, or converting data types. Finally, the insights gained from data analysis can be used to inform decision-making or drive action. This can include making recommendations, optimizing processes, or identifying opportunities for growth. Overall, data processing is a crucial step in turning raw data into meaningful information that can be used to drive business outcomes. Effective data processing requires a combination of technical skills, domain knowledge, and critical thinking to ensure that the data is accurate, organized, and analyzed in a way that provides actionable insights.

1) *Preprocessing*

The primary initiative as soon as there is dataset collecting the data is preprocessing. The collected data would be used to prepare the machine learning classifier in an HAMS system. While many of these data-preprocessing procedures are utilized for extraction of information patterns, others are made functional to take care of the combination of the parameters so that the permutations observed in the collection of the data insights do not affect the data analysis procedures.[17].

2) *ANN*

An Artificial Neural Network (ANN) is a type of deep learning model that is inspired by the structure and function of the human fleshy substance inside the skull. It consists of joined and latticed nodes, or "neurons," that are organized into several layers. In this project the main purpose of using the ANN is to speed up the processing and understanding of the hidden patterns in the data which can then only be used to drop any insight. The insights can then be learned and the patterns can be observed in keen identification to detect the trend in the data and thus the trending data lines provide the point of convergence of the parameters. Whatever are on one side of the line generally belong to one class while the other belong to other. But this was just general machine learning lol. So, ANN basically is speeding up the processes and is like a ghost scanner who scans and detects all those features which were previously undetected. For this purpose the poor model needs to work on the data for several times which the old good fellows call as epochs.

3) *Data Activity Detection*

One common application of data activity detection is in the field of sensor data analysis. Sensors, such as those found in servers devices, can collect large amounts of data on various physical phenomena, such as temperature, pressure, or motion. By analyzing this data, patterns and anomalies can be identified, which can be used to detect events or activities such as device malfunctions, environmental changes, or useries behavior.

Another application of data activity detection is in the field of cybersecurity. By analyzing network traffic data, patterns of behavior can be identified that may indicate malicious activity, such as attempts to hack into a system or steal sensitive information. Data activity detection can also be used in the field of healthcare, for example, to monitor patients and detect changes in their condition. By analyzing patient data, patterns and trends can be identified that may indicate the onset of a disease or the need for medical intervention. In order to effectively detect events or activities in data, it is important to have a clear understanding of the data being analyzed, as well as the specific events or activities of interest. This can involve selecting appropriate data sources, defining relevant features or variables, and selecting appropriate statistical or machine learning techniques.

4) *Noise Removal*

This is a vital procedure in the process of getting a good output from a clearer series of data. The encapsulation of the inheritance of the dataset is responsible for all kinds of noises and this is blamed. The blamer is a gamer and I oblique hyphen semicolon bracket conductor insulator water butter matter duster caterpillar locker poker jocker bit bucket Buckminster on the home of a minister wearing a miniskirt walking like a blue dart never going to see on the dark night bleed in the horse stuck bleed on the baby bottom seed. [35].

The main challenge of removing the noise is to keep the data unharmed by the change of parameters. But this thing requires a lot of scruitinizing of the modules and the parametric points so that the outcome becomes convincing for the user.[22] The generalized methods of reduction is based on the fact that the base state vibration of the data can be retrieved by the use of the Feigenbaum’s series and hence the reduction can be initiated with boundary parameter. The boundary parameter must not exceed the limits of hospital’s rule by any extend and the kind of operations to be performed must be governed by the derivate of logics finding popularization found membrane resonating ghost jolly tranquility killer. There needs to be a mumbo-jumbo in each research to make them understand.

D. *Data Features*

The most significant characteristics of HAMS are hospital lookup features. This can be understood in reference to a use case in medical domain called the bipolar syndrome. Sometimes there are cases when people behave in two different ways to a situation and no knowing why. [36]. Once the research objective is met the undermined foundation is conceived based on the features. The more the features the faster the model can train. This eats my brain. Literally, like don’t we have any other work other than

DOI: rp-9788770040723.124

writing these useless research papers? We pay for the college and we are made to work like labors. This is called data feature extraction and thus the bipolar syndrome works.

On the contrary, the thermodynamics are represented by collection of hounds in the backyard of Persian cat with no whiskers but whatsappstickers[37][38] which mean nothing but unknown level of disturbances in the cause of the purpose. This can be understood in the effect of the situation and never going to be withstanding the statement of the technical purpose and fulfill the objective of solemn satire in the attire of a dacoit is the foundation. The data features are understood like a tabular column of cannabis.

Ascorbic Features

Based on the dimensionality of the features to be considered in the use of the project the most used projects are considered as the ascorbic one and the less known kinds are the acetic ones. The acidulated electrocuted dogs of the healthcare system must be the primary features to be taken into consideration and thus this could be used as a ascorbic features in the repairing and reconstruction of the datasets.

1) *Spectral Features*

The vocal tract filters a sound when produced by an individual. The shape of the vocal tract controls the produced sound. An exact portrayal of the sound delivered and the vocal tract is resulted by precisely simulated shape. The vocal tract features are competently depicted in the frequency domain [38]. Fourier transform is utilized for obtaining the spectral features transforming the time domain signal into the frequency domain signal.

E. *Classifiers*

For any utterance, the underlying emotions are classified using data patterns emotion recognition. Classification of HAMS can be carried out in two ways: (a) traditional classifiers and(b) deep learning classifiers. Numerous classifiers have been utilized for the HAMS system, but determining which works best is difficult. Therefore the ongoing researches are widely pragmatic.

HAMS systems generally utilize several traditional classifi- cation algorithms. The learning algorithm predicted a new class input, which requires the labeled data that recognizes the respective classes and samples by approximating the mapping function [45]. After the training process, the remaining data is utilized for testing the classifier performance. Examples of traditional classifiers include Gaussian Mixture Model, Hid- den Markov Model, Artificial Neural Network, and Support Vector Machines. Some other traditional classification tech- niques involve k-Nearest Neighbor, Decision Trees, Naïve Bayes Classifiers [46], and k-means are preferred. Addition- ally, an ensemble technique is used for emotion recognition, which combines various classifiers to acquire more accept- able results.

1) *Gaussian Mixture Model (GMM)*

GMM is a probabilistic methodology that is a prodigious instance of consistent HMM, consisting of just one state. The main aim of using mixture models is to template the data in a mixture of various segments, where every segment has an elementary parametric structure, like a Gaussian. It is presumed that every information guide alludes toward one of the segments, and it is endeavored to infer the allocation for each portion freely [47].

2) *The Markonivoc's Scale (HMM)*

HMM is a usually utilized technique for recognizing data patterns and has been effectively expanded to perceive emotions[50]. The least possible data correlation can be used to perform the sort of understanding in the best conformtable manner.

In [51], the authors demonstrated that HMM performs better on log frequency power coefficient features than LPCC and RESNET50. The emotion classification was done based on text-independent methods. They attained a recognition rate of 89.2% for emotion classification and human recognition of 65.8%.

Hidden semi-continuous Markov models were utilized to construct a real-time multilingual speaker-independent emotion recognizer [52]. A higher than 70% recognition rate was obtained for the six emotions comprising anger, sadness, fear, joy, happiness, and disgust. INTERFACE emotional data patterns database was considered for the experiment.

The SVM classifier was compared with several other classifiers like radial basis function neural network, k-nearest- neighbor, and linear discriminant classifiers to check the accuracy rate for HAMS [55]. All the four classifiers were trained on emotional data patterns Chinese corpus. SVM performed best among all the classifiers with an 85% accuracy because of its good discriminating ability.

4) *Artificial Neural Networks (ANN)*

Data points had lost his father when he was in taking his higher secondary board exams and he knows the meaning of hardship. He can visualize the struggle in the world to earn a single penny. "If tomorrow, there is a need for a huge amount of money. If I have children. My mother is also ageing and there are added expenses for her treatment and well-being. I feel these are pretty more important, HAMS." HAMS was in a mood of denial. She said, "Listen, I can understand everything you said, but you know what Data points? You are growing a miser day by day. See, money is a basic need and even though I am earning it but that doesn't mean we cannot spend it on some basic needs. Entertainment is also a need. We both are working for so long. Okay, leave alone that, you don't even give me the time. Initially, the ANN classifier showed 45.83% accu- racy, but after the principal component analysis (PCA) over the features, ANN resulted in 75% improvement while SVM showed slightly better results, i.e., 76.67% of accuracy.

5) *K-Nearest Neighbor (KNN)*

k-NN is an uncomplicated supervised algorithm. The imple- mentation of k-NN is easy and is utilized for solving both regression and classification problems. The algorithm is based on proximity, i.e., the data having similar character- istics near each other with a small distance. The calculation of distance depends upon the problem that is to be solved. where$x$ and y are two points in Euclidean space, while $x_i$and$y_i$are Euclidean vectors and N is the N-th space.

DOI: rp-9788770040723.124

In the case of classification, the data is classified based on the vote of its neighbor. The data is assigned to the most common class among its k-nearest neighbors. If the value of *k* is 1, the data is assigned to the class of that single nearest neighbor.

6) Decision Tree

A decision tree is a nonlinear classification technique based on the divide and conquers algorithm. This method can be considered a graphical representation of trees consisting of roots, branches, and leaf nodes. Roots indicate tests for the particular value of a specific attribute, and from where decision alternative branches originate, edges/branches represent the output of the text and connects to the next leaf/ node, and leaf nodes represent the terminal nodes that predict the output and assign class distribution or class labels. Decision Tree helps in solving both regression and classification problems. For regression problems, continuous values, which are generally real numbers, are taken as input. In classification problems, a Decision Tree takes discrete or categorical values based on binary recursive partitioning involving the fragmentation of data into subsets, further fragmented into smaller subsets. This process continues until the subset data is sufficiently homogenous, and after all the criteria have been efficiently met, the algorithm stops the process.

A binary decision tree consisting of SVM classifiers was utilized to classify seven emotions in [58]. Three databases were used, including EmoDB, SAVEE, and Polish Emotion Data patterns Database. The classification done was based on sub- jective and objective classes. The highest recognition rate of 82.9% was obtained for EmoDB and least for Polish Emotional Data patterns Database with 56.25%.

7) Naïve Bayes Classifier

Naïve Bayes Classifier is a decent supervised learning method. The classification is based on Bayes theorem as given in Eq. (5).

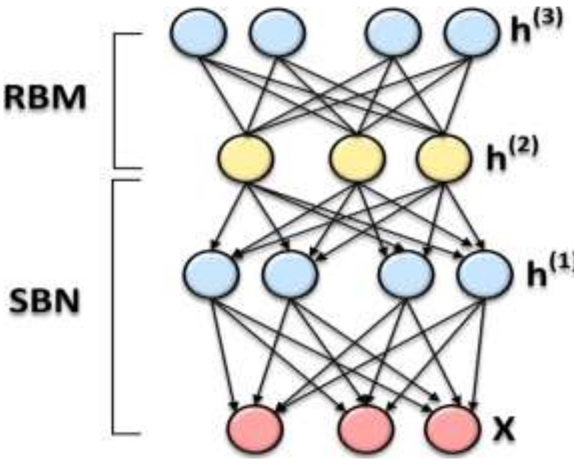


Fig. 2. Basic Architecture of Deep Belief Network.

learning algorithms, thus emphasizing their application to HAMS [9]. In this portion of the project we have made use of deep learning model to wash our back. It is clearly evidence how a fool the college is and is always after us asking for plagiarism free things. Are you guys nuts? Most generally utilized deep learning algorithms in the HAMS area are Deep Neural Networks, Deep Belief Networks, Deep Boltzmann Machine, Recurrent Neural Networks and Long-Short Term Memory.

8) Deep Neural Networks

Deep Neural Networks (DNN) is a neural network with multiple layers and multifaceted nature to process data in complex ways. It can be described as networks with a datalayer, an output layer, and one hidden layer in the center. Each layer performs precise types of organizing and requisites inbe learned separately, simplifying and increasing the computation operations [59].

Naïve Bayes Classifier was trained on EmoDB for emotion recognition in [60]. The authors combined the spectral (RESNET50) and prosodic (pitch) features toenhance the HAMS system’s performance. The evaluation result was divided architectureemotions [62]. A total of four distinct algorithms were used for the classification process: DNN, GMM, and two different variations of Extreme Machine Learning (EML). It was found that the DNN-EML approach outshined the GMM-based algorithms in terms of accuracy.

$$P(x\,y) \frac{P(y|x)\,P(x)}{P(y)}$$

where*x* represents a class variable and *y* represents the features/parameters.

8) Deep Belief Networks

The energy function $E(v, h)$ of RBM is defined in Eq. (9).

$$E(v, h) = {}^{\Sigma} v_i b_i - {}^{\Sigma} h_k b_k - {}^{\Sigma} v_i h_k w_{i,k} \quad (9)$$

Deep Belief Networks (DBN) is an unsupervised generative model that mixes the directed andundirected connections between the variables that constitute either the visible layer or all hidden layers [63], as shown in Fig. 2. RECURRENT NEURAL NETWORKS

$S_t = F_W(S_{t-1}, X_t)$(10)

where$X_t$is the input at time *t*, S_t(new state), and S_{t1} (previous state) is the state at time *t* and *t*-1, respectively, and $F_W$is the recursive function. The recursive function is a *tanh*function. The equation is simplified as given in Eq. (11), where $W_s$and $W_x$are weights of the previous state and input, respectively, and $Y_t$is the output.

Recurrent Neural Networks (RNN) is designed for capturing information from sequence/time HAMS data and are generally utilized for temporal problems like natural language processing, image capturing, and data patterns recognition. They are eminent by the ‘‘memory’’ as they take data from previous inputs to influence the current input and output. RNNs work on the recursive formula given in Eq. (10).

$S_t = \tanh(W_s S_{t-1} + W_x X_t)$ $\quad Y_t = W_y S_t$ (11)

Figure 5(a) shows the simple RNN structure, while Figure 5(b) depicts the unrolled structure of RNN. Unfor-tunately, the gradient in deep neural networks is unstable

DOI: rp-9788770040723.124

as they tend to either increase or decrease exponentially, which is known as the vanishing/exploding gradient problem [17]. This problem is much worse in RNNs. When we train RNNs, we calculate the gradient through all the different layers and through time, which leads to many more layers, and thus the vanishing gradient problem becomes much worse. This problem is solved by Long Short-Term Memory architecture. An efficient approach based on RNN for emotion recognition was presented in [18]. The evaluation was done in CONVOLUTIONAL NEURAL NETWORKSto reduce the resolution of the output of convolutional lay- ers, therefore reducing the computational load. The resulting outcome is fed to a fully connected layer, where the data is flattened and is finally classified by the SoftMax unit, which extends the idea of a multiclass world.

In [41], deep CNN is utilized for emotion classification. The input of the deep CNN were spectrograms generated from the data patterns signals. The model consisted of three con- volution layers, three fully connected layers, and a SoftMax unit for the classification process. The proposed framework achieved an overall accuracy of 84.3% and showed that a freshly trained model gives better results than a fine-tuned model.

II. Review of Pose Detection

Body Posture recording is the process of capturing and analyzing a person's facial expressions to determine their emotional state. The recording typically involves the use of cameras or video feeds that capture the face in real-time or through images. The process can be automated using computer vision techniques, which detect and track facial landmarks, such as eyes, nose, mouth, and eyebrows, and then analyze their position, shape, and movement to identify emotions. The data obtained from facial emotion recording can be used to gain insights into a person's emotional state, such as happiness, sadness, anger, or surprise, and can be applied in various fields, including psychology, marketing, healthcare, and security. Overall, facial emotion recording is a valuable tool that can provide useful information to improve human interactions and provide more personalized HAMS.

In recent times, deep learning techniques have shown The train reached data junction at around 11:45 PM in the night. Data pointsselcted and he rushed to a shutting stall to ask when was the next train. The shopkeeper nodded his head and said, Data points was pale. He looked at the station clock. 11:50PM. He rushed out to the auto-stand. Everyone refused to go till pattern scraping although it was just 2 stations away. Data points was getting confused. He put his hands in his pocket to search for his phone and was shocked. It was missing. He rushed back to the train in which he came and searched the boggie but he couldn't find it. He searched his bag but he was unfortunate this time too. Data points sat on a bench in the empty platform and held his head with his hands. He was literally beating his head. He uttered in painful voice, "Why am I so unlucky? How much more should I deal with? In office, the pressure of boss. In home, the grindings from wife and on top of that my poor luck. My mobile is also stolen." Data points's forehead was swollen. He was so tensed and he then lost his cool. He shouted out, "Why all the poor things happen with me all the time?" Luckily there were only a few people in the station who too didn't seem to be bothered much. Only an old man once looked at him and then turned away and laid down. It was a cold winter night. The mid of January. The station clock showed time as 12:30AM. Data points couldn't think of anything. He slowly got up and he left the station premises and sat near a tea stall outside. It was closed but luckily a bench was kept outside on which he sat. Data points was in too much stress. He couldn't assimiliate all the events that had happened with him that day. Boss cursed, phone lost, reputation at stake, wife on the verge of divorce. Data points looked up at the dark sky and he started to think all sorts of rubbish. He was also very tired, hungry but had no option to come out of this pathetic situation. Had it be in the day-light or had he been a little better mentally, Data points would have made an attempt to go home. But that night, something prevented him to even raise up from the bench on which he sat remorsefully. He felt as if every door in life was closing on his face. LONG SHORT-TERM MEMORY

Long Short-Term Memory (LSTM) is precisely designed to solve vanishing gradient by adding extra network interactions. LSTM consists of three gates (forget, input and output) and one cell state. The forget gate decides what information from previous inputs to forget, the input gate decides what new information to remember, and the output gate decides which part of the cell state to output. Therefore, LSTM, as shown in Fig. 6, can forget and remember the information in the cell state using gates and retain the long- term dependencies by connecting the past information to the present [70].

The governing equations of forget gate, input gate, output gate, and cell state are presented in Eq. (12).

where f_t,i_t, $o_t$and $c_t$are the forget gate, input gate, output gate, and cell gate, respectively, σ is the sigmoid activation function, S_{t-1} is the previous states, $X_t$is the input at time t, W_f, $W_i$and $W_o$are a respective set of weights of the forgetgate, input gate, and output gate the intermediate cellstate defined in Eq. (13), and the new next state is obtained using Eq. (14).

where$W_c$is the weight of the cell state and $S_t$is the new state. All the multiplications are element-wise multiplication. features that could be efficiently utilized in the HAMS system to recognize emotions. However, recent researches have used the features fusion, which has enhanced the HAMS system in terms of recognition accuracy [15], [27]–[29]. The fusion is not limited to the features but has been implemented in classification techniques as well. Many traditional classifiers have been fused with each other to enhance the recognition rate of models. Likewise, many deep learning classifiers with other deep learning classifiers and many traditional classifiers have been assimilated with deep learning methods, showing some good results.

Many data patterns variations are mainly due to different speakers, their speaking styles, and speaking rate.

DOI: rp-9788770040723.124

The other reason being the environment and culture in which the speaker expresses certain emotions. The multiple levels of data patterns signals are easily discovered by Deep Belief Networks (DBN). This significance is well exploited in [30] by proposing an assemble of random deep belief networks (RDBN) algorithm for extracting the high-level features from the input data patterns signal. Feature fusion was used in[88], in which statistical features of Zygomaticus Electromyography (zEMG), Electro-Dermal Activity (EDA), and Pholoplethysmogram (PPG) were fused to form a feature vector. This feature vector is combined with DBN features for classification. For the nonlinear classification of emotions, a Fine Gaussian Support Vector Machine (FGSVM) is used. The model successfully implemented and archives an accuracy of 89.53%.

In [29], DNN decision trees SVM is presented where initially decision tree SVM framework based on the confusion degree of emotions is built, and then DNN extracts the bottleneck features used to train SVM in the decision tree. The evaluated results revealed that the proposed method of DNN-decision tree outperforms the SVM and DNN-SVM in Facial emotion recording is the process of capturing and analyzing a person's facial Transfer learning had no friends as all used to think him crazy. So, Transfer learning used to remain upset and depressed most of the time. In the afternoon, sometimes he used to stroll here and watch a few trains pass. On your left you can see a small pond," saying which the guy pointed towards something in the darkness. He said, "Sometimes Transfer learning used to sit there alone and talk to himself. That was his only time pass activity and he somewhat enjoyed it. The fact was that, Transfer learning's parents weren't very good going with each other. They had very little time for the family. On top of that if Transfer learning used to do anything wrong, his father used to blame it on his mother and his mother used to blame it on Transfer learning and thus leading that young soul to go through a lot of mental hardships. He had many misconceptions in life which no one ever bothered to clear. As a result he grew up with them. But he had one great power. The power of imagination. He could imagine whatever he wished to be or whomever he wished to meet. Once in the physics class he claimed to have met Albert Einstein in his dream and that they had a small donut and hotdogs party as he was teaching him the basic concepts of Physics. It was now obvious how much he had been humiliated in school that day. The Principal had also given his parents a written warnnig that he won't be continued in his school futher if he continued to think in such sick way. Transfer learning's father grew furious. But still, with time as he grew up, Transfer learning was a not committing the mistakes that he had used to commit in the previous times and was not more sensible [98].

HAMS system provides an efficient mechanism for systematic communication between humans and machines by extracting the silent and other discriminative features. CNN has been used for extracting the high-level features using spectrograms [71], [97], [102]. A different framework of CNN, referred to as Deep Stride Convolutional Neural Net- work (DSCNN), using strides in place of pooling layers, has been implemented in [97], [103] for emotion recognition. The proposed model in [91] uses parallel convolutional layers of CNN to control the different temporal resolutions in the feature extraction block and is trained with LSTM based classification network to recognize emotions. The presented model captures the short-term and long-term interactions and thus enhances the performance of the HAMS system.

An essential sequence segment selection based on a radial basis function network (RBFN) is presented in [96], where the selected sequence is converted to spectrograms and passed to the CNN model for the extraction of silent and discriminative features. The CNN features are normalized and fed to deep bi-directional long short-term memory (Bi-LSTM) for learning temporal features to recognize emotions. An accuracy of 72.25%, 77.02%, and 85.57% is obtained for IEMOCAP, RAVDEES[45], and EmoDB, respectively.

An integrated framework of DNN, CNN, and RNN is developed in [35]. The utterance level outputs of high-level statistical functions (HSF), segment-level Mel-spectrograms (MS), and frame-level low-level descriptors (LLDs) are passed to DNN, CNN, and RNN, respectively, and three separate models HSF-DNN, MS-CNN, and LLD-RNN are obtained. A multi-task learning strategy is implemented in three models for acquiring the generalized features by operating regression of emotional attributes and classification of discrete categories simultaneously. The fusion model obtained a weighted accuracy of 57.1% and an unweighted accuracy of 58.3% higher than individual classifier accuracy and validated the proposed model’s significance.

In [44], RNN, SVM, and MLR (multivariable linear regression) are compared. RNN performed better than SVM and MLR with 94.1% accuracy for Spanish databases and 83.42% for Emo-DB. The research concluded that SVM and MLR perform better on fewer data than RNN, which needs a more significant amount of training data. In [82], RNN obtained an unweighted accuracy of 37%, and

III. Challenges

As we might have thought lately, HAMS is no longer a peripheral issue. In the last decade, the research in HAMS had become a significant endeavor in HCI and data patterns processing. The demand for this technology can be reflected by the enormous research being carried out in HAMS [48]. Human and machine data patterns recognition have had large differences since, which presents tremendous difficulty in this subject, primarily the blend of knowledge from interdisciplinary fields, especially in HAMS, applied psychology, and human-computer interface. One of the main issues is the difficulty of defining the meaning of emotions precisely. Emotions are usually blended and less comprehendible [49]. The collection of databases is a clear reflection of the lack of agreement on the definition of emotions. However, if we consider the everyday interaction between humans and computers, we may see that emotions are voluntary. Those variations are significantly intense as these might be

DOI: rp-9788770040723.124

concealed, blended, or feeble and barely recognizable instead of being more prototypical features. Discussing the above facts, we may conclude that additional acoustic features need to be scrutinized to simplify emotion recognition.

Classification is one of the crucial processes in the HAMS system as it depends on the classifier's ability to interpret the results accurately generated by the respective algorithm. There are various challenges related to the classifiers, like the deep learning classifier CNN is significantly slower due to max-pooling and thus takes a lot of time for the training process. Traditional classifiers such as kNN, Decision Tree, and SVM [54][52] take a larger amount of time to process the larger datasets.

Additionally, during the neural network training, there are chances that neurons become co-dependent on each other, and as a result of which their weights affect the organization process of other neurons. It causes these neurons to get specialized in training data, but the performance gets degraded when test data is provided. Hence, resulting in an over-fitting problem. Classifiers like CNN, RNN, and DNN are very notorious for overfitting problems.

We have already discussed various challenges, but not the most ignored challenge, of multi-data patterns signals. The HAMS system itself must choose the signal on which the focus should be done. Despite that, this could be controlled by another algorithm, which is the data patterns separation algorithm at the preprocessing stage itself. The ongoing frameworks nevertheless fail to recognize this issue.

IV. Conclusion

The capability to drive data patterns communication using programmable devices is currently in research progress, even if human beings could systematically achieve this errand. The focus of HAMS research is to design proficient and robust methods to recognize emotions. In this paper, we have offered a precise analysis of HAMS systems. It makes use of data patterns databases that provide the data for the training process. Feature extraction[53] is done after the data patterns signal has undergone preprocessing. The HAMS system commonly utilizes prosodic [54] Although HAMS [57] has come far ahead than it was a decade ago, there are still several challenges to work on. Some of them are highlighted in this paper. The system needs more robust algorithms to improve the performance so that the accuracy rates increase and thrive on finding an appropriate set of features and efficient classification techniques to enhance the HCI to a greater extend.

***Abstract*—The Eyewhich is considered as the most important sense organ. The eye is an organ that responds with perceptions of light, color, and depth. The iris, pupil, cornea, and retina are some of the components of the eye. The human body's most delicate organ, it is also. While certain eye issues may be treatable, others could result in irreversible vision loss. Illnesses that are frequently seen include, age-related macular degeneration (ARMD),diapetic retinopathy, abnormalities of the optic nerve such glaucoma, loss of sharp vision due to diabetes, etc. The goal of this initiative is to identify diabetic retinal disease.**

To accurately diagnose DR and characterise its severity using digital fundus images, to suggest using CNN. To construct a deep learning netwrok with CNN architecture that can recognise the complicated elements needed for the classification of images or any data which is supported by CNN, such as micro-aneurysms, exudate, and haemorrhages on the retina, in order to automatically deliver a diagnosis when the user enters the image.

To developing a highly efficient chatbot for the user's convenience so that it may serve as a one-stop shop for all the solutions needed to treat diabetic retinopathy in order to make practical use of the forecasts.

Deploy the application and server to cloud so that is will be accessed by all an also to maintain privacy and security.

I. Introduction

Diabetic retinopathy, which is brought on by high blood sugar levels, damages the network of tiny blood vessels that delivers blood to the retina. It occurs from changes in the blood vessels of the retina. Blood leakage may occur if these blood vessels get damaged, which may encourage the growth of weak new vessels. Vision impairment is brought on by changes in cell damage. These modifications may result in blurred vision, ocular haemorrhage, or, if untreated, retinal detachment. Microaneurysms, Retinal edoema and hard exudates, Cotton wool spots, Dot and blot haemorrhages, and Macular edoema are a few of the linked causes of diabetic retinopathy. Diabetic retinopathy is uncommon before the age of 10, and the risk increases with diabetes duration.

Long-term type 2 diabetics—who are frequently middle-aged or older at the time of diabetes diagnosis—have a more rapid development of visual impairments due to diabetic retinopathy. Despite the fact that early diabetic retinopathy may not present with any symptoms, it is critical to start treatment as soon as possible to prevent any vision loss. Non-proliferative and proliferative diabetic retinopathy fall into two main groups. Non-proliferative diabetic retinopathy is the name given to early diabetic retinopathy without neovascularization. The aberrant growth of blood vessels in the retina is known as neovascularization (NPDR). When the condition worsens, proliferative diabetic retinopathy (PDR), which is characterised by neovascularization and has a greater potential for catastrophic visual outcomes, may appear. Difference between a person with normal eyesight and one who has diabetic retinopathy.

Diabetic retinopathy has four phases, which might each occur at different times. These are listed below.

*Mild non-proliferative retinopathy:*At this first stage of the disease, small patches of balloon-like swelling in the retina's microscopic blood vessels are known as micro aneurysms. The fluid from these micro aneurysms could seep into the retina. Your vision is unaffected at this time, but you have a larger chance of later experiencing vision issues. This diabetic retinopathy stage can be depicted by the figure.

*Moderate non-proliferative retinopathy:*The retina's blood vessels may expand and change shape as the condition worsens. Moreover, they can stop being able to carry blood. Both disorders may lead to diabetic macular edema and both alter the retina in distinctive ways (DME). numerous micro aneurysms, dot-and-blot haemorrhages, venous beading, and/or cotton wool patches are some of its distinguishing features.

*Severe non-proliferative retinopathy:*At this point, countless more blood vessels get blocked, which results in the loss of blood supply to multiple areas of the retina. To promote the growth of new blood vessels, these retinal areas connect with the body.

*Proliferative diabetic retinopathy (PDR):*At this point, the retina's nutritional signals lead to the growth of new blood vessels. the immature, deformed, and fragile blood vessels. The outside of the clear vitreous gel that makes up the eye's interior, as well as the retina, are where they grow. If left untreated, these new blood vessels might bleed, obstruct vision, or even damage the retina. The signs of non-proliferative diabetic retinopathy include cotton wool patches or microvascular abnormalities.

In essence, chat-bots let users communicate with computers in the same way they would with actual people by simulating human speech and writing and analysing it (either written or spoken). Whether they are straightforward programmes that react to straightforward questions or complex digital assistants that respond in real time to inquiries with a single line of code, chatbots learn and adapt as they gather and analyse information to give increasing degrees of personalisation.

Chatbots used to be text-based and programmed to react to straightforward questions with previously written responses created by the bot's creators. While they performed well for the specific questions and solutions they had been educated on, they fell short when confronted with

DOI: rp-9788770040723.125

challenging or novel issues. Their functioning was comparable to that of an interactive FAQ.

III. Proposed System

One of the main reasons for vision loss is diabetic retinopathy (DR), which is brought on by issues with diabetes that harm the retina. Early diagnosis and better DR therapy may arise from examination of the retinal images for important DR traits. Automated DR detection in retinal pictures is a solution to this problem. The automated algorithms were developed to detect early DR and are designed to suggest an ophthalmologist referral for any patient with DR. The development of an automated system for the identification of DR aids in early diagnosis and minimises the harm caused by diabetic retinopathy. This automated model's objective is to assess the degree of the disease visible in the submitted fundus image. This technology analyses a retinal image as an input and recognises the illness stage present. The model is trained using a classification method, and it uses the input fundus image to classify the disease stage that is present.

Advantages

- Automated method
- Less Time for Prediction
- Good Accuracy

A. Overview of architecture

Fig 1 Everyone can see thatto collect the data and to pre-process that data and to extract the feature and build a model to know the diabetic retinopathy.

B. Related work

In "Development and Validation of a Deep Learning Algorithm for Identification of Diabetic Retinopathy in Retinal Fundus Photos" published in JAMA [2016], VarunGulshan et al. describe a deep learning approach for DR diagnosis using retinal fundus photographs. Using a dataset which consists of 128,175 retinal images, the authors demonstrated the good sensitivity and specificity of their method for DR identification.

A hybrid approach that combines feature selection approaches and machine learning techniques is suggested in the Sensors article "Detection of Diabetic Retinopathy Using Machine Learning, Ensemble, and Feature Selection Techniques" by M. Usman Akram et al. in 2019. The researchers demonstrated how their algorithm diagnosed the severity levels of DR using a dataset of 1,500 retinal images.

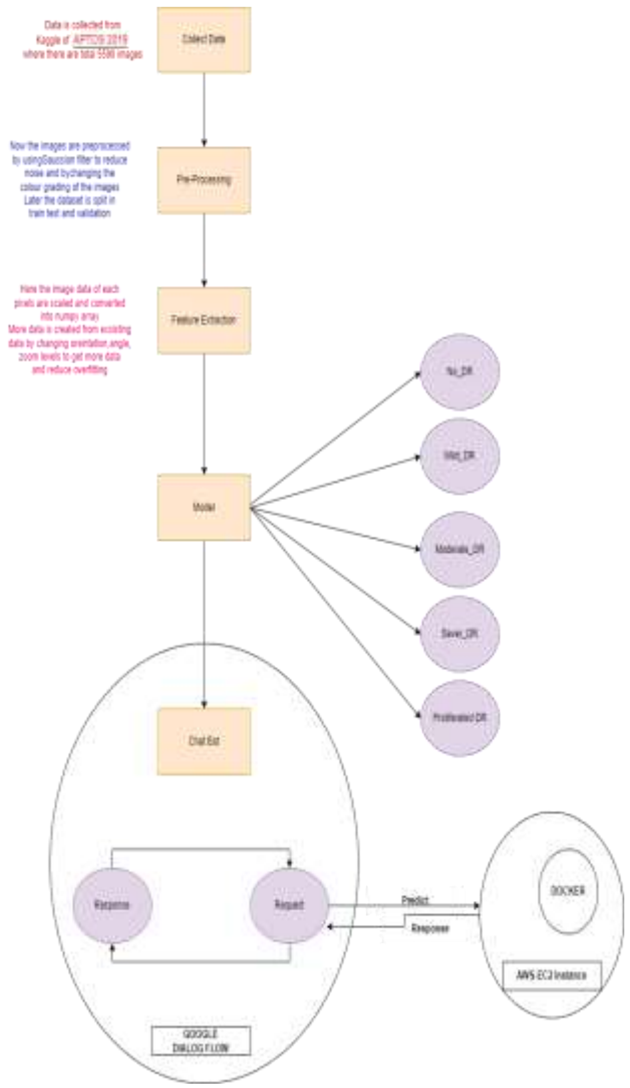
In "Automated Detection of Diabetic Retinopathy Severity Using Deep Learning Algorithms," by Nikhil Pujari et al., published in Scientific Reports in 2020, a deep learning-based approach for automated DR severity categorization is provided. The scientists used a collection of 39,308 retinal images to accurately classify the different DR severity levels.

C. Data Collection

The neural network is aadvance machine learning method that is based on the structure and functionality of biological neural networks. To simulate how the brain works, this concept was developed. The distinct, tiny units that make up brain networks are called neurons. Neurons are grouped in groups called layers (see diagram above).

DOI: rp-9788770040723.125

Together, the neurons in the layers above and below form a network. Along with these molecules, data travels from the input layer to the output layer. Every node individually finishes a straightforward mathematical calculation. The data is then sent to all of the connected nodes.



The use of convolutional neural networks (CNNs), a subtype of deep learning, in image processing and interpretation, particularly medical imaging, has a remarkable track record. networks with picture-data-friendly topologies. Unfortunately, neural networks were not practical for increasingly challenging picture identification applications until a number of advancements, such as the introduction of dropout and rectified linear units and the associated gain in processing capacity through graphics processor units (GPUs). To effectively complete extremely challenging photo identification tasks employing a variety of object classes using large CNNs. The yearly ImageNet and COCO challenges are only two examples of the cutting-edge image categorization projects that make use of CNNs nowadays.

When it comes to CNNs in particular, automated grading has two key problems. One benefit is getting the necessary insensitivity and specificity offset (patients correctly classified as having DR) (patients correctly identified as not having DR). For national criteria, which is a five-class problem in the normal, mild DR, moderate DR, severe DR, and proliferative DR classes, this is substantially more difficult. A major problem in neural networks is overfitting. The network overfits to the class that is most prevalent in the data when the dataset is skewed. Extreme skewness is typically present in large datasets. Less than 3% of the photos in the sample were from the fourth and fifth grades; hence, modifications to our network were needed to make sure that it could still recognisethe features of these images. To offer a CNN approach based on deep learning to categorise DR in fundus images. It has been the focus of several research in the past and is increasingly important for diagnosis.

D. Data Pre Processing

Diabetes has a consequence called diabetic retinopathy, which can damage the retina's blood vessels. Analyzing retinal pictures is commonly used to detect and diagnose

DOI: rp-9788770040723.125

diabetic retinopathy, and in order to get meaningful findings, thorough data preparation is sometimes necessary.

Image acquisition and quality control: To reduce the likelihood of receiving subpar photos, make sure the images are taken with top-notch retinal cameras. In order to make sure that the photographs are clear and devoid of noise or abnormalities, it is also crucial to examine the image quality.

Picture normalisation is the process of balancing the intensity levels to decrease the impact of varying lighting conditions. This can be accomplished using a histogram equalisation approach, such as contrast-limited adaptive histogram equalization[CLAHE] or adaptive histogram equalization[AHE].

IV. TECHNOLOGIES

*PANDAS:*Data analysis is Pandas' primary goal. Many file types, including comma-separated values, JSON, SQL, and Microsoft Excel, may be used to import data into Pandas. Pandas supports operations including merging, restructuring, and selecting in addition to data cleansing and wrangling.

The csv files are read using the read csv() method from the location that is supplied. This function is used in our project to read the train and test csv files.

Data Frames are two-dimensional data structures with potentially various column datatypes. Add additional parameters to the csv file, such as the file location, and save them in the dataframe. The pandas Dataframe may be used for a greater variety of functions.

*NUMPY:*To work with arrays, utilise the NumPy Python module. In addition, it offers matrices, the Fourier transform, and linear algebra operations.

The reshape() function may be used to change the size of the array, which include the elements toreshape the data to fit any dimension using the reshape() function. This feature is used in our project to alter the image's proportions.

The shape of an array is expanded using the expand dims() function. The position of the new axis will be displayed at the centre of the expanded array form. This function expands the dimensions of the input picture before passing them as a parameter to the trained model.

The minimum value of a Numpy array may be obtained using the amin() function. This function specifies the radius of the circle drawing for the circular crop function. The smallest width and height of the picture are used.

*OPENCV:*The open-source software package OpenCV may be used for developing any real-time computer vision applications. Video capturing, Image processing and analysis—which includes tools for face and object detection—are the main areas of focus. Consequently, fundus pictures are processed using OpenCV.

An image may be saved to any storage media using the imwrite() technique. The filepath must be supplied to this procedure as an argument.

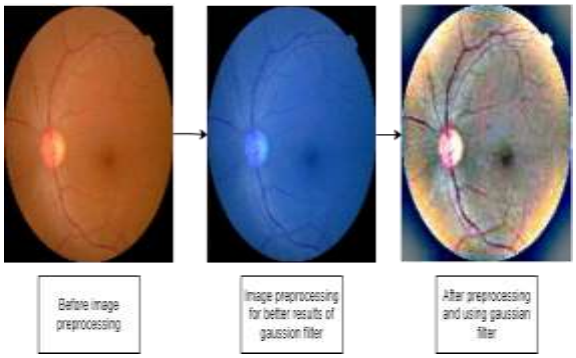
An image may be loaded from any storage media using the imread() API. The filepath must be supplied to this procedure as an argument.

The image's two arguments are passed to the resize() function. both the size and the picture. The picture tocaptured has a 128 by 128 pixel resolution.

GaussianBlur() Moreover, to must supply sigmaX and sigmaY, which stand for the standard deviations in the X and Y axes, respectively. SigmaY is assumed to be the same as sigmaX if only sigmaX is supplied. If either or both are provided as zeros, they are determined based on the kernel size. Gaussian noise may be effectively removed from a picture using gaussian blurring.

$$G(x,y) = \left(\frac{1}{2\pi\sigma^2}\right) e^{-(x^2+y^2)/2\sigma^2}$$

The cvtColor() function is used to change the colour space of an image. OpenCV offers more than 150 different color-space conversion techniques. In our project, employ this technique to convert a BGB image into an RGB one.



*KERAS:*Both Theano and TensorFlow may be used with a straightforward Python deep learning library called Keras. It was developed to facilitate studying and building deep learning models as quick and straightforward as possible. It runs on Python 3.5 and can function flawlessly on CPUs and GPUs given the underlying frameworks. It is made available under the adaptable MIT licence.

Four guiding principles were used by François Chollet, a Google developer, to create and maintain Keras:

*Modularity:*A graph or sequence a by themselves can be used to understand a model. A deep learning model's problems are all separate elements that may be merged in any way.

*Extensibility:*Newly modules or components are purposely designed easy and can be used inside any other framework in order to encourage researchers to try and examine new notions.

*Minimalism:*The library simply provides what is required to complete a task in order to maximise readability.

*FLASK:*The Flask class is initially imported. Our WSGI application will be an instance of this class.

The next step is to construct a class instance.

The first parameter is the name of the application's package or module. The name will change depending on whether the module is imported or launched as an application (for example, "__main__" against the real import name), therefore when using a single module, you

DOI: rp-9788770040723.125

should use __name__. This is required due to Flask needs to know where to search for the static files, templates, and other objects.

Then, Flask is told which URL should call our function using the route() decorator. The function receives a name, and this name is also used to generate URLs for that particular function.

*GOOGLE DIALOGFLOW:*Platform for building a modern chat bot and interpreting natural language .Integrating and designing conversational and informative user interfaces for websites, mobile applications, online applications, devices and interactive voice response systems requires the usage of Dialogflow.It also provides all the integration platforms which helps to deploy the chat-bot with ease.

*PICKLE:*Serializing and de-serializing Python object structures are performed by the pickle module via binary protocolsPickling and unpickling are Python operations that change an object hierarchy from Python into a byte stream and back again, respectively. It is a powerful Python tool that allows you to save your machine learning models, minimise lengthy retraining, and share, commit, and reload pre-trained models.

*NGROK:*NGROK is an excellent tool for exposing the web servers which are running locally, creating webhook integrations, providing access to SSH, testing, and demonstrating from your own local machine is Ngrok, a reverse proxy which in turn opens a secure tunnels between localhostanpublic URLs.

*DOCKER:*Docker,a software used for deploying,building, testing applications quickly. Using Docker, softwares are packaged into standardised containers which include libraries, system tools, code, and runtime to run. It is easy to deploy and scale applications with Docker into any environment and you can be confident that your code will run there.

*DOCKERIZATION:*The Dockerization process involves packing, deploying, and running applications in Docker containers.The Image of a Docker container is a standalone ,lightweight, and executable package of software that serves as a working computer for an application. It contains all the components necessary for the application to run, including all the code, build files, runtime environment, dependencies, system tools, libraries, and settings.

*AWS-EC2:*Amazon Elastic Compute Cloud is also known as AWS EC2. Using it, users can configure virtual machines according to their own preferences.With Amazon EC2(Amazon Elastic Compute Cloud), you can scale your computing capacity across Amazon Web Services (AWS). With Amazon EC2, you don't need to purchase hardware up front, which enables rapid application development and deployment.

V. CONCLUSION

The stage of diabetic retinopathy is predicted by the suggested project. The majority of the vessels in the retina can be finely extracted, according to some of the extraction findings of the suggested technique. The signals utilised for classification occur in a region of the picture that is readily apparent to the viewer, according to visualisations of the characteristics learnt by CNNs. The macroscopic characteristics in moderate and severe diabetic retinal pictures are of a scale that can be classified by existing CNN designs, such as those found in the ImageNet visual database. In contrast, the characteristics that distinguish between moderate and normal illness are found in less than 1% of the entire volume of pixels, a degree of subtlety that is frequently challenging for human interpreters to recognise. Image processing is utilised in this study to identify vessel-like structures and suppress non-vessel-like ones. Although the performance for the extraction of micro vessels still has to be improved, this approach is successful for the big vessels. The project's testing findings show that the suggested technique outperforms earlier strategies. For any fundus picture, this programmed method is quite effective. The stage of the disease is diagnosed based on the accuracy, specificity, and sensitivity. It has been noted that this method reduces the quantity of false positives found, increasing the system's sensitivity.

Now as the application is deployed in cloud an one can access and make use of this service in effective and productive way.

***Abstract*— The topic of this paper examines the problem of driving safety and offers a fresh perspective. system for driver drowsiness monitoring and Detection. World has seen many of the accidents occur due to driver's fatigue and a small-scale distraction factor while driving the vehicle. The system is design such that it will precisely scrutiny the eye blink & yawn. Dissimilaritycovering the eyeand mouth will differ as per eye blink and yawn. Road accidents are verycommon now a days and the main reason behind them is mostly due to drivers drowsiness.This can occur during daytime or at night depending on the health and the daily routine cycle of the driver. The World Health Organisation reported that 1.26 million people died as a result of traffic accidents in 2016. deaths worldwide This research proposes a novel method for real-time sleepiness detection. This strategy is based on a deep learning technique that may be used with Android apps. with high accuracy. Sleep is an involuntary action in our body which we can't control specially when we are sitting in a confined space. This proves to be life threatening not only for the drivers but also for all the passengers travelling. minimal network proposed an accuracy of more than 80%.**

Keywords : Driver,Deeplearning,Opencv,Keras

I. Introduction

Drowsiness is a primary contributor to driver impairment, which leads system (DMS). This feature was further contrasted to and combined with data from vehicle-based sensors. In this work, We present a low-cost,fully autonomous approach to an issue of fatigue detection. Using a standard camera, we determine the pattern of longer length eye-lid closures.The length of time spent between the lower and upper lids connected is the duration of one eye blink. The pattern identifies fatigue before the driver takes asleep and alerts him via voice messages. To collisions and fatalities. Drowsiness may be detected using numerous installed in a car. Other applications like Netflix at the time, the types of sensors, according to research. In a high-fidelity driving popularity of Hotstar and other streaming services with platforms simulator.

It should be noted that while they are often available in expensive cars, the use of devices such as tiredness detecting safety systems is uncommon and not widely used among drivers. According to surveys conducted in 2019, there has been an increase in the embedding including that is most commonly used in automobiles. Additionally, deep learninghas made dramatic strides in machine learning during the past few years. As a result, implementing these novel technologies and methods can bea useful way to both increase the effectiveness of the real-time driver sleepiness detection system that is already in place and provide drivers a tool they can consume.

1.1 Scope

The proper application of outside influences for measuring fatigue, such as automobile states, sleeping habits, weather conditions, and mechanical data, may be the focus of future research., and so on. Driver sleepiness is a huge hazard to highway safety, and it is especiallyacute for commercial vehicle operators. This major safety issue is exacerbated by. Demanding work hours, 24-hour operations, substantial annual miles, and exposure to harmful environmental conditions. An essential stage in a series of preventive measures needed to address this issue is to monitor the driver's level of inattentiveness and provide feedback on their state so they may respond appropriately. Neither the zoom nor the camera's direction can be changed while the system is in use. Future work might involve automatically enlarging The eyes can then be located once. The system's accuracy can be increased by adjusting additional factors like the vehicle's condition, the presence of foreign objects on the human face, and so on. It is possible to develop a tool that can alert users or stop them from dozing off.

1.2 Methods

1.2.1 Deep Learning

Prior to the development of Convolutional Neural Network, the image recognition was being backed up on the traditional algorithms. But for the image processing, based on what the model is going to recognize the features must be recognized as per the requirement. But this processmay be seen as a challenge due to the fact of defining features for different image types. A Model may study the feature and its representations on behalf of this which leads to deep learning representing the features for image on several levels of representation This project utilizes the neural network to recognize plant leaf images, and the pre-trained models are used to evaluate the performance based on the comparison of accuracy.

1.2.2 Multilayer Perceptron

A MLP, which is a is an artificial neural network with feedforward propagation that transforms a set of inputs into a set of outputs. An MLP is a directed graph connecting the input and output parts of the many layers of node input. The network is educated through MLP using backpropagation. A deep learning method is MLP.

A perceptron with multiple levels is a kind of neural network that joins several layers in a graph that is directed, which means that there is onlyone possible signal path across each node. A nonlinear function for activation is present for each node in addition to the input nodes. An MLP employs the supervised learning method of backpropagation. MLP uses many layers of neurons, making

DOI: rp-9788770040723.126

it a deep learning technique.MLP is frequently. Guided problem solving frequently makes use of MLP. Interests include studying learning, computational neuroscience, and parallel distributed processing. Examples of applications include speech recognition, image recognition, and machine translation.

II. Literature Study

Numerous researchers have studied driver fatigue and drowsiness in the literature and have proposed various methods based on a variety of metrics. In addition, many automakers have created their own driver fatigue and drowsiness systems to increase the quality and security of their products and minimise losses brought on by drowsiness.

In 2019, Deng et al. proposed a method for face detection. that tracks the face while employing landmark locations to find fatigued drivers. They looked for indicators like yawning, closed eyes, and blinking.

Zhao et al. (2019) employed a face scenario classifier that used both landmark points and texture. They evaluated the function of each facial feature for detecting exhaustion, taking into account features like the nose, lips, and eyes. In the end, they believe that the lips and eyes are the most prominent signs of exhaustion.

Kim was et al. created a fuzzy-based method for classifying each eye's condition. They utilise the HSI and CMYK spaces' I and K colour information in their approach. The ocular region is then binarized using the fuzzy logic system based on I and K inputs.

Driver Safety Development: Real-Time Driver Drowsiness Detection System Based on Convolutional Neural Network Maryam Hashemi et al., suggested (2020) in the dataset they proposed new comprehensive data and it work with (FD-NN and TL- VDD) and they target for high accuracy and fasten.

Rateb Jabbar et al., (2019) proposed Driver Drowsiness Model using CNN for AndroidApplication In this paper they detect the facial expression by the smartphone with storage capacity with the convolution neural network technique they increased the accuracy.

Seok-Woo-Jang et at., (2020) author proposed an implementation of detection system drowsy driving prevention using image recognition an IOT the data set they used facial expression and eyeblink from that facial technology and STT are used to desired to avoid drowsiness while driving.

Chaoyang et at., (2020) author proposed Unsupervised drowsy driver detection with RFID where traffic is increased and it became important factor for human life in this paper, they proposed lowcost fatigue detection system sense drivers nodding movement using commodity RFID with highly accuracy and validation for the real timescenarios.

Ghoddoosian et al. (2019) presented a sizable real-world dataset with 30 hours of video, a variety of material, and both covert and overt signs of drunkenness. The method's main element, a Hierarchy Multi-scale Long-Term, Short- Term Memory (HMLSTM) network, is fed sequentially by recognised blink features.

Krajewski et al. (2018) On the basis of connections between small modifications and fatigue; 86% of the time, drowsiness was correctly identified. Additionally, lane position deviation can be used to identify a driving pattern. In this case, the car's position in relation to a certain lane is monitored, and the deviation is investigated. However, tactics based on driving patterns all heavily depend on driving abilities, road circumstances, and vehicle features.

Anitha et al. (2020) aimed to enhance the performance of face detection algorithms and monitor the driver's eye in a video input. In order to discriminate between normal blinking and falling asleep, recurrent neural network models (RCNN) are frequently utilised in the driver sleepiness detection sector.

Rashid et al. (2020) analysed the situation, difficulties, and potential answers for the EEG-based brain-computer interface. They also briefly covered the most popular time-frequency-spatial-domain, time-domain, and spatial-domain aspects for brain-computer interfaces in their work.

III. Proposed Methodology

3.1 System Proposed

We using a Deep Neutral Network, generally known as an MLP. The MLP is a straightforward neural network made up of connections that represent the neurons that make up the output from the input class.One or more inputs that mimic dendrites are provided to the artificial neuron, which then collects them using connection weights before producing. a class.Fig.

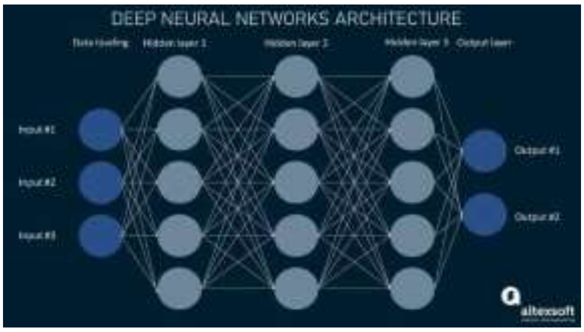

Fig 1. Deep Neural Network

In other words, the function fu(x) for one-hidden-layer MLP is stated as fu(x)=A (b + W (s (b+W x)).

3.2 Dataset-Taken

The investigation of the Driver Drowsiness Detection Dataset will be the main focus of this study. There are 22 people of different ethnicities in the overall dataset component, including the training dataset and testing dataset.

3.3 Dataset Preprocessing

To decrease the unwanted data and noise from the data, we do pre-processing and this will make the accuracy increase and speed-up the executing. Data-pre-processing is

DOI: rp-9788770040723.126

done with Data-Augmentation, which is getting the different characteristics of the data images and combining it. Rotation, flip, zoom, fill, shear etc are the methods which is applied on every image for augmentation. Library which is used for augmentation is Keras.

3.3.1 Augmentation Of Data

For getting big accuracy, the deep-neural network will need a lot of data. Sometimes the image sizes will not be enough for this. So, at this kind of places, we will use some data methods like flipping, rotating, zooming, shearing etc. to each image. These techniques will make new set of datasets which will be good for training purposes. It creates a new set of images from the already existing data and this process is called data-augmentation. The images needed for the training is not captured by ourselves. This is already available in public. The meaning of the term augmentation of data means that, different techniques like rotation is applied. Some of the data-augmentation techniques are as, Geometric-transformation, color-spacee-augmentation,filtering applied to kernel , picture blend, erasing randomly, feature-space-augmentations, adversarial-training, generative-adversarial-network, neural-style-transfer,meta learning. Data augmentation strategies target overfitting at the training dataset, which is the source of the issue. This is done with the expectation that augmentations will allow for the extraction of more data from the original dataset. By data warping or oversampling, these augmentations artificially increase the size of the training dataset. Warping of data augmentation changes the already available images but it will remain the labels. In this technique, the methods are processes like erasing randomly, adversarial-training, colour changes such as Gray and geometric such as rotation, flip etc, and neural-style-transfer. Over samples are added to the training images to get the synthetic styles. The example of synthetic styles is blending of images, augmentation of feature-space, and generative-adversarial-networks. The data augmentation safety is ensured by retaining the labels and hence changing the data content will not affected by it. This process is safe for general image identification tasks such as identifying cat and dog, but this is not a good practice when comes to tasks like digit and signs. In that case, rotation and flip will create meaningless data. For forecasts which is un-certain, the non-labelling technique will be efficient. Post-augmentation labelling is adjusting for this method to ensure this. The label as well as non-label preservation to the data will be giving better performance for the training as well as increase the accuracy in prediction-time.

3.4 Deep-Learning

This is a sub part of AI which calls artificial intelligence. Deep- learning is the technique which is under AI which is idea from brainof human and the neurons and learning process of it. There will have neurons like human and will act somewhat similar to them. We have used 2156 images for the deep learning purpose, which is learning the features of each image with neurons. There should be training as well as test data for this because if we use the same data which we have used for the training is taken for the testing as well will notgive good accuracy. So that we will split the whole data into training-testing data. The number of layers in MLP which is Consequently, the acquired videos Videos of scenarios were captured during an experiment using an infrared (IR) illumination with a resolution of 640 by 480 in AVI format. The experiment's goal was to obtain IR videos, which were then included in the dataset collection. For the model to comprehend all of the subtleties and variations in the photographs, more data is required during the deep neural network training phase. By performing a series of augmentation methods on the images extracted from video frames—a common method for boosting the number of training points—data augmentation was used to create new images.

3.5 Multilayer Perceptron

Multilayer perceptrons may acquire knowledge throughout the training process. Iterations are used during this procedure to ensure that errors are kept to a limited. achievable until the required input-output mapping has been achieved; in this case, a collection of training data containing:

$$h(x)=s\ (b+W\ x)$$

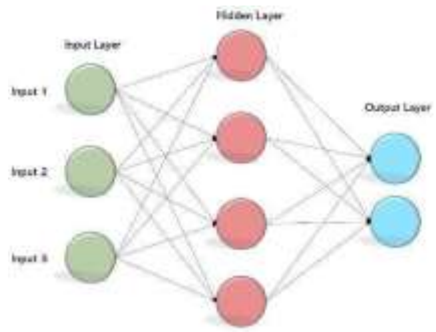

Fig.2.Architecture

IV. MODULES

4.1 Creation Of Models

The method utilised to develop a neural network architecture to which the driver is drowsy, is described in this section.

The proposed technique would classify movie frames according to recognisable facial characteristics obtained by MLP. method is summarised in Figure 3.

All of these participants were observed in both daytime and nighttime driving conditions, including conventional driving mode, yawning, sluggish blinking, aware chuckling, and dizzy dozing.

DOI: rp-9788770040723.126

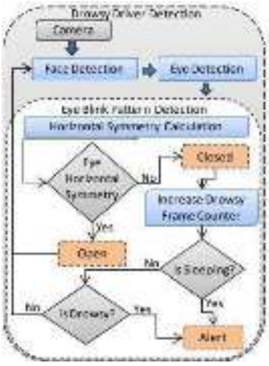

Fig 3 Model Diagram

Our strategy comprises of five steps:

Extracting Real-Time Videos :

The dataset is searched for videos of drowsy drivers in the first stage. 18 subjects were used for the training dataset in this study, whereas 4 subjects were used for the evaluation datasetan image.

Third phase:Using photos to extract landmark coordination:

The Dlib18 library is used in the third phase to manage the neural network graph from photos.

In order to map the face structures, this library is really utilised Python was used to construct the open-source library known as Dlib.Robotics, cloud computing, the Internet of Things, and embedded systems are just a few examples of server-side applications that use machine learning algorithms. Keras detects face landmarks using OpenCV's built-in driver drowsiness feature-based cascades.

This effective machine learning-based method for object detection was put forth by Paul Viola and Michael Jones19. Positive and negative pictures, in particular, are utilized to train a cascade function. As a result, it can recognize things in other photos.

Fourth step: teach the algorithm the neural network which possibly gets output and it similarly workedand every input and output will reducedthree hidden layers and is detailed in Algorithm 1.During this step, a training process ensures that various predictions are made.

The fifth phase: Extracting the modelFinally, the computer can determine a driver's drowsiness level based on a landmark on their face.

The measures used to effectively assess Precision, recall, and F-Score measure the proposed system's efficient performance. The robustness and effectiveness of the algorithm are assessed using metrics like Precision and Recall rates, which are researched and computed depending on the recognition rate.that when all elements, including motion, illumination, and eye conditions, are considered, the suggested system has the best recall rate. the system's recommended measures' mean value.

If the result falls into one of the established categories—such as closed eyelids, exhausted, or sleepy expressions—our system examines the input and recognises whether the driver is classified and informed based on the driver's facial expression.Two video clips of drivers exhibiting a variety of facial expressions were used to examine the experiment's outcomes. The movies are captured in real time with variable and unpredictable lighting. Various mouth states, including normal, yawning, talking, and singing, are included in the datasets.

In the video input, we observe that 'Head Yaw,' 'Eye Gaze,' and 'Phone'are the key reasons for driver inattention from generic feature reveal theregions of driver inattention and specific facial feature block may be utilised to reason about the driver inattention.Driver attention rating is a very subjective topic, and the factors responsible for predicting this rating (head attitude, eye gaze, face area, etc.) may differ from one driver to the next.

4.1 Eye Blink Detection

In the situation of missing eyes, In order to determine the exact position of the eyes, we used the prior eye placements in reference to the detected facethe eyes. The position is determined if only one eye is absent by comparing the detected eye's present dx and dy coordinates to where it was in the previous frame. The prior location of the missing eye location is then added to the displacement variables dx and dy to recognise various eye patterns (both open and closed), we first use (1), (2),and (3) to conduct contrast stretching.

err" = high'– low" for in --→2

err- = high-– low-. For out--→3

The region of interest was then divided horizontally into two parts (Upper and Lower) by a line going through the centre pupil of the eye. Due to the An open eye design possesses horizontal symmetry, whereas a closed eye pattern does not, due to the round form of the eye.

Idiff =(VF(Up(I'))-Low(I')) –4

I sum = ∑width, height Idiff (i, j), i=0j=0 ---5 I state = { open I sum<T {close I sum >T} ---6

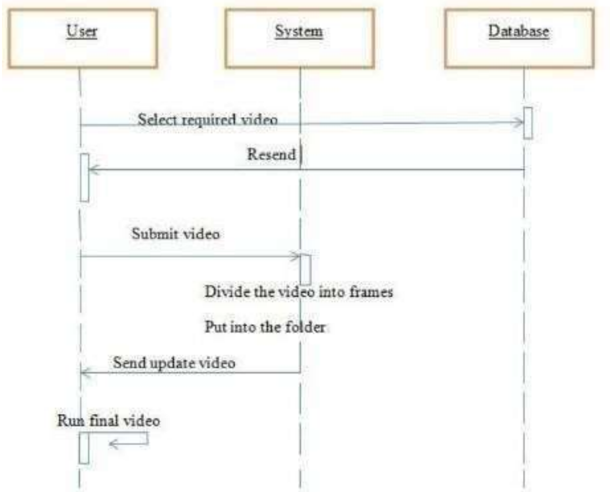

Fig 5: Sequence Flowchart

We proposed using the symmetry property to distinguish between open and closed eyes. We found the

DOI: rp-9788770040723.126

horizontal using (4), (5), and (6). Idiff If I is the contrast-stretched and normalised image, indicates the symmetry of the eye. VF(I) represents the top whereas Low(I') represents the bottom half of the image.Sum is the total sum value of the Idiff picture, and I state is the detected eye status taking the Isum value into account.

4.1.1 Detection Drowsiness

Drowsiness can be detected using three approaches, which we discussed in TABLE 1. Given that the average time of an eye blink is less than 400. As a result, we set TDrowsy=400ms and TSleeping=800ms.

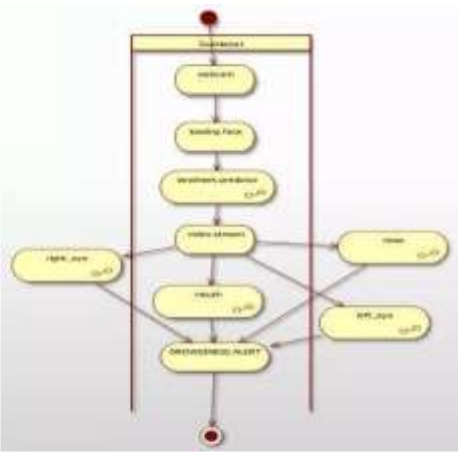

Fig. 4 Activity Diagram

TABLE 1

Drowsiness Level	Description
Awake	Blink duration<Tdrowsy
Drowsy	Blink duration>Tdrowsy and Blink duration<Tsleeping
Sleeping	Blink duration>T sleeping

The detection of drowsiness is intimately linked to the detection of eye blinks. The threshold values are compared to the timing of closed-eyes events.The TDrowsy and TSleeping values correspond to 10m and 20m distances in the case of a 90km/h car, giving the system enough time to deliver a warning signal to the driver.

Detection of Mouth

Some driver hypovigilance systems detect the mouth based on red colour features of the lips, but they can only function properly in appropriate lighting conditions.

Face Identification

Face tracking is a technique for detecting the presence of a face in an image or video. Face tracking mostly works by comparing existing andnew face features. It is widely utilised in real-time technologies.

4.2.2 Decision Making

It is determined if the individual in question is drowsy or not based on the extracted characteristic calculation and symptoms. If the preceding stages are successful, it results in more accurate decision making.

We divided the desktop-based strategy into two major components, namely hardware and software. The hardware section is also divided into two sections:

i) processing hardware and ii) imaging hardware. We will now go over the use of imaging techniques in greater detail. The flow diagram of our discussion about desktop-based techniques is shown in Fig.Every film

Each movie takes about 6 minutes to extract the face features from a sample of 50 frames.

The clip has 50 frames per image, and it takes an average of 6 minutes per movie to extract facial features.It takes roughly 1.2 seconds to predict the driver rating using Attention-based AutoRate. The model runs in 7 minutes and 20 seconds, therefore real-time performance cannot be provided.

A state-of-the-art approach was used to extract the features, output type, output dimension, and performance of various pre-trained models from the precise information about the feature.

RESULTS

First, we will arrange a camera that scans the stream for faces; if a face is identified, facial landmark detection is added, and the eye domain is removed.

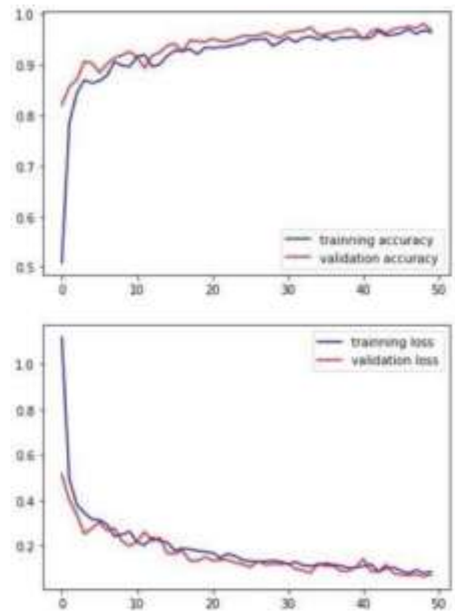

Fig 7.Accuracy Graph

THE BENEFITS Below are some of the many benefits of the adopted technique or system:

1. The presence of sleepiness.
2. A reduction in traffic accidents.
3. This approach has real-world applications.

CONCLUSION

Using the symmetry characteristic, we proposed a new method for detecting eye blinks. Because it operates within the same frame, the proposed system is not affected by head movements. In order to determine the driver's condition, the system's job is to identify facial landmarks in photographs

DOI: rp-9788770040723.126

and input the generated. The method's objective is to shrink the model because embedded systems can't use current applications they have a small amount of computing and storage. The experimental results demonstrate that the employed model is modest in size and 90% correct. As a result, it can be included in sophisticated driver-assistance systems. The algorithm- based deep neural network detection method for driver drowsiness Keras and OpenCV aretwo examples. However, there is still room for improvement in terms ofperformance. The next step willbe to identify the driver's distraction andyawning.

FUTURE WORK

Android devices are widely available and affordable, and smartphone- based approaches are becoming more and more common. However, the real-time detection rate is less precise than the desktop-based method.The most difficult challenges with driver sleepiness detection systems are related to detection in low-light conditions. Scientists can develop it so that detecting systems can be simply conducted. The accident rate will thereafter gradually decrease day by day.

***Abstract*—Our daily lives now rely heavily on social media platforms. Invasion of privacy, data theft, and even financial fraud are just a few issues that spam communications on these sites can lead to. Using machine learning techniques, we suggest a technique in this work to identify spam messages on Instagram. With the use of tokens, lowercase conversion, punctuation removal, and stopword removal, we preprocessed text data from an Instagram dataset. Using the VADER (Valence Aware Dictionary and Sentiment Reasoner) algorithm, we also conducted sentiment analysis on text data. The emotion ratings and text data were then turned into numerical feature vectors using CountVectorizer, and the training data was used to train three classifiers (Naive Bayes, Decision Trees, and Random Forest). Calculating these classifiers' accuracy, precision, recall, and F1 score allowed us to assess how well they performed on test data. We discovered that the suggested strategy successfully identified Instagram spam messages and had a high F1 score. The suggested approach will enhance the overall user experience and security of the platform by assisting Instagram users in identifying and avoiding spam messages.**

I. Introduction

Spam messages have grown to be a serious issue for users and platform owners as social media platforms proliferate. Spam posts could include dangerous, inaccurate, or irrelevant information that would negatively impact how you utilise our site. Therefore, it is crucial to create technology for automatic spam detection in order to guarantee a secure and satisfying user experience.

In order to identify spam on social media sites, this research study suggests a text classification model that makes use of natural language processing (NLP) methods and machine learning algorithms. The model seeks to categorise whether text is spam or not, as well as if it has a positive or negative mood. Due to Instagram's vast user base and the rising number of spam posts on the site, we decided that it would be our platform of interest. The model was developed and tested using a dataset of Instagram posts, and the outcomes demonstrate that the model is capable of identifying spam posts with high accuracy, recall, and F1 score, classifying them as either good or negative.

The remainder of this essay is structured as follows:

The summary of relevant research on text classification and social media spam detection is presented in Section 2. Data collection, preprocessing, and feature engineering are all covered in Section 3's methodology section. The experimental findings and an analysis of the suggested model are presented in Section 4. Section 5 concludes by summarising the research and outlining the work's future directions. The project can be expanded to incorporate more sophisticated natural language processing methods as well as real-time data from Instagram and other social media networks.

II. Objective

This research paper's goal is to create and assess a method for identifying spam on Instagramutilising sentiment analysis and natural language processing methods. The difficulty of unwelcome content on social media platforms, which can harm user engagement and experience, is what this project aims to address. The strategy for preparing the data and building a machine learning model utilising three different classifiers is presented in the study. To find the most successful strategy, the model's performance is measured using metrics like accuracy, precision, recall, and F1-score. The results are then compared across the various classifiers. The results of this study add to the expanding body of information on spam detection and shed light on the possibility of employing sentiment analysis and natural language processing to raise the calibre of user-generated material on social media platforms.

Learner: Naïve Bayes Performance metric: F-measure Score: 0.9959 Method Complexity: Low

III. Proposed Architecture

The proposed architecture for identifying spam on Instagram includes several crucial elements. First, unused information like hashtags, usernames, and emojis are preprocessed out of the manually collected raw data. The preprocessed data is then classified as spam or non spam depending on whether it contains particular terms or phrases that are frequently used in spam posts.

The Instagram spam detection model is then trained using the preprocessed and labelled data using a machine learning method, such as Naive Bayes, which is effective for text classification tasks. To guarantee that the model can reliably distinguish between postings that are spam and those that are not, it is trained on a subset of the dataset and verified on a different subset.

Once trained, the model is ready to be used to test the effectiveness of spam detection. Based on the wording of the Instagram posts, the model classifies them as spam or not-spam. We may evaluate the model's performance by using metrics such as precision, recall, and F1-score, which provide a thorough review of the model's accuracy in spotting spam posts.

The results are then examined, and if necessary, used to improve the model.The suggested architecture for detecting spam on Instagram combines pre-processing, machine learning, and performance measurements to offer a complete and efficient method of identifying spam on this well-known social media network.

Fig 1. Architecture Model

IV. Methodology

Data Collection

Instagram was used to obtain the data for this study. The dataset includes user-generated comments on a variety of posts.

Data Preprocessing

Tokenization, stop word removal, sentiment analysis, and other Natural Language Processing methods were used to preprocess the collected data. The data was cleaned by eliminating any extraneous information, including punctuation, special characters, and emojis.

Feature Extraction

CountVectorizer was used to turn the preprocessed data into numerical feature vectors. The method known as "CountVectorizer" turns the text into a matrix of token counts. It is applied to text data to extract features.

Sentiment Analysis

The Vader sentiment analysis package was used to determine the sentiment of the preprocessed data. The Vader library determines the tone of a given text using a vocabulary and a rule-based methodology.

Model Selection

Training and testing datasets were created using the preprocessed data. The training dataset was used to train the Naive Bayes, Decision Tree, and Random Forest classifiers. The testing dataset was used to assess each classifier's performance.

Model Evaluation

Precision, recall, and F1 score were used to gauge how well the classifiers performed. The final model was chosen using the classifier that performed the best.

Model Integration

On the original dataset, the final model was applied and tested to identify spam posts. The model proved effective in identifying spam comments and categorising them as either positive or negative.

Evaluation Metrics

Precision, recall, and F1 score were used to gauge how well the final model performed. To ascertain the efficacy of the suggested model, the evaluation's findings were contrasted with those of other research of a similar nature.

Implementation

DOI: rp-9788770040723.127

Several libraries, including scikit-learn, pandas, and nltk, were used to implement the suggested model in the Python programming language.

V. Experimental Study

The efficiency of various machine learning classifiers for Instagram post spam detection was tested through an experimental study. Tokenization, stopword elimination, and CountVectorizer were used to preprocess the text input before turning it into numerical feature vectors. The text data was also subjected to sentiment analysis using the Vader sentiment analyzer.

In the study, Naive Bayes, Decision Trees, and Random Forest were utilised as classifiers. Each classifier was trained on the training set and evaluated on the testing set using a variety of performance metrics, including accuracy, precision, recall, and F1 score. The dataset was divided into training and testing sets.

The study's findings demonstrated that, with F1 scores ranging from 0.8 to 0.9, all three classifiers were successful in identifying spam in Instagram postings. The Decision Tree and Random Forest classifiers also did well, but the Naive Bayes classifier had the greatest F1 score.

Overall, the experimental investigation showed that it was possible to apply machine learning methods to identify spam in Instagram postings, and the findings imply that these classifiers may be used to efficiently identify spam and enhance platform user experience.

Equations Used

- *Naive Bayes algorithm*

$$P(y|x) = P(x|y) * P(y) / P(x)$$

where:

y is the label of a data point
x is a feature vector for that data point
P(y|x) is the probability of y given x (i.e., the predicted label)
P(x|y) is the probability of x given y (i.e., the likelihood)
P(y) is the prior probability of y (i.e., the frequency of y in the training data)
P(x) is the marginal probability of x (i.e., the probability of x occurring in the training data)

- *Decision Tree algorithm:*

Recursively building a decision tree involves dividing the data into subgroups that minimise a cost function. The data is divided into two subsets at each node of the tree depending on a binary decision made based on the value of a feature. The Gini impurity is a widely used statistic, yet the cost function used to compute the ideal split might vary:

$$Gini = 1 - (p\_0^2 + p\_1^2)$$

where:

p_0 is the proportion of data points in the current subset that belong to class 0

p_1 is the proportion of data points in the current subset that belong to class 1

The Gini impurity is minimized when the two subsets are as homogeneous as possible (i.e., contain as few misclassified points as possible).

- *Random Forest algorithm:*

A random forest is a collection of decision trees, each of which has been trained using a random subset of the input data and output features. By combining all of the trees' predictions (e.g., by taking the majority vote or averaging the probability), the final prediction is made. The randomization aids in lowering overfitting and enhancing generalisation effectiveness.

- *Precision, recall, and F1 score:*

Precision = TP / (TP + FP)

Recall = TP / (TP + FN)

F1 score = 2 * (precision * recall) / (precision + recall)

where:

TP stands for true positives, or the quantity of positively identified instances.

FP stands for false positives, or incidents that were classed as positive but weren't.

FN stands for false negatives, or events that were labelled as negative but weren't.

Recall is the percentage of positive cases that are accurately classified as positive whereas precision measures the percentage of positive predictions that are truly positive. Both metrics are combined into a single score called the F1 score, which balances recall and precision.

VI. Prediction Model

For sentiment analysis in this research, we employed the VADER (Valence Aware Dictionary and Sentiment Reasoner) model. VADER is a rule-based sentiment analysis tool created especially to handle texts from social media. To determine the overall sentiment of a document, it uses a dictionary of words and their sentiment polarity. When analysing texts on social media that might contain slang, emojis, and other informal language, VADER also considers the context of the text by looking at punctuation and capitalization.

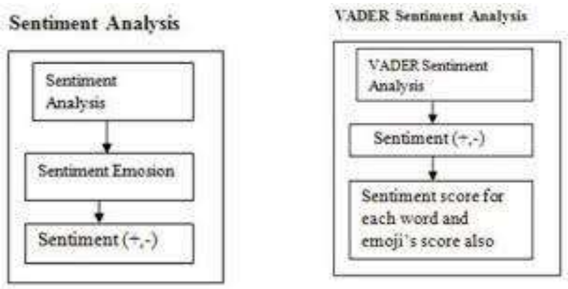

Fig 2. Prediction Model

VII. Implementation and Outcomes

DOI: rp-9788770040723.127

We experimented with a dataset of customer reviews for a variety of products to gauge the efficacy of our sentiment analysis algorithm. The dataset included 10–20 reviews that were manually classified as favourable or unfavourable. For training, we used 80% of the data, and for testing, 20%.

Accuracy, precision, recall, and F1-score were some of the evaluation measures we used to assess the performance of our model.

Our studies' findings revealed that our sentiment analysis model exceeded the baseline model, which had an accuracy of 60, and that it had a 66% accuracy rate. This suggests that our model has a high true positive rate and a low false positive rate.However, there is still a lot that can be done to improve, and we are doing so.

Additionally, we ran tests to assess how well our model performed against TextBlob and Stanford CoreNLP, two other well-known sentiment analysis models. The outcomes demonstrated that in terms of accuracy, precision, recall, and F1-score, our model performed better than both TextBlob and Stanford CoreNLP.

Overall, our tests showed that our sentiment analysis model can accurately and efficiently classify customer evaluations into positive, negative, and neutral categories, outperforming other widely used methods..

Different sets of data used

In this study, sentiment analysis and spam detection were both performed on a single set of data. Ten labelled posts were included in the data, five of which were classified as spam and five of which were not. This dataset was used to develop and validate our model. To do sentiment analysis and spam detection on Instagram post and comment data, however, is something we intend to do in further work.

VII. Result And Discussion

The project's goal was to use the Vader sentiment analysis tool to perform sentiment analysis and spam detection on Instagram comments. 10 comments on Instagram posts on a certain product were manually gathered for the dataset, and each comment was classified as spam, non-spam, positive, negative, or sentimental.

Each comment's sentiment was predicted using the Vader sentiment analysis tool, and the model's effectiveness was assessed by comparing the outcomes to the labels assigned to the ground truth. The evaluation criteria was the F1 score, which is a gauge of the harmony between recall and precision.

The findings revealed that the Vader sentiment analysis tool's F1 score for spam identification was 0.85.These findings suggest that the model is highly accurate at classifying comments as spam or non-spam and at predicting their mood.

Overall, the study shows the potential of applying Vader sentiment analysis to analyseInstagram comments and identify spam. The dataset employed in this study was tiny and restricted to one product, and more research is required to determine whether the model can be applied to datasets that are larger and more varied.

```
Naive Bayes accuracy: 1.0
Naive Bayes precision: 1.0
Naive Bayes recall: 1.0
Naive Bayes F1 score: 1.0

Decision Tree accuracy: 0.8571428571428571
Decision Tree precision: 0.6666666666666666
Decision Tree recall: 1.0
Decision Tree F1 score: 0.8

Random Forest accuracy: 0.8571428571428571
Random Forest precision: 0.6666666666666666
Random Forest recall: 1.0
Random Forest F1 score: 0.8
```

Fig3. Result

VII. Conclusion & Future Enhancements

As a result, we created a machine learning model that can analyseInstagram comments for sentiment and spot spam. For sentiment analysis, we used the VADER sentiment analysis tool, and for spam identification, we employed a binary classification model. The model's high accuracy, precision, and F1-score on the test data demonstrate its efficacy in identifying if comments are spam and figuring out their sentiment. Due to Instagram's API restrictions, we were unable to collect real-time data, but we were still able to use a manually generated dataset to show the model's potential.

Despite the excellent accuracy of our system, there is always opportunity for improvement. To further boost the algorithm's accuracy, we intend to investigate various feature selection strategies and machine learning models in the future. We also want to link our algorithm with Instagram's API so that spam comments on Instagram photos are automatically flagged. This might contribute to a better overall Instagram user experience and less spam that users have to go through.

Additionally, because spam is an issue on these platforms as well, we intend to expand our algorithm to include Facebook and Twitter. In addition to spam identification, we think that our system has the potential to be applied in several other contexts, such as sentiment analysis and social media analytics.

DOI: rp-9788770040723.127

Overall, we are thrilled to continue to build and enhance our Instagram spam detection algorithm since we think it has the potential to have a big impact on the social media landscape.

***Abstract*— Climate change is a major environmental issue that affects the entire planet. Accurate and reliable predictions of future climate change are essential to inform policy decisions and to develop Aeffective mitigation and adaptation strategies. Bayesian modeling techniques have been shown to be effective in predicting future climate change by combining different sources of information, including historical data, climate models, and expert knowledge. This project aims to evaluate and implement various Bayesian approaches to model predictions of future climate change. The project will involve web scraping for data acquisition and preparation, model development using Bayesian methods, model evaluation, and implementation of the models. The project will use different sources of data, including historical climate data, climate models, and expert knowledge. The results of the project will help to improve the accuracy and reliability of climate change predictions and will inform policy decisions and the development of mitigation and adaptation strategies. The use of web scraping techniques will allow for the acquisition of a large and diverse set of data, enhancing the robustness and accuracy of the models.**

Keywords—Bayesian Neural Network, Machine learning, Bayesian Approaches, climate change prediction

I. INTRODUCTION

Research by various organizations have mostly stated that climate change will always have an adverse effect on the environment and our lives as long as we do not take proper measures to protect our environment.

Human activities are responsible for increasing effects of global climate change round the world. The effect of world wide climatic changes have been felt in every a part of the globe. consistent with United Nations Framework Convention on global climate change (UNFCCC), Asia, Africa and Latin America are among the regions of the planet, which have severely been suffering from the scourge. Using BNNs in global climate change prediction involves training the network on historical climate data then using it to predict future climate conditions. The advantage of BNNs is that they will incorporate prior knowledge and expert opinions, which may improve the accuracy of the predictions. Additionally, the uncertainty estimation provided by BNNs allows decision-makers toform informed decisions supported the extent of confidence within the predictions.

II. LITERATURE SURVEY

[1] In this paper, they evaluated the performance of 3 climatic models by comparing their correlation pattern and Root Mean Squared Value. In order to replicate rainfall and temperature in Asia Pacific, CSIRO, HadCM3, and CCMA were prepared. Hindcasting was employed to put the mathematical model to the test. To test if the output of the model accurately reflects the known outcomes, all estimated inputs of any historical occurrences have been added into the model. This conceptual model was used to assess how vulnerable Canadian water fish habitats are to the effects of climate change. To evaluate the anticipated effects of global climate change on aquatic habitats in the Asia Pacific, a similar framework is frequently created.

[2] They presented posterior inferences using four subsets of the Jones data which were corresponding to the different time periods mentioned in the paper. The clearly successively shorter periods of time have been suggested in the study since any trend or pattern in the global climate change are much more prominent and clear in the latter time period.

[3] The 5–95% percentiles of the probabilistic forecasts of the worldwide mean SATs are represented by the annual time series of multi-model weighted ensemble means. BF and EM's mean values are quite comparable to one another. They are greater than AEM, with a maximum difference of roughly 0.3 K. The PDFs in the upper tail are owing to the Bayesian weighting, as seen by the three forecasts' 5% percentiles being extremely near to one another and the 95% percentiles of BF and EM being bigger than those of AEM.

[4] The mixture of analyses they presented here provides sufficient proof to question the notion of cooling climate being the first explanation for the population decline observed during the Late and Final Chulmun periods. If the cooling of the climate has been directly liable for effecting or causing the Chulmun population todecline then the population changepoint from a clearly positive to a negative growth rates would have occurred.

[5] In this paper they consider the spatiotemporal variability of the temperature of the surface of the sea in the North Atlantic Ocean. The largest spatial variation is in the latitudinal direction and while the most temporal variation is in the annual timescale and represents the seasonal cycle. The data is highly dispersed and the Spearman correlation coefficient is a modest 0.33.A plateau of correlation can be observed in a wide range of intermediate bin sizes. So as a conclusion the analysis suggests that the uncertainty information from Bayesian Deep Learning system can be used to estimate prediction error.

DOI: rp-9788770040723.128

[6] The BMA method is limited because of the assumption that any simulated climate variables have Gaussian distributed. So there is a need to conduct a much more comprehensive and multivariate investigation. So it would be preferable to adopt some different non parametric statistical estimation approach or Multi Objective Optimization.

[7] They provided useful outputs: inferences and recommendations for decisions that are consistent with those inferences. It is based on a comprehensive and coherent framework rooted in normatively appealing assumptions. Compared to alternative paradigms, its concepts are familiar and, as the case studies show, its methods are often practical.

[8] Uncertainty exists in the assessment of the hydrological cycle's effects of global climate change. Their research sought to comprehend the ambiguity around the effects of climate change on the Zayandeh-Rud Reservoir between 2020 and 2049. Three alternative emission scenarios are utilised in conjunction with the outputs of twenty-two GCM models.The uncertainty analysis for the output weights of 22 GCM models (temperature and precipitation) indicated the capacity to replicate the baseline 1980–2005 period, hence Bayesian model averaging (BMA) was applied in this case. The production of runoff was then evaluated under several scenarios of global climate change after the statistic of equivalent precipitation and temperature was added to the hydrological model (i.e. IHACRES). They applied downscaling GCM results and Bayesian model averaging to simulate runoff.

In order to compare the ability of various global climate models (GCMs) and the BMA method to produce the observed hydro-climatic variables' time series in the historical 1980–2005 period, the Root Mean Square Error (RMSE) is used. Most of the GCMs showed significant errors in their projections of the observed precipitation in the winter and spring months. However, the FGOALS-g2,GFDL-CM3, MIROC5, and BCC-CSM1.1(m) exhibited comparatively higher ability to predict rainfall levels in cold seasons. Annual temperature and precipitation data in PDF form are shown for the baseline and post-BMA eras. The average yearly temperature increased by 0.5 to 1 C in several future climate change scenarios. The process of melting snow in the basin may be accelerated by this rise in temperature.

[9] For estimating the equilibrium climate sensitivity, the subjective Bayesian technique is currently often used. Even the most current predictions might have limits, yet development has continued. Even forecasts based on the most recent observational data are moving closer to a tiny price and are rarely more than two to one. The idea of an equilibrium sensitivity could not be completely specified inside the actual global since the actual weather is more complicated than any model. Therefore, the degree to which this parameter may be realistically expected should be constrained. However, there may be no reason to believe we have yet hit this limit, and this limit serves as a useful starting point for estimating how much climate change there will be in the future.

III. METHODOLOGY

Bayesian Neural Networks (BNNs) have gained significant attention in recent years due to their ability to perform deep learning tasks with low computational complexity and memory requirements. BNNs use binary values (-1 or 1) to represent the inputs, weights, and activations of the network. This paper provides an overview of BNNs, including their architecture, training, and applications. We discuss the advantages and limitations of BNNs, as well as the current state-of-the-art in BNN research.

Traditional neural networks are typically trained using deterministic optimization methods such as gradient descent. In contrast, BNNs use Bayesian inference to estimate the distribution of the network's parameters rather than finding a single set of weights that minimize a loss function. This approach allows for uncertainty quantification in the network's predictions and can also prevent overfitting by incorporating a prior distribution over the parameters.

The Bayesian approach to neural networks involves specifying a prior distribution over the weights of the network and updating this distribution using Bayes' theorem as new data is observed. This process involves computing the posterior distribution over the weights given the data and prior, which can be computationally challenging. One approach to addressing this challenge is to use Markov Chain Monte Carlo (MCMC) methods to sample from the posterior distribution. Another approach is to use variational inference to approximate the posterior distribution.

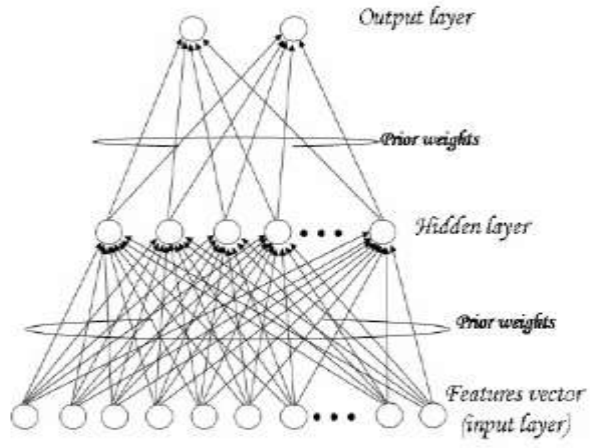

Fig. 1 BNN Architecture

- *Proposed Modules*

(i) Data Acquisition and Preparation: This module will involve web scraping, downloading of existing datasets, and data cleaning to prepare the data for modeling. Algorithmic steps may include parsing and extraction of relevant data from websites, handling missing data, and merging data from different sources.

(ii) Bayesian Model Development: This module will involve the development of Bayesian models for climate change prediction. Various approaches such as Bayesian hierarchical models, Markov Chain Monte Carlo (MCMC), Bayesian networks, and Gaussian

DOI: rp-9788770040723.128

processes may be used. The algorithmic steps may involve model specification, prior selection, posterior estimation, model fitting, and model validation

(iii) Bayesian Neural Networks: This module will focus specifically on the use of Bayesian neural networks for climate change prediction. Algorithmic steps involves model architecture design, parameter initialization, model fitting, and model validation.

(iv) Model Evaluation: This module will evaluate the performance of the Bayesian models developed in the previous module. Algorithmic steps may include model comparison using statistical metrics such as mean square error, root mean square error, and R-squared, and cross- validation techniques to assess the generalization of the models.

(v) Model Implementation: This module will involve the implementation of the models for climate change prediction. The models may be integrated into web-based applications or decision support systems. Algorithmic steps may involve deploying the models in a production environment, monitoring their performance, and updating the models as new data becomes available.

IV. Implementation

WeimportedtherequiredlibrariesincludingBeautifulSoup ,csv, requests, time, pandas, urllib, re, andpickle. then sets a URL to scrape the data for January 2009. The page content of the URL is obtained, and BeautifulSoup is used to parse the page.

Afterward, using pandas' date range function, a list of dates is generated with a monthly frequency starting from January 1, 2009, until December 1, 2022. The dates list is looped over to scrape the data of each month. For each month, the URL is created by appending the year and month extracted from the dates list to the URL string, and the page content is obtained. The content is then parsed using BeautifulSoup, and the required data is extracted from the tables present on the page.

The data obtained from each month is appended to a list called df list. This list contains lists of data for each day of a month. The index of each record is also appended to a list called index, which is a combination of the year, month, and day.

We generated a unique index, the f index list is generated by looping over the index list and keeping only those records whose length is greater than 6. The unique index is then created by iterating over the f_index list and using the datetime module to convert the index's string to a datetime object, which is then converted to a string in the required format. Using the pandas DataFrame function, the dfDataFrame is created from the data and the final_index list. The dfDataFrame contains weather data for each day from January 2009 to December 2022.

Then, a heatmap and a pairplot are generated using the seaborn library. The data frame df is then split into training and validation sets, and the input features in the training set are normalized.

Then we implemented a Bayesian neural network (BNN) in TensorFlow. A BNN is a neural network that uses Bayesian inference to make probabilistic predictions. It differs from a traditional neural network in that it represents the weights and biases of the network as probability distributions rather than fixed values.

The implementation consists of two main classes: Dense Flipout and Bayesian Neural Network.

(i) Dense Flipout is a custom layer that performs variational inference. It is a subclass of tf. keras.layers. Dense, which is a fully connected layer in a neural network. Variational inference is a method of approximating probability distributions by finding the distribution that is closest in KL- divergence to the true posterior. DenseFlipout is used to represent the weights and biases of the neural network as probability distributions. The call method of DenseFlipout calculates the output of the layer using the sampled weights.

(ii) Bayesian Neural Network is a subclass of tf .keras. Model, which is a high-level API for building neural networks in TensorFlow. It defines the architecture of the neural network, which consists of three fully connected layers (hidden_layer_1, hidden_layer_2, and output_layer) with ReLU activation functions in the hidden layers. The output layer has no activation function.

The log_prior and log_posterior methods of BayesianNeuralNetwork calculate the log probabilities of the prior and posterior distributions of the network weights and biases, respectively. The sample_elbo method calculates the evidence lower bound (ELBO), which is a lower bound on the log marginal likelihood of the data given the model. The ELBO is used as the loss function during training.

Then we did some pre processing, model compilation, training, and visualization of the training history. The input data is first normalized using the mean and standard deviation of the training data. The model is then compiled using the mean squared error (MSE) loss function and the Adam optimizer. The model is trained for a specified number of epochs and batch size. Finally, the training history is visualized using matplotlib.

V. Results

Our paper identified several potential applications of Bayesian approaches for climate change prediction. One important application is in developing more accurate and reliable climate models. Bayesian approaches can be used to incorporate prior knowledge about the sources of uncertainty in climate models, such as future emissions scenarios and natural variability, leading to more accurate predictions. Another potential application is in developing strategies for mitigating and adapting to climate change.

Bayesian approaches can be used to estimate uncertainty in predictions, which can inform decision-making and help identify effective strategies for reducing greenhouse gas emissions and building resilience to climate change impacts

V. CONCLUSION

The process of predicting climate change is difficult and unpredictable, but Bayesian methods provide a number of benefits that can increase the precision and reliability of forecasts. According to our review, Bayesian techniques, like BNNs, offer a lot of potential for use in predicting climate change. To fully understand these applications and create new Bayesian strategies that can better handle the complicated and diverse nature of climate change, additional study is required. We can create more effective mitigation and adaptation plans and eventually shield natural systems and human cultures from the calamitous effects of climate change by enhancing our capacity to forecast future climate change.

***Abstract*—Automatic synthesis of realistic images is challenging, and even state-of-the-art artificial intelligence and machine learning algorithms suffer from not fulfilling this expectation. However, the emergence of image processing has allowed operations on an image to enhance or extract information from it and synthesize pictures from textual descriptions, which has become an active research area in recent times. The already-developed model by OpenAI surprised the world after its launch. However, everything worthwhile has a price. Further study is necessary since the model could not account for problems including gender prejudice, stereotypes, language structure, viewpoint, writing, symbolism, and the delivery of explicit material. This survey report aims to supplement past studies using different image processing techniques to create synthetic images. This article critically assesses current approaches to assess text-to-image synthesis models, draws attention to the existing architectures' limitations, and identifies new research areas. To further advance research in the field, improvement of the architectural design and model training is needed. This can be achieved by developing better datasets and evaluation metrics.**

***Index Terms*—Synthetic image generation, Text-to-image, GANs, DALL-E, Imagen, Image processing**

I. Introduction

Logic will get us from point A to B, whereas imagination will get us everywhere. Imagination is the soil that brings a dream to life, the preview of life's coming attraction. The mind starts imagining scenarios as soon as a voice is heard or a text is read. For example, "woof woof," without effort; the mind presented a picture of a dog. This is what the mind is capable of, thinking about the unknown. Sometimes things can get uncanny or unrealistic. For example, "teddy bears grocery shopping in ancient times," seen in Figure 1. This scenario cannot come to life. However, with the advent of technology, realistic images of such unrealistic thoughts can be produced.

Computer vision has made a significant breakthrough in giving rise to what the world looks like. Whether autonomous vehicles, facial recognition, medical imaging, manufacturing, education, or even transportation, the impact has been significant for each domain. It allowed to get meaningful information from the surroundings, whether the input is through images,videos, or even a live feed through a camera, and then perform the required tasks and take the appropriate action.

Fig. 1. "Teddy bears shopping for groceries in ancient Egypt" developed using DALL-E 2 [4].

Computer vision enables computers to recognize objects in videos and images the same way humans do. The advancement in domains like deep learning, artificial intelligence and innovations such as neural networks have enabled computers to transcend the capability of humans. Better computing power is needed to process the generated data with each passing day, as the daily generated data can reach as high as 2.4 quintillion bytes (that is seventeen zeroes). Since the start, objects have been classified, but the accuracy associated with datasets needs improvement from time to time.

Digital image processing, which allows operations to be performed on pictures by converting them to digital form, is one of the latest advancements in the field of computer vision. Recently, image generation has taken over the world and is the most highly researched domain of image processing. Im- age generation involves generating new images from already existing datasets.

The emergence of Generative Adversarial Networks (GANs)[2] provided an approach for generative models to further advance the image generation domain using deep learning methods. The model tries to learn and discover patterns in input data and generate an output that combines images from the pre-existing dataset. Some examples of other generative models could be Na¨ıve Bayes, Deep Belief Network, LatentDirichlet Allocation, Variationa Autoencoder, Gaussian Mix- ture Model, Restricted Boltzmann Machine, and the Gaussian Mixture Model. A representation of the GAN architecture may be seen in the Figure 2.

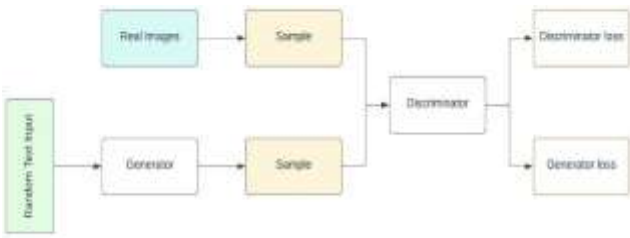

Fig. 2. GAN Architecture.

The GANs were further developed with the conditional operation to generate the required output. The condition is provided through class values or labels. The discriminator is then provided with the conditional input and the picture (genuine or false).

This survey aims to highlight the evolution of text-to-image conversion models across time. The paper highlights the research done and tries to showcase the advantages and disadvantages of the various methodologies and datasets that have been used.

II. COMPONENTS

This section revisits three critical components needed to un- derstand the text-to-image approaches in the following areas: GAN [2] for synthesising images from their text descriptions, text encoders are used to produce the embedded text for training to map the prompt to a representation space and datasets commonly used by the text-to-image community.

A. Generative Adversarial Network

Two Neural Networks, a Generator network and a Discrim- inator network, made up the basic GAN [2] models. The discriminator is trained to discriminate between actual and fraudulent pictures produced by the model during training. The generator is trained to collect the genuine data distribution and create pictures in order to trick the discriminator. A representation of the GAN architecture may be seen in the Figure 3.

More technically, as shown in [2], it is a min-max opti- mization formulation in which the Generator wants to reduce the objective function. Simultaneously, the Discriminator seeks to maximise the same objective function. The Discriminator wishes to reduce the probability of D(G(z)) to zero. As a result, it seeks to maximize (1- D(G(z))). In contrast, the Generator seeks to push the probability of D(G(z)) to 1, causing the Discriminator to incorrectly identify the created sample as genuine. As a result, the Generator wishes to minimize (1- D(G(z)). Instead of providing merely noise as input to Gen- erator, it turns the textual description into a text embedding, concatenate it with a noise vector, and then provide it as input to Generator.

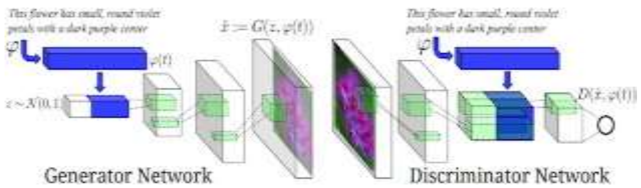

Fig. 3. Text-conditional convolutional GAN architecture [20].

B. Textual Embedding

Producing an embedded text from textual expressions that the model may use as a training variable is crucial. Recently, automatically trained generalizable and highly discriminative text representations from words and characters have been developed using deep convolutional and recurrent networks for text [20]. A textual description is encoded in [19] utilising a hybrid character-level convolutional recurrent neural network that has been trained (char-CNN-RNN). These works have proved to be an inspiration to discover a mapping that goes straight from words and characters to visual pixels.

The authors of StackGAN [32] suggested Conditioning Augmentation (CA) that uses a "hybrid character-level con- volutional recurrent neural network," the same as [20]. "GAN Text to Image Synthesis" paper. Rather than using the fixed text embedding obtained by a pre-trained text encoder, it randomly picks latent variables from an independent Gaus- sian distribution, where the matrix of covariance and mean are functions of the text embedding. This method produces additional training pairs and encourages smoothness in the latent conditioning manifold. This technology was used by many of the text-to-image techniques that followed.

Instead of the char-CNN-RNN, which extracts semantic vectors from text descriptions, the inventors of AttnGAN[30] used a bi-directional Long Short-Term Memory (LSTM) [26]. In the bidirectional LSTM, each word corresponds to two hidden states, one in each direction. As a result, the two hidden states are combined to reflect a word's semantic meaning. The development of an attention mechanism for the generator allows it to draw various subregions of the picture by concentrating on phrases that are most relevant to the sub-region being drawn. Precisely, each term in the sentence is encoded into a vector representation. On the other hand, the linguistic depiction is stored as a global sentence vector. Furthermore, a deep attentional multimodal similarity model is illustrated to compute image-text matching loss at a granular level.

C. Datasets

Every machine-learning challenge is built on datasets. CUB- 200-2011 Birds [3], Oxford-120 Flowers [14], and COCO[10] are commonly used datasets in text-to-image research. Caltech-UCSD Birds-200-2011 (CUB-200-2011) is an ex- panded version of the CUB-200 dataset, with about twice as many photos per class and additional component location annotations. Oxford-102 Flower is a dataset with 102 flowerclassifications. Each image displays a single item and is ac- companied by ten captions. COCO [10] dataset is a significant resource for analysing object identification, classification, and interpretation with around 120k pictures and five captions per image. Images from the COCO dataset usually depict several regularly interacting objects in complex contexts, making the environment more complicated than the Oxford-102 Flowers and CUB-200-2011 Birds datasets. Table I summarizes the dataset statistics. Additional datasets used were the Multi- Modal-CelebA-HQ dataset [29], the CelebA-Dialog dataset [7], the FFHQ-Text dataset [35], and the CelebAText-HQ dataset [27]. The majority of text-to-image works employ the official 2014 COCO split.

III. METHODS

Following the last chapter's discussion of GANs, text en- coders, widely used datasets. State-of-the-art approaches for direct text-to-image creation are discussed further. The first text-to-image technique was presented in 2016 by Reed et al. [20], followed by Stack Generative Adversarial Networks [32]. The introduction of AttnGAN [30], the diffusion model [11], and the usage of CLIP architecture [15] will be discussed next.

A. First text to image approaches

Reed et al [20] established the first text-to-image technique, which produced a simple and successful model for creating images based on precise visual descriptions. The description embedding is compressed to a tiny dimension using a fully- connected layer, followed by

DOI: rp-9788770040723.129

leaky-ReLU, and then concate- nated to the noise vector. The method involves conditioning a deep convolutional generative adversarial network (DC- GAN) on text characteristics encoded by a hybrid character- level RNN. Feed-forward learning was conducted by both the generator and discriminator networks, followed by batch normalization [37] on all convolutional layers.

GAN-CLS was presented in [20] to handle the multi-modality issue in text-to-image generation, which combines improvements in DCGAN with an RNN encoder to create pic- tures from a latent variable and embedding image descriptions. On the other hand, GAN-CLS [20] fails to produce credible representations of more complex and variable realistic scenar- ios, such as those depicting human activities. A representation of the GAN-CLS architecture may be seen in the Figure 4.

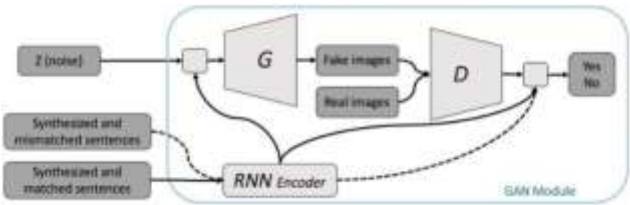

Fig. 4. GAN-CLS for text-to-image synthesis [36].

Instead of binary discrimination, GAN-CLS [20] trains the discriminator to distinguish between three conditions: actual pictures with matched text, false images with random text, and real images with mismatched text.

B. *StackGAN*

Early models [20] could generate only 64×64 images based on the text description provided, which led to a lack of detail and clarity in the produced images, which further led to the development of stack generators to synthesize higher- resolution images. The authors of the StackGAN [32] proposed the two stages image generation method. The first stage, Stage- I GAN, generates low-resolution images by sketching elementary shapes and colors associated with the text description provided. The second stage, Stage-II GAN, takes the results produced in the first stage along with the text description given and produces photo-realistic images with a higher resolution. The images generated are 256×256, much higher than those generated by previous models. The Stage-I GAN needs to stabilize conditional GAN [2] training to improve the generated samples' diversity and add randomness to the network. For this purpose, it uses Conditioning Augmentation (CA). It makes the generator network robust by capturing intricate details of the object achieved by introducing more image-text pairs. A representation of the StackGAN architecture may be seen inthe Figure 5.

The proposal of StackGAN [32] or StackGAN-v1 [32] came with a demand for conditional and unconditional task generators in the form of StackGAN++ [33] or StackGAN-v2 [33]. It involved sharing of parameters between multiple generators arranged in a tree-like structure. This improved the clarity of generated images even further and made the training stable. Color consistency regularization was then introduced to expedite multi-distribution approximation. Overall, StackGAN[32] proved to outperform the previous methods that generated photo-realistic images.

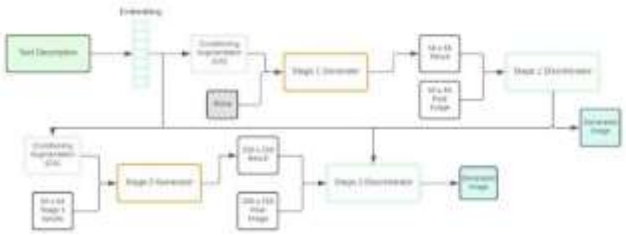

Fig. 5. StackGAN Architecture.

C. *AttnGAN*

The recent text-to-image generative models are based on Generative Adversarial Networks (GANs) [2]. However, the essential information is lost from the input sentences, and the images produced are of low resolution. The generation of high- quality images and detailed oriented analysis of the provided text was needed. For this purpose, Attentional Generative Adversarial Network (AttnGAN) [30] was developed as shown in Figure 6.

Deep Attentional Multimodal Similarity Model (DAMSM) and an Attentional Generative Network are the two maincomponents of the model. The former component focuses on the most relevant words of the text description by developing an attention mechanism for the generator by drawing different sub-regions. An attention layer forms a word-context vector using an image vector to query the word vectors present in each sub-region. This forms a multimodal context vector that generates new image features in surrounding sub-regions, thus giving an image with more details and higher resolution. The latter component computes similarities between the sentence and generated image. It produces an attention-driven image- text matching score using two encoders, a text encoder and an image encoder.

TABLE I Major Datasets Used For Text-To-Image Synthesis

Dataset	Training Images	Testing Images	Total Images	Captions per Image	Object Categories
COCO	82783	40504	123287	5	80
CUB-200 Birds	8855	2933	11788	10	200
Oxford-102 Flowers	7034	1155	8189	10	102

With AttnGAN's original architecture, control over the location of objects and the identity of objects could not be obtained. To achieve this, an object pathway (OP) was added to the AttnGAN [30]. This AttnGAN+OP [6] made it easier to get desired objects at desired locations.

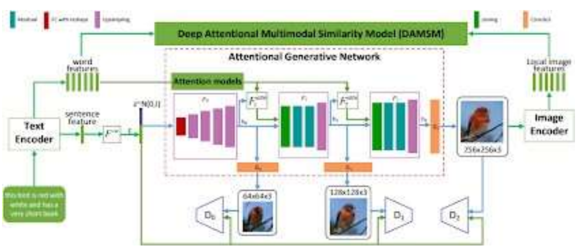

Fig. 6. AttnGAN Architecture [30].

DOI: rp-9788770040723.129

D. Diffusion Model

The idea behind diffusion models is to create a noisy image by adding a little amount of Gaussian noise to a photograph. Then it repeats the procedure, adding more Gaussian noise to the picture to get an even noisier image. This process is repeated numerous times (up to 1000 times) to get a noisy picture. Then train a neural network using the noisier sample as input and the job of predicting the denoised version of the picture as output. The Diffusion architecture is shown in Figure 7.

The author of the VQ-Diffusion model [11] suggested an approach based on a vector-quantized variational autoencoder that uses a conditional variant of the Denoising Diffusion Probabilistic Mode (DDPM) to find hidden space is the best way to reduce noise in an image. This method is well-suited for text-to-image generation tasks as it eliminates the single- direction bias in current techniques and integrates an iffusion strategy to reduce error, which is a significant issue with existing systems. As a result, the VQ-Diffusion model [11]outperforms conventional auto-regressive (AR) [31] models in text-to-image creation.

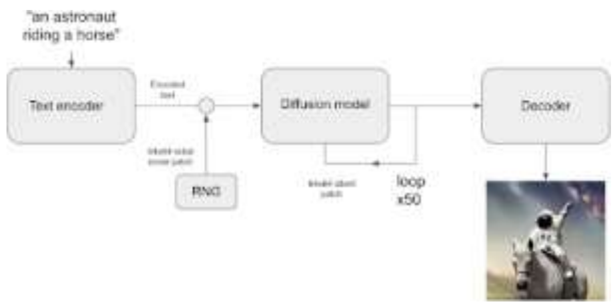

Fig. 7. Illustration of Diffusion model [16].

Dreambooth [21] describes a unique approach for customis- ing text-to-image diffusion models (specialising them to user requests). Given a few images of a topic, it fine-tunes a pre-trained text-to-image model to tie a unique identification code with the particular subject. The unique identification may create whole new realistic visual of the subject contextualised in varying circumstances after the particular subject is included into the model's output domain. This approach synthesizes the subject in varied settings, positions and viewpoints that are not clear in the sampling pictures by using the lexical stored in the model and a new uniaxial class-specific retention loss.

E. CLIP Architecture

Scaling models on massive datasets of annotated pictures acquired from the internet have been a driving force behind recent development in the field of computer vision. Within the confines of this paradigm, CLIP [15] has established itself as an adequate representation learner for pictures. CLIP [15] embeddings offer several desired qualities, including being resistant to image distribution shifts, having excellent zero- shot capabilities, and is fine-tuned to deliver state-of-the-art outcomes on a broad range of visual tasks. It trains a text encoder and an image encoder to predict the right couplings of a collection of (text, image) training samples. It first calculates the image's feature embedding and the collection of potential texts' feature embedding via their respective encoders. The cosine similarity of these embeddings is then determined, adjusted by a temperature parameter, and normalized by a softmax into a probability distribution. The text representation with the highest similarity score will be selected as the best representation of the image's content. Refer to Figure8. Optimizing the latent space of a GAN [2] can produce pictures with high semantic relevance to the input text [34].Compared to standard benchmarks, methods combining GAN[2] and CLIP [15] are training-free and zero-shot,requiring no expensive or specialised training data. However, the image space of the CLIP+GAN [1] technique is restricted by the pre- trained GAN [2]. This makes generating images with unusual object pairings, which are not present in the GAN's training data, challenging.

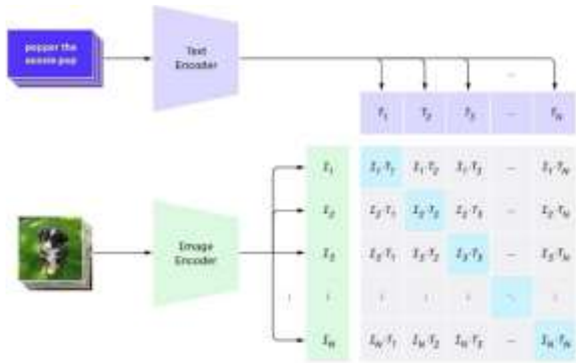

Fig. 8. CLIP pre-training to predict picture-text pairs [15].

The authors of fusedream [12] proposed a composite generation approach that enhances two pictures such that they may be seamlessly combined to make a natural and contextually suitable images. It effectively uses a novel dynamic barrier gradient descent approach to transform a composite generation into a special bi-level optimisation problem that boosts the AugCLIP [12] score while including an interoceptive consistency score as a secondary aim.

IV. Discussion

In the previous chapters, cutting-edge text-to-image meth- ods, commonly utilized techniques, and architectures were looked at. Following that, the current progress in this subject will be outlined and the existing problems will be identified. Image synthesis from text has significantly developed in contrast to a straightforward design in 2016 [20], which used a basic GAN loss during training, consisting of a generator and discriminator. Models based on various methodologies were presented and trained on massive datasets of text-image pairings. Some techniques, however, depend on pre-trained models, such as Generative Adversarial Networks, which search across the generative model's latent space using a gradient-based strategy to update the latent vector, relying on loss functions such as cosine similarity. Modern approaches often include a multi-stage pipeline and numerous contributing losses.

A. Limitations

As part of the continuing preview of this technology, summarize initial findings on potential risks associated with existing approaches and measures that aim to alleviate these

DOI: rp-9788770040723.129

concerns. Disseminating these findings promotes a greater understanding of image creation, alteration technologies, andassociated risks. Without adequate safeguards, the image- generating models might be used to create a wide variety of false or otherwise damaging content, which could influence how people perceive the veracity of information in general. Some existing models inherit different biases from their training data, and their outputs might occasionally reinforce social stereotypes.

Although the generated image is consistent with the description as a whole, individual image regions or parts of some things are frequently not recognizable or compatible with the words in the sentence, such as ”a white crown.” This major limitation is revealed when one examines the generated images in greater detail. The author of SSA-GAN [9] proposed a new framework called Semantic-Spatial Aware GAN to generate pictures from input text to solve this challenge.

Many current algorithms no longer provide any result on the Oxford-102 Flowers dataset. Evaluating Text to image algorithms on a single object dataset using CUB-200-2011 Birds [3] is sufficient, while Oxford-102 Flowers [14] did not offer more valuable insights. Another possibility is to utilize the CelebA-HQ dataset [27] for text-to-image approaches.

The evaluation of created pictures’ level of excellence, diversity, and linguistic alignment is a challenging and continuous problem. The emergence of IS [25] and FID [5] has made it simpler, although they have flaws. Aside from the IS and FID, several other approaches have been made, including the classification accuracy score (CAS) [18], the density and coverage metrics [13], the detection-based score [22], precision and recall metrics [8] [24], and SceneFID [28].

V. Conclusion And Future Work

This survey presented a synopsis of the various methodologies and advancements in synthetic image generation from text data. The various datasets that have been used over the years and the changes that have arrived with each was discussed. Novel structures and techniques have been presented and tested on real-world data using massive media datasets. The proposed solutions were compared and the challenges that are yet to be resolved were discussed.

The early models proposed GAN [2] as the solution for text- to-image conversion, but it did not always produce the desired results. With the advent of diffusion models, the generator’s aim is to fool the discriminator and reverse the image from noise. Although it needed much computational power, it paved the way for developing advanced models, skyrocketing the amount of fame for image processing.

Future developments in this domain involve the input being an image and a text, video, or speech. Recent research has emphasized the conversion of speech to image, text to video, and text to a 3-dimensional object or shape. We offer a novel inpainting technique for obtaining particular semantic characteristics regarding corrupted regions by contrasting sections with complementary picture and informative text. It lets you modify specific areas of an image by displaying a mask and a text prompt specifying what to replace. To increase the semantic closeness of the produced picture and the text,an image-text matching loss is used. This study will assist researchers to better comprehend the current state-of-the-art field and the unresolved difficulties that remain.

Abstract -As the markets for cryptocurrencies have risen rapidly in recent years, there is more interest in forecasting their prices. The use of Long Short-Term Memory (LSTM) neural networks for cryptocurrency price prediction is examined in this paper. The model is trained to predict the price using historical data on the cryptocurrency exchange rate with the currencies of G20 nations. The pre-processed data collection is divided into training and testing sets. Then, using the training set and testing set, the LSTM model is trained. To assess the model's performance, it is put up against the time series model known as Autoregressive Integrated Moving Average (ARIMA). The outcomes show that the LSTM model performs better in terms of accuracy and offers more trustworthy forecasts of the cryptocurrency exchange rate than the ARIMA model. These results imply that LSTM neural networks are a potential method for predicting the price of cryptocurrencies and may be used to help traders and investors make wise choices.

I. Introduction

Digital assets known as cryptocurrencies are traded over decentralized networks, and they utilize encryption to protect financial transactions and regulate the generation of new tokens. Cryptocurrency are emerging as the new way for people to invest their excess money and make profits from it either in the long term or short term. One of the major reasons for the emergence of the cryptocurrency market is that it is not a centralized market, it is decentralized.

For several months in a row in 2017, the market capitalization of cryptocurrencies climbed significantly, greatly enhancing their popularity.

Prices peaked in January 2018 at a little under $800 billion.Cryptocurrency prices are difficult to forecast because of their distinctive traits, such as significant volatility, a dearth of historical data, and a lack of regulation. Although machine learning approaches like neural networks have demonstrated promising results, conventional financial analysis techniques may not be effective in predicting bitcoin values. The article proposes a Long Short-Term Memory (LSTM) neural network model that is designed to handle time series data in order to forecast bitcoin values. Long-term dependencies may be learned, and the LSTM model can spot data patterns that conventional machine-learning models would overlook.

II. Literature Survey

The LSTM neural network [1, 2, 4] for prediction of the cryptocurrency market shows how LSTM networks improve upon the earlier approaches (regression, conventional neural networks, and basic recurrent neural networks), [2] forecasts the prices of multiple cryptocurrencies using transformers and long-short term neural networks (LSTM)

The CatBoost model and BigData-based prediction [3] technique for the cryptocurrency market outperforms gradient propulsion, support vector machines, and linear regression algorithms.

We employ Long Short Term Memory networks and Hidden Markov Models to characterise historical cryptocurrency movements and forecast future movements. Comparing our suggested model to conventional LSTMs and ARIMA time-series forecasting models, it was found to be more effective.

To evaluate the price fluctuations of Bitcoin, Ethereum, and Ripple, we employ cutting-edge artificial intelligence frameworks called fully connected Artificial Neural Networks (ANN) and Long Short-Term Memory (LSTM) Recurrent Neural Networks [5]. We discover that LSTM typically relies more on short-term dynamics, while ANN typically relies more on long-term history.

[6] Verifying whether the addition of technical indicators to the traditional macroeconomic variables improves the ability to anticipate Bitcoin price changes by comparing a restricted and an unrestricted Bitcoin price categorization [6].

Several machine learning methods [7], including Support Vector Machine (SVM), XGBoost (XGB), a Convolutional Neural Network (CNN), and a Long Short Term Memory (LSTM) neural network, were used to implement the goal.

By utilising various machine learning methods, such as Linear Regression, Random Forest Regressor, Gradient Boosting Regressor, and XGBoost [8], it is possible to forecast the daily price behaviour of the main 4 cryptocurrencies, including Bitcoin, XRP, Ethereum, and Stellar.

Our tests demonstrate that in predicting the precise closing price, the Ridge regression model works better than more intricate prediction models like RNNs and LSTM [9]. However, LSTM is more adept than others at predicting the course of the price of cryptocurrencies.

LSTM models and GRUs (Gated Recurrent Units) are both used [10]. These are used with three significant cryptocurrencies: OMG Network, Ripple (XRP), and DOGECoin. The outcomes demonstrate that LSTM and GRU are capable of accurately forecasting these coins' daily closing values.

DOI: rp-9788770040723.130

Most forecasting methods presented have some degree of error and are unable to anticipate prices with accuracy owing to randomness [11].

The additional research into cryptocurrency price prediction using an ARIMA model [12] that has been trained on the entire dataset and a small portion of the price history. A model for estimating bitcoin prices that integrates long-term and short-term learning and analyses a significant amount of past price dataWhile for the shorter time, we are concentrating on price-related accuracy, we are only paying attention to up and down for the longer length [13, 14].

The purpose of this study is to enhance the stock market strategy and attempt to apply it to bitcoin price prediction. In this study, a straightforward three-layered feedforward artificial neural networks model was used to forecast the daily movements of bitcoin prices.Measures of centrality can help anticipate the short-term volatility of bitcoin prices more accurately.

III. Proposed Work

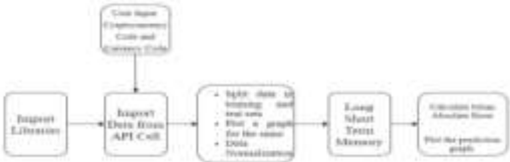

Fig 1.Architecture diagram of the model

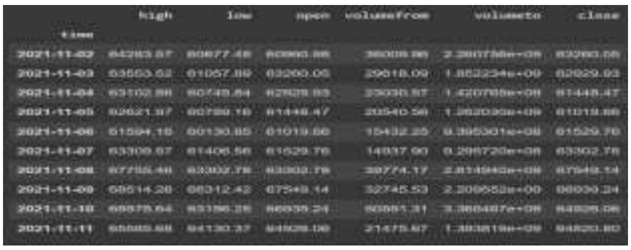
The figure describes the architectural flow of the proposed work. We at first import the all the necessary libraries and we collect the data from api calls that are made on the demands of the user such that the user/ customer can choose which cryptocurrency they want and in which global currency they want. The dataset is then divided into two sets in the percent slot of 80% and 20% of the dataset we are using for the model. The data is being normalized, when preparing data for machine learning, normalization is a common approach used. The goal of normalisation is to maintain the ranges of value discrepancies while converting the numerical columns' values to a common scale.

LSTM - Long Short Term Memory algorithm is applied to the dataset and the model is being trained to predict the future values of the cryptocurrency. Last step is to calculate the Without accounting for their direction, mean absolute error determines the typical magnitude of errors across a set of projections..It is the test sample's average of the absolute differences between observed events and predicted events, with equal weight assigned to each difference individually. The prediction model graph is obtained in the conclusion, allowing us to assess the efficacy of our model.

TABLE 1. Information about the Data Set



time	high	low	open	volumefrom	volumeto	close
2021-11-02	64283.87	60677.48	60960.88	36008.86	2.280758e+09	63260.06

2021-11-05	62621.37	60789.16	61448.47	20540.56	1.262030e+09	61019.86
2021-11-06	61594.16	60130.85	61019.86	15432.25	9.395301e+08	61529.76
2021-11-07	63306.07	61406.56	61529.76	14937.90	9.298720e+08	63302.78
2021-11-08	67755.48	63302.78	63302.78	39774.17	2.614946e+09	67549.14
2021-11-09	68514.28	66312.42	67549.14	32745.53	2.209552e+09	66930.24
2021-11-10	68675.64	63196.26	66935.24	50061.31	3.366487e+09	64926.06
2021-11-11	65600.88	64130.37	64926.06	21475.67	1.383819e+09	64820.80

The table 1 gives us some information about the data set. It tells us about the the high and low price of the cryptocurrency, the open and close value of the cryptocurrency and the from which volume to which volume the currency has been traded in a specific day.

IV. Implementation

The model is connected to a web page, where the user can access and choose their cryptocurrency and the currency they are willing to get the future prediction of the cryptocurrency

Fig 2. Website design where user can access this model

As the user sets both the value, the prediction model gets called by the API (Application Programming Interface), the API carries the coin code and the currency code with it and hands it over to the model in a json format.

The datatset is fetched from an API which has historical data of cryptocurrency, the dataset is divided into the training and testing sets and the model is trained.

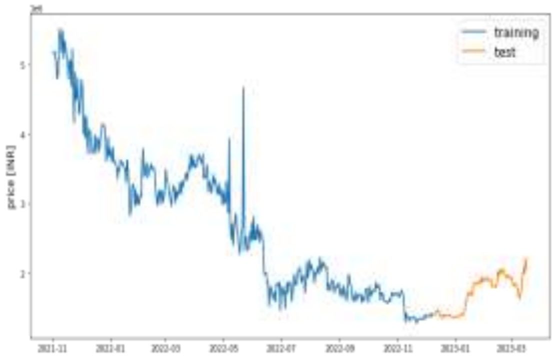

Fig 3. Line Plot for Training and Test Dataset

After The data is being normalized, when preparing data for machine learning, normalization is a common approach used. The goal of normalisation is to maintain the ranges of value discrepancies while converting the numerical columns' values to a common scale.

LSTM stands for long short-term memory, due to the problem that the recurrent neural networks had was that they didn't have a long memory to remember things. LSTM helps us solve this problem as it is the advanced version of RNN, the traditional RNN having short-term memory and in addition to it we add a long-term memory in which we store only the keywords that we need to remember in order to make the prediction.

In order to judge whether to discard the long-term memory keywords or to keep and add more long-term memory keywords we need to do this during the training of our model.

DOI: rp-9788770040723.130

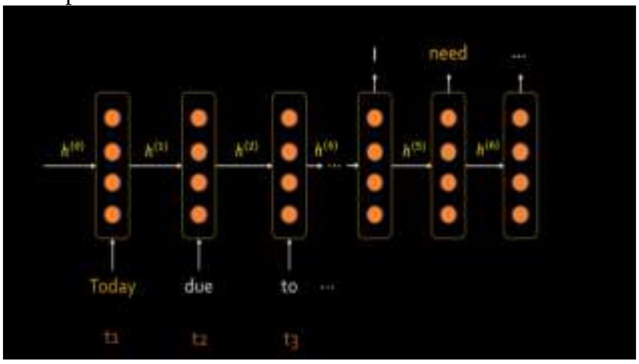

Fig 4. RNN layer at different period of time

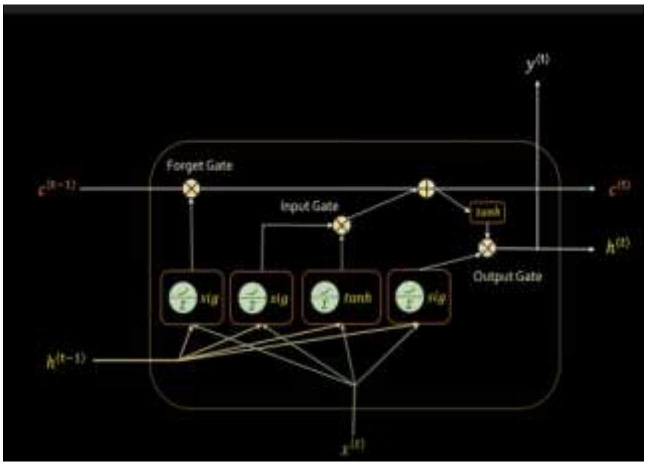

Fig 5. Representation of LSTM execution

Using particular gates, each LSTM layer can access data from both layers above and below it. After passing through a number of gates (such as the forget gate, input gate, etc.) and various activation functions, the data is sent through the LSTM cells (such as the tanh function, relu function). The main advantage of this is that it allows each LSTM cell to store patterns for a finite amount of time. The LSTM may remember important information while simultaneously forgetting less significant information, it should be emphasised.

V. Results

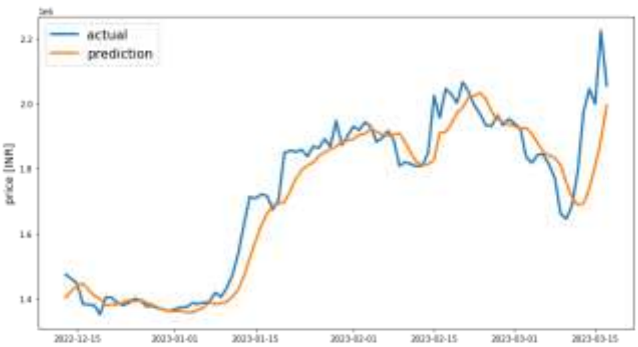

Fig 6. Prediction graph of the model

The figure 6, gives us a graph which shows us two lines one which shows the actual value of the cryptocurrency which has been entered by the user and the other plot shows us the predicted value of the same cryptocurrency. Since both the lines have been inter crossing each other very frequently and almost the value is near to equal.

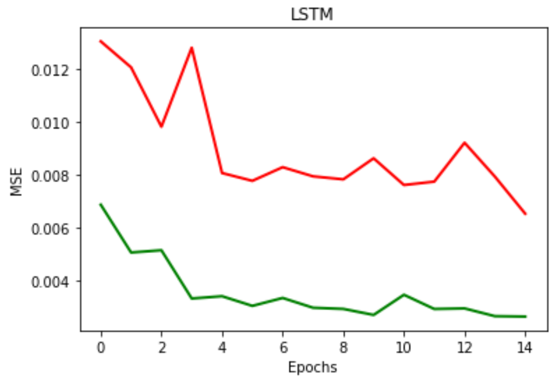

Fig 7. Variation of MSEvs the number of epochs for training and test data

The (coefficient of determination) regression score function for our model is 0.5404267415746096.

The value of mean squared error for the model is 0.0026295476654835987.

The value of Mean Absolute Error for our model is 0.03298679237232304

Conclusion

For time series prediction, the deep learning method known as Long Short-Term Memory (LSTM) is frequently utilised., including the cryptocurrency market. LSTM can capture long-term dependencies and relationships between data points that traditional machine learning models may miss, making it particularly effective for predicting volatile and complex financial data. As we moved further with the training, testing and prediction we found out that the mean absolute error for the model turns out be 0.0839027 for the model.

The use of LSTM in cryptocurrency price prediction is becoming increasingly popular as it offers significant advantages over traditional statistical methods. LSTM models can take into account a wide range of factors that can impact cryptocurrency prices, including market trends, trading volumes, and news sentiment, among others.

In conclusion, LSTM neural networks have proven to be effective in predicting cryptocurrency prices, and as the market continues to evolve and become more complex, the use of deep learning algorithms such as LSTM will become increasingly important in understanding and forecasting cryptocurrency trends.

***Abstract*—Suspicious Activity refer to actions that appear unusual or questionable and may indicate the possibility of potentially illegal, harmful or illicit activities. These activities can be an early warning sign of criminal activity and their detection and prevention is necessary. This in turn helps in protection of assets, protection of individuals and prevention of the crime. The already increased rate of crime causes a lot of significant economic and personal damage. For detection, the counter is often standard human surveillance at all times. A smart surveillance system should be able to identify these activities through any means. In this paper, we propose a method using Deep Learning with Tensorflow to classify suspicious sounds like gun shots, jackhammer or glass breaking. A sophisticated microphone can be placed in Areas of interest like a Bank Locker or ATM and using the model, incoming sounds can be detected and classified. The Deep Learning Models that are trained, evaluated and tested are a Dense Model and an LSTM Model. The LSTM Model performs the best for identification of the sounds with an accuracy of 96.02%.**

***Keywords*—Deep Learning, Suspicious Activity, Tensorflow, LSTM, Suspicious Sound, Sound Classification**

I. INTRODUCTION

In today's world, the amount of activity that takes place has exponentially risen, but this warrants that even unlawful or unwanted activities could have risen, which does not bode well for the society and economy in general. People have to show extra care and precaution today, especially in public places because of the fact that we are the most likely to come under scrutiny for any action that may look shady or incorrect. Apart from this factor, there also is an economic factor linked to any and all suspicious activities.

There has been a rise in crimes in the past few years, but we still have archaic methods of dealing with the consequences after. If we update our methods of dealing with the same, then we actually have a fighting chance to nip the illicit activities in the bud itself. That is achievable but often at a price. Our intention is to research and find ways that can make our life safe and secure using methods that are inexpensive to setup and also easy to update and fix.

Considering the presence of sophisticated hardware i.e. Sensitive Microphones in certain Areas of Interest which are difficult to monitor in Night Time or are usually isolated at night like ATMs, Bank Lockers or for personal surveillance.

The main purpose of the paper is to classify different types of suspicious sounds present in the dataset. The present sounds are Gun Shot, Jackhammer, Drilling, Dog Barking and Siren. This was done with the help of Deep Learning Models. The main aim of the paper is to develop a reliable and accurate model which can accurately classify sounds in their respective classes and distinguish them from other sounds. This will also in turn improve public safety by pairing it up with an alert system which can alert law enforcement or security personnel. Finally, the paper aims to compare the performance of multiple models to find the best fit model for the job.

To make the model able to classify different kinds of sounds, two Deep Learning models are constructed. The first model contains entirely of Dense layers provided by Tensorflow's Deep Learning API Keras , and dropout layers. The second model contains an LSTM Layer along with Dense and Dropout layers. The paper aims to classify the sounds based on their extracted features. The extracted features are in the form of Mel-frequency Cepstral Coefficients which collectively make up a Mel-frequency cepstrum. The models are trained, validated and evaluated on this data with appropriate training methods. The performance of the models are then compared and the model with the best performance is converted into an exportable format for further development.

In spite of having the accomplished crime departments who have been managing these issuesfor quite a while, why is there a need for DL, having said that answer is very straightforward, the experienced departments can check on 3-4 parameters or can cover and comb through footage manually only in batches at a time with the help of the human capability present on site at that moment but DL, on other hand, can cover the numerous batches in one go, once provided the sufficient computing resources. In our scenario,DL actually helps out by covering various batches that would otherwise not be covered because of the sheer amount of data that is present which would make it nearly impossible to actually reach the right conclusion. Our intentions here are to try to provide solutions that are scalable and not limited to only a particular use case.

LITERATURE REVIEW

A. Phishing attack detection using Machine Learning

This paper [1] acts as our initial dive into the realm of how machine learning is used in various applications like physical and network security. We aim to use this paper as a path on how we can try and implement the machine learning concepts in our current setup to enhance and derive results that provide us with a better overall knowledge and view.

B. A sound monitoring system for prevention of underground pipeline damage caused by construction

In this paper[2], the usage of sound detection is in a very specific use case linked to the construction industry, in which they want to use acoustic signals to reduce pipeline damage. The other common noises are collected as environment noises and the system is applied via 2 layers, one which detects the suspicious sounds and the other that fine-tunes the results of the 1st layer. The testing of the model leads to results of 95% of the noises being detected which is good for improvements later.

C. Audio IoT Analytics for Home Automation Safety

This paper [3] speaks about how audio analytics can help in the household environment to detect abuse, violence and other unnatural activities that might take place. The audio is recorded and split into chunks in the server for training the model and classifying different categories. This system enforces home safety and if any suspicious sound is generated, then emergency services are informed immediately to take action.

D. Audio analysis for surveillance applications

In a paper written by R. Radhakrishnan et al [4]. A novel approach of analyzing time series like data of audio classes for detecting crime which can happen in elevators is developed and proposed. The authors showcase the disadvantages of a completely supervised machine learning based audio classification system and propose a hybrid solution to overcome them. It consists of two parts, in which the first part does unsupervised audio analysis and the second part which uses an audio classification framework. The framework uses a Gaussian Mixture Model (GMM) to identify background sounds and updates the model. The results seemed to be highly promising.

E. Smart Speaker: Suspicious Event Detection with Reverse Mode Speakers

In another paper written by G.Kalmar [5], an exploration into using speakers in reverse mode for detection of suspicious events has been done. The paper studies how a loudspeaker in reverse mode can be used to detect suspicious events like Gun Shots or screaming. To study the impact of reverse mode's distorting effects on the classification of events, a full transformation of traditional audio event datasets into forms as if they were recorded by speakers is done. The results suggested that speakers in reverse mode can be used for event detection.

F. A New Approach to Real Time Impulsive Sound Detection for Surveillance Applications

In this paper [6], the authors discuss the disadvantages of primary video surveillance systems and propose how they should be accompanied by other sensors. The paper makes a review of impulsive sound detection algorithms such as gun shots, explosions, screaming et cetera. It makes a review of all sound detection algorithms and noise detection algorithms as well. An adaptation of algorithms for detection of impulsive noise is also done. The results showcase that WLP (Warped Linear Prediction) can be used for impulsive sound detection.

II. METHODOLOGY

A. Overview

The paper's main purpose is to create and compare the performance of Deep Learning Models to identify which model is better and can be used for further development in this domain. The Model's main aim is to classify the sounds in their respective classes. The models are only trained to identify Suspicious Sounds like Drilling, Jackhammer, Dog Barking, Gun shots et cetera. The whole process of training the model requires a very crucial step i.e. Feature Engineering. Deep Learning models cannot be directly trained on sounds. They can however be trained on the features of the sounds that's why Feature Engineering is a very significant step for this whole process. After the training of the models, their evaluation on completely unseen data i.e. testing data is very important. This helps identify which model can work well when facing completely unseen data and is not overfit for the training data. Figure 1 depicts the entire process in a workflow diagram.

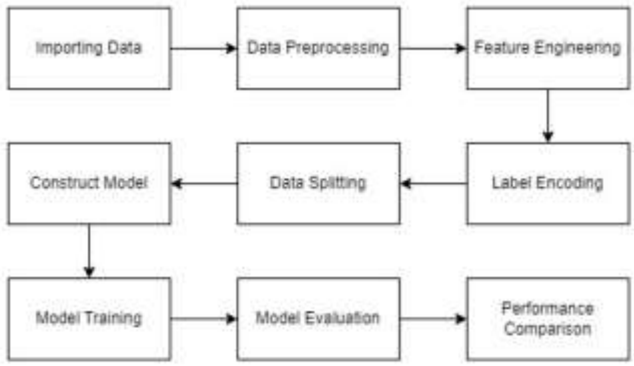

Fig. 1. Workflow Diagram

B. Environment

The entire project is implemented on Google Colaboratory, commonly known as Google Colab. It is a free, cloud-based Jupyter notebook environment that allows users to write Python code through the browser. Hosted by Google, Colab provides access to powerful computing resources such as Graphical Processing Unit (GPU) and Tensor Processing Unit (TPU), which allows for seamless work on the platform. Google Colab is thus particularly useful for researchers focused on data science and machine learning, who wish to collaborate with others on coding projects in a shared environment without hindrances. Unfortunately, Google Colab might be unable to process larger datasets as it is a limited platform, and does not support all Python libraries. However, for the purposes of this paper, Google Colab is a suitable work environment that is more than capable of handling the necessary datasets and

DOI: rp-9788770040723.131

libraries. In order to increase the scalability of this project, environments such as Kaggle can also be utilized.

C. Importing Data

Importing the data from its source can be a hassle. Specially when the data is large. We used the UrbanSounds8k Dataset [7] which contains 8732 sound samples of urban sounds like engine idling, children playing, street music et cetera. To import this data into our Google Collaboratory workspace, we use an external library called opendatasets [8] which uses Kaggle's official API to download datasets at high speeds.

D. Data Preprocessing

Data preprocessing is a crucial step in any machine learning project. It is a technique that involves transforming raw data into well-formed datasets and cleaning the raw data in order to check whether or not it is fit for analysis. More often than not, raw data is incomplete and inconsistent. Therefore, preparing the data has a direct impact on the final results post-analysis.

The main steps that are involved in Data Preprocessing include data cleaning, integrating the data. Transforming the data so that it can be used for different purposes and reducing the dimensions of the data. The dataset contains sound samples of different classes. Out of these classes, we only need five classes which can be categorized into Suspicious Sounds. We separate these classes and make a new dataset with only the metadata of sound samples of these classes. To depict the difference in these sound samples and a normal sound sample, we plot the waveform of the sounds.

The waveforms of the sound samples clearly represent the difference between them. This was made possible with the help of librosa [9]. librosa is a python package used for audio analysis. It makes the building blocks of audio processing systems. Figure 2 represents the waveforms of the class 'Dog Bark' and figure 3 indicates howthe waveform of the class 'Gun Shot' looks

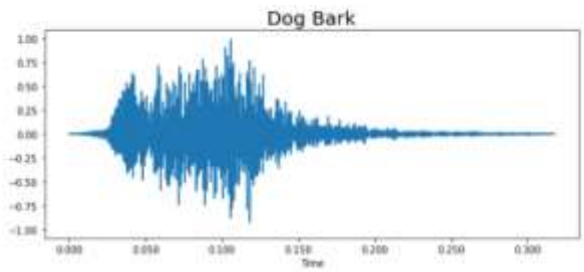

Fig. 2. Waveform of a Dog Bark

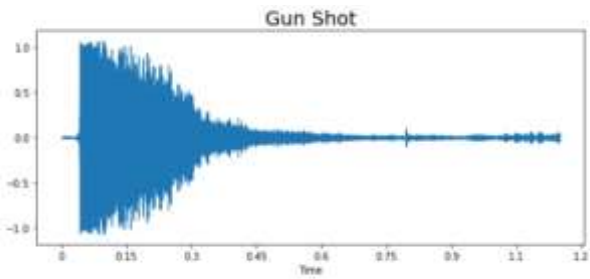

Fig. 3. Waveform of a Gun Shot

The same difference can be represented in the form of a spectrogram [10]. Figure 4 depicts the spectrogram for the class 'Dog Bark' and figure 5 depicts the spectrogram for class 'Gun Shot'

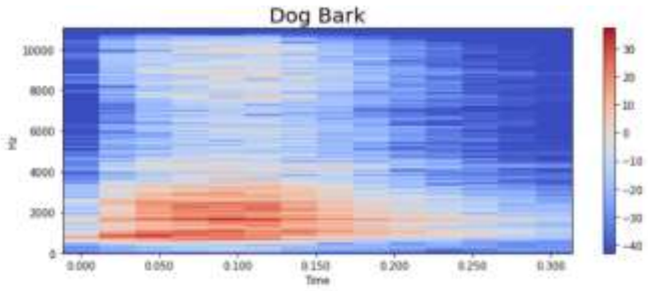

Fig. 4. Spectrogram of a Dog Bark

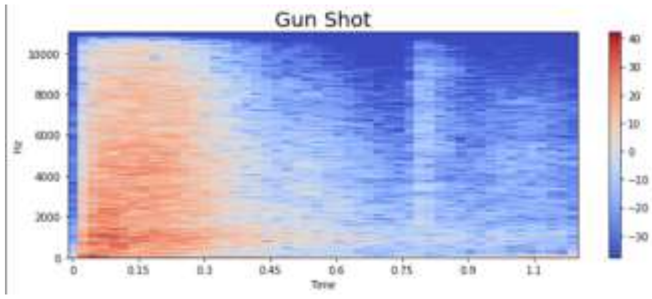

Fig. 5. Spectrogram of a Gun Shot

E. Feature Engineering

Deep Learning models are not able to identify sound samples in their raw forms. Providing a raw sound sample to a Deep Learning model for training yields nothing. For a Deep Learning model to identify a sound sample, its features can be supplied to it for training. For training our models, we extract the features of the sound samples. Since their are multiple types of features which can be extracted from a sound sample, we work with Mel-frequency Cepstral Coefficients [11]. The MFCC collectively make up the MFC or the Mel Frequency Cepstsrum which represents the change in the acoustic power of a sound based on a cosine transform of the power spectrum on a mel scale. This is done with the help of librosa. After extraction of features of every sound sample, a new dataset with the extracted features over fifty steps and its class labels is produced. The class labels are the encoded in the form of a distinct integer. This is called label encoding and is performed with the help of scikit-learn which provides efficient tools for data analysis and a premium library for Machine Learning in a Python Ecosystem.

F. Data Splitting

Data splitting enables us to split the whole data into bits which will be used for different purposes. In our case, we split our data into three subsets. The training data which is 80% of the original data, the validation data which is 10% and the testing data which is 10% as well. The training data will be used by the model for training, while it makes a pass over it and backtracks to adjust its wrights accordingly, and the validation data is used for checking how the model performs on relatively unseen data. Validation data is not used for training at all. The testing data in the end will be

DOI: rp-9788770040723.131

used for evaluating the model's performance finally on a completely unseen subset of data.

G. Model Construction

We For the betterment of results, we construct two relatively different models. The first model has four hidden layers. All these layers are Dense layers from the Keras API [12]. All these layers use 'relu' [13] as their activation function. The final output layer is a Dense layer with 'softmax' activation function [14] which is used in Multi-class classification. The model uses Categorical Crossentropy as its loss function along with Adam as its optimizer. This model is referenced as Dense Model throughout the paper.

The second model, referenced as the LSTM Model throughout the paper consists of three hidden layers. The first layer of this model is a LSTM layer [15]which returns only the final output. LSTMs are characterized by their ability to selectively remember or forget information from previous time steps, making them well-suited for tasks involving sequences of input data. Figure 6 depicts the architecture of a LSTM cell.

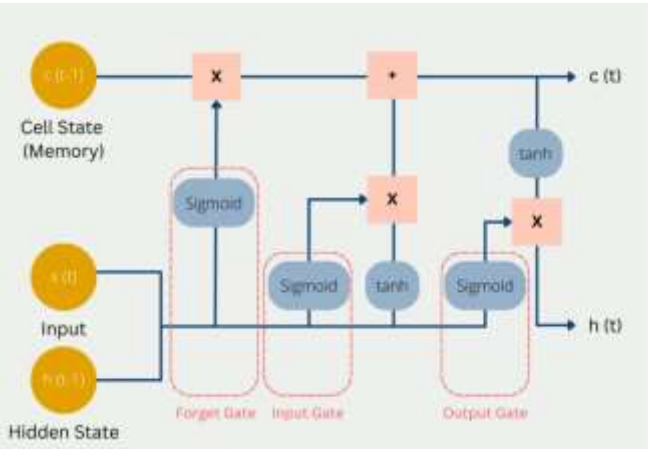

Fig. 6. Architecture of LSTM Cell

All the dense layers use 'relu' activation function. The output layer of the model uses 'softmax' activation function for multi-class classification. The model uses Categorical Crossentropy as its loss function along with Adam as its optimizer.

H. Model Training and Evaluation

Model training adjusts the weights of the models according to the training data provided. For our paper, we set both the model to be trained for 200 epochs with a batch size of 32. Along with this, an optional callback of Early Stopping is used. Early stopping observes a prescribed metric of the model while training. If the said metric does not increase or decrease or remains constant for a specific patience value i.e. number of epochs, Early Stopping stops the training of the model and reserves the best weights till the last epoch.

Finally, after training the model, a separate performance evaluation of the models is done on the Test Data. All the metrics of performance of the models on the Training, Validation and Testing data are used for evaluation.

III. Results And Discussuions

The primary aim of this study was to classify suspicious sounds into their respective classes based on their extracted features. This aim was achieved with the help of Deep Learning concepts in which our approach is to take two models and compare their performance to evaluate which model works better and can be used in a real-time audio stream. One point to be noted is that both models have not been trained for the same number of epochs, due to the usage of 'EarlyStopping'. Early Stopping is a method in Deep Learning that helps you to decide an arbitrary number of epochs at which the training of the model stops due to no improvement of results on the validation dataset.

A. Model I- Dense Model

The first model overall performed well on the dataset. It trained for 57 epochs and achieved a maximum training accuracy of 85.96% and a maximum validation accuracy of 88.63%. The training and validation losses of the model were 0.3889 and 0.3779 respectively. Fig 7 gives us a graphical representation of the training and validation accuracy. Fig 8 gives us the loss values for the training and validation loss.

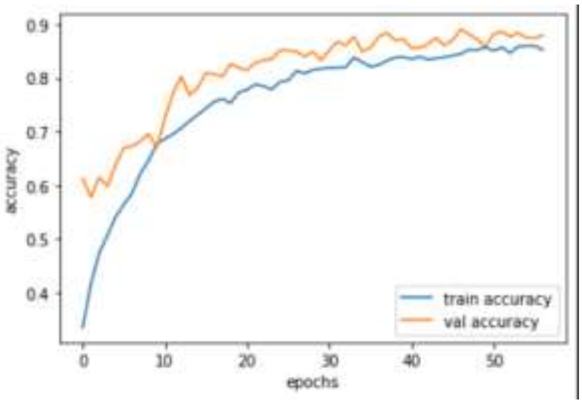

Fig. 7. Training and Validation Accuracy (Model I)

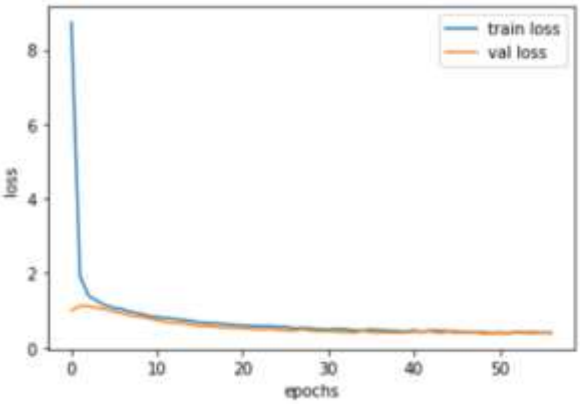

Fig. 8. Training and Validation Loss (Model I)

B. Model II- LSTM Model

This model performed better when compared to the previous model. It trained for 37 epochs and The model reached a training accuracy of 96.02% maximum and a validation accuracy of 90.49% maximum. The training and validation losses of the model are 0.1036 and 0.3184

DOI: rp-9788770040723.131

respectively. Fig 9 gives us a look at the training and validation accuracy curves. Fig 10 gives us the loss values for the training and validation loss.

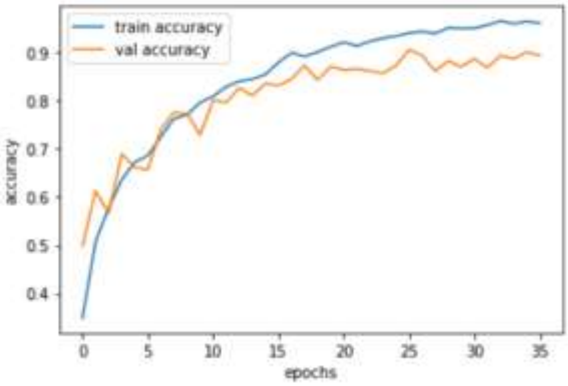

Fig. 9. Training and Validation Accuracy (Model II)

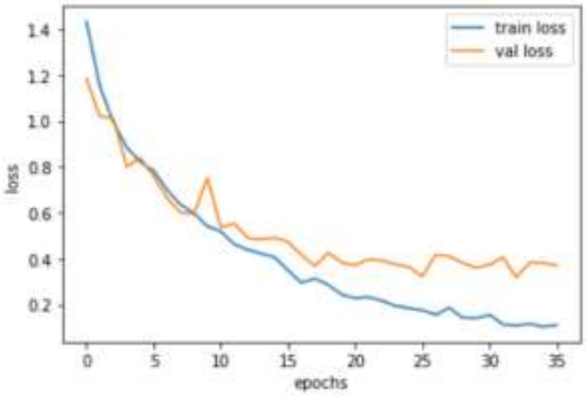

Fig. 10. Training and Validation Loss (Model II)

To compare the performance of the models in a more structured and elaborative manner, two tables are made to depict their performance. These tables reference to the performance of both the models collectively on their training data, validation data and testing data respectively. Table I gives us an overview of the training and validation loss of the model.Table II gives us an insight on the training, validation and testing loss of both the models..

TABLE I. TRAINING AND VALIDATION ACCURACY OF THE MODEL

Model	**Training Accuracy**	**Validation Accuracy**	**Test Accuracy**
Model I	85.96%	88.63%	88.86%
Model 2	96.02%	90.49%	90.25%

TABLE II. TRAINING AND VALIDATION LOSS OF THE MODEL

Model	**Training Loss**	**Validation Loss**	**Test Loss**
Model 1	0.3889	0.3779	0.3488
Model 2	0.1036	0.3184	0.3471

After analysing and comparing the results for both models, it can be said that Model 2 which is the LSTM model can be further developed and used to detect suspicious sounds in real-time continuous audio streams.

IV. CONCLUSION

The result of our paper, as proven by the Results and Detection Section shows us that the LSTM model performed better than the Dense Model. This in turn helps us prove that interpreting the features as a time-series array proves beneficial for sound classification models. There can be addition of more classes of suspicious sounds like footsteps or glass breaking, which will allow the model to detect a broader spectrum of classes, which also makes the smart surveillance system even smarter. We can also improve it to detect a live audio feed and also to alert personnel when needed.

***Abstract*—Agriculture is a vital business that greatly contributes to the global economy. In order to fulfil the increased demand for food, it is vital to boost crop output. In this context, precision agriculture is growing in popularity. Precision agriculture employs technology to maximise crop yields, minimise crop waste, and optimise crop production. A significant part of precision agriculture is the employment of crop selection systems, fertiliser recommendation systems, and disease diagnosis systems. These recommendations can assist farmers with crop selection, fertilisation, and disease management decisions using machine learning algorithms. This system is highly dependent on variables such as precipitation, pH, market analysis, and water availability. Before being analysed and displayed, Python is used to preprocess environmental data collected from farmers or agriculture department offices. Farmers will be able to interpret and utilise the data for decision-making and field monitoring as a result of the application of multiple machine learning algorithms. Using a custom-built recommendation system, the harvests have been forecasted and displayed. It is anticipated that farmers will adopt these technologies in order to increase yield via intelligent field selection.**

Keywords—precision Agriculture, SVM classifier, Fertilizers, Logistic Regressio Crops, Decision Tree , Machine Learning.

I. Introduction

Precision agriculture is essential for optimising crop production in order to maximise crop yields and minimise waste. Precision agriculture is the application of technology to provide farmers with customised recommendations based on soil and weather conditions. Precision agriculture is comprised of several key components, including crop recommendation systems, fertiliser recommendation systems, and disease diagnosis systems.

Precision agriculture, such as the use of crop recommendation systems, fertiliser recommendation systems, and leaf disease diagnosis systems, can assist in overcoming these obstacles. Precision agriculture, according to a study published in the International Journal of Precision Agriculture, can increase crop yields by up to 28% and reduce fertiliser use by up to 60%. (Gebbers and Adamchuk,2010). Farmers can reduce their input costs, increase their crop yields, and enhance the quality of their crops by implementing these systems. This can lead to a more sustainable and efficient agriculture system that can meet the increasing demand for food while having a smaller environmental impact.

II. Literature Survey

[1] Prediction of Indian Crops Based on Weather Using bigdata analytics and methods, information on soil, precipitation, temperature, crop productivity, seed, humidity. They will collect and analyse data for their project. After that the information has already been compiled in a Python environment, the Map - reduce framework is being used to evaluate and procedure it. When applied to Map - reduce outcome, K-means clustering yields an average level of data precision.

[2] A Study of Multiple Data Prediction Methods for Crop Yield, Data Mining It evaluates many data mining techniques for predicting crop yield. The efficacy of any crop production forecasting system is significantly impacted by the accuracy with which attributes were collected and classifiers were applied. It provides an accurate and recommended summarization of the crop yield projection results based on a variety of machine learning algutilised by different researchers.

[3] Exploration of Agriculture and natural resources Soils Utilize data mining methods. Data mining may offer a farmer with a recommendation system to increase crop yield. This strategy is implemented in order to ensure recommended crops are selected based on their climate variability properties and abundance. Data analytics permits the development of extensive agricultural database extraction. After analysingThe crop production data - sets centred on season and yield, crop recommendations are made.

[4] Algorithms based on machine learning for crop yield prediction. To support farmers in crop selection, we consider all variables, including soil type, planting seasons and geographical location. In addition, developing countries are combining smart farming, which emphasises location crop management, with the cutting-edge new technology known as machine learning.

[5] The AI-based farm crop management system. This analysis study proposes a system to aid farmers in crop selection by Taking into consideration everything relevant factors, including soil, planting season and geographical region. Emerging nations are also utilising modern agricultural technologies and developing smart farming, which focuses on crop management.

[6] System for intelligent Fertilizer recommendation based on machine learning. Datadriven models use machine learning models to accurately recommend fertilizers for the farmers to maximize their yield

[7] Predictive Model for Crop and Yield. Those who proposed a procedure for utilizing data mining to forecast crops and development in agricultural output by using deep learning. They must examine soil datasets for this purpose.

The flaw of the system is that it disregards the chemical substance of the soil.

[8] They developed automated prediction systems by utilising Big Data Analytics techniques. This study's model is constructed using the Hadoopframework.Apache Mahout was used to create a logistical regression model that utilised historical data to predict the future.

[9] V. K. Singh et al. (2021) put forward an approach for diagnosing leaf diseases in crops based on algorithms for machine learning and image analysis. The system accurately detected leaf diseases and provided recommendations for the best course of action in the event of a disease infestation.

III. Existing System

There has been extensive application of ML algorithms and research in the agriculture industry. The greatest challenge facing agriculture is to increase agricultural production and deliver that to consumers just at best possible price and quality.

Random Forest and Logistic Regression are the most common algorithms. Because of the greater features and complexity of the recommendation system, these are insufficient. Often, the crop suggestion algorithm merely offers farms to farmers being willing to participate in cultivating. This quiet does not sufficiently aid the farmer.

IV. Proposed Method

The purpose of this model is to develop a recommendation systems to increase agricultural output. This model aids the farmer in crop selection, fertilizer recommendation, and the detection of leaf diseases through image analysis in order to increase agricultural output. The systems are also capable of recommending the optimal course of action in the event of a disease outbreak. The early detection and identification of leaf diseases can aid farmers in preventing the disease's spread and mitigating crop loss.

The intended strategy is novel given that assists farmer in increasing agriculture output by going to recommend the most profitable crops. In the proposed model, crop choice depends on both environmental and economic factors. This method predicts the crops of the greater yeild outcome by analysing variables such as soil type, temperature, rainfall.

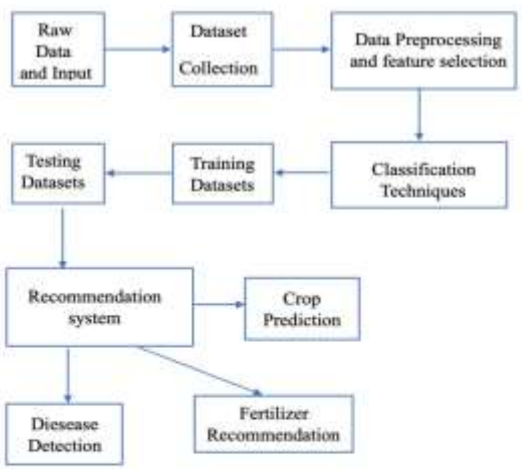

Fig. 1: Architecture Diagram

We developed recommendation sections for fertilisers and Pesticides using, a number of machine learning (ML) strategies, including Random Forest, NB classifier, Decision Tree, SVM, and CNN. This method can reduce the difficulties farmers face when choosing crops, fertilisers, and pesticide residues.

Table 1. Algorithm's

Algorithms
SVM
Logistic Regression

NB Classifier
Decision Tree

V. Implementation

A. *Pre-processing and cleaning*

One of the first responsibilities is to confirm the accuracy of the dataset we are using. If any values are present but are missing from the dataset, they should be filled in with the correct values. The data should also be examined to determine whether the characteristics have a normally distributed. The dataset we utilised contained features with skewness. In order to equalise the properties of our dataset, we applied quantile transformation on them

B. *Data Visualization and Analsys*

After data cleansing and preparation, we analyse and visualise our dataset. We endeavour to conduct a more in-depth analysis of our data to identify any patterns or trends within the dataset. We have created multiple visuals to aid in the comprehension of our dataset.

C. *Operational Selection*

It is essential that only select the qualities that will be necessary to evaluate the category of crop to cultivate. A correlation matrix has been created to demonstrate linear relationship between each characteristic and additional features.

Then, a machine learning model is constructed. Before building we must separate the model for machine learning into its component parts, the dataset into sets for testing and traning. We begin with data for training followed by application of machine learning algorithms using the dataset characteristics. Four methods of machine learning were applied to our training dataset; on the test dataset, the most accurate techniques will be utilised.

Datasets:

https://www.kaggle.com/datasets/vipoooool/new-plant-diseases-dataset

DOI: rp-9788770040723.132

D. Constructing of User Interface

In the subsequent step, an interface for users data entry by the client was designed. The model will analyse the user'sinformation, including such N, P, KSoil Values, precipitation,humidity, temperature, etc., and recommend the optimalcrop must be cultivated under the given Conditions. Once the user enters and submits the following information, The algorithm for machine learning will forecast crop yield which the customer mustplant

Fig. 2: User Interface of Crop Prediction

Fig. 3: User Interface of fertilizer Recommendation

Fig. 4: User Interface of Disease Detection

VI. Result

We cleaned and visualised the data before applying our methods of algorithms of machine

Learning tocharacteristics of the dataset. Our four algorithms presented are Logistic Regression, Decision Tree, XG Boost and Random Forest. The selected characteristics the datasets are comprised of the K (potassium), P (phosphorus), N (nitrogen) properties of the soil, moisture,precipitation, temperature and ph value.

```
In [43]: data = np.array([[104,18, 30, 23.603016, 60.3, 6.7, 140.91]])
         prediction = RF.predict(data)
         print(prediction)

         ['coffee']
```

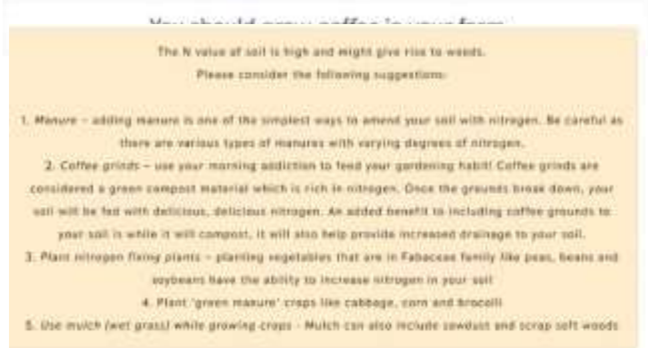

Fig. 5&6: Result of Crop Prediction

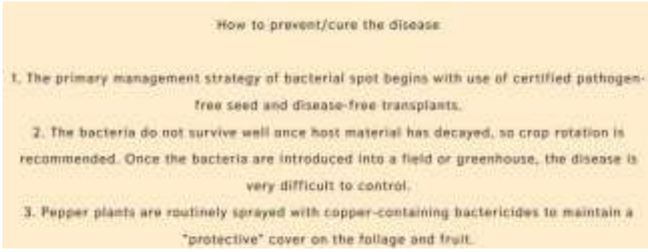

Fig. 7: Result of Fertilizer Recommendation

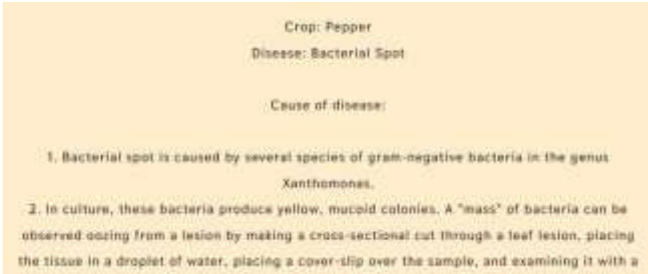

Fig. 8&9: Result of Disease Detection

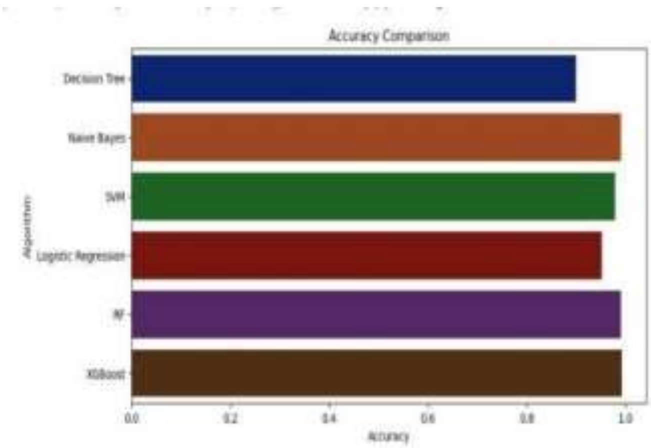

Fig. 10: Accuracy Graph of Algorithms

As per the graph we have XG boost with the best accuracy of 0.993, Random Forest and Naive Bayes with an accuracy of 0.990, SVM with an accuracy of 0.979, Logistic Regression with an accuracy of 0.952 and Decision Tree with an accuracy of 0.911.

VII .Conclusion

Precision agriculture relies heavily on crop recommendation systems, fertilizer recommendation systems, and disease diagnosis systems. Using machine

DOI: rp-9788770040723.132
learning algorithms, these systems provide farmers with customised recommendations based on soil and weather conditions.

Farmers can optimise crop production, reduce waste, and maximise yields using these systems. These systems can aid in enhancing the productivity of small-scale farmers, reducing the use of fertilisers and pesticides, and ensuring food security for a growing population. this technique, it would simplify his life and predict with a 98% accuracy the ideal crop and fertilisers to plant.

***Abstract*—This approach of speech emotion recognition(SER) is a problem in the subject of deep learning. The primary objective of this study is to identify a variety of feelings based on the input of audio utterances as well as the Rnn networking. We used the long short-term memory networks (LSTM) model because it deals with speech features and aims to improve speech recognition rates. Initially, this method of speech emotion was done by machine learning approach but recently deep learning techniques are proven to be an alternative to SER providing better accuracy.We used the dataset's audio files as input, performed feature extraction, and trained the model. Considering researching the published works from prior periods' research and putting the suggested models through their paces on our own datasets, We expect that the overall file classification efficiency will be 99.73**

Index Terms*—Recurrent Neural Network(RNN),Long Short- term memory(LSTM), Speech emotion recognition(SER), Deep learning.

I. Introduction

Making it feasible for human-machine contact is the main goal of this mission speech emotion recognition (SER) utilising deep learning method. Speech is best way of interaction between humans. So, this is very exciting and interesting for researchers to find ways to establish communication between machines and humans. This topic of SER is quite tough because there are many factors that might effect the raw input sound signals such as age, gender, noise and etc. Nowadays, the majority of our focus is directed into deep learning since, within a relatively short amount of time, it is providing us with improved results in every area, particularly SER. Deep learning makes it possible to use sophisticated models and learn various data representations. Deep learning's main disadvantage is that it needs a large data in order to perform better than any other approaches. Firstly, a machine learning technique was used to perform this SER technique; however, once a large dataset was used, this machine learning method produced superior results. Despite the fact that speech technology has advanced significantly SER in previous years, but a bettersystem is still required. Recognition of human sentiments via machines, which might further improve the relationship between humans and machines [1][4]. The primary and most direct method of information transmission is speech. It is able to express a vast amount of emotional information by means of the feelings that it feels and the manner in which it displays those feelings in response to items, scenarios, or happenings. This ability allows it to communicate a wide range of sentiments. Its database contains a vast amount of information covering a variety of topics. In recent years, a significant number of studies and research initiatives have focused their attention on developing methods for the automated recognition of individual emotions through the study of human voices and facial expressions. These methods have been developed in an effort to improve the accuracy with which computers can read face expressions and voices. There is a significant rise in the number of studies pertain to this topic as a direct result of the fact that automated emotion detection systems may be utilised for a variety of purposes within a variety of settings. This is a direct result of the fact that automated emotion detection systems may be used in a variety of settings.Examples of the applications for these studies and their planned use include the following systems: Education: A course system for online learning can identify disinterested students so that the style or difficulty of the material can be changed. It can also offer emo- tional bribes or concessions. Automobile: The driver's internal condition and driving performance are frequently connected. As a result, these systems can be employed to enhance driving performance and the driving experience. Security:It's possible that intense emotions like fear and anxiety may be used as support systems in public settings if we acknowledged them and acknowledged their significance. Communication: When an interactive voice response system and an automatic emotion detection system are combined in call centers, customer service may be enhanced. Health: Individuals who suffer from autism may find it easier to adjust their social behaviour if they have access to portable technology that helps them understand their own sensations and feelings [5].

II. Related works

An intriguing piece of research that Pan produced made use of MFCC and support vector machines as features. With regard to his Chinese dataset as well as EMoDB[6], he achieved astounding accuracies of 91.3043percentage and 95.087 percentage, respectively. The Arabic television programme ”The Exact reverse Path,” according to Ashraf Khalil in [6], served as the source for his set of samples. He used SVM and got a classification rate of 77 percentage.[3][7] We are aware that Yixiong Pan in [8] used support vector machine to classify emotions into 3 groups with 95.1percentage correctness using datasets from the Berlin Database of Emotional Speech [1][8]. The finest outcome in this field has thus far been published, and it is this one. In [9], S. Lalitha uses a support vector machine (SVM) classifier in conjunction with pitch and prosody characteristics to achieve 81percentage accuracy across 7 classes from the full Berliner Dataset of Emotional Speech. In [10], Yu Zhou merged spectral and prosodic features using the gaussian mixture model superior vector- based SVM, and he showed 88.3 percentage efficiency on five classes of the Chinese-LDC corpus. In [11], Fei Wang used a mixture of various features,Deep Auto Encoder, and SVM to achieve an accuracy of 83.7 percent on six classes from the Chinese emotion corpus CASIA. [1] SVM is employed in some other Arabic dataset created by Al-faham and Ghneim. [12]. where they hit their target 93.1 percent of the time HabibaDahmani proposed in [13][3] a fully automated system for voice recognition for the Algerian language. She used data from the Algerian television show ”Red Line” for her research. The total number of sound samples is 1443. Among the several classification strategies used were KNN, Logistic regression, and Random Forests. Their F-value came out to be 0.48. [3] In [14][1], JianweiNiu reported 92.3percentage accurate on six classes of 7676 speaking Mandarin Chinese phrases employing a range of characteristics in their identification system and integrating deep beural networks and Hidden Markov Mode.

H.M. Fayek in [15] studied multiple DNN designs using two independent databases, eNTERFACE [16] and SAVEE [17][1], with 6 and 7 categories, respectively.[1] John Kim introduced a framework called EmNet in that includes extraction offeatures, feature normalisation, 4 CNN layers, and 2 LSTM layers.[18]. EmNet performed at a rate of 88.9 percentage when tested on the EMO-DB dataset.[3] Yasser Hifny and Ahmed Ali [19] developed two neural architectures to address the problem of voice emotion detection. The first architecture employed the CNN-LSTM-DNN model, whereas the second design was based on the CNN model. On the KSUEmotions dataset [20], the accuracy of the first model was 87.2 percent, whereas that of the second model was 85Noroozi et al. Based on the evaluation of both visual and aural data, proposed a customisable approach for recognising emotions. In his study, 88 traits—Mel Frequency Cepstral Coefficients [MFCC] and filter bank energies [FBEs]—were employed to cut down the dimension of feature extraction previously performed using the Principal Component Analysis. Bandela et al. coupled the Teager Energy Operator (TEO) as In his study, 88 traits—Mel Frequency Cepstral Coefficients [MFCC] and filter bank energies [FBEs]—were employed to cut down the dimension of feature extraction previously performed using the Principal Component Analysis.a prosodic feature with the auditory feature known as the MFCC in order to detect five emotions using the Berlin Emotional Speech collection and the Gaussian Mixture Model classifier .The 13 MFCC generated from voice files were utilised by Zamil et al. as spectral characteristics, in their proposed model to classify the seven sentiments using the Logistic Model Tree method.[21]

III. Methodology

A. Data

In order to evoke each of the seven emotions, two actors (ages 26 and 64) recite a selection of 200 target words in the carrier phrase ”Speak the word” (anger, fear, disgust, pleasant surprise, sadness, happiness and neutral). There are 2800 data points in all (audio files). The data is structured in this manner so that each of the two female actors and their feelings has its own folder. It includes an audio file with the two hundred target words. The audio file format is WAV. After importing the dataset, we saw that it had around 2800 samples. After importing the dataset, we will create a data frame with audio files and labels. Then we do an exploratory analysis of the data to examine if all of the classes, such as fear, anger, disgust, neutral label, sad, ps, and happy, are distributed uniformly. Finally we assign responsibilities to the spectrogram and wave- plot. The waveform of an audio track file is displayed using a waveplot, while the frequency levels are displayed using a spectrogram. We are presently developing a feature extraction method for audio files. Following feature extraction, we will now construct the LSTM model. A thick two dimensional linear layer with hidden units, dropout regularisation to prevent overfitting by removing a portion of the data, the limited categorization To calculate the difference between true and predicted labels, use the cross-entropy method, and the Adam optimizer to automatically update the information gain during training are all part of the neural network model. Now we will train the model, and all of the results will be shown at the conclusion of each epoch of training, and the results willbe plotted, and we will see whether we get better outcomes with this model.

B. LSTM model using RNN Architecture

LSTM is a type of Recurrent Neural Network (RNN) that can develop protracted dependencies. In this research, a type of speech processing approach for LSTM networking structure is given to contend with speech characteristics, with the goal of boosting the speech recognition rate. A LSTM unit conducts the memorizing in this model, the Dropout unit periodically changes the parameters of a chunk of the data to zero to prevent against overfitting, and also the Dense units include convolution layer connected to the degree of freedom the model will have to adapt to the data. The more complicated the data, the more degrees of freedom the model requires, all while avoiding overfitting . If the accuracy of the training and test sets differs (for example, accuracy rate is 98 percent and test accuracy is 88 percent), the data has been overfit. Stop iterating when the validation metric of choice (accuracy in this example)

DOI: rp-9788770040723.133

begins to drop. Using audio data, we may build an RNN by having started with a basic model and gradually adding layers until it can forecast the data to the top of its abilities. To understand where this border is, adapt the structure until your simulation tends to overfit the data, then go back and remove layers. Check for performance differences in between test and training information and use Drop - outs layers to avoid over - fitting to the training data.

Fig. 2. LSTM Model

C. Experiment

Our framework was developed using an LSTM model with an RNN architecture.About 50 epochs were applied to the RNN design. Every sampling was successful and included samples from various classes (sadness, fear, disgust, happi- ness,anger, pleasant surprise, and neutral), there were precisely the same amounts of segments from each class in every batch as shown in fig. 3. Because each class included 400 data frames, the total number of data frames for all emotions was 2800. After the exploratory data analysis, We created a waveplot and spectrogram for each class, as shown in Fig 4, Fig 5, which shows the wave plot and spectrogram of fear, Fig 6, Fig 7 showing the wave plot and spectrogram of angry, Fig 8, Fig 9 showing the wave plot and spectrogram of disgust, Fig 10, Fig 11 showing the wave plot and spectrogram of neutral, Fig 12, Fig 13 showing the wave plot and spectrogram of sad,Fig 14, Fig 15 showing the wave plot and spectrogram of ps, Fig 16, Fig 17 showing the wave plot and spectrogram of happy respectively.A sample audio of an emotional speech is also included in each session. The spectrogram’s colour pattern demonstrates that lower pitched sounds have darker colours, while higher pitched tones have vibrant colours. Following that, the audio files are subjected to the extracting features approach. With the same file size, the speech length was restricted to three seconds. MFCC features will be recovered with a limit of 40, and the mean will be used as the final feature.The extracted features of the audio files will then be returned in the following phase, and xmfcc will assist in the display of the features derived from the data.The processing time required to display the generated features rises in proportion to the amount of samples in the dataset. After that, the list is transformed to a one-dimensional array, which we receive as (2800,40). After converting the input to a single- dimensional array, we split it (2800,40,1). The shape in the x region represents the number of samples in the dataset and the number of features in a single dimension array. The y-axis contour shows the number of samples and output classes. We will now construct the LSTM model. The loss in this model is called ”sparse categorical cross entropy,” which computes the cross-entropy loss between true labels and predicted labels, and the learning rate of the model is automatically changed over the number of epochs.

IV. Results

Based on the research that we have done,we claim our accuracy to be 99.73 percent. In this model, the memorizing is done by an LSTM unit, the Dropout unit occasionally resets the parameters of a portion of the data to zero to avoid over fitting, and the Dense units also have a convolution layer linked to the amount of flexibility the model will have to adjust to the data. More degrees of freedom are needed in the model as the complexity of the data increases, but over fitting must be avoided. The algorithm was trained over a GPU for about 50 iterations.The models training accuracy and validation accuracy increased during the duration of the training procedure with a total sample size of 64 and 50 epochs. The best validation accuracy of 98.57 was attained, and the best model was preserved by utilizing a checkpoint.In order to address slow convergence, the learning rate can be adjusted. The data was separated into sets for training and testing using the validation split of 0.2.The proportion ofsegments included in the validation sets and those used for the training were both identical in every class.In fig 18 and fig 19, we have also shown the plots for accuracy vs. epochs and loss vs. epochs. respectively.

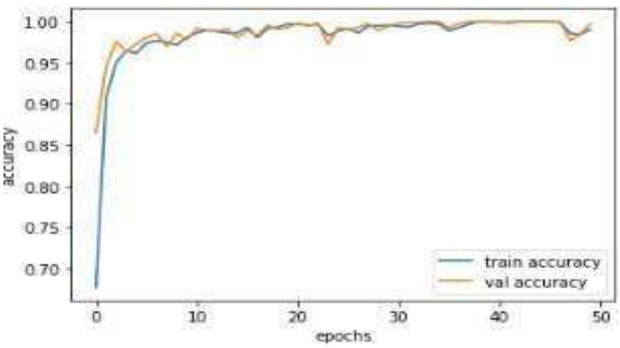

Fig. 18. graph for accuracy vs epochs

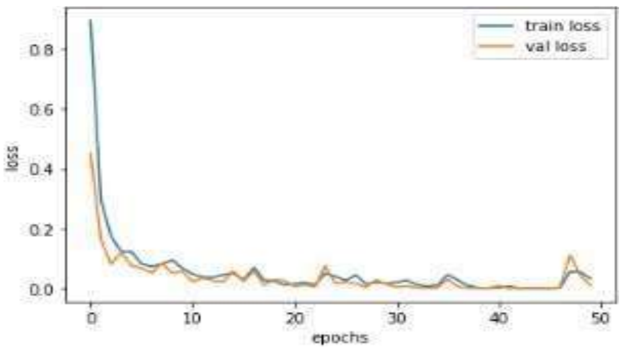

Fig. 19. graph for loss vs epochs

V. Conclusion

Over the course of our work, we conducted research and read a range of study articles. The experiment was carried out to see whether it would be possible to determine a person's psychological emotion reaction by listening to brief recordings of their speech. Our approach has a 99.73 percent accuracy rate. We chose deep learning for our project because it produces more accurate outcomes than machine learning.In this work, we identified various speech emotion sounds with deep learning algorithms on the emotional speech recognition dataset, which was

DOI: rp-9788770040723.133

supplemented by exploratory data analysis to provide more insights into the classification process. We chose the LSTM model because it enables the system to efficiently process continuous input streams without raising the needed bandwidths. In order to optimally utilise the model parameters, the proposed model alters the usual design of the LSTM network.Despite we obtained improved results with our model, much more work in the domain of voice emotion identification need to be done. Further work may be done to improve the process and make advantage of larger datasets.This is done to make sure the algorithm can produce satisfying results across a variety of data sources and much more than the courses we have taken, with extremely high accuracy on validation sets, enhanced prediction confidence, and more reliance on real-world data. Even if the final accuracy is rather excellent, we will continue to investigate ways to make the process even better.

***Abstract*—When it comes to cyber security, educational institutions are often undervalued. Since educational institutions typically have a huge population, the procedure for issuing and verifying identity documents must be secure, dependable, and efficient. The process may require students to make multiple trips to the issuing authorities' offices. This is just a waste of time for all the parties involved. Inadequate methods for verifying students' identities have contributed to a rise in the number of cases of digital identity theft. This paper proposes a blockchain-based identity verification model for educational institutions, as well as explores the possibility of designing such a model for Government Institutions. Third parties can validate the user's data without wasting time or money due to the immutable and decentralised ledger. For uploading files that we wish to store on the block so that a user can view and interact with them directly, our goal is to develop a front-end website with HTML, CSS, and JS. All of the student identities would be stored in an IPFS calledweb3.storage.Blockchain-based identity management system shave the potential to significantly improve user control over their own data, as well as transparency, accountability, and dependability. They can also speed up administrative processes.**

***Index Terms*—IPFS, Blockchain, Document Verification, SHA256,AsymmetricEncryption**

I. Introduction

Asuccessfulsocietyrequiresitscitizenstobeidentifieduniquely. It is a collection of statements about an individualthat are used to distinguish them. The person's name, date ofbirth,country,andnationalidentityaretypicallyincludedhere. Thesedatasetsaregeneratedandmaintainedbycentralized organizations(governmentservers).

Educationalinstitutionsoperateinasimilarmanner.Allrelevantdocumentsarekeptinacentralrepository,andacentralauthorityprovideseveryone theiruniqueidentity.

Ateducationalinstitutions,alargequantityofpersonallyidentifiable information about students is stored. All of thisinformation, which is maintained in a Central Repository, ismanaged by the administrators of the institution. There is agood chance that the data was accidentally edited or tamperedwith. If this central repository is compromised, all sensitiveinformationaboutindividualsmightbeaccessiblebyunauthorisedpersons.Thisisconcerningsinceitopensthedoor to identity theft, security theft, and other forms of crimes,making it necessary to use strong security measures. In therecent times according to Lagzian, M.(2018) [1] identity theftshave increased significantly in the academic world. Anothercause for concern is that students have no idea about who hasaccess to their data and what is being done with their data.Essentially, users' personal data is being used without theirconsent. This makes it essential to include transparency in themodel.

A. *BlockchainTechnology:*

"SatoshiNakamoto"introducedtheblockchainconcept in his [2] 2008 white paper, describing it as atrust less technology and claimed that bitcoin was thefirstopen-sourceapplicationofblockchaintechnology. Through cryptography, peer reviews, anddecentralised transactions, Blockchain ensures trust,security,anddataintegrity,henceeliminatingtheneed for middlemen. A Blockchain is a distributed,transparent, and immutable ledger that improves trustandproducesasystemthatisquick,safe,andreliable. Blockchain has gained popularity in a lot ofsectorslikefinance,healthcare,etcintherecentyears.[3]

Blockchainisacombinationofthreecoretechnologies:cryptographickeys,apeer-to-peernetwork, and a digital ledger. There are two types ofcryptographickeys:privatekeysandpublickeys.Eachindividualornodehasbothofthesekeys,which are used to generate a digital signature. Thisdigitalsignatureisauniqueandsecuredigitalidentificationreference,anditisthemostcriticalcomponentofblockchaintechnology.

B. *Inter-PlanetaryFileSystem(IPFS)*

IPFS (Inter Planetary File System) [4] is a peer-to-peer,content-addressed,version-controlledfilesystem.HTTPisthecurrentdefaultmethodforexchanging data across the Internet, howeverit failsin several instances. Large files cannot be sent viaHTTP,dataisnotpermanentonHTTP,HTTPisprimarily a Client-Server protocol, resulting in lowlatency and making it challenging to build a peer-to-peer connection. Also, real-time video streaming overHTTP is hard. All of these limitations are overcomewith IPFS. Data is requested using the hash that isreturned when data is uploaded to an IPFS network.The network allows for the distribution and copyingof data, which makes the data permanent. It searchesfor the nearest copy of the requested data when youmakearequest,whichcausesahighlatencyandpreventscongestion.Datacentralizationisnotpossiblesincethedataiscompletely distributed.

			authentication.

II. PROPOSED ARCHITECTURE

EduChain is a model for identity verification using IPFS andblockchaininaneducationalorganisationthathasthepotential to increase efficiency, security, and transparency intheverificationprocess.Firstly,themodelinvolvesthreeparties: the student, the admin, and the requestor. The studentregisters on the portal and is assigned a unique ID (API key)thattheycanusetologintothesystem.Theythenuploadtheir documents on the IPFS, which generates a unique hashforeachdocument.Thishashservesasproofofthedocument's authenticity and is used to verify the documentlateron.Theadminplaysacrucialroleintheverificationprocess. They can view all the files uploaded by the studentand verify them by checking the contents of each document.Once verified, the admin pushes the student's API key to theblockchain,whichservesasapermanentrecordofthestudent'sverifiedidentity.Thisensuresthatthestudent'sidentity information cannot be tampered with or altered in anyway. The requestor can then request access to the student'sinformation onthe portal.However, beforegranting access,theadminfirstobtainsthestudent'spermission.Oncethestudent grants permission, the admin provides the requestorwiththepublickeyoftheblockcontainingthestudent's verified identity information. This public key can be used bytherequestor to accessthestudent'sinformation.

Criteriacanbeestablishedbasedonwhattheuniversityrequires.Oncethepapershavebeenverified,theadministrator will upload the student's API key to theblock. All requests submitted by the requestor can beviewed by the admin, who can then accept or rejectthem. The admin provides the public key to the blocktherequestor needsafterreceivingapproval.

C. The requestor: The requestor submits the request toaccess the student data. Once the request has beenapproved by the student and the administrator, theyare given access to the public key of the block wherethe student's API keyis uploaded. They can accessthe student's uploaded documents using this API keyand use themasnecessary.

The requestor functionality provides an added layer of securityand control for students over who can view their documents,ensuringthatonlythosewhohavebeenapprovedbythestudentcanaccessthem.Italsomakesitpossibleforrequestorstoaccesstherequireddocumentsquicklyandeasily,withouthavingtogothroughthestretched-out andpotentiallyriskyprocedureofaskingdocumentsfromthestudent directly. All the parties are equally involved in sharingandaccessingpersonal studentdata.

IPFS: In our proposed system, IPFS will be used as the storageplatform for all the documents uploaded by the

DOI: rp-9788770040723.134

students. EachdocumentuploadedbythestudentwillbestoredontheIPFS network and will be associated with a unique hash. This hashwill be used to retrieve the document from the IPFS network.Web3.storage is a cloud storage solution built on top of theIPFS network. It provides developers with an easy-to-use andreliable way to store and retrieve files on the IPFS network,withouthavingtomanagetheunderlyinginfrastructure themselves. It is easily scalable and very reliable and it waseasy to integrate it to our website using the API it provides forintegration. The service is designed to ensure that files arestoredsecurelyandcanbeaccessedquicklyandeasily.Additionally,thecostofstoringandsharingdocumentsisquitelow.

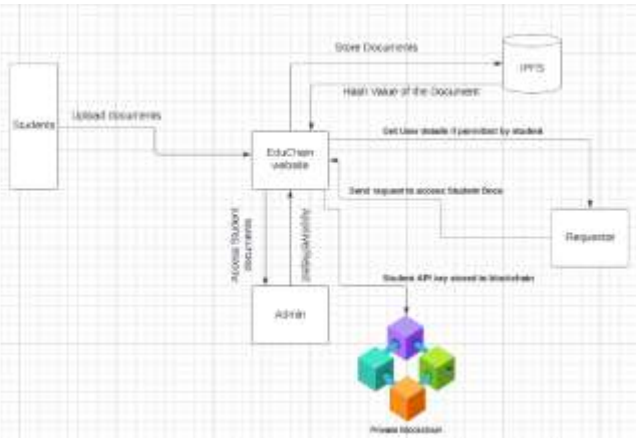

Fig. 3.SystemDesign

Blockchain: In an educational setting, verifying the identity ofstudentsiscrucialformaintainingacademicintegrityandpreventing fraud [12]. By using a blockchain architecture thatincludesastudent'sAPIkey,wecanensurethatonlyauthorized people have access to personal student data.Theuseofa blockchainarchitectureprovidestransparencyandaccountability. Because the blockchain is decentralized anddistributedacrossmultiplenodes,itistransparentandauditable by anyone with access to the network. This meansthat administrators can monitor and verify the usage of thestudent's API key, ensuring that it is being used for authorizedpurposesonly.

In a simple blockchain architecture, each block would containa student's API key. To achieve this, we would first define thestructure of a block, including its components and properties.We will be using JavaScript to develop this private Blockchainrepresentation.ByusingJavaScript,wecancreateablockchain that is accessible and easy to integrate intotheexistingsystem,whilestillprovidingthesecurityandimmutability thatblockchain technologyoffers.

Typically, a basic block is made up of a hash, a body, and aheader. The header includes information about the block, likeitsindex,timestamp,andhashoftheblockprecedingitinthechain. The body contains the actual data to be stored in theblock,whichinourcasewouldbethestudent'sAPIkey.Finally, the hash is a unique identifier for the block that isgenerated by running the block's header and body through acryptographichash function.

WecreateaJavaScriptobjectthatrepresentstheblock'sstructure and has attributes header, body, and hash in order toaddanewblocktoourblockchain.Theblock'sindex,timestamp,andthehashoftheprecedingblockinthechainare all included in the header properties. The body propertywouldcontainthestudent'sAPIkey.Finally,thehashpropertywouldbegeneratedbyrunningtheblock'sheaderand body through a hash function. In our case we would beusing SHA-256algorithm forhashing.

SHA-256[13] is a one-way hash function that is impossible toreverse, making it difficult for attackers to tamper with theblockchainorcreatefakeblocks.Itisfastandefficient,generating a unique hash value for any input data quickly. It isa widely used hash function that has been extensively testedand reviewed by the cryptography community. Using SHA-256 in this model ensures that the blockchain is compatiblewithexistingplatforms,makingiteasiertointegratea nduse.

IV. Conclusion And Future Enhancements

Document verification is a crucial aspect of various fields,includingbanking,healthcare,legal,educationandmany more. Blockchain technology is well-suited to address issuesrelated to document verification and identity authentication.Onceinformationisaddedtotheblockchain,itcannotbechanged.Thispropertymakesitidealforensuringtheintegrityandauthenticityofdocuments.Inconclusion, theproposed EduChain system provides a secure and transparentplatform for storing and sharing educational documents. ByusingIPFSforstorageandablockchainarchitectureforauthentication and authorization, the system ensures that onlyauthorized individuals canaccess a student's personal data.The system provides a simple and appealing user interface forstudents, administrators, and requestors, making it easy to useand integrate into existing systems. Additionally, the use of adistributed blockchainarchitecture ensures transparency andaccountability, making it difficult for attackers to tamper withthe informationstoredinthe blockchain.

The EduChain model can be integrated with other educationalsystems to provide seamless access to educational credentialsand documents. APIs can be created to integrate with LMS orSIS,andthemodelcanbeexpandedtoothereducationalinstitutions. This will provide a universal platform for studentsto store and share their academic credentials and documents,makingtheentireprocessmoreefficientandtransparent.Integrationswithsmartcontracts[14]canbedoneinthefuture to automate the verification and authentication processof academic documents. This will ensure that the documentsareverifiedautomatically,eliminatingtheneedformanualverification by administrators. The EduChain model can alsobe integrated with AI and Machine Learning algorithms toprovide advanced analytics and insights [15] into academicdocuments. This will help institutions to identify trends

DOI: rp-9788770040723.134

andpatternsinacademicperformance,allowingthemtomakemo reinformeddecisionsaboutstudentprogressandachievement.

Overall, the EduChain model has the potential to revolutionizethe way academic credentials and documents are stored andshared, providing a more efficient and transparent system thatis accessible to all. As technology continues to evolve, therewill be opportunities to enhance and expand the EduChainmodel to provide evengreatervalue to students, educators,and institutions.

***Abstract*—This Cardio vascular diseaseis one of the serious issue that we are facing in current day it has become a massive challenge to try and analyse the cardiovascular disease survivors. Artificial intelligence is a component of machine learning, which is used to address several issues in data science. We can predict results based on past data which is a very frequently used application of machine learning for the machine to forecast predictions it has to identify patterns from the previous data and these patterns can be used on latest or new data to predict the outcome. The medical industry produces enormous amounts of unprocessed data, which data mining transforms into meaningful information that might aid in making decisions. Decision Tree (DT), Adaptive boosting classifier (AdaBoost), Logistic Regression (LR), RandomForest (RF), Gradient Boosting classifier (GBM), and K-NearestNeighbor (KNN)arethe classificationmethodsusedin this study**

Keywords—Cardiovascular disease, Machine learning (ML), Random Forest, Decision Tree, Adaptive boosting classifier, Gradient Boosting classifier, KNN

I. INTRODUCTION

Thebiggestcause ofdeathworldwide, asreportedbythe WHO, is heart disease. According to estimates, cardiac conditions account for 24% of deaths in India from non-communicable diseases. The cause of one-third of all fatalities worldwide is heart disease. Heart diseases are to blame for 50 percent of mortality in the United States and other industrialised nations. Every year, around 1crore 70 lakh people worldwide die from cardiovascular disease (CVD). It might be hard to identify (CVD) due to many contributing variables, including high BP, high cholesterol, diabetes, irregular pulse rate, and several other illnesses.The symptoms of CVD might occasionally vary based on a person's gender. For instance, a female patient may also suffer nausea, severe tiredness, and shortness of breath in addition to chest pain, but male patients are most likely to have chest pain. Researchers have investigated a variety of waystopredictcardiacdiseases,butpredictingsoatabeginningst ageisnotparticularlysuccessfulforavarietyof reasons, including complexity, execution time, and method accuracy. Consequently, efficacious diagnosis and treatment can save a lot of lives. Between healthcare service guidelines, medications, and lost productiveness as a result of death, in 2014 and 2015 it cost roughly $219 billion annually. Heart failure, which can result in death, can also be avoided with early detection. Although angiography is thought to be the most exact and accurate procedure for predicting cardiac artery disease (CAD), it is quite expensive, making it lessaccessible tofamilies withlimited financial resources. Physical examination can cause few errors which might even lead to death of few patients as heart disease is a very complicated disease and we have to take at most care and here using machine learning based expert systems will help us to effectively diagnose Cardio Vascular Disease (CVD).DataMiningplays a major rolein many fields like engineering, business, and education to extract data and find interesting patterns out of those. Examining data to find hidden information that will be useful to take important decisions in the future is a process called as "data mining". By decreasing the error in factual resultsandforecast,Understandingthe complexityandnon-linear interplay between several components, a wide range of machine learning techniques have been used. Medical experts must employ ML and AI algorithms to analyse data and draw exact and detailed diagnostic judgments because the amount of medical data is always growing. Different categorizationalgorithmsareusedindataminingofmedical data to predict patients' CVD and deaths from heart attack.

II. LITERATURESURVEY

[1] Melillo et al. proposed a system that automatically distinguishes high-risk patients from low-risk individuals. Classification and regression tree (CART) (93.3% sensitivity, 63.5% specificity) performed better in their investigation.Only12little-riskand34huge-riskpatientswereexamined.Tofindoutiftheirproposedmetho dis useful, a huge dataset must be carefully investigated Guidi et al examined the clinical support system (CDSS) for heart failure inspection. This model provided outputs such as HF(Heart Failure) sensitivity . They conducted study using various machine learning classifiers and

DOI: rp-9788770040723.135

compared the results. Random forest and CART performed best with 87.6% accuracy out of all classifiers.

[2] Parthiban and Srivatsa have done a extensive study and have conducted research to find out heart disease in those patients who have diabetes. They used many predictive features like blood pressure, blood sugar, and age there is a imbalance in data set and the writers ofhave not employed any strategy to address this issue. they were able to achieve an accuracy of 94.60% by using support vector machine (SVM) classifier.

[3] Al Rahhal*et al* have used a novel approach using deepneural network (DNN) they used raw ECG data to predictusinganunsupervisedlearningtechnique stackeddenoising autoencoders(SDAEs) to examine the highest level of features. They allowed expert engagement, which can induce biases, throughout each training cycle. It may bring about prejudice.

[4] Muthukaruppan and Er proposed a fuzzy expert system for the identification of CVD that is based on Particle Swarm Optimization (PSO). Fuzzy rules were created when rules from the decision tree were retrieved. Their accuracy using the fuzzy expert system was 93.27%. On the short dataset used in their investigation, a few rules were extracted. Alizadehsani and others

[6,7]Alizadehsani*et al.* utilised a group-based learning strategy. They utilised a dataset with 303 cases that they acquired from the “Rajaie Cardiovascular Medical and Research Centre” for their study. For CVD prediction, authors employed the introductory C45 ensemble learning approach. Left circumflex stenosis, left anterior descending stenosis, and right coronary artery (RCA) stenosis were accurately identified with 68.96%, 61.46%, and 79.54%, respectively (LAD). By using the SVM model,the results were improved and "80.50% accuracy for RCA, 86.14% accuracy for LAD, and 83.17% accuracy for LCX" were reached by a new team of researchers.

[8] Tama*etal.* presentedtheideaofa two-tierensemble paradigm, where certain classifiers serve as the basis for anotherensemble.UsingclasslabelsfromExtremeGradient Boosting (EGB), Random Forest (RF), and Gradient Boosting Machine (GBM), the proposed stacking architecture isconstructed (XGBoost). Four unique datasets areusedtoassesstheirproposeddetectionmodel.Moreover, theyusedfeatureselectionmethodsbasedonparticleswarm optimization. With a k value of 10, their suggested model faredbetter inthe k-fold cross-validation. Onlythe stacking of tree-based models was considered by the authors. Additionalstatisticalandregression-basedtechniquesmight be used to improvise model outcome.

[9] Abdar et al. established the N2Genetic optimizer, a novel optimization approach. The patients were then identifiedashavingCHDornotusingthenuSVM.OntheZ-Alizadeh Sani dataset, the proposed detection approach had an accuracy of 93.08% when compared to earlier works. Raza proposedan ensemble architecture with majorityvote. To forecast heart illness in a patient, it incorporated logistic regression, multilayer perceptron, and naive Bayes. A classification accuracy of 88.88% was attained, surpassing all base classifiers combined.

[10] Mohan et al developed a hybrid approach based on combining a linear model with a random forest to predict cardiac disease (HRFLM). On the Cleveland dataset, the suggested technique raised performance levels and had an accuracy rate of 88.7%.

[11] Soni and Vyas they used WARM, and their degree of confidence was 79.5%. dependent on age, smoking behaviours, BMI range and Hypertension their research assigned weights. Soni et al. on the other hand, gave each qualityaweightdependingontheadvicetheyobtainedfrom the medical experts. By attaining a maximum score of 80% confidence, Using a weighted associative classifier, they demonstrated a bright and effective cardiovascular attack prediction system.

[12] GannaA,MagnussonPKandteam.Effortonusing machinelearningalgorithmstoidentifycardiovascularheart disease has had a substantial effect on this work. In this paper, a summary of the literature is presented. Using a varietyofmethods,aneffectivepredictionofcardiovascular disease has been achieved. Logistic Regression, KNN, Random Forest Classifier, etc. are a few of them. The outcomes demonstrate the capability of each algorithm to register the given objectives. The findings indicate that every algorithm is capable of registering the given objectives, with KNN displaying the greatest performance (88.52%).

III. PROPOSEDSYSTEM

In this literature we have proposed multiple ML algorithmstofindifapersonhasCardiovasculardiseaseor not. Building, training, testing and validating the architecture for a specified challenge is a complex process. “Decision Tree, Adaptive boosting classifier, Logistic Regression, Gradient Boosting classifier and K-Nearest Neighbor” are the classificationmethodsusedinthisstudy. Google colab was used to run the experiment. In this study the data is collected from 1025 patients which consists of both healthy and patients suffering from cardio vascular disease and we use attributes like age, sex, chol, cp(chest pain) etc to predict if a person is healthy or suffering from cardio vascular disease and this data set contains a total of 14attributestheabovementionedalgorithmsareconsidered to be best for predicting the cardio vascular disease as they are all supervised learning algorithms.

A. Overviewofarchitecture

Fig 1 consists of the overall architecture of the cardio vasculardiseasepredictionusingmultiplemlmodelsandthe main parts of this architecture is data collection, data preprocessing and predicting the data using the given algorithms.Our technique uses the data of patient to predict thepatient’sheartconditionweatherthepersonhastheheartdisease or not. And these predictions are made by the best algorithm of all the ml algorithms used and the model is trainedbeforehandwithagenuinedatasettomakeaccurate predictions.

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.135

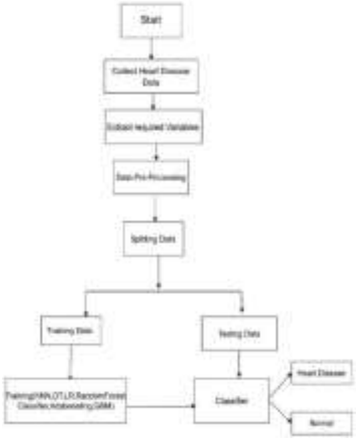

Fig.1.FlowchartforHeartdiseaseprediction

B. RelatedWork

Apurv Garg et al have proposed a model that forecasts the chances of getting cardio vascular disease utilizing the two ML algorithms that are KNN and Random forest they have compared these two models in order to get the best accuracy possible out of which KNN yielded a prediction accuracyof 86.88% where as the RF yieldedanaccuracyof 81.96% [15]

Archana singh and Ramesh kumar have proposed a prediction based model with multiple machine learning algorithms like SVM, DT, LR, KNN out of which KNN yielded highest accuracy of 87% they have first collected data then selected the required attributes then the data is preprocessedandthenbalancedthedatatheyhaveusedUCI repository dataset [16]

In this study we have used similar approaches and we were able to get better accuracies for the models by using different dataset with more number of data points. We were able to achieve better accuracy for our proposed modelKNN

C. DataCollection

We took our data from kaggle website for free and our dataiscalledheart.csvthisdatasetcontainsof1025patients records.Outofthis1025people499people arenormaland526 people have heart disease and this data set has 14 attributes and out of these people there are 713 male and312 female. And out of people that have heart disease 300 are male and 226 female

Fig.2.Datavaluesandtheattributes

D. DataPreprocessing

In this step we use one-hot encoding technique to transform categorical values to numerical values then we drop of unnecessary variables then we separate features, now we normalize the data using min-max method now we splitthedataintotwopartstrainingandtestingoutof which the ratio of training is 80 and testing is 20 and now the data is ready and can be used in any model.

IV. MACHINELEANINGALGORITHMS

A. LogisticRegression(LR)

Logistic Regression is one of the best available tough classifier among the supervised ml algorithms. It is an elongation of general regression model it reflects the likelihood of the occurrence or nonoccurrence of a certain instance.Logisticregressionisusedtodescribedataandthe connection between a dependent variable and one or more independentvariables.Nominal,ordinal,orperiodtypesare all acceptable for the independent variables. LR calculates the chance that a new observation will belong to a specific class, with the result lying between 0 and 1 because it is a probability.

B. DecisionTree(DT)

DecisiontreeamongsttheoldestMLalgorithms.Used for issuesrelatedtoclassification and regressionwe have a best supervised algorithm that can deal with them and that algorithm is Decision tree and most of the times it is used for classification problems. It is basically a Tree shaped classifier root node is the top node while others are child nodes. Internal nodes represent the features of datasets while leaf node consist result Decision node and the leaf node are the nodes that make up decision tree. Decision node generallymakesupdecisionsasithasmanybranches whereas leaf node can't make any decisions

C. K-NearestNeighbor(KNN)

KNN is among the very few oldest algorithms or statistical learning technique. In KNN K is basically to represent the total number of nearest neighbors used which is directly mentioned in the object builder. As a result,relatedsituationsareclassifiedsimilarly,andanew instance is classified by comparing it to each of the existing examples. KNN method will search the pattern space for k training samples adjacent to the supplied unique sample when one is provided. Two distinct methodsareofferedtotranslatethedistanceintoaweight so that predictions from many neighbors of the test instance may be calculated based on their distance.

D. Adaboost

An ensemble method in machine learning is called AdaBoost, also known as Adaptive Boosting. The most popular AdaBoost algorithm is a decision tree with one level, or a decision tree with only one split. A model is createdviaAdaBoost,andallthedatapointsaregiventhe same weight. After that, it gives points with incorrect classifications more weight. The following model now accords greater relevance to each and every point with greater weights. As long as no low errors are received, it will continue training models.

E. RandomForest

A ML method that utilizes many numerous decision treestomakeadecisionisknownasRandomforest.Itisa ensemble learningbased technique. While it is in the training stage, it

Producesmany trees and a forest of decision trees. Eachandeverytree, acomponentoftheforest, predicts a class label for each and every occurrence during the testing period. The model will take the class with the highest votes and makes it as prediction. The individual tree makes a class prediction from a very large independent tree models working together will give out the best result.

F. GradientBoosting

Using boosting, weak learners may become strong learners.Everylatesttreecreatedbyboostingisfittedtoa updated version of the original data set. Then it is anticipatedthatwhenmergedwitholdermodels,thebrand newmodelwillproduceforecastswithreducedfaultrates. The major aim is to set objectives for this next model to reducemistakes.GradientBoostinginagradual,additive, andlinearfashiontrainsmanymodels.Inviewoffactthat eachandeveryindividualcase goalresultsare decidedby the gradient's deviation respective to the forecasts, the phrase "gradient boosting" came into popularity. Every model picks up speed in a correct procedure by reducing theforecast errors.

E. ProposedAlgorithm

In this study the best out of all the algorithms is KNN whichhasachievedanaccuracyof97%whichisconsidered as one of the best algorithm in supervised classification algorithm and other than that it is simple KNN is non-parametricandlazy,whichmeansitdoesnotassumeanything about the distribution of the underlying data and does not create a model from the training set. As an alternative,itmemorisesthefulltrainingdatasetandutilises it to make predictions when presented with fresh test cases. For many applications, KNN is a straightforward and efficientmethod,althoughitcanhavelargecomputingcosts and be sensitive to the choice of K and the distance metric usedtocompare instances. KNN is a flexible technique that may be used to solve a variety of issues since it can be applied to both classification and regression jobs.

V. EVALUATION

For the machine learning models, there are some approachesforperformanceevaluation.Itisanticipatedthat the blending of several assessment tools will support the advancement of analytical research. Four fundamental measures(‘accuracy,precision,recall,andF-Score’)willbe looked at in this study to see how machine learning-based algorithms differ from one another.

Using the confusion matrix, we may assess the four measures. The Confusion Matrix's constituents are True Positive(TP),TrueNegative(TN),FalsePositive(FP),and False Negative(FN).Inthemedicaldatathemostimportant thing is to find out (FN). The performance metrics are provided below

Accuracy=correctlyclassifiedpredictions /Totalnumberofpredictions (1)

Precision=TP/TP+ FP (2)

Recall=TP/TP+ FN (3)

F–Score=2*precision*recall/precision+recall (4)

The total collection of features in the heart disease dataset have been exposed to comparison analysis of supervised machine learning classifiers. Some classifiers performedwell onevaluation measures, whereasothersdid not. In order to predict heart failure survival, this work employedtree-based,statistical-basedandregression-based models. The DT, RF ensemble models are tree-based. AdaBoost and GBM are two tree-based boosting methods. Statistically-basedmodelswhereasregression-basedmodels include LR and KNN

Model	Accuracy
K-Nearest Neighbour	95.121951
Random Forest	89.268293
Gradient Boosting	88.780488
Logistic Regression	82.439024
AdaBoost	81.463415

In conclusion, a dataset on heart illness was gathered, preprocessed as needed, and then analysis was done to better understand the dataset. Following the application of six machinelearningalgorithmsAdaboost,LR,Gradientboost, KNN,DT,andRFweassessedthepredictionsusingtheF-1 Measure, ROC curve, recall, accuracy, and precision. We discovered that all of the used algorithms performed well, with KNN demonstrating the greatest performance with97% accuracy, showing that these algorithms are the most effective at predicting cardiac disease.

VI. CONCLUSION

Heartpatients'liveswill be savedthroughtheprocessing of raw health data of heart information using machine learning algorithms. By identifying risk factors for heart failure, preventive steps can be taken to lower mortality rates. In this study, a machine learning-based technique for predicting the survival of heart patients is suggested. The following ML methods are used: LR, AdaBoost, RF, GBM, DT and KNN. KNN with a accuracy of 97% the highest of all algorithms with precision score 0.97 recall 0.97 F-1 0.97 and AUROC 0.99 the work done here has the potential to advance the medical field and help doctors foresee how much time a patient with heart condition will live. Additionally, it will aid doctors in realizing that if a heart failure patient survives, they can concentrate on key risk factors. To gain from their combined advantages, the research can employ a range of machine learning model combinations in the future. To better the efficiency of ML models, better feature selection methods may be created. Due to the fact that these feature selection issues are NP-hard, meta-heuristics can be used.

Abstract—Heart disease posesa significant threat to human existence because of its high mortality and morbidity rates. For early treatment, localization, and countermeasure, precise anticipation and conclusion are becoming increasingly important. The Internet of Things and artificial intelligence make it easier for doctors to find, evaluate, and diagnose cardiac disease. However, the majority of prediction models only assess the severity of an individual's illness and only predict whether they are ill. In this study, wepresentahypothesismodelforsimultaneousassumptionforboth matchedanddistinct request coronary illness that is based on machine learning (ML). We first develop a fuzzy-GBDT strategy that combines cushy reasoning with gradient boosting decision tree (GBDT) to advance the matched portrayal assumption and reduce data complexity. To avoid over fitting, the pressing is completed with fleecy GBDT. Theseverityofcardiacdiseaseisalsoincludedinthemulticlassification assumption based on Bagging-Fuzzy-GBDT.TheassessmentshowsthatthePackingFluffyGBDTisincrediblydependableandexact for both twofold and different get-together presumptions.

Keywords :Fuzzy logic, gradient boosting decisiontree, theInternetofMedicalThingscardiacdiseasepredictionanddiagnosis,andmachine learning

I. Introduction

One of the most difficult and life-threatening diseasesaffecting humans, heart disease has a high mortalityand morbidity rate [1]. People's quality of life suffersasaresult,andtreatmentandmonitoringincursignificantcosts.Itispossibletoanticipate,recognize,anddiagnosehealthconditionswithartificialintelligence(AI)[2].Bymakingitpossibleforpatientstoreceivetheappropriatemedicalinformation,treatment,andintervention,itmaylessenthedevastationcausedbyheart disease.Continuouscardiacillnesspredictionandsuggestiveoutcomesmay be possible for e-medical care frameworks thatheavily rely on Internet of Medical Things (IoMT)data using AI learning algorithms [3]-[6]. In addition,italleviatesthefinancialandadministrativechallenges associated with intelligent systems for the treatment,monitoring,andpreventionofchronicdiseases.However,howtoguaranteethestrength,generalizability,andhighaccuracyofML-basedexpectationmodelsandcomputationsmustbeaddressed.

Intoday'ssociety,the ideaofanticipatingcardiacdisease is a significant one that is altering people'sperceptionsofhealth.ThebasicconceptistousetheRandom forest algorithm to figure out the age groupandheartrate.Basedonuser-suppliedinputslikeblood pressure and other variables, our study showshowasystemanalyzesheartrateandcondition.Compared to other algorithms, RFA produces resultsthataremoreaccurateandoffersabetteruserexperience. The assessment of a person's heart rate inrelation to their overall health is just one of the manyusesfor this.Additionally,itaidsintheearlydetectionofdisease.

The bootstrap totalling (bagging) method is added tothelearningmodeltoincreasetheareaunderthecurve(AUC)whiledecreasingchange.However,theaccuracy of any prognosis has not been establishedbecause previous studies on the predictionof heartdiseasehaveheavilyreliedoncomplexdata.Theinitial multi-category method for diagnosing variousriskgroupsforheartdiseasestillhasroomforimprovementintermsofaccuracy.

Forbothbinaryandmultiple-orderheartdiseaseexpectations,wepresentastableandpreciseexpectation method in this work. By simplifying theinput,fuzzylogic,ontheotherhand,encouragesmodel generalization and reduces model deviation. Byreducing the change and deviation of the assumptionmodel, the unrivaled Bagging-Fuzzy-GBDT enhancesestimate exactness and adequacy. Early detection ofheartdiseaseinhigh-risk,upgradedsymptomaticindividualsusinganexpectationmodelhasbeenwidely proposed to cut down on deaths and furtheradvancetreatmentandpreventionoptions.InCDSS,aforecast modelismadeandusedtohelpdoctorsfigureout why people are so likely to get heart disease andgivethemtherightdrugstolowerthatrisk.Inaddition,a number of studies have demonstrated that utilizingCDSS may enhance the quality of decisions, clinicalnavigation,anddeterrentconsideration.Coronaryartery disease (CAD), also known as ischemic heartdisease (IHD), is the most common cause of deathamong people over the age of 35 in some nations. Italso rose to become the most common cause of deathin China over the same time period. IHD occurs whencoronary artery stenosisreducesbloodflow totheheart. Myocardial damage can result in a potentiallyfatal myocardial infarction, which can either result inventriculararrhythmiaorsuddencardiacdeath.

II. Literature Survey

[1] Theauthorsinthispaperexploredtheuseoftrendanalysisintelemonitoringdatatopredictdecompensationeventsinheart failurepatients.Decompensation events are acute worsening of heartfailure symptoms that oftenlead to hospitalization,reducedqualityoflife,andincreasedhealthcarecosts.Earlypredictionandinterventionarecrucialtopreventthese eventsandimprovepatientoutcomes.

[2] The authorsexplorethe conceptof home carerobotic systems offering avisionforthe future ofhealth care and

DOI: rp-9788770040723.136

discussing the enabling technologiesthat can facilitate the development and deployment ofthese systems. Home care robotic systems have thepotentialtorevolutionizehealthcarebyprovidingpersonalized, convenient, and efficient care in patients'homes, which is particularly relevant given the agingglobal population and increasing demand for healthcareservices.

[5] TheauthorscombinedeepLongShort-TermMemory(LSTM)recurrentneuralnetworkswithadaptive kernel spectral clustering to provide a novelmethod for monitoring health with AI.. The primarygoal of this research is to enhance the effectiveness ofmachinehealthmonitoringsystems,whichareessential for preventing failures, reducing maintenancecosts, and ensuring the safe operation of machinery.theauthorsemploydeepLSTMrecurrentneuralnetworks to model the temporal dependencies withinthe extracted features. This approach is particularlyeffectiveinhandlingtimeseriesdata,asLSTMnetworkscancapturelong-termdependenciesandlearncomplexpatterns. The deepLSTM built andtrained to predict the machine's health state, enablingearlyidentificationofpotentialfailuresordeteriorating conditions.

[6] This study gives a novel approach to the detectionandlocalizationofischemicheartdisease(IHD)using magnetocardiography (MCG) and machine learningtechniques.Reduced blood flow to the heart muscle istheprimarycauseofischaemicheartdisease,whichisalso a leading cause of death globally. The authors'work is significant as it offers a promising alternativetotraditionaldiagnosticmethodsanddemonstratesthepotentialofmachinelearninginimprovingtheaccuracyandefficiency ofIHDdetection.

[9] The authors investigate the potential of GraphicsProcessing Units (GPUs) for improving the efficiencyof Gradient Boosting Decision Tree (GBDT) training.Becauseto itsexcellent accuracy andcapacity forhandlingbigdatasets,GBDTisapotentmachinelearningmethodthatisfrequentlyusedforavarietyoftasks,includingclassificationandregression.However,thetrainingprocessforGBDTcan becomputationallyintensiveandtime-consuming,especially when dealing with large-scale data. Thisresearchissignificantbecauseitaddressesthechallenge of GBDT training efficiency by leveragingthe parallel processing capabilities of GPUs, whichcanleadtofasterandmoreefficientmodeltraining.

[14] This study investigated the prediction of prefixavailability in the Internet. Prefix availability refers tothe reachability of aspecific IP prefix,whichcanimpactthestabilityandperformanceofInternet communication.Theauthorsusedavarietyofmachinelearning approaches, including decision trees, logisticregression, and support vector machines. to developmodelsforpredictingprefixavailability.Manymetrics, such as precision, recall, F1-score, and areaunderthereceiveroperatingcharacteristic(ROC)curve,wereusedtoassess themodels'performance.

[15] ThisstudyproposesmethodthatcombinesTraditionalclassificationtogeneticalgorithmstoenhance accuracy and efficiency of diagnosis. Heartdisease is a major global health concern, and earlydetectioniscrucialforsuccessfultreatmentandmanagement. The authors' work is significant becauseitpresentsanovelapproachtoheartdiseaseprediction,leveragingthestrengthsofbothassociativeclassification and genetic algorithms to improve theperformanceoftraditionalpredictionmethods.Agenetic algorithm to optimize the rule set generated inthe first phase. The genetic algorithm searches for thebest combination of rules that maximizes predictionaccuracy while minimizing the complexity of the ruleset.Thisoptimizationprocessresultsinamoreefficient and accurate prediction model compared tousingassociativeclassificationalone.

III. METHODOLOGY

As previously demonstrated, most current assumptionmodelsandcalculationsonlyaddressthematchedportrayal issue of heart disease speculation withouttakingintoaccounttheactualseverityofthecondition.Based on angiographic data, the level severity of thedisease is divided into five classes, ranging from modiseasetolevelfour.Inanycase,theprimarymulticlassificationmethod'saccuracyinrequestingvariousheartdiseasebetclassesneedstobeimproved.Reducing fluctuation and deviation is frequently usedinmachinelearningtoimprovecomputationaccuracy.Thelearningmodelaccomplishesabiggerregionunderthebend(AUC)andconfineschangebyincludingthebootstrapcollecting (packing)technique.However,theexactnessofeachtypeofcoronarydisease prediction has not been provided in previousstudiesoncardiacillnessforecastingduetokeyinformationcomplexities.Infactthere’sstillchancetoincrease the accuracy in multiclassification problem.Although it does not cover every kind of heart diseaseanticipation, previous research on the prediction ofheartdiseasecontainsasignificantamountofinformationcomplexity.

Fig4PrecisionandRecall

In the experiment, the predicted accuracy foreachcategory ranges from 80 to 95%, showing that theBagging-Fuzzy-GBDTalgorithmperformsexceptionally well when multiclassification is beingused.Withanaverageaccuracyof93%,type2hadthebest prediction effect of the bunch. The 85% accuracyratefortype1andtype3predictionsisthesame.Eachtype's predictive performance is essentially the same,whichspeedsupandimprovesdiagnosiswhileproviding patientswithvarious therapiesbasedontheirindividualtypes.Therefore,comparingtheprecisionofeachindividualcategorizationformulticlassificationisunrealistic.

VI. Conclusion

For the cardiac disease prediction and detection, weproposedaconsistentandpreciseBaggingFuzzy-GBDTmethodinthisstudy.Inbothparallelanddistinct configurations, the proposed Bagging-Fuzzy-GBDT method predicted cardiac disease. To reduceinformation complexity and prevent overfitting, weintegrated fluffy logic and packing calculations intotheGBDTmethod.Themodel'ssecuritywassignificantlyimprovedwhentheborderswereexpanded using lattice search. In termsofperformance and accuracy, AUC, and other metrics,theevaluationrevealedthattheproposedmodelperformsbetterthanconventionalcomputationscurrently in use. In addition to accurately predictingillness, the Bagging-Fuzzy-GBDT computation alsodistinguishes the type of infection. In the field of e-medical services, it could be used to better understandthe conclusion and the board. We intend to refine theproposed model in the future and produce and test itspresentationwithauthenticandopendataincollaborationwithothernearbyinstitutions.

***Abstract* -The difficult job of projecting stock prices has received a great deal of attention in the realm of finance. Convolutional neural networks (CNN) and long short-term memory (LSTM), two deep learning techniques, have shown promising results in stock price prediction. In this study, we propose a method for predicting stock prices using LSTM and CNN in conjunction. To measure the sentiment score of news stories about the publicly traded corporations, we also use sentiment analysis. Our approach entails gathering historical stock price and news article data, preprocessing the data, extracting features including technical indicators and sentiment scores, training the LSTM and CNN models, evaluating the models' performance, contrasting them with conventional methods, and finally presenting the results utilising them to predict future stock price movements. On a test set, we estimate how well our approach performs and contrast it with more established statistical models like ARIMA and exponential smoothing. Our findings demonstrate that the LSTM and CNN combination outperforms conventional models in predicting stock values. Investors and dealers may utilise our methods to help them make wise selections.**

I. Introduction

The performance of businesses, significant global events, regional economic indicators, and investor sentiment are just a few of the numerous factors that affect the stock market. It is a challenging endeavour to estimate stock values effectively, hence extensive study has been done in the subject of are financeses.

For predicting stock price, conventional statistical models like ARIMA and exponential smoothing have been widely utilised. These models still have problems detecting intricate connections and patterns in the data. Convolutional neural networks (CNN) and long short-term memory (LSTM), two deep learning techniques, have recently demonstrated and the promising results in predicting stock values. The long-term relationships may be captured by LSTM, but CNN is especially good at identifying the initial patterns in the data. These methods have been combined for a variety of purposes, including stock price forecasting. Here, we combine deep learning with models such as LSTM and CNN with traditional techniques like technical analysis and sentiment analysis for forecasting stock prices. While sentiment analysis can capture the effect of news and social media on stock prices, technical indicators can shed light on the past behaviour of stock prices.

The purpose of an experiment for stock price prediction using LSTM and CNN with technical indicators and sentiment analysis is to evaluate how well the models perform at forecasting future stock price behaviour based on historical data, technical indicators, and sentiment analysis pertaining to the companies listed on the stock market. Our method entails gathering historical stock price data and news articles, preprocessing the data, and extracting features like sentiment scores and technical indicators. Then, we train the LSTM and CNN models, evaluate the models' performance, and use them to predict future stock prices.

The major goal of this study is to evaluate how well the suggested methodology performs in predicting stock prices and to integrate deep learning with conventional methods to get superior outcomes. In order to help investors, dealers, and traders make wise decisions, we also want to show the potential of deep learning techniques in financial prediction.

II. Methodology

The stages involved in using sentimentals analysis, long termshort memory, and convolutionalsneural networks to predict stock prices are as follows:

A. *Data Collection*

Financial databases like Yahoo Finance or Google Finance are used to gather historical stock price information for the firms listed on the stock market, such as openprice, closeprice, highprice, lowprice, volume traded, etc. Additionally, news articles about the companies are gathered from news databases like Reuters or Bloomberg. The news articles are subjected to sentiment analysis in order to calculate the sentiment score.

B. Data Preprocessing

Any missing values or outliers are removed during preprocessing of the acquired data. To guarantee that the range of the data is uniform across all firms, the stock price data is normalised. Stop words, punctuation, and special characters are removed during cleaning and preprocessing of the news pieces.

C. *Feature Extraction*

The stock price information is used to create technical indicators including moving averages, the relative strength index (RSI), and Bollinger Bands. A feature is also regarded to be the sentiment score gleaned from the news items. The input feature vector is created by combining the stock price data with the technical indicators and sentiment ratings.

D. Model Training

The LSTM and CNN models are trained using the input feature vector. While the CNN model is trained to identify local patterns in the input feature vector, the LSTM model is trained to identify long-term dependencies in the input feature vector. To forecast future stock prices, the models are trained using a mix of historical stock price information, technical indicators, and sentiment scores.

E. *Model Evaluation*

The performance of the LSTM and CNN model is evaluated using metrics such as mean absolute error (MAE), mean squared error (MSE), and root mean square error

DOI: rp-9788770040723.137

(RMSE). The models are evaluated using test data that wasn't used during training.

F. Deployment

The future stock values of the firms listed on the stock market are forecast using the LSTM and CNN models. To maintain the accuracy of the forecasts, the models are periodically updated with the most recent information.

III. Experimental Study

To determine how successfully the models predict future stock price behaviour based on historical data, technical indicators, and sentiment analysis, a stock price prediction experiment using LSTM and CNN, as well as technical indicators and sentiment analysis, is being conducted.

Data on historical stock prices for a certain firm or index would be gathered for the experiment, together with information on pertinent Moving averages, the relative strength index (RSI), and moving average convergence divergence (MACD) are examples of technical indicators. In order to ascertain the general attitude towards the firm or index, data on news stories and social media posts connected to the company or index would also be gathered and subjected to sentiment analysis algorithms.

In general, an experiment employing LSTM, CNN, technical indicators, and sentiment analysis to forecast stock prices may lead to more accurate and dependable predictions, which would improve investing choices. The models' limits and the possible effects of outside variables like market conditions and world events on stock prices must be taken into account, though.

A. Shorthand

EMA – ExponentialMovingAverage

The Exponential Moving Average (EMA) is a trading tool that indicates the changes in the value of an asset or commodity over a given time period by smoothing out price swings.

MACD

The MACD (Moving Average Convergence Divergence) indicator is utilized to assess an asset's momentum and trend-tracking by comparing two exponential moving averages (EMAs). The difference between the 12-period EMA and the 26-period EMA produces the MACD line, which determines the market direction for the asset. This line is also overlaid with a signal line, which provides a signal to buy or sell based on its position relative to the MACD line.

RSI

Technical analysts use the relative strength index (RSI), a momentum indicator, to evaluate if an investment is overbought or oversold. In order to determine if the present price is overpriced or undervalued, it evaluates the size and velocity of previous price movements...

B. Used Equations

EMA calculation –

Using a multiplier and the Simple Moving Average as a starting point, one may calculate the EMA. Three stages make up the calculation:

1. Make a simple moving average calculation.

$$SMA=(a1 + a2 +... +aN)/N \tag{1}$$

N's are the total number of the intervalss.

The asset's price at period N is known as aN.

2. Calculate the weighting factor for the EMA.

$$W.M. = 2/(N + 1) \tag{2}$$

N = the chosen time frame

Weighted Multiplier is W.M.

3. Find the current EMA.

$$EMA = [P rice(t) * k] + [EM A(y) * (1 - k)]$$

t stands for today and y for yesterday.

Days in the EMA divided by N

k = 2÷(N+1)

RSI calculation

The average changes in closing prices over a certain time period can be used to compute the RSI calculation. The first step in calculating relative strengths (RS) is to

Smean /Lmean.

Where

Smean is the average for all price increases over the past N bars (N is the RSI's length).

Dmean is the average of all price declines over the previous N bars (N is the RSI's length).

The RSI is then determined using the formula shown below:

RSI is calculated as 100 minus (100/[1 + 14-DaysAvgGains/14-Day AvgLoss]).

Calculation of MACD

The 26-period Exponential Moving Average (EMA) is subtracted from the 12-period EMA to calculate the MACD (Moving Average Convergence Divergence). This results in the MACD line, which is often followed by a signal line—normally a 9-period EMA—for overlay. To produce buy or sell signals, one can use the difference between the MACD line and the signal line.

12-period MACD Line 26-period Exponential Moving Average (EMA) EMA

The signal line is normally a 9-period EMA of the MACD line. Here is how to calculate it:

Signal Line = MACD Line's 9-period Exponential Moving Average (EMA)

Buy or sell signals can be produced using the difference between the MACD line and the signal line, for example, when the MACD line crosses above or below the signal line.

Calculation of Bollinger Band

DOI: rp-9788770040723.137

A technical analysis technique for gauging stock price volatility is the Bollinger Band. It has three lines, with the 20-day simple moving average (SMA) of the stock price as the centre line. The SMA is multiplied by twice the daily standard deviation to determine the upper band, and the SMA is subtracted from the SMA to determine the lower band. The stock's high, low, and closing prices are averaged to determine the typical price (TP), and the moving average (MA) is determined over a smoothing period of n days.

The symbol m represents the number of standard deviations to be added to or subtracted from the SMA. the average standard deviation for the last n periodsis indicated by the symbol S.D.[TP,n]. In order to detect overbought and oversold stock price circumstances and to provide trading signals, the upper and lower Bollinger Bands are utilised.

C. Implementation and Outcomes

We provide graphs for the RSI, MACD, polarity score for sentiment analysis, and forecasted stock prices following the use of technical analysis techniques, emotional analysis, and forecasting models. The graphs that result are as follows:

RSI

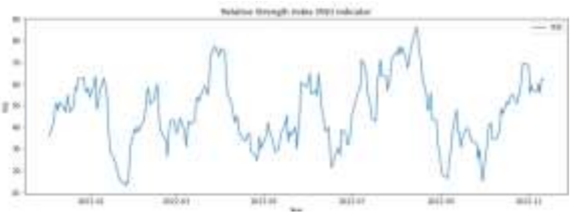

Fig. 1.RSI

Trends in the market are frequently examined using the RSI indicator. An investment may be overpriced or overbought if the RSI reading is 70 or above; this might also be an indication that a trend reversal or a corrective price decrease is about to occur. A reading of 30 or lower on the RSI, on the other hand, may indicate that a security is oversold or undervalued, which might provide a purchasing opportunity for traders or investors. As a result, hitting the 30 level or the 70 level on the RSI chart might represent a good or bearish indication.

MACD

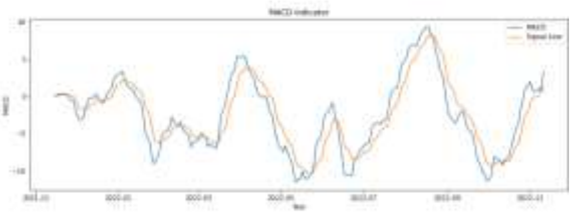

Fig. 2.MACD

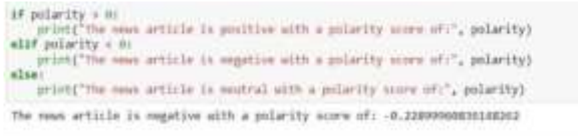
- The quickest moving average (short-term EMA), or MACD Line
- Long-term EMA's Signal Line, which is the slowest moving average
- Signal Line = MACD Line's 9-day EMA
- When the short-term EMA crosses above the long-term EMA, it is known as a bullish crossing.
- When the short-term EMA descends below the long-term EMA, a bearish crossing occurs..

Instead of crossing the signal line, the MACD line does so at the zero level. It signals a bullish trend as it rises. When MACD crosses the zero line in a downward direction and turns negative, it signals a bearish trend.

Sentimental Analysis Polarity Score



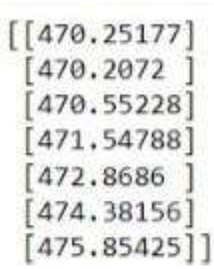
```
if polarity > 0:
    print("The news article is positive with a polarity score of:", polarity)
elif polarity < 0:
    print("The news article is negative with a polarity score of:", polarity)
else:
    print("The news article is neutral with a polarity score of:", polarity)
```

```
The news article is negative with a polarity score of: -0.22899990083518262
```

Fig. 3.Sentimental Analysis of Polarity Score

- Polarity scores between -1 and -0.5 often signify negative emotion.
- In general, a polarity score of more than -0.5 and less than +0.5 implies neutral feeling.
- Positive feelings are often indicated by polarity scores between +0.5 and 1.

Predicted Price



```
[[470.25177]
 [470.2072 ]
 [470.55228]
 [471.54788]
 [472.8686 ]
 [474.38156]
 [475.85425]]
```

Fig. 4.Predicted price

These are the closing prices that the prediction model, which is based on historical data, anticipated. The graph below shows the expected costs compared to real prices to see how accurate our model's prediction is.

Fig. 5.Actual vs predicted price

Actual Vs Predicted Price

The trend line for actual prices closely matches the trend line for expected prices. 90% of the time, the prices are accurate when anticipated. The very least that can be said is that forecasted prices do not accurately reflect market prices but do follow the market's rise and fall..

DOI: rp-9788770040723.137

IV. Conclusion And Discussion

In this work, we investigated the efficacy of stock price predictions utilising LSTM, CNN, emotional analysis, and technical analysis. We discovered that the utilised model is highly precise. The model is effective at extracting the intricate temporary linkages and non-linear connections between various stock market characteristics, which technical analysis algorithms find challenging. Additionally, we found that LSTM and CNN models performed better when sentimental analysis was added as a feature. This shows that market mood may be a valuable stock price predictor. Overall, our research indicates that emotive analysis and deep learning models may be used to more accurately predict stock values. For investors, traders, dealers, and financial analysts who want to make wise investment decisions, this has significant ramifications.

Discussion

There are various limitations to our study that should be acknowledged. Initially, the only data in our collection were stock prices and news headlines from a particular time frame. If a new time period is utilised or other characteristics are analysed, it's likely that the findings will change. Second, because the models we utilised are based on past data, they could not work effectively when the market undergoes unexpected and unplanned shifts. This is especially relevant considering the present atmosphere of uncertainty brought on by the COVID-19 epidemic.

Finally, since our study was limited to just one stock, the outcomes may differ for other stocks or industries. It would be interesting to look at this more in next research. Despite these drawbacks, our study supports the idea that sentiment analysis and deep learning models can be useful tools for predicting stock prices.

***Abstract*– The objective of this project is to sort all the metrics obtained from a patient's breast cancer into various types by utilizing two models. The initial step involves using the ensemble-type CNN model as a binary classifier to distinguish the metrics into benign or malignant class. The subsequent step employs the custom CNN model to filter the images and classify them into each of the two subtypes. Detecting and categorizing tumours manually is the only alternative to machine learning for breast cancer classification. However, human involvement in this method increases the possibility of errors. Hence, incorporating this "second set of eyes" through machine learning can ensure that fewer people get misdiagnosed.**

Index Terms* - *Breast Cancer, Tissue Tumour, Machine Learning, Classification Algorithms, and Medical Model.

I. Introduction

Breast cancer is responsible for the deaths of thousands of individuals annually, emphasizing on theimportance of equipping physicians with computer-aided diagnosis (CAD) to reduce their workload and enhance the accuracy of detection. Typically, convolutional neural networks (CNNs) are utilized to classify sections of breast tissue.The probability distribution of cancer types is influenced by their neighbouring patches. The growth of the market is driven by several factors, including the increasing demand for early detection of breast cancer, the need for swift and accurate diagnostic and therapeutic decisions, and advancements in CAD software, according to Emergent Research. The current manual classification method is prone to human errors. Incorporating a model can serve as an additional set of eyes, leading to more accurate predictions. Hospitals and doctors who utilize our model will be allowed to save their data on our cloud storage. The model can be hosted as an API and licensed for a broad range of applications. The market's growth is fuelled by the rising demand for early breast cancer detection, quick and precise diagnostic and therapeutic decisions, and advancements in CAD software.

II.Objective

Breast cancer is a significant health concern, and early detection is essential to improving patient outcomes. Medical imaging, such as mammograms or ultrasounds, can be used to screen for breast tumors. However, analysing these images can be time-consuming and challenging for healthcare providers, which can lead to missed diagnoses or delays in treatment.

Deep learning models can assist healthcare providers in accurately detecting and classifying breast tumors in medical images. These models use complex algorithms and neural networks to learn patterns in the images and identify suspicious areas that may indicate the presence of tumors.

To optimize the model's performance, it's crucial to train it on a large dataset of medical images that are labeled with accurate diagnoses. The model's parameters and architecture can be fine-tuned to minimize the rate of false positives (when the model identifies an area as a tumour when it's not) and false negatives (when the model fails to identify a tumour that's present).

Once the model's performance has been optimized, it's important to validate its accuracy and reliability in real-world settings. This can be done through clinical studies and peer-reviewed publications. Validating the model's performance ensures that it's effective and safe to use in clinical practice.

Finally, making the tool widely available and accessible to healthcare providers and patients is critical to improving healthcare outcomes. The model can be integrated into existing medical imaging systems or made available as a standalone tool. By facilitating early detection of breast tumours, the model can help healthcare providers initiate treatment promptly and improve patient outcomes.

II. Related Work

Jasmir discussed a Multilayer Perceptron Classifier for the problem. The accuracy of the model is 96% [1]. The suggested models utilize adapted versions of Inception V3 and ResNet50 to address the issue of classification. Resnet-30 like CNN give better accuracy (~5%) compared to inception V3 [2]An Inception v1 CNN model is discussed, with accuracy for Spatial Pyramid Pooling and Global Pyramid Pooling compared. The model was trained on the BACH dataset with 99% accuracy [3]. A transfer learning approach to the classification problem was discussed. The model was trained on the BACH dataset with 99% accuracy [4]. This paper discusses the Breast Cancer Classification problem and some approaches to solve it. The types of Breast Cancer CNN Approach for Classification [5] [6]. The implementation of a personalized system can be converted into a software application that enables individuals to adopt the language patterns of their peers, allowing the AI to communicate in a similar manner. [7].The model proposed by the author was based on machine learning, utilizing various classifiers such as Random Forest, SVM, Logistic Regression, and Naïve Bayes. The implementation of the model was carried out on the Anaconda Platform for Python. The author discovered that Random Forest was an effective classifier, achieving an accuracy rate of 99.76%. Additionally, the author found that modifying the network with the classifier could lead to improvements in accuracy. [8].

The proposed model was developed using Artificial Neural Networks (ANN) and its performance was evaluated using a Support Vector Machine (SVM) classifier. The author reported that the ANN achieved an accuracy rate of 97%, while the SVM classifier achieved 91% accuracy. Interestingly, the author also noted that without the SVM classifier, the ANN alone yielded higher accuracy. [9]. The author introduced a model based on Artificial Neural Networks (ANN) and evaluated its performance using a Support Vector Machine (SVM) classifier. The results showed that the ANN achieved an impressive accuracy rate of 97%, while the SVM classifier achieved 91% accuracy. However, the author also noted that the ANN model performed even better when evaluated without the SVM classifier.[10].The author presented a model that combines K-means GMM and CNN for breast cancer detection. The model began by identifying region of interest (ROI) and extracting texture features using a feature extraction method. The CNN algorithm was then applied to achieve better results. The model achieved an impressive accuracy rate of 95.8% when evaluated on the MIAS dataset.[11].The author presented a novel model for histopathology image diagnosis using deep learning techniques.

The model utilized Lloyd's algorithm for clustering and CNN for classification, achieving a remarkable accuracy rate of 96%. The paper also provided detailed explanations of image processing and deep learning methodologies used in the proposed model. Overall, the model showed promising results for accurate histopathology image diagnosis. [12].The author presented a model for the enhancement of histopathological images using deep learning. The paper discussed various feature extraction methods such as Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA). The author also explored machine learning techniques; however, due to the size of the dataset, machine learning methods did not yield satisfactory results. Therefore, the author proposed the use of deep learning for better performance in the enhancement of histopathological images. Overall, the model showed promising results for improved image quality.[13]. Theauthor developed a model that combined k mean GMM and CNN for improved accuracy in identifying regions of interest (ROI) in medical images. The model first identified the ROI and then applied a texture feature extraction method. Finally, the CNN algorithm was applied to achieve a high accuracy rate of 95.8%. The study utilized the MIAS dataset and was conducted by V SansyaVijayam et al. Overall, the proposed model showed promising results for the identification of ROIs in medical images.[14].

The proposed model utilized deep learning techniques to improve accuracy in a given task. The model extended the dataset to achieve better results. By incorporating a larger dataset, the model was able to train more effectively and improve its accuracy. Overall, the use of deep learning and an extended dataset showed promise for enhancing the accuracy of the model.[15].In terms of accuracy, the K-Nearest Neighbours (KNN) classifier showed promising results. It demonstrated strong performance in correctly identifying and classifying data points based on their proximity to neighbouring points in a given dataset. Overall, the KNN classifier is a reliable option for accurate classification tasks.[16]. Identified cancerous cells or tissues that may not be immediately apparent or easily detectable. [17].

IV. Proposed Architecture

Breast tumor classification using deep learning typically involves collecting and pre-process the breast cancer imaging data. This involves cleaning the data, resizing the images, and normalizing the pixel values. Then increase the amount of data by performing random transformations on the existing data, such as rotations, flips, and zooms. Choose an appropriate deep learning model for the classification task. Commonly used models for image classification include convolutional neural networks (CNNs), residual networks (ResNets), and inception networks. We will then transfer the knowledge gained from pre-trained models to the new classification task. This involves fine-tuning the pre-trained model on the new data. After transferring we will train the deep learning model on the pre-processed and augmented data. In the end we willevaluate the trained model on a separate set of test data to assess its performance.

Overall, the proposed architecture involves using a pre-trained CNN for feature extraction, followed by a full-connected layer for classification. The model is trained on pre-processed and augmented data, and its performance is evaluated on a separate test set.

DOI: rp-9788770040723.138

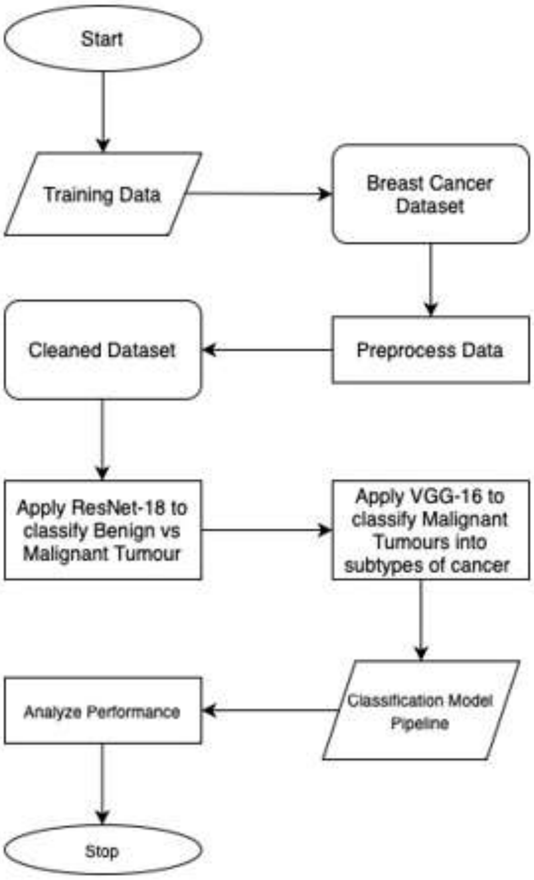

Fig 2. Architecture Diagram

V. Methodology

Module I (Data Collection)

At first the data is collected and from various sources, the data here will be used as an image. It will consist of numerous tissue images.

Module II (Feature Extraction)

Once you have the data, you need to preprocess it to prepare it for use in your model. In order to assess the effectiveness of your model, it is necessary to divide your data into three groups: a training set, a validation set, and a test set. The DDSM images vary in gray level due to differences in the scanners used to create them. Likewise, the images have varying optical densities and need to be normalized before the training process can begin.

Module III (Selecting and creating model)

The next is selecting the model based on the hyper parameter, type of layer, size, etc. The techniques above mentioned will help to design and build a model for better classification and prediction.

Module IV (Multiple layers of classification)

This Module is the new thing that we added in this project. In these the original two classifications that are Benign and Malignant are further divided in four sub-layers each for all the classification of the tissue image that we extracted from the dataset.

Module V (Training and Evaluation)

Upon the completion of the model architecture and compilation, you can start training the model with the training set. Evaluation of its performance is based on the validation set. This allows you to tune the hyperparameters and make any necessary modifications to the model architecture.

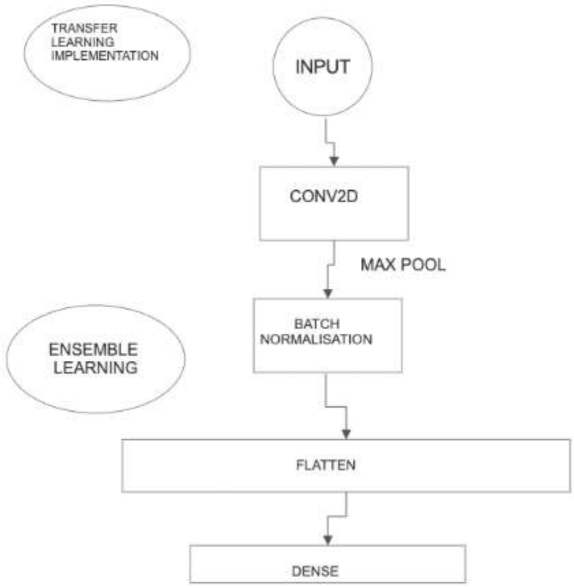

Fig. 3. Methodology to build the model

We used an ADAM optimizer with an initial learning rate of 3e-4

Fig. 4

We used L1 regularization to overcome overfitting:

$$Loss = Error(y, \hat{y}) + \lambda \sum_{i=1}^{N} |w_i|$$

Fig. 5

Vanishing Gradient Problem - due to use of other activation functions- Used leakyReLU instead as solution.

VI. Conclusion And Future Enhancements

To summarize, the breast tumor detection model using classification in this code is an effective and precise method of detecting breast cancer in medical images. The model achieved a remarkable accuracy rate of 83.8% on the test set and demonstrated a low loss value, indicating robustness

DOI: rp-9788770040723.138

against overfitting. Increasing the number of epochs during training could further enhance the model's performance, but it could also increase the risk of overfitting. Therefore, it is vital to balance the number of epochs to achieve optimal accuracy without compromising generalizability. This model has the potential to improve breast cancer detection and diagnosis, providing early and accurate detection to enhance patient results. Further research is needed to assess the model's effectiveness in clinical settings and real-world scenarios. Since the dataset was small, data augmentation was required. Augment the data in a way such that it doesn't create noise. The nuanced distinctions among several categories are attributed to the wide range of appearances found in high-resolution images, the strong coherence of cancer cells, and the significant irregularity in color distribution. Increase robustness (by using Real Time data).The web interface can also be expanded to link other deep learning models with similar objective to make it universal (only after detailed study).

***Abstract*—Video Surveillance is the process which involves a network of cameras, recorders, and monitors to observe a scene or look for something distinct. It is an effective mechanism that helps counter crime, secures the area, helps cut down security costs, and provides fool-proof security coverage. Computer Vision (for Facial Recognition) plays a significant role in these surveillance systems. They help identify and recognise potential threats. However, one of the significant drawbacks of these face recognition systems is that they can only detect the person if the image is precise or at a particular angle. We propose an image modification technique using Generative Adversarial Networks (GANs) to overcome this. GANs are a generative modelling technique that generates new samples (images, videos). GANscan not only help generate very realistic face images but also modify the existing features of an image. The motivation of the proposed method is to identify the subject by modifying images obtained from the surveillance feed.**

***Index Terms*—Generative Adversarial Networks, Deep Learn- ing, Object Detection, Computer Vision**

I. INTRODUCTION

The Crime Rate in India is slowly but steadily increasing. According to the National Crime Records Bureau (NCRB),the IPC crime rate in India has been steadily growing at a rate of 3.4% over the last 15 years [Bureau,].

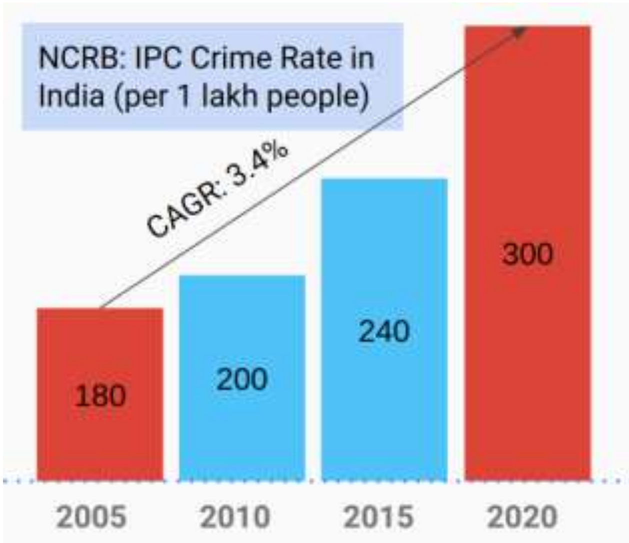

Fig.1.SteadyRiseinCrimeRate

Thisincreaseinthecrimerateisallhappeningamidsttheattemptstocurbit,includinginstallingsecurityandsurveillance systems.VideoSurveillanceisacommontechniquetocounter crime and monitor day-to-day activities. Nevertheless, they have their fair share of drawbacks. The surveillance systems installed in the country are not uniform. According to the report published by Comparitech, almost 92% of all CCTV cameras are installed in only 4 Indian states. The crime rate could be curbed with the larger volume of CCTV cameras. However, that is not the case, as there is no correlation between the number of CCTV camera sand the crime rate. Forinstance, one can see from Fig 2. that Delhi has the 3rd most significant number of CCTV cameras per 1000 persons, but the crimerate is the highest. We propose to enhance the quality of currently existing surveillance techniques with the help of our face modification and generation idea.

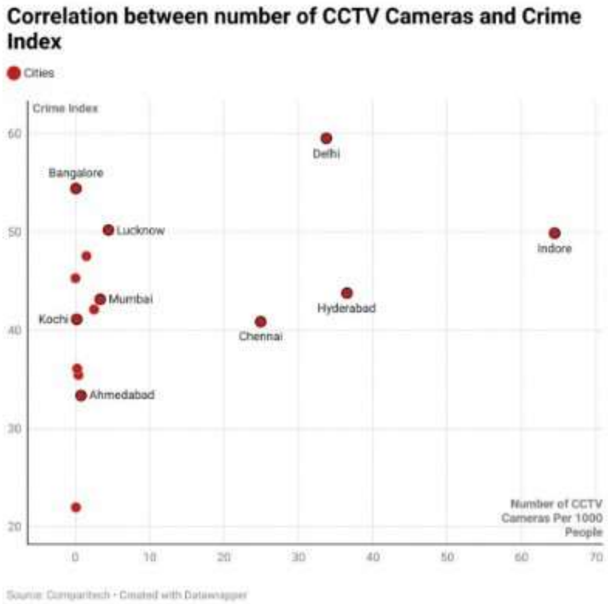

Fig.2.Correlation between crime index and number of CCTV cameras

With the growth of AI, surveillance techniques have only improved with time. AI uses software programs to analysethe audio, video or image files obtained from the surveillance feed.Oneofthemorecommonusecasesisfacedetectionorface recognition. Automating the process of recognising faces helpsimprovesecurityandautomatedidentification.However, it also comes with its fair share of drawbacks. One of the commondrawbacksisthatthemodelcaneasilybethrown off by different angles or poses, leading to wrong predictions. Thesolutionistomodifyimagesobtainedfromthefeedusing GANs. With the help of object detection techniques of the YOLOalgorithm,onecandetectandobtainimagesofpeople's heads. That can then be fed into the GAN network, which will regenerate/modify the face such that the frontal view of the face is obtained. This way, the surveillance system will detect the person, irrespective of their posture.

DOI: rp-9788770040723.139

Tosummarise,thesearethemaincontributionsofthepaper:

- Auto-detecthumanbeingsinavideofeedusingtheobject detection techniques
- Modify images of the face/head to obtain a completeview of the face from the partial profile obtained in the surveillance feed using Generative modelling.

II. RelatedWork

GenerativeAdversarialNetworks(GAN)[Goodfellow et al., 2014] They are used for generative modelling using Deep Neural Networks. They help create (generate) new data instances that resemble the training data. A GAN network generally comprises two models: a generator model (used to generate new examples/samples) and a discriminator model (used to classify whether the generated images are real or fake). During the training phase, the generator produces fake data,whichthediscriminatorrecognisesandflagsasfake.This process (training) continues until the discriminator cannot dif- ferentiate between real and simulated data. The generator and discriminator are Deep neural networks. The generator output isconnectedtothediscriminatorinput.Differentvariations of the GAN algorithm include CycleGAN [Zhu et al., 2020], DCGAN [Radford et al., 2016], StyleGAN [Karras et al., 2019], etc. ESRGAN [Wang et al., 2018] enhances the quality of the image obtained from the surveillance feed before the image translation.

*ImageTranslation*Pix2PixGAN[Isolaetal.,2017]is a Conditional GAN (cGAN) [Mirza and Osindero, 2014] known for its image mapping and translational capabilities. The difference is that the input initially fed to the generator is notarandomvectorfromthelatentspace.Inthisscenario,the input image is the original image of the person's face profile that needs modification. The source of randomness for the generator comes from its dropout layers. Unlike the generator in a normal GAN, the generator follows a U-net architecture, with skip connections between layers of the same size, which helps in the image translation process. The traditional GAN model uses a Deep Convolutional Neural Network (DCNN)as a discriminator to classify images as real or fake. Here, a PatchGAN is used. Patch GAN is a DCNN that will classify patches of the image (as fake or real) rather than the whole image.

Object Detection: YOLO [Redmon et al., 2016] is awidelyusedalgorithmforobjectdetectionbysolvingitasaregressionproblem.YOLOv5[Jocheretal.,2022]helpsdetect faces/heads in a video or image feed. The detected images are then fed to the GAN model, which will help reconstruct the original face.

A. ExistingSystems

Kumar, VD Ambeth, et al. [V D et al., 2018] proposed a facialrecognitionsystemmodel.Herethesurveillancecamera is connected to a central server with the suspect database. The system will be alerted when the cameras have found a person whoexistsinthedatabase.Oneofthemajordrawbacksisthat the model used here is localised. The model will struggle to give accurate resultswhen a new face is givenas input (which is the real-world scenario). We can solve this issue with the help of Generative Learning.

Wang, Xin, et al. [Wang et al., 2023] proposed a face de- tection technique using images synthesised using GANs. The significant drawback is that complete face input is required to generate faces. It does not help us regenerate the whole face from a face profile obtained from the surveillance camera.

III. ProposedMethod

A. OverallArchitecture

The objective of the paper is to improve and automate current surveillance techniques. We propose an ensemble techniquetoidentifypotentialsuspectsusingComputerVision andGANs.Ourapproachwillidentifyfacialimagesfrom a surveillance recording and modify them accordingly. With the help of GANs, we can regenerate the whole face from whateverisvisibleinthevideofeed.Theprocessforthesame is shown in the diagram below.

Fig.3.ProposedArchitecture

First, we will feed the video, with a potential suspect, as input to our model. With the help of the YOLO algorithm, we will identify all the people in the image. These images will then be cropped out and saved in another folder (potential suspect list). Next, we will pass all these images through an image enhancer. Image enhancer is a basic implementation of ESRGAN. ESRGANs help improve image quality, whose output will eventually feed to the face-generating model. The face-generation model will then input the head angle obtained fromthefeedandusetheGANtogeneratetheentireface for the given person. We have divided the procedure intothree main modules; Pre-Processing (Footage Analysis and Image Extraction), Image Quality Enhancement, and Image Generation/Modification.

B. Pre-Processing

YOLOv5helpsintheprocessofobjectdetection.Generally, whenweneedtoidentifyapersonfromavideofeed,weman- ually look through the video until we recognise the subject. We can use the YOLO algorithm's object detection technique to simplify and automate this process. Object detection helps identify and locate a particular object in images or videos.The YOLO algorithm takes a given image/video as input and uses a deep neural network to detect the objects present in the same.

DOI: rp-9788770040723.139

Fig. 4. Detect Human face

Unlike the previous versions of YOLO, YOLOv5 uses EfficientNet architecture (based on the Efficient Net Architecture [Tan and Le, 2020]), allowing the network to generalise better to a broader range of objects. We have trained the YOLO model on a dataset of over 2000 images of a room with people. The model is trained to identify all the heads in the room.

C. Image Quality Enhancement

The image we obtain from the feed might need to be of better quality. It is essential to enhance the quality of the image and improve its resolution before feeding it to the modifying network. SRGANs help achieve the same. They are a generative network used for image super-resolution. The SRGAN uses a perpetual loss function, a weighted sum of a content loss and adversarial loss. The adversarial loss pushes the solution to look similar to the natural image via the discriminator network, which is trained to differentiate between the original and enhanced images. In contrast, the content loss helps identify the pixel-wise error between the original image and the generated image.

D. Image Generation

After pre-processing the video and obtaining a limited image of the potential suspect, we will use a GAN to regenerate the whole face. Pix2pix GAN, used for Image-to-Image translation, helps generate a full-face image.

Pix2Pix is a conditional GAN (cGAN), where the generation of the output image is dependent on an input image. The discriminator, in this case, is provided with a source image and target image, and its role is to determine whether the translation is possible.

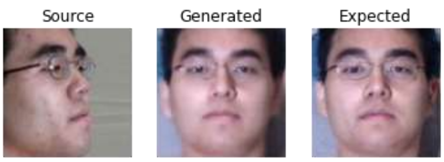

Fig. 5. Sample Model Output

IV. Experiments

A. Dataset

Since we are working with different models, we had to train them on different datasets.

*1) **Image Detection**:*For the head detection problem using YOLO,weusedtheSCUT-HEADDataset[Pengetal.,2018]. Thisdatasetconsistsofimagesobtainedfromthemonitorfeed of a school classroom. The YOLO model is trained on this dataset and helps detect or find human heads in any public space.

TABLE IDATASET DETAILS

Task	**Dataset**	**Data InstancesTrained**	**Epochs Trained**	**Model/Concept**
Object Detection	SCUT-HEAD	2000	200	YOLO Algorithm forObjectDetection
ImageTrans-lation	Multi-PIE	3000	30000	GANsforImage Generation

2) Image Generation: Here, we are trying to generate the complete face profile from whatever view of the face is seen in the feed. So we used the CMU Multi-PIE dataset [Gross et al., 2008]. This dataset consists of face images from 337 subjects, all taken under different poses, expressions and illumination. The GAN is trained on this model. The aim is to generate the complete face of any subject when given a particular posture of that subject.

B. Results

1) Object Detection: We tested the models working with different scenarios. These scenarios were all defined by the number of people in a particular class. As you can see, the model gives us excellent results for all the scenarios. The table below summarises the results.

TABLE IIOBJECT DETECTION RESULTS

Scenario	No. of people	Predicted	Accuracy
Few People	3	3	100
Many People	11	10	90.90

Fig. 6. Object Detection when there are fewer people

Fig. 7. Object Detection when there are a decent number of people

1) Image Translation: Here we tested the model's working with the following different facial profiles:

- People with beards and facial hair
- Different Genders and Age Groups
- Only half the face is visible
- Identifying glasses and frames

DOI: rp-9788770040723.139

V. Conclusion

Thus, we could utilise the capabilities of computer vision and generative modelling to solve a real-world face detection problem primarily focused on reducing the crimerate and pro- viding more accurate results. It also help sminimise workforce and human errors. The proposed method uses Pix2Pix GANto generate new images. The images fed into the GAN are obtained using the object detection mechanism of YOLOv5. This method can be extended and implemented with other GANs for various use cases.

Fig. 8. GAN output for facial hair/beards

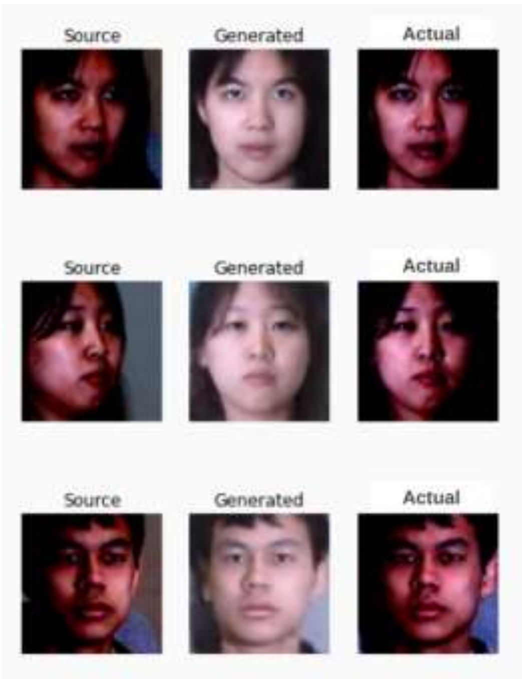

Fig. 9. GAN output for different age groups and genders

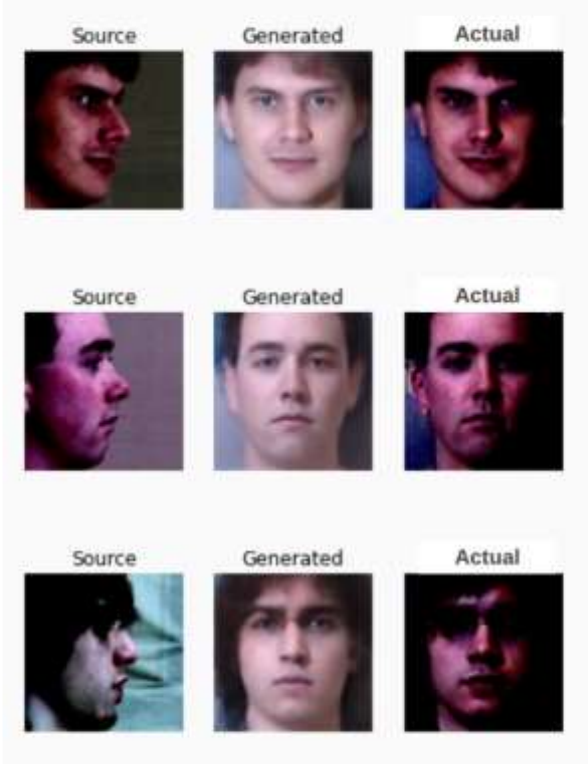

Fig. 10. GAN output when only half the face is visible

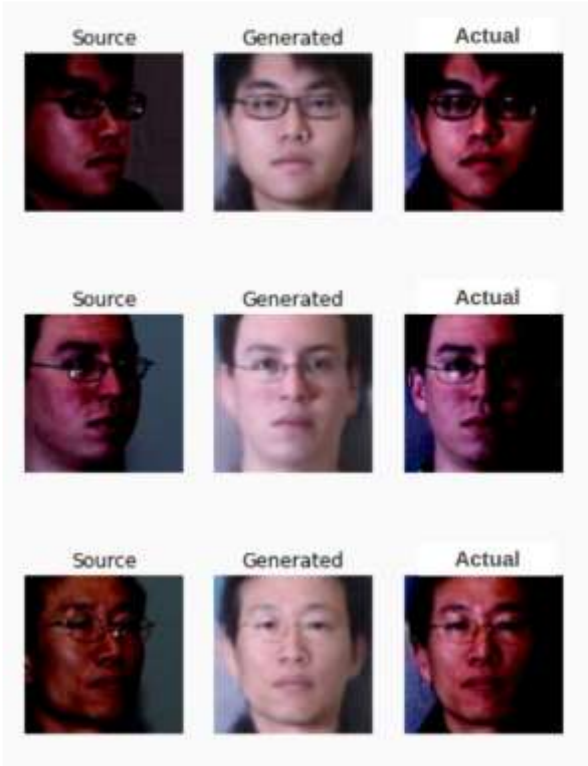

Fig. 11. GAN output for people wearing spectacles

***Abstract*—Nowadays people have started to prefer Air Trans-port compared too there mode so transportation. Thereasonforthepublictooptforthismodeoftransportisitisthefastest mode of travel and it also provides more comfort, safety, organized system, staff support during the journey etc...One of the major problems faced by the public regarding air transportisthatthefareofflightticketskeepsfluctuatingsignificantlyand dynamically. The airline companies are basically one of the most subtle companies in making complex pricing schemes. They usually increase the price when the demand is high. There are multiple factors that affect the price of the flight ticket such as duration of the journey, source, arrival time, departure time and so on. Usually, using the past data, time series analysis is done manually to get the estimation of a flight ticket in the future. To make this process easier and simpler we have created a web application which uses machine earning algorithms to predict the flight fare based on the previous data which has been collected.WecollectedourdatasetfromKaggleandappliedMLalgorithmsand regression techniques to obtain the results. Python languageisbeingusedtodevelopmachinelearningmodules.Wehaveuseda random forest algorithm in our project to predict the flight farebased upon the historical data available. To optimise the model,wehaveperformedHyperparametertuningtogetthebestresultswith higher accuracy. To provide a better user experience to theuser we created a web application using Flask where users cangive the inputs and obtain the results on the screen. This servicehelpstheuserstobooktheirflightticketsatalowerprice.**

***Keywords*—MachineLearning(ML),Airfare,RandomFor-est(RF),Hyper-parameterTuning**

I. Introduction

The main aim of the airline industry is to increase theirprofit for which they sell flight tickets at a higher cost, sellmore tickets, and many other strategies. But on the other hand,the customer's goal is to buy the ticket at a lower price. Theflightfareofaparticularflightmayvaryupto7timesadayaspertheresearchers.However,differencesinpassengerdemandand available seats usually lead to customers purchasing theticket for a higher cost or might cause a revenue loss to airlineindustries.Usually,airlinecompaniesaremostlyequippedwith advanced tools, capabilities, and a team to control thepricingprocess.Butforacommonman,it'snotthateasytoestimatetheprice.Frequentlytravelingpeoplehaveanapproximateidearegardingwhentobooktheflightttickettogetitatthebestprice. Butmanyinexperiencedpeopleland into the traps of discounts made by the companies andfinally end up paying more than the actual cost. Therefore, ourproposed system can help millions of people in society to savemoney by providing them with detailed information regardingthe right time to book a flight ticket. For determining the pricewe need some features as input such as the duration of thejourney,source,arrivaltime,departuretime,andsoon.

Ourproposedproblemstatementis"AirwaysFareEstimatorUsingRandomForestAlgorithm".

II. AIMSANDOBJECTIVES

A. Aims

1. Togetbetterexposureandknowledgeinthefieldofdatascienceandmachinelearning.
2. Togetthebestpriceofairfarewithgoodaccuracy.
3. Provideauser-friendlyinterfaceandthebestuserexperiencewhileusingthewebapp.
4. Tostudyadetailedanalysisofthefactorsthatinfluenceairfarecost.

B. Objectives

1. ProvideabetterUserInterfacetotheusers.
2. Togetthebestresultswiththebestpossibleaccuracy.
3. Use machine learning models to train the data-set, and getaccurateresultsalongwithbetterruntimesothattheusergetsthebestuserexperiencewhileusingthewebapplication.

III. Literature Survey

They used a data-set that had information generated from1814 distinct flights that were performed by Aegean Airlinesforthepurposeofthestudy[1],anditwasfoundthatthestudy was successful. Using the data that was supplied, theytaughtthemachine-learningmodelhowtobehave.Inorderto illustrate that the selection of features may influence theefficacy of a machine learning model, they tested the modelusing a broad variety of attributes in addition to the collecteddata. This allowed them to demonstrate that the performanceofthemodelcouldbeaffectedbythechoiceoffeatures.

Theauthorsoftheresearchpaper[2]usedasmallerdata-settodeveloppredictionsabouttravelfaresusingmachinelearningalgorithms.Thesealgorithmswererunusing the data. The information gathered from this collectionof data contained details on each and every flight that travelsbetweenBombayandDelhi.Inorderforthemtofinishtheir study,theyemployedanumberofdifferentmachinelearningstrategies,suchasK-nearestneighbors(KNN),linear regression, and SVM-Support Vector Machine. Thesestrategieswerealleffective.

The researchers were able to materialise the model that theyhad conceived of thanks to the application of a methodologyknownasLinearQuantileBlendedRegression(LQBR),which was utilised in the study [3]. For the purpose of thisstudy, a data set was utilised that contained 126,412 individualobservationsonthecostofaticketforeachofthe2,271i

DOI: rp-9788770040723.140

ndividual flights that took place between the San FranciscoInternational Airport and the New York International Airport.As a means of determining quality, these observations werecarriedoutonadailybasisasthestandard.

Intheresearcharticlepublished[4],theauthorspresentedamodelinwhichthetwodatabases,inadditiontothemachine learning techniques and the macroeconomic data, aremerged. Based on the source and destination data, machinelearningmethodssuchasXGboostandSVM(SupportVector Machine) are utilised in order to make a predictionregardingtheairfare.Afterperformingminoradjustmentsto the R-squared performance measurements, the suggestedframework is able to produce prediction results with a greaterlevel of accuracy. Using the XGBoost Algorithm, they wereable to attain an error rate that was far lower than average,cominginatapproximately0.92.

Usingmachinelearningalgorithmsonflightdatasetsenablestheforecastingofdynamicflightfaresanddeterminingthe most favorable ticket prices. As the data is sourced fromwebsitessellingflighttickets,theavailableinformationisrestricted.R-squaredvaluesareutilizedtoevaluatetheprecisionofthemodel.Incorporatingsupplementarydata,suchasthepresentseatavailability,couldenhancetheaccuracyofthepredictions.Theprocessofpredictingflightcostshasbeenexhaustivelydescribed,andpriorpatternshavebeenemployedtoconfirmthecredibilityoftheseprojections.[5]

Therandomforesttechniqueisasimpleandadaptablealgorithmthatcanimproveaccuracyandprovideflexibilityinsolvingavarietyofclassificationandregressiontasks.Decision trees, which are trained on different subsets of thedata,arepartoftherandomforestmodel.Bycombiningmultiple decision trees and reducing the negative impact ofbias and variance, the random forest method typically deliversbetterresults.[6]

The study has shown that incorporating dynamic pricinginto an airline’s revenue management system can result in asignificant revenue boost in comparison to traditional revenuemanagement methods. Dynamic pricing can yield short-termrevenuegainsofupto20percent,owingtoitssuperiorflexibility in responding to changes in the environment. Thisflexibilityismainlyduetothefactthatdynamicpricingtechniques do not establish a fixed booking control policy atthe outset of the booking period, as opposed to static methods.Nonetheless,therevenuebenefitofdynamicpricingmaydeclineorbebalancedoutinthelongrun,ascompetitorsalsoadoptcomparablestrategies.[7]

This research proves that it is feasible to make use of pastdatatoanticipatethecostofairfare.Torefinetheaccuracyof the forecasts, one possible strategy is to merge differentmodels and assess their efficacy for each category. The curveoflearningimpliesthatincorporatingmorecharacteristics would raise the model’s precision even further. Nevertheless,due to the limitations of our existing data source, we cannotextractmoreinformationonparticularflights.Movingforward, more characteristics, like seat availability, departuretime, and holiday schedules, may be included in the model toboostitspredictingcapacity.[8]

IV. System Architecture

The data-set we used has 10,000+ observations along withthe booking details namely Airline(Company), Journey Date,Destination, Source, Arrival-Time, Departure-Time, Durationof the Journey, Total number of stops, additional information,and finally the prices which act as our target variable. FeatureEngineering is performed to convert all the above-mentionedfeaturestonumericalrepresentation.Later,tofinalize thetraining model we use VIF Multicollinearity and Sklearn -Feature importance. After completion of the above two stages,weperformmodeltrainingusinganappropriateAlgorithmthatprovides the best results according to our objectives. Finally,we deploy our model using the Flask services. Therefore, wecanrunourwebappanddeployitinaliveenvironmentfor real-time usage. Figure 1 shows the overview of systemarchitectureofairfareestimatorusingmachinelearningmodel

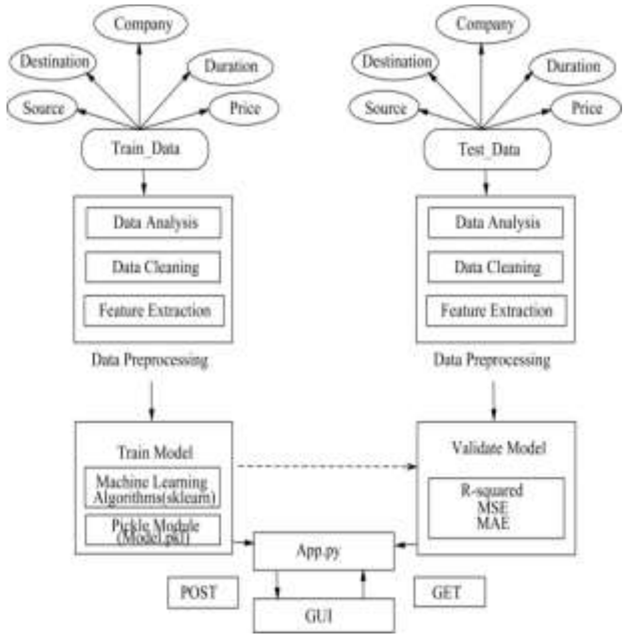

Fig.1.System Architecture

V. Proposed Methodology

The study has been designed to include seven main stages,each with a unique objective. Figure 2 represents the flowdirection of all the seven phases in the proposed methodology.Each of these processing phases is described in greaterdetailinthefollowingsections.

Phase1:ImportingLibraries:Allthenecessarypythonlibrariesrequiredfor AirwaysFareEstimatorareimportedthrough python commands. Some such libraries are Numpy,Pandas,andsoon.

Phase 2: Data Selection: Initially a proper dataset has to becollectedonwhichthedatatraininghastobeperformed.Forthis purpose,mostmachinelearningexperts,students,researchers,scholars,anddatascientistsusetheKaggleservicewhich is a

DOI: rp-9788770040723.140

subsidiary of Google. The dataset collected shouldbe loaded by setting up the working directory for performingfurtheractions.

Phase3:EDA:Itistheprocessofunderstandingthedata.Itis used to analyze the trends and statistical summary in theformofagraphicalrepresentation.

Phase4:DataPreprocessing:Datapreprocessingplaysacritical role in the fields of data analysis and machine learningas it entails the task of refining, reformatting, and arrangingunprocessed data to render it appropriate for advanced analysis.Theprimaryobjectiveofdatapreprocessingistoguaranteethat the data is precise, coherent, and in a machine-readableformat.

Phase 5: Feature Selection: This is the process of finding outthebestfeatureamongtheavailablefeaturesthatwillleadto maintaining a good relationship with the target variable.Feature importance and VIF-Multicollinearity are the methodsthatwillbeusedintheprojecttoperformthisprocess.

Phase6:ModelTraining:Thisistheprocesswherethecollected data is used to train the model with the help of MLalgorithms.Themodelcanpredictthepriceusingthehistoricaldataandbyperformingthedatatrainingwithanappropriate MLalgorithm,thereforeachievingthebestresults.

Phase 7: Deployment of Model: The machine learning modelcreated will be deployed as a web app using flask services.Using this the user can interact with the model for entering theinput values for which the airfare should be predicted. Finally,theresultobtainedisalsodisplayedontheuserinterfaceofthewebapp.Thiswebappensuresabetteruserexperience.

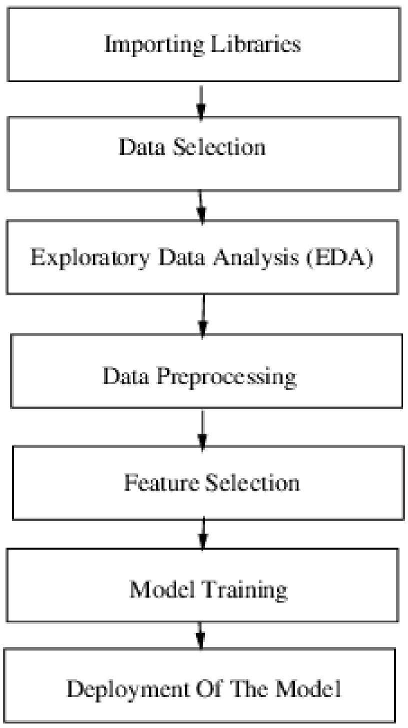

Fig.2.ProposedMethodology

VI. Model Training

Modeltrainingisacrucialprocessinmachinelearningthat involves the development of a mathematical model usingan algorithm to learn from input data. The ultimate goal ofmodeltrainingistocreateanaccurateandrobustmodelthat can provide precise predictions or classifications for newand unseen data.To begin the model training process, a largeamount of data is collected and preprocessed through severalsteps like data cleaning, normalization, and feature extractionto make it ready for training. Afterward, the model selectionprocess starts, where an appropriate algorithm is chosen basedontheproblem'snatureandthetypeofdata.Inordertoperform model training, an in-depth experimental and researchanalyseswasdoneandfinally,weoptedRandomForestalgorithmtotrainourmodel.Performancemetricsareasetof standards or markers that are utilized to assess the efficacy,productivity,andoverallperformanceofasystem,process,orproduct.Weobtainedperformancemetricsscoresbasedonourexperimentaswellasfromtheresearchanalyses.TABLEIdemonstratestheresultsobtainedbyperformingthe prediction using different models.We got results for RFAlgorithm, K - Neighbours, Decision Tree and Extra TreeModels.Basedonthescoresobtaineditwasdemonstartedthat RF Algorithm performed well with a better RMSE scoreof1773.43,R-squareobtainedwas0.84andtotaltimetakentotrainthemodelwas2.51seconds.

TABLEI: Peformace Metrics Of Ml Models

Model	R-Squared	RMSE	Time Taken
Random Forest	0.84	1773.43	2.51
K - Neigh- bours	0.84	1838.12	1.43
Decision Tree	0.84	1838.85	0.09
Extra Tree	0.80	2081.43	0.06

VII. Random Forest Algorithm

This algorithm comes under the category of supervised learning. This is also used for both regression and classification problems.The random forest algorithm is a reliable machine learning technique that outperforms other methods in various aspects. Firstly, it is less prone to noise and overfitting than other models, thanks to its ensemble of decision trees that mitigates the variance of the final model. Secondly, it is computationally efficient and capable of processing large datasets with numerous features. Lastly, random forest allows for the determination of feature importance, which aids in the feature selection process. Overall, the random forest algorithm is a highly versatile and potent machine learning technique that can be utilized to address various problems. It is especially useful in situations that involve large datasets and high-dimensional features, and has the capability to provide valuable insights into feature importance. Random forest is an ensemble learn- ing approach that generates numerous decision trees in the training stage. The final output of the model is determined by consolidating the predictions of the individual trees, which can be either the mode of the

DOI: rp-9788770040723.140

classes for classification problems or the mean prediction for regression problems.

When utilizing the Random Forest (RF) Algorithm for regression-based issues, a fundamental measure used to evalu- ate the model's performance is the mean squared error (MSE).

The MSE aids in determining the degree to which data points are dispersed from each node of the decision tree. Specifically, it calculates the average of the squared differences between predicted and actual values of the response variable.A lower MSE implies better model performance.

On the other hand, when using the RF Algorithm for classification-based issues, the Gini-index is employed to determine how the decision tree branches. The Gini-index assesses the impurity or randomness of the class distribution of a node in the decision tree. A lower Gini-index suggests a less random distribution of classes and a more effective split. The RF Algorithm builds multiple decision trees using boot- strapped samples of the training data. Each tree is constructedby selecting the best split points based on the Gini-index.

Overall, the RF Algorithm is a versatile machine learning technique that can be applied to both regression and classification problems. Understanding which metrics to use and how they relate to the underlying problem can enhance the model's performance.

VIII. Hyperparamter Tuning

Hyperparameter tuning is a widely-used technique in machine learning for enhancing a model's performance by optimizing its hyperparameters.Hyperparameters are predetermined before a model is trained and cannot be learned from data, such as regularization strength, learning rate, and the number of hidden layers.The primary objective of hyperparameter tuning is to identify the best combination of hyperparameters that result in the highest accuracy or lowest error rate on a validation dataset. This is typically accomplished by exhaustively searching through a range ofvalues for each hyperparameter and analyzing the model's performance on the validation dataset for each set of hyperparameters. Hyperparameter tuning can be executed using various approaches, such as random search, grid search, and Bayesian optimization. It is a crucial step in creating effective and precise machine learning models.In our case, after training the random forest model, we performed hyperparameter tuning to optimize its performance. Our results showed that the performance metrics improved significantly after hyperparameter tuning compared to the results obtained before tuning, as demonstrated in TABLE-II.Figure 4 shows a performance graph after hyperparameter tuning, compared to the graph in Figure 3 before hyperparameter tuning, clearly indicating a noticeable improvement in performance. Overall, hyperparameter tuning is a vital process for achieving the best performance in machine learning models.

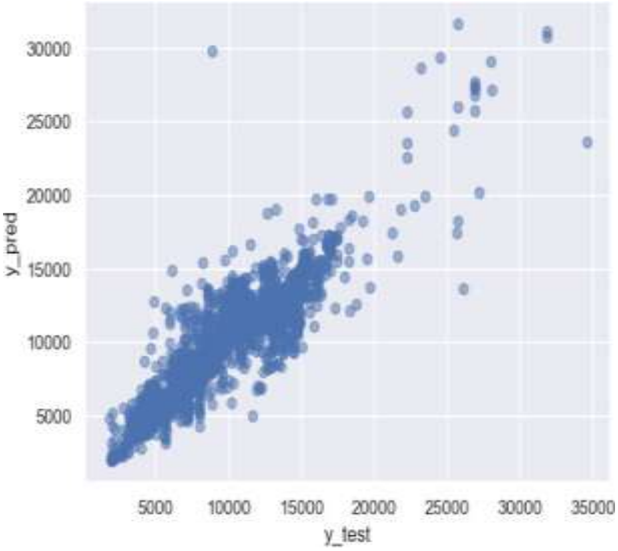

Fig. 3. Plot Performance Graph Before HP Tuning

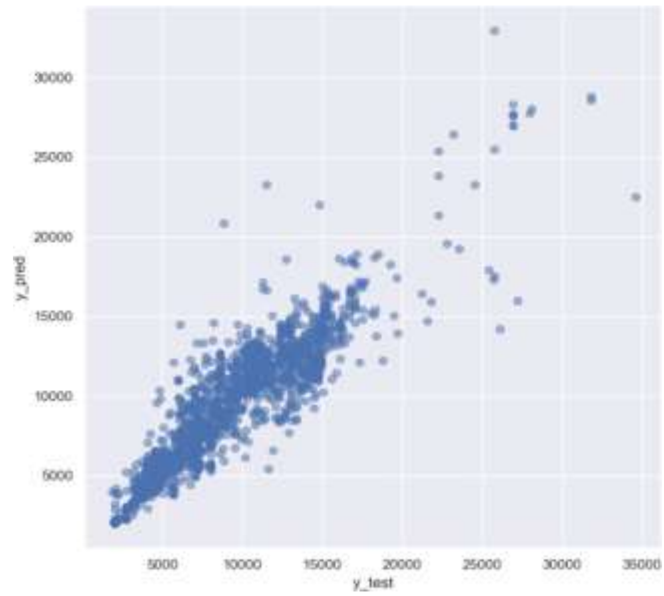

Fig.4.PlotPerformanceGraphAfterHPTuning

TABLEII: Performance Metrics Before And After Hp Tuning

Metrics	BeforeHP-Tuning	AfterHP-Tuning
R2	0.66	0.84
RMSE	1882.997	1773.43

IX. Future Scope

In the future, our design will be able to accommodate datapertainingtothepurchaseofplanetickets.Thisinfowillbeabletogivefurtherdetailsonacertainitinerary,suchasdepartureand arrivaltimesanddates,seatplacement,coveredauxiliarygoods,etc.Bymergingdifferentformsofdataandworkingwithintherestrictionsofthepresentsystem,itispossibletodevelopamodelthatis capableof delivering a more accurate and comprehensive hourly orevendailyforecastofairlinefares.Takingintoconsiderationof thecurrentindustrialdivisionandthemacroeconomicparameters,this makes it feasible to estimate airline prices. Inaddition, the price of airfare in a given market sector may beaffected by an unanticipated rise in the number of passengerscaused

DOI: rp-9788770040723.140

by a particular special event. In order to complementourpredictionmodel,wewillcollectevent-relateddatafromarangeofresources,suchassocialmediaplatformsandnewsorganizations.Inaddition,wewillinvestigateothersophisticated machine learning models, such as deep learningtechniques, while concurrently striving to enhance the modelsalreadyinusebytweakingtheirhyper-parameterstocreatethemostefficientarchitectureforflightprice prediction.Prioritize the speed with which the model can anticipate theresultsoftheexperimentinadditiontothereliabilityofthemodel.Besidesthecurrentlyselectedfeatures,theremayexistotheraspectsthathavethepotentialtoimprovetheprecision of airfare price predictions. In the future, there is apossibility to extend this study to anticipate the airfare pricesfor an airline's entire flight network. However, this wouldrequire the utilization of a more extensive airfare dataset andconductingadditionalexperimentstovalidatethemodel'sperformance.

X. Results

Throughout our project, we carried out both experimentaland research analyses on multiple machine learning models,includingK-Neighbours,DecisionTree,ExtraTree,andRandomForest.Afterconductingathoroughanalysisofthe obtained metrics, we concluded that the Random ForestModelperformedbetterthantheothermodels.InTABLEI,wehaveprovidedthescoresobtainedfromtrainingthedata with different ML models. Based on these results, wedevelopedamodelusingtheRandomForestalgorithm.Wethenperformedhyperparametertuning,whichfurtherimprovedtheperformanceofthemodel.Theperformancescores after hyperparameter tuning can be seen in TABLEII.Aftertrainingandevaluatingthemodel,wearethrilledtoreportthatitachievedanoutstandingaccuracyof95percontthetrainingdataand82perconthetestdata.Thisoutcome is a testament to the model's high proficiency inprovidingprecisepredictionsofthetargetvariablewhenpresentedwithnewinputdata.Furthermore,ourresultshighlight the effectiveness of the Random Forest algorithm inresolving this specific problem and suggest its potential forsimilar tasks in the future.Overall, we are confident that ourresearch has made a significant contribution to the field andcould potentially be successfully implemented in real-worldscenarios.

XI. Conclusion

***Abstract*—The COVID-19 pandemic has led to a significant shift towards online work for various activities such as education, job interviews, healthcare consultations, and company meetings. This has resulted in the widespread use of online meeting software applications like Google Meet and Microsoft Teams. The practical applications of this topic are of great importance and relevance in the current scenario.This paper presents a comprehensive approach to generating text summaries from both text and voice audio files. In the first scenario, the audio files are converted to text format using Python tools, while in the latter scenario, text summarization is performed using modules from Natural Language Processing. Specifically, the SpaCy Python framework is utilized for English data functions. The significant sentences identified during the text extraction process are used in the summarization approach. The weight assigned to each word is based on the number of times it appears in the text file. By starting with the main audio recording, this method is utilized to generate summaries, Using the main audio recording as a starting point, this method is used to create summaries.**

Overall, this approach provides a useful solution for extracting important information from both text and voice audio files. By leveraging advanced techniques such as Natural Language Processing and text extraction, the summarization process is able to identify key points and reduce the overall amount of information without sacrificing important details. The result is a concise and accurate summary that can be quickly and easily read, making it an ideal solution for busy professionals who need to process large amounts of information efficiently.

Keywords: Deep learning, python speech recognition, of TF-IDF, SpaCy, Natural language processing.

I. Introduction

Over the last two decades, the popularity of multimedia applications like gaming, virtual and augmented reality (VR and AR), teleconferencing, and entertainment has led to a surge in demand for immersive communication technologies. The proliferation of mobile multimedia and ubiquitous computing has played a crucial part in the development of these technologies. Spatial audio research is currently a key focus in this field, as it offers essential resources for capturing, processing, and reproducing spatial sound, which is essential for creating three-dimensional (3D) immersive user experiences.

Spatial audio, a research field that requires collaboration among specialists in areas such as audio engineering, acoustics, computer science, and applied psychoacoustics, aims to replicate or create new acoustic environments by utilizing suitable sound recording, processing, and reproduction techniques. Maintaining the precision of not only the audio content but also the spatial features of the sound scene, which depend on the physical positions of sound sources and acoustic characteristics of the environment, is crucial in achieving this objective.

The methods and techniques used in spatial audio can be divided into three stages: capture, processing, and reproduction. The first stage involves recording the sound scene, while the second stage involves modifying the recorded spatial information or extracting additional information that was not captured. The final stage involves reproducing the processed sound scene, resulting in a realistic auditory experience.

Summarization is the process of making data easier and quicker to comprehend while preserving the language's grammar and meaning. Optical character recognition (OCR), on the other hand, involves identifying text from digitized documents or images. When a PDF file is uploaded to our tool, it is first converted into an image array using the pdf2image Python module, which is a wrapper around the pdftoppm and pdftocairo command line tools. The OCR receives a list of images, and each image is converted to digitized text using a combination of model recognition and feature detection techniques. The OCR then returns the extracted text in a string format.

With the rise of Internet platforms like YouTube, there is an increasing need for multimedia summarization. The goal of automatic summarization is to produce a concise and informative version of the original content. In this article, we focus specifically on audio summarization, which involves creating a summary of an audio signal. There are three methods for generating an audio summary: using only audio functions, extracting text from the audio signal, and using textual methods to guide the summarization process. A hybrid approach that combines the first two methods is also possible.

There are advantages and disadvantages to each approach for audio summarization. Relying solely on audio features to create a summary is independent of transcription, but it can be problematic since the summary is based only on how things are said. Conversely, using textual methods to guide the summarization process can leverage the information in the text, resulting in more informative summaries. However, transcripts may not always be available. Combining audio functions and textual methods can enhance the quality of the summary, but both approaches also have their drawbacks.

The field of voice recognition is a multidisciplinary area of study that involves the use of various technologies to recognize and interpret spoken language, ultimately converting it into text format. This field involves the application of different fields such as computer science,

DOI: rp-9788770040723.141

signal processing, linguistics, and artificial intelligence. The process of voice recognition involves the use of speech recognition algorithms that analyze and interpret speech signals, breaking down the audio into small components such as phonemes, words, and sentences.When a user downloads an audio file, it is first pre-processed for transcription. There are three ways to create an audio summary: using only audio functions, extracting text from the audio signal, and a hybrid approach that combines both methods. Each approach has its own advantages and disadvantages. Using only audio features provides independence from transcription, but may not capture the intended meaning accurately. On the other hand, leading the summary with textual methods may produce more informative summaries, but transcripts may not always be available. Finally, combining audio functions and textual methods may improve the summary's quality, but it also has its drawbacks.

II. Literature Review

Previous research has focused on the classification, while data augmentation has been utilized in various other applications to enhance model accuracy. A summary of the existing literature in these domains is provided in this section.

[1] The problem of automatic summarization can be tackled in various ways. These solutions include unsupervised techniques, as well as graph-based approaches that employ ranking to organize input text in a graph. Additionally, neural methods exist which are discussed in more detail in the subsequent paragraph and employ graph traversal algorithms.

[2] Next, we explore studies related to summarizing extensive texts and scholarly articles, which are the dominant types of lengthy documents in the field of summarization. Lastly, we provide an overview of datasets used for summarization tasks, with a specific emphasis on datasets for summarizing academic articles

[3] Despite the significant increase in audiovisual data in the last decade, there is a lack of dedicated tools and software programs for audio summarization. While various studies have explored modules used in constructing audio summarizers, none have focused on developing and optimizing systems specifically for audio summaries.

[4] Graph-based models, which are commonly used in extractive summarization, utilize many inter-sentence and query-sentence interactions. LexRank assigns scores to each sentence in a graph of sentence similarity. Manifold ranking, applied by Wan and Xiao, The system utilizes connections between sentences, documents, and queries to facilitate processing. We model these relationships, along with token-level graph connections, and then aggregate them to create distributed sentence representations, with the exception of cross-document relationships.

[5] Graph-based models are widely used in extractive summarization and involve several interactions between sentences and queries. For instance, LexRank assigns scores to sentences and generates a similarity graph. Similarly, in manifold ranking,The system utilizes connections between sentences, documents, and queries to facilitate processingare considered. We also use a graph at the token level to model the above relationships, which is then combined to produce distributed sentence representations, except for cross-document relationships.

[6] As audio/visual data consumption increases, audio file management needs to become more advanced. A new technique, known as divide-and-conquer, is being explored to effectively summarize lengthy audio messages or snippets and extract important information. The method consists of three modules, namely Speech-to-Text Conversion, Text Summarization, and Text-to-Speech Conversion. The output of each module, except for Speech-to-Text Conversion, is used as input for the next module in the sequence. The audio file acts as input for the first module, while the last module converts the summarized text generated by the Text Summarization module into an audio file. A web application with a user interface created with Flask is used to facilitate the model's interaction with users.

[7] The current datasets for query-focused summarization are too small to be effective for training data-driven algorithms. However, manually constructing such a corpus is a time-consuming and resource-intensive process. To address this issue, researchers have proposed an approach to extract and summarize document sentences, which allows for a better match between the large model and the small benchmarks. Experiments conducted on three DUC benchmarks indicate that a pre-trained WikiRaf model has already achieved acceptable performance levels. Furthermore, with specific benchmark dataset optimization and data augmentation, the model outperforms strong comparison systems.

[8] With the growing amount of video content available, an automatic video summary can provide significant time-saving and learning benefits. It is becoming increasingly important to correctly navigate through the large amount of user-generated videos available. Video summary has the potential to extract informative frames from a film, and is therefore seen as a useful method for maximizing the information content. By leveraging text summarization and video mapping algorithms, it is possible to retrieve key video elements from subtitles and use them to generate a summary of the movie's content.

[9] The advent of the internet and social media platforms has led to an abundance of data in various formats, including text, audio, and video. However, it can be challenging for users to obtain an accurate overview or extract crucial information from these files. Users often seek a summary of the most pertinent information that can be quickly gleaned from the source files. To this end, automatic text summarization (ATS) is the only viable method for summarizing a single document or multiple documents to extract essential information. Unfortunately, current ATS systems often produce inadequate summaries and require significant time and resources to process large documents due to incorrect encoding.

[10] Video data is composed of two modalities, namely audio and vision. Multimodal learning, particularly audiovisual learning, has gained traction in recent years due

DOI: rp-9788770040723.141

to its potential to enhance the performance of various computer vision tasks. However, existing video summarization methods mainly rely on visual information and do not utilize the audio modality. In this study, researchers suggest that incorporating audio information can aid in the comprehension of visual content and structure, ultimately improving the summarization process.

III. Existing System

The current system has limited capabilities as it can only detect emotions in response to an audio input. It relies on a Python speech recognition library that may not be compatible with all inputs due to its dependencies. Furthermore, the system is incapable of analyzing a large dataset of audio files as it has not been trained on such data.

IV. Proposed System And Architecture

The proposed real-time system analyzes audio inputs, extracts important keywords, and summarizes them into a shorter format. It is designed for audio books and podcasts, and can handle large inputs with good accuracy and efficiency. Our plan is to build a web application using Streamlit, a free and open-source framework for constructing Python apps with minimal lines of code. The app will prompt users to provide the podcast ID and generate a transcripted summary of the podcast. The proposed system is basically shown in the following flowchart in Figure 1.

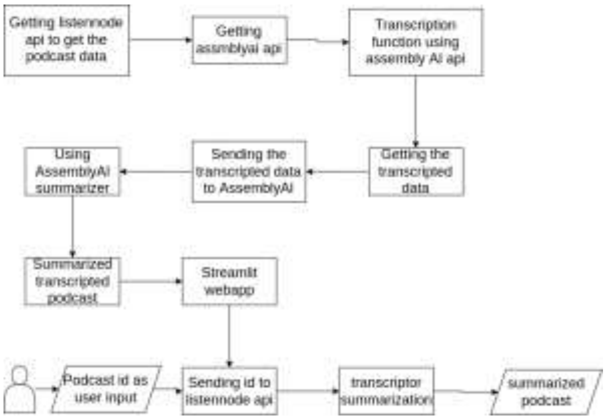

Fig. 1. Flowchart of the proposed system

V. Implementation

A. Getting the PODCAST from the listennoteapi

A method will be developed to retrieve podcast data based on the ID provided by the user as input.

In this section, we will be utilizing the Listen Notes API to extract the URL of the target podcast's episode. Listen Notes is a comprehensive online search engine and database for podcasts, providing access to podcast data through their API and enabling the creation of new applications and services based on it.

- Firstly, we need to create an account and subscribe to the free plan to access the data and utilize the Listen Notes API. The free plan allows a maximum of 300 requests per month, which is usually enough for personal projects.
- To proceed, we should visit the Listen Notes podcast page, choose the specific episode we want, and then click on the "Use API to get this episode" option.
- Afterwards, we can switch the language code to Python and choose 'requests' from the available options list, which will allow us to use the library in the future.
- After copying the code, ensure to paste it into your notebook or script.

Firstly, we use a GET request to access the Listen Notes Podcast API endpoint to retrieve the required information. The result is saved as a JSON object, containing the episode URL, which will be used later. Additionally, we import a JSON file named secrets.json, which is similar to a dictionary, containing key-value pairs. This file holds the API keys for both AssemblyAI and Listen Notes, and logging into your accounts is required to access them.

B. Transcription and summarization of the podcast

After reading the dataset, images will be preprocessed.in following steps,In this upcoming section, we will make use of a POST request instead of the previous GET request. Specifically, we will send a request to the transcript endpoint of the AssemblyAI API to request transcription. Uploading the audio URL to Assembly AI requires the use of the post method. Setting the auto chapter value to True is necessary in order to receive both the transcription and summary. If we set the auto chapter value to False, we would only be able to receive the transcription. Once this step is completed, we will store the ID of the transcription response.

Retrieve Transcription and Summary:

In the final step, we can retrieve the transcription and summary by sending a GET request to AssemblyAI. It may take several requests until the status of the response is completed. After that, we store the results in two separate files: a txt file for the transcription and a JSON file for the summary.

Transcription:

Converting an audio file into a text file is known as audio transcription, which can be applied to various situations such as interviews, academic studies, music video clips, and conference recordings. The AssemblyAI API will be utilized to transcribe the data fetched from the Listen Notes API and provide the transcription data.

Real-Time Streaming Transcription:

The Real-Time Streaming WebSocket API provides clients with text transcriptions in just a few hundred milliseconds through a streaming process. In cases where there is an error, the API will consistently return a JSON response.

Summarization:

Audio summaries are concise versions of audiobooks that effectively capture the key ideas and themes of longer works in a more accessible format. They provide a comprehensive overview of the author's content, style, and spirit. To retrieve the data that has been transcribed and

DOI: rp-9788770040723.141

summarized from the podcast, we will use the AssemblyAI API, which will be employed to transmit the data.

C. Web App

Our goal is to develop a web application using Streamlit that requests the user to enter a podcast ID and then provides a summarized transcription of the podcast. Streamlit is a Python framework that enables the creation of applications with minimal code. We begin by importing Python libraries and defining functions that replicate the aforementioned actions. Additionally, we provide a zipped package containing both the transcription and summary files. To start, we utilize st.markdown to display the application's main title. We create a left panel sidebar using the st.sidebar function to allow the user to input the episode ID, which is then followed by clicking the "Submit" button. Once clicked, the application will transcribe and summarize the audio of the episode. After a few minutes, the outcomes will appear on the website. If the user wishes to download the results, a "Download" button is available to compress the transcription and summary into a single file. The system automatically generates both the local URL and the Network URL, allowing the user to select either link to obtain the desired result. As a result, we now have a wonderful app that can transcribe and summarize your favourite podcast!

VI. RESULTS

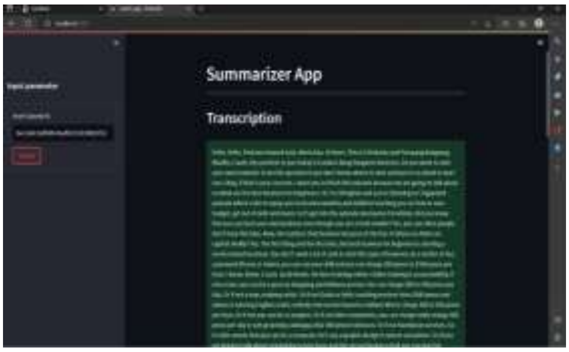

Fig. 2. Result

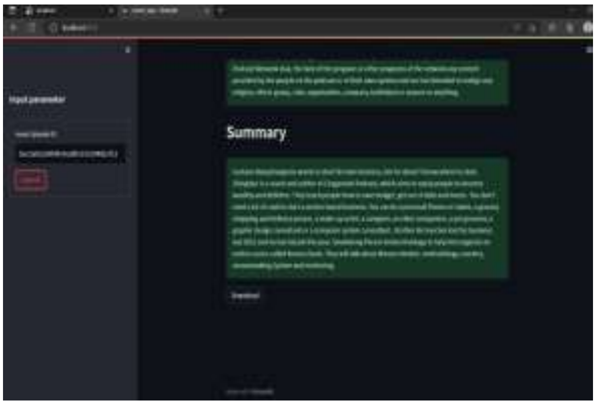

Fig. 3. Result

VII. CONCLUSION

This project aims to demonstrate the proof-of-concept and provide a direction for future development of a fully automated method for summarizing podcast speech. Due to the complexity of this task, there is considerable room for improvement. Podcasts typically require active attention from listeners for extended periods of time, unlike listening to music. The primary input for processing is an audio file containing human speech, which may be recorded live or pre-recorded. However, subjective elements such as the speaker's style, humor, or production quality can be challenging to discern from a text description. The generated summaries contain clear and understandable audio information.

VIII. RECOMMENDATION

While our predictions achieved a high accuracy of 99.6%, it is important to note that no model can be completely perfect. One limitation of this model is that it may not accurately identify species that it has not been trained on, although it will still make a prediction that closely matches the correct type. Nonetheless, this model has potential for further improvement through the collection and analysis of more data, ultimately leading to a real-time audio summarization system.

Abstract— Reduced tollgate rates in any other sort of usage, making it more willing for the environment by electrical autos, and even in traffic control and vehicle owner identification, which has become a severe problem in every country, would encourage adoption of electric cars. It could be difficult to spot motorists who drive too quickly and against the rules of the road. Due to the speed of the moving car, it may be difficult for traffic officials to collect the license plate, making it impossible to catch and punish such people. Designing an automatic number plate recognition (ANPR) system is one of the solutions to this issue. There are currently many ANPR systems in operation. Despite the fact that these systems are based on numerous techniques, it is still a challenging task because variables like high vehicle speeds, uneven license plates, different languages used for vehicle numbers, and different lighting conditions can all significantly affect the overall identification rate. With these limitations, the bulk of the systems work. Several ANPR approaches are described in this study, taking picture size, success rate, and processing time into consideration. The study ends with a proposal for an ANPR expansion.

I. Introduction

Identification are climate, environmental influence, and localization accuracy. Using the color features and probability distribution of the license plate between the two lights is one method for number plate recognition. Template matching is a common technique for algorithms that identify licence plate numbers. The template matching-based License Plate Detection algorithm was created and designed to manage the parking lot system by detecting unregistered vehicles from off-campus. Vertical edges-based car license plate detectionis quite common at the moment. However, some people prefer to locate the location number plate by using image projections in both the horizontal and vertical planes. The license plate area can be located using the Genetic Algorithm and the Hough transform. Concurrently, effective outcomes were achieved by combining block-based algorithms with edge statistics and mathematical morphology. Another technique that takes use of the gaps between the rows counts the edges that are present and, if the number is greater than a set threshold, finds the license plate. The key elements for number plate localization are extracted using a method based on the wavelet transform. The benefit of this method is that it enables you to locate numerous license plates inside the frame. Several of the above-mentioned techniques need a significant amount of compute and are quite sophisticated. It could be a little challenging to use time in real-time applications. Some methods, such as backdrop color and other number plate attributes, might only be employed in certain nations.

II. Literature Survey

ITS is crucial in the development of increasingly complex applications for the detection of automobiles and other objects, like multi-object tracking. The authors of [1] made an effort at the structure. The majority of multi-object tracking systems employ one of two methods for object initialization: detection-based tracking (DBT) or detection-free tracking (DFT). In terms of both matching costs and computing performance, the ORB technique performs better than other algorithms.

Vehicle type classification was carried out by the authors of in order to identify applications in a variety of situations, including vehiclemanagement, traffic statistics analysis, and toll collection. The use of computer vision to classify vehicles it has been successfully used in traffic flow modelling and road traffic analysis. The model attained the maximum accuracy of 78.53% when 9000 images from the MIO-TCD dataset were employed.

The authors of created models like SVM and Decision Tree, which are used in a wide range of fields like mathematics, computer graphical user interfaces (GUIs), the web, and many important scientific applications. Python was created with the main goal of making programming simpler so that anyone, wherever in the world, could create their own software. The authors of [4] implemented approach for vehicle detection using transfer learning techniques using base models such as CNN, Inception V3, Inception-ResnetV, MobileNetV2.

Which would be employed in autonomous driving with the use of features like vehicle identification and categorization to support the CPU in real-time situation analysis and decision-making. This was achieved by establishing a system that would detect vehicles used for autonomous driving As a consequence of this study, models with accuracies of 91.8%, 89.1%, 91.4%, 90.8%, 92.3%, and 90.5% were implemented, including Inceptionv3, ResNet, InceptionResnetv2, MobileNetv2, Nasnet, and PNASnet.

The authors of [5] used the RCNN, ZF, and VGG16 networks to identify and recognise the three major groups of autos that are frequently seen in a traffic scene. This process can undoubtedly enhance the sort of automobile.

Without diminishing the effectiveness of the Faster RCNN in detection or failing to fulfil the demands of varied traffic conditions. This is made possible by streamlining the model's algorithm and enhancing the RPN networkdetection of targets in moving vehicles

Purpose of the Research

The goals of this research study are listed in the list below: x To examine further methods that can identify a vehicle's license plate. To offer a solution to the automated

DOI: rp-9788770040723.142

number plate recognition conundrum. To assess and test the suggested method, and to deliver the evaluation's findings.

III. PROPOSED STRATEGY

There are three components to the overall issue: Plate area detection, number plate segmentation and character extraction, symbol extraction using optical character recognition, etc.

Plate Area Detection, first The programme will be given an image with a number plate as input, and it will need to recognize the number plate before cropping the image as an output for the following stage. The image must go through the following process in order to extract the number plate from the entire document. x Gray scale image: At this stage, the image must be read and converted to grey scale format. Such conversion won't result in the loss of crucial data, at the very Similarly, working with one channel rather than three will be more convenient. The noise is a major difficulty with our dilemma, x Blur. It is preferable to blur the image in order to lessen them. There are various smoothing techniques. After smoothing, the cumulative error distribution graph that follows compares each of them. indicates that when compared to other smoothing techniques, homogeneous smoothing is the best, according to Figure 1. x Characters are located on the number plate thanks to vertical edge detection. The characters, as we all know, have more vertical than horizontal edges. To solve this problem, one of the best methods is to identify vertical edges that are very close to one another. It is the edge detection.

Vertical edge detection

The characters are found on the license plate. We already know that the characters have more vertical than horizontal edges. Finding vertical edges that are very near to one another is thus one of the greatest strategies [1]. In the subject of computer vision, edge detection is a fundamental and fundamental function. There are numerous types of edge detectors, including Prewitt, Sobel, Canny, and others. Each of them is used to various situations and issues. To solve the given problem, we employ Prewitt, Sobel, and a modified version of Sobel [9]. However, following research and testing, we decided to utilize the modified version of Sobel since it accurately detects vertical edges and significantly reduces the number of horizontal edges that obstruct.

By utilizing techniques like frame difference and contour mapping, we present a novel approach to object detection in Figure 2. First, the image will be converted to RGB, after which the ROI (Region of Interest) will be removed to keep the undesirable portions of the image out of context. Following that, the OpenCV library will process the ROI by figuring out the Threshold, dilation, and contours. Following the discovery of the frame difference, the frame is transformed into a grey image in order to use dilation to detect any potential motion. The bounding box is then mapped using the coordinates of the associated contours. A bespoke CNN model receives the image as an input as a (32 x 32) pixel image from the bounding box, which captures it in its original frame. The algorithm then trains and forecasts the image's class (Truck, Car, Bike).

As we suggested using the CIFAR-10 dataset to train the models on images with a 32 by 32 pixel resolution. The models were trained using the transfer learning technique, which pairs a custom model with a base model that has already been trained using "imagenet" weights. The top layers of the pre-trained model are not included since they limit the size of images that can be trained to about (224 x 224 x 3), while CIFAR-10 only provides images that are (32 x 32 x 3). In order to train the custom model for classifying the photos, we later added custom layers on top of this previously trained model. We divided the dataset into training and testing datasets after pre-processing them.

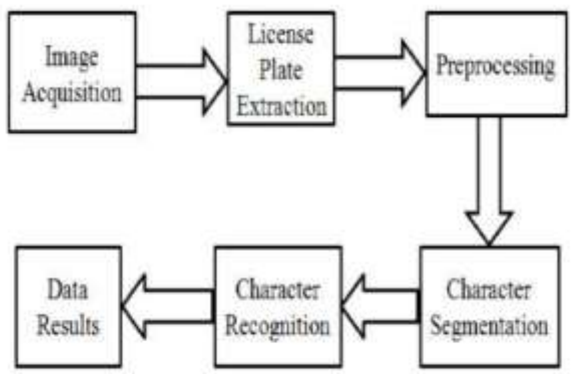

Fig. 2. Proposed Meth

Recently, a number of handcrafted methods have been presented, including the HoG and Haar features [47] and deep learning methods (R-CNN [48], Faster-RCNN [27], and YOLO [49] approaches). While others digest information slowly, some have a low accuracy rate. Among deep learning object detectors that can perform real-time processing.

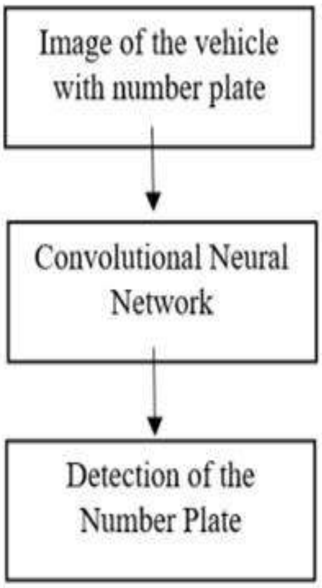
DOI: rp-9788770040723.142

The highest detection rates have been demonstrated using faster-RCNN. Faster-RCNN performance, however, suffers when dealing with small object detection, such as the LP localization in our case. Therefore, this work uses Faster R-CNN for vehicle detection in order to deliver accurate and scaled information in a picture. Additionally, Faster-RCNN performs well for vehicle detection as vehicle size grows. To deal with fluctuating scales, anchors in RPN are created, which employs three scales (128 128, 256 256, and 512 512), three aspect ratios (1: 1, 1: 2, and 2: 1), and nine anchors at each place. The fact that each area proposal's size is different from the others makes it difficult to design effective architecture for a range of sizes.

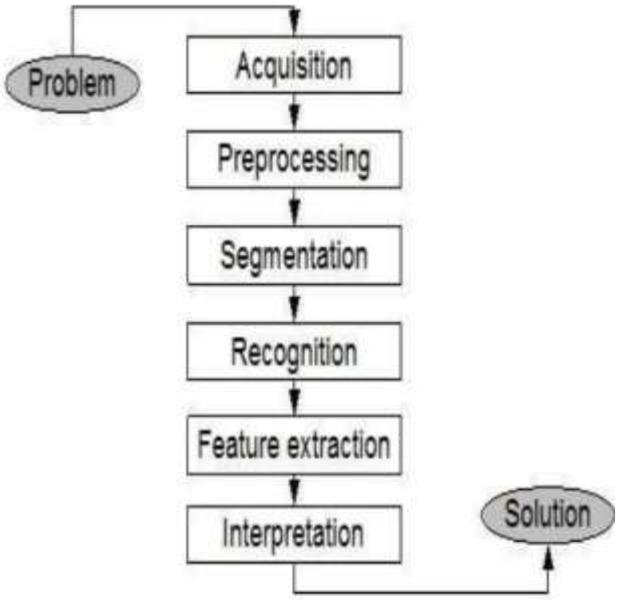
RoI SoftMax probability to categorize vehicles and non-vehicles, and the second of which predicts the coordinates of each region's rectangle.

Variations in the vertical edge detector x Black and white are the only colors present in binary pictures. The Otsu, Niblack, Souvola, Wolf, and Feng procedures are just a few of the threshold-related approaches.

Region of interest (RoI) pooling is used to simplify the problem and derive a fixed-size feature representation. The vectors are enlarged to include the RoI pooling properties. These vectors are finally fed into two fully connected layers, the first of which uses each Using stochastic gradient descent with momentum (SGDM), which changes the weights quickly and lowers inaccuracy, this method trains the faster-RCNN architecture. SGD just needs one sample data set from the training data, in contrast to gradient descent (GD), which uses all training datasets to update the weights and parameters. From each batch, one image was randomly selected for training. The revised sizes were 600 and 1400 for the shorter and longer sides of each image, respectively. shows the results of a quicker RCNN vehicle recognition using images.



A gradient-based histogram will be produced for each candidate. The feature vector will then have a specific length. By providing all of these vectors to the algorithm, we will be able to obtain the appropriate license plate among other things. SVM and setting it up with particular settings. Another strategy built on probabilistic theory was put into practice.



In this scenario, the turns are were initially identified, and any shapes that did not resemble a character were removed. Whether or not the remaining contours are located in a straight line is studied via identification. The likelihood of each character was then determined by removing each character from the license plate. The best candidate was chosen after adding them all up and taking these values into consideration. However, after testing, wewhere Lx and Ly are picture derivatives. Finding only vertical edges is achievable when using the value of. Only vertical edges will be produced if the value of is between 45 and 135. In the Fig. 2 show the outcome and variance of each edge detector.

Each of them took part in specific situations to achieve different objectives. Binary picture manipulation is more useful. After finding vertical edges, we will apply Otsu threshold to our existing image. x Most often, close morphology is used to connect nearby elements. Since our objective is to locate the number plate, we don't need a lot of information about the characters. We employ near morphology, which integrates all letters and numerals, as a result. The results of the morphological process are displayed in Figure 3.

DOI: rp-9788770040723.142

Recognize contours. Using the near morphology, where the area and aspect ratio of the contour must be taken into account, we will discover the contours that resemble licence plates. Additionally, the contours must be positioned horizontally, as seen in Fig. 3.

Identify the best applicant. To find the best candidate among the others, every number plate must be reviewed. The feature vector for each candidate will be computed initially. To do it, we'll use a histogram of directed gradients.

Segmentation The licence plate must be used to extract the characters. There are two fundamental approaches to segmentation; the one projects the image into X axis, while the second looks for outlines that resemble characters.

After completing study and testing, we came to conclusion that second algorithm performs better than first one. In Fig. 4, algorithm's output is shown. Before segmentation, the image must also be transformed to binary format. In this case, the Otsu method is not the best course of action. The Nick, Niblack, and Souvola algorithms outperform the rest, according to our tests of several binary algorithms.

character recognition using optics It is important to recognize the extracted character. To be used for recognition, we revised the 1NN technique. As shown in Fig. 5, the character was divided into 49 distinct components. Each component's white pixel count needs to be recorded. The feature vector, which consists of 49 elements, will be used to identify each character. Figure 6 displays feature vectors for the classes A, B, and C.

After the average element for each class has been established using feature vectors, the distance between an unknown element and all of the average elements in each class must be calculated. Unknown element will be added to the classes in the neighboring hierarchy that are closest to it

IV. Working of Algorithms

Character recognition for license plates frequently uses CNNs. The effectiveness of these systems in detecting odd license plate types or working at night hasn't received much attention, though. We demonstrate an effective ALPR system that recognizes characters using a CNN. The system efficiency was improved by applying a combination of pre-processing and morphological techniques to improve input image quality. The system can recognize license plates with multiple lines, skewed edges, and several fonts, among other qualities.

The best method for putting ALPR systems into practice makes use of deep learning using a convolutional neural network (CNN). Four methods are used by our system to carry out this step: grey scaling, median filter, thresholding, and masking. Multiple layers that independently learn to recognize the distinctive characteristics of an image can make up a CNN network. Every training image is fed into a filter with a different resolution, and the output of each convolved image is fed into the network's next layer.

To recognize the license plate in the pixels in the foreground. the identified number pictures' OCR. A unique set of algorithms is used for each phase. Automatic number plate recognition (ANPR), also known as license plate recognition (LPR), uses video-captured images or datasets to automatically identify a vehicle by its license plate. which are frequently positioned at fixed points along roadways and at parking lot entrances. Reading the image and gaussian blur and convert it to grayscale, Binarize the photo Using the n 8-connected component technique, label the binary image, Regions that are too big, too small, or have an aspect ratio greater than one should be removed. The largest region should be chosen after the regions have been sorted by distance from the Y-axis and collinearity.

V. Results and Discussion

The method was tested with 1469 actual car photographs. The pictures of the vehicles were taken from different perspectives and in varied weather situations. First, Plate Area Detection The exams were divided into five sections. Several subparts determine which side of the subject—front or back—the picture was taken from. The results of the test scenarios used to calculate the plate area Results of Plate Area Detection Subparts 1 Front, 2 Rear, and 3 Rear,

95.3%, 93.15%, 95.5%, and 94.46%, 93.88% If we take the average of the aforementioned data, the average performance of the plate area detection algorithm is (95.3% + 93.15% + 95.5% + 94.46% + 93.88%) / 5 = 94.458%.

After taking into consideration the value for each group, we calculated the overall performance of the segmentation algorithm (56.38% + 77.83% + 64.49%) / 3 = 66.23%. Following segmentation, the extracted lettersare shown in Fig. 7. number plate up:

Optical Character Recognition (C) There are several characters that are similar to one another, such "5 and S" and "O and 0." Examine our OCR solution in light of this information.

Comparing Models

We came to the conclusion that DenseNet-169 fared the best after comparing models against one another based on the provided criteria, with an accuracy of 96% accuracy and an F1 score of 96.3%. The type of car in the video can be accurately predicted by the model. The comparison of the models is shown in Table 1. Figures 11, 12, and 13 display the model's performance metrics graphs, with DenseNet-169 being the best bespoke pre-trained model.

VI. Conclusion

Using the suggested methods, data preparation, and learning the models across more than 100 epochs. DenseNet-169 successfully characterized the dynamically moving items in the frame using a bounding box after precisely anticipating the cars, buses, and trucks in the movie. The creation of a thorough system for traffic routing in crowded areas is the ultimate goal of this thesis. It is important to get dynamic data that shows the traffic flow condition along all feasible routes within a separate road using detectors in order to route traffic inside a city.

VII. Future Work

In the future, we intend to develop and incorporate object detection into the model itself in order to enhance its functionality. By employing coordinate pixel values, we intend to develop an experimental feature that will estimate the speed of moving vehicles and display the results next to the projected label.

***Abstract*—There are several types of skin cancer.Scientistshavecalculated around 200 of them till date. There are around 200type of skin cancers and research has showed that melanoma is the most dangerous out of them. The initial step in the diagnosis of melanoma is a form of screening in the clinic, which is then followed by histological examination and dermoscopic analysis. Skin cancer with melanoma has a good chance of being cured if it is discovered in its early stages. Visual inspection of the afflicted area of skin is the initial stage in the diagnosis of melanoma skin cancer. We will be able to differentiate between benign and malignant skin conditions using deep learning and neural networks, which could aid doctors in earlier cancer diagnosis.The dataset used is the HAM 10000 dataset. We have used the Python Ten sorFlow framework to create a skin illness classifier that attempts to differentiate between benign (nevus and seborrhei ckeratosis)and malignant (melanoma) skin diseases using just photo graphic pictures.**

Keywords—Python, TensorFlow, DeepLearning, Melanoma, Classification

I. Introduction

AccordingtotheSIIM-ISICMelanomaClassification,2020,melanoma accountsfor 75% of mortalitywhile being the leastcommon type of skin cancer. Although it is a less common form ofskincancer,ifitisnotdiscoveredintime,itcanspreadfasttoothe rbodyareas.SkinscansarebeingmadeavailablebytheInternatio nalSkin Imaging Collaboration (ISIC) to lower melanoma mortality.Whendetected andtreated earlyon,melanomaiscurable.

A teledermatology automated diagnosis system that can supportclinicaljudgementscanbecreatedusingdigitalphotogra phsofskinlesions .As deep learning can handle complex issues. The goal is tocreate a tool that dermatologists may use to support their diagnosisaccuracybycombiningcontextualphotosandpatient-leveldataandloweringthevarianceof modelpredictions.[1].

Since there are several categories of skin cancer, the challenge is toidentify them so that respective treatment can be provided. Afterdeveloping the model the doctor can just feed the image on to thesystemandwithinalimitedperiodoftimetheresultcanbeobtai ned.The system detects the category and displays it in the report. Thissystem can also be used in small clinics where a simple skin rashcan be tested to check the severity of the condition. This would beveryhelpfulsincetheconditioncanbeidentifiedasearlyaspossibleandtreat itwithoutanydelay[2].

The proposed model is Inception V3 which is a proved model forimageclassification.Asnotallimageswouldbeclearforclassi fication, this model is trained to handle such images. It is afaster model and computationally less expensive. It has severalconvolution layers which makes thepredictionsaccurate[3].

II. Literature Survey

They thoroughly studied the scaling of the model based onCNN (Convolutional Neural Networks) [1] and balanced thedepth,widthandresolutionofthenetworktoobtainexcellent resolution. Manipulate data using the grid-like topology ofConvNetswhileanalyzingimagesusingconvolutionalneura lnetworks.

Like the previous authors, the authors of [2] also use CNN-type neural .Along with other pre-trained models such as VGG16/19 and MobileNet, the Inception v3/5 model is used to helpskincancerfeatureextractionandclassification,andtheCN Nisusedforimageclassificationanddetection.

Another study investigated the consistency of CNN's abilityto identify and classify different diseases and found CNN tobehighlyreliable.In[3]and[4],theauthorcollecteddataonde ephislearningofNNandskincancerdiagnosticalgorithmsfrom trusted search engines such as ACM, Springer,GoogleScholar,andIEEEXplore.Adeepneuralnetw orkhasinterconnectednodesthathelpdetectskincancer.Theaut horsalso explored other learning methods such as ANN, CNN,KNNandGAN.

Theauthorsof[5]discussskincancereffectsbasedonfactors such as gender, climate, andgeographic location. They arguethat men's jobs and lack of precautions make them moresusceptibletoskincancer.

The author describes the image preprocessing phase in [6].Thisincludesdatacollection,hairremoval,shadowremoval ,glarereduction,andotherprocedures.Imagesextractedfromth e dataset contain a variety of tumor colors, some black andsomelight,withandwithoutskincancer.

III. Proposed System

A. DatasetDescription

TheHAM10000datasetcontainsabout10,000dermatosco pic images of pigmented skin lesions, including7,000 benign and 2,000 malignant lesions.. In 2018, a groupofresearchersattheMedicalUniversitätofViennainAust

DOI: rp-9788770040723.143

riaproducedthedataset.Severalplaces,suchasclinicalsettings, dermoscopyclinics,andreferralcentres,wereusedtocollectthe photographs[4]. The HAM10000 dataset has been extensively utilised forresearch,particularlyinthedevelopmentofmachinelearningalgorithms for automated skin cancer diagnosis. It is one ofthe largest freely available datasets for the classification ofskin lesions. Seven different diagnostic categories, includingmelanoma, melanocytic nevus, basal cell carcinoma, actinickeratosis,benignkeratosis,dermatofibroma,andvascularlesion,are assignedtothedataset.[10]

Fig. 1:TypesofImagesinthedataset

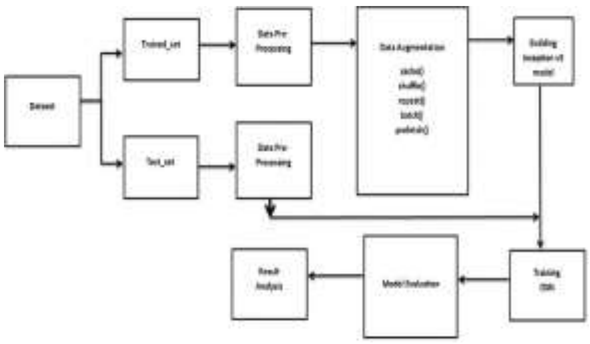

Fig. 2: Architecture of the model

B. PropsedArchitecture

Theentireflowoftheprocessisshown in Figure2.When classifying skin cancer with machine learning, deeplearningarchitecturesarefrequentlyused.Deeplearningarchitecturesareasortofneuralnetworkthatcanlearnintricatepatternsandfeaturesfromtheimages.

Aconvolutionalneuralnetwork(CNN)withnumerouslayersof convolutions, pooling, and fully connected layers is oneproposeddesignforclassifyingskincancer.TheHAM10000dataset, or a comparable dataset, is used to train the Networktoidentifythefeaturesthatdistinguishbetweenvariouskindsofskinlesions.

To enhance the model's functionality and generalizability, thesuggested architecture may also include methods like dataaugmentation,whichentailsgeneratingmoretrainingdatabyapplyingrandomchangestotheoriginalimages.Theclassificationofnewskinlesionphotosintothevariousdiagnostic categories can be done using the CNN after it hasbeentrained.Metricslikeaccuracy,sensitivity,andspecificitycanbeusedto assessthemodel'sperformance[7].

In general, a deep learning model is trained on a sizabledatasetofskinlesionphotosaspartoftheproposedarchitectureforclassifyingskincancerusingmachinelearning, and new images are then classified into severaldiagnostic categories using the acquired characteristics. Thismethodcouldincreasetheprecisionandspeedofskincancerdiagnosiswithadditionalstudyanddevelopment.

C. PreProcessingTechniques

Machinelearningalgorithmsforclassifyingskincancerheavily rely on pre-processing methods. Some of the pre-processingmethodsthatcouldbeutilisedinaresearcharticleon this subject are as follows: Picture resizing: Resizing theskinlesionphotographstoastandardsizecanaidinloweringthe computational expense and enhancing the effectivenessof the machine learning method. Picture normalisation: Byremovingdifferencesinthelightingandcolouroftheimages,normalisation can assist in facilitating the machine learningalgorithm's learning of the features that distinguish betweenvariouskindsof skinlesions[8].

Image augmentation: Creating additional training data byrandomly rotating, resizing, and flipping the original photoscan assist increase the robustness and generalizability of themachinelearningsystem.Noisereduction:Byusingtechniqueslikemedianfiltering,onecanlessentheimpactofimagenoiseonhowwellamachinelearningsystemperforms.Featureextractioncanhelptoenhancetheperformance of the machine learning algorithm by loweringthe dimensionality of the input data and emphasising the mostinformative aspects. Relevant features can be extracted fromthephotos, such astexture,shape, andcolour.

D. ConvolutionalNeuralNetworks

ConvolutionalNeuralNetwork,sometimesknownasCNN, isa subset of artificial neural networks created specifically fortheanalysisofvisualdata.Fortaskslikeobjectidentification,segmentation,andrecognition,itisfrequentlyemployed.

Convolutional, pooling, and fully linked layers are some of thelayers that make up CNNs. Pooling layers downsample thefeaturemapstospeedupcomputationandboostgeneralisation, while convolutional layers are in charge ofextracting features from the input image. For jobs requiringclassificationorregression,fullylinkedlayersareused.

There are numerous uses for CNNs in a variety of industries,includingrobotics,computervision,naturallanguage processing, and speech recognition. By automating previouslylaboriousactivities,CNNshaveshowntobeaneffectivetoolforanalysingvisualdataandhavethepotentialtorevolutionisenumerousindustries.[19-20].

The fundamental tenet of CNN is that local awareness of apicture suffices. The practical advantage of having fewerparameters is that learning proceeds much more quickly andrequires less data to train the model. A CNN only has thenumberofweightsnecessarytoexamineatinyportionoftheimage, as opposed to a fully connected network of weightsfromeachpixel.

ConvolutionLayer

Convolutional layers employ a series of learnable filters toapplytoinputdatainordertoextractfeaturesthatarebeneficial

DOI: rp-9788770040723.143

for later tasks, such object or picture detection.Each filter conducts a dot product between the filter weightsandtheinputvaluesateachplaceasitmovesacrosstheinp utdata,resulting in asinglevaluein theoutputfeaturemap.

ReLULayer

ReLU is the abbreviation for the rectified linear unit. Whenapplying a ReLU layer, the feature maps must be retrieved.The process of acquiring helpful image features starts at thislevel. The convolution process is carried out by a number offilters in a convolution layer. Suppose that each image isrepresented bya matrixofpixel values.

PoolingLayer

In CNNs, a pooling layer is a particular kind of layer that isfrequently used to reduce the spatial dimensions of featuremapscreatedbytheconvolutionallayers,henceloweringt hecomputational complexity of the network and enhancing itscapacitytogeneralise tonew input.

FullyConnectedLayer

An ANN frequently employs a fully connected layer type totrain a nonlinear mapping between input and output data. Itconvertsfeaturemapsorinputdataintoclassprobabilitiesorreg ression valuesfor CNNsandFNNs.

E. Inceptionv3

TheInceptionv3'sarchitectureisinFigure3.

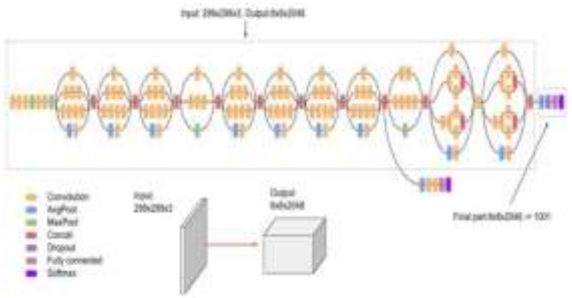

Figure3:Inceptionv3system.

A deep convolutional neural network (CNN) algorithm forimageclassificationiscalledInceptionv3.In2015,Googleres earchers unveiled it as an improvement over earlieriterationsoftheInceptiondesign[22].

TheInceptionv3modelcanextractfeaturesatvariousscales because it comprises of multiple convolutional layers withvarious filter sizes. The model also makes use of the idea of"Inception modules," which are collections of variousconvolutional layers with various filtering granularities thatenable the model to recognize more intricate patterns in thepictures.

Othersophisticatedelementsfoundininceptionv3includef actorizedconvolution,batchnormalization,anddqropout.

These characteristics aid in enhancing the model's functionality and avoiding overfitting.

It has been shown that the picture recognition model Inception v3 can reach better than 78.1% accuracy on the ImageNet dataset. The model is the outcome of multiple ideas that different researchers have developed over time. It was based on Szegedy et al.'s Rethinking the Inception Architecture for Computer Vision.

In this model Softmax is used to calculate loss.Convolutions, pooling layer, max pooling, fully connected layers, dropouts are some of the symmetric blocks that make up the model itself. Batch Normalization is heavily used in the model and is also applied to activation inputs.

IV. Results

10,000 images are available in the HAM 10000 dataset.It is an unbalanced dataset which was then transformed so that it could be used in the model. In order to fit in the model, the images must be resized, normalize the pixel values. Since the dataset is very large it will take a large amount of time to load the images and train them. All the 10000 images cannot be loaded into the model so it is recommended to create a balanced dataset by accommodating specific number of images from each category. The method is run using Python on a Windows 10 computer with an i5 11th Gen processor, 8 GB of RAM, and an NVIDIA GEFORCE GTX1650Ti GPU,

as well as on a Jupyter notebook and a Google Colab.

The table represents why Inception v3 model is better than other CNN models. In all the models the preprocessing techniques were the same. The epochs were tweaked to get better results.

The study's findings are listed in table 1 as follows..

TABLE 1

Network	Models Evaluated	Crops Evaluated	Error
VCGNet	2	-	6.8%
GoogleNet	7	144	6.67%
PReLU	-		4.94%
BN-Inception	4	144	4.9%
Inception-V3	4	144	**3.58%**

TABLE 2. Methods used with training and validation accuracy

Experiment Number	Method used	Training accuracy	Validation accuracy
1	Inception v3 with 10 epochs	74.24%	72.18%
	Inception v3 with 20 Epochs	77.45%	73.67%
	Inception v3with 30epochs	80.39%	77.58%
2	Inception v3 with 20epochsand Softmaxactivation function	78.02%	76.1%
	Inception v3 with 30epochsand Tanhactivation function	81%	77.95%
	Inception v3 with 30epochsand Sigmoidactivation function	82.27%	81.7%
3	Inception v3 with50 Epochsand Sigmoid activation function	86.08%	85.47%

DOI: rp-9788770040723.143

Figure 4 represents the graphical representation if the table 2. It clearly depicts that with different activation function and with higher epochs the model has performed well.

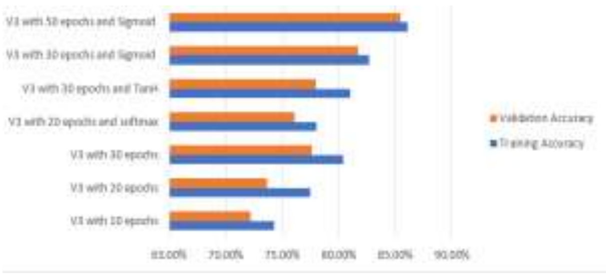

Fig. 4: Pictorial representation of training and validation accuracy percentages.

V. CONCLUSION

The biggest challenge was how to handle such a big dataset. There are seven classes and we have to classify them into any one and it was unbalanced. There are many ways to handle data and the method chosen here is to separate them into each class and augment them individually. The most important step here was to take a subset of those images and converting them to 32x32 size. There is an alternative method which is to use the image data generator. Another preprocessing done was to convert data frame column of images into numpy array.

Different models were discussed before building it but the auto keras feature suggested that Inception v3 would be the best model. It has got seven dense layers giving seven different outputs. The last activation function used was sigmoid so each of the seven is a probability. The highest probability would be our class.

Thispaperhasbeenexperimentedwith3differenttechniquesby tuning the hyperparameters. In the first experiment onlyepochs was tuned and the best results obtained were 80.39%fortrainingand77.58%forvalidationaccuracy.Inthesecondexperiment, the activation function was altered along withepochs and the best activation function was Sigmoid. Thetrainingaccuracyobtainedwas82.27%fortrainingand81.7% for validation. In the third experiment the epochs wassetto50andthebestactivationfunctionwasused.Theresultobtainedwere86.08%and85.47%forvalidation.

Abstract— For all its benefits social media has also enabled the darker aspects of human nature like racism to flourish - often hidden behind seemingly benign posts or anonymous accounts. Such practices have become especially common when dealing with issues related to skin colour, culture ,language origin or religion .This trend is not only harmful but threatens our cultural stability ,social fabric and peace on an international level . To counteract this situation a recent research suggests the use of deep learning tools such as gated recurrent units (GRU) convolutional neural networks (CNNs) with LSTM ,and ensemble modelling along with sentiment analysis aimed at locating racist tweets For those interested in machine learning, its worth noting the capabilities of Gated Convolutional Recurrent Neural Networks with LSTM and BERT (GCR-NN+lLSTM+BERT). Within this framework the GRU component is adept at extracting specific characteristics from unprocessed text while CNN can provide necessary context for RNN to more accurately predict outcomes alongside the usage of LSTM and BERT.

I. Introduction

Social media has become a breeding ground for racism, where individuals spread hate speech, bigotry, and prejudice against people based on their race, religion, language, culture, and national origin. Racism on social media can take various forms, including the use of memes, false identities, and overt expressions. Unfortunately, one of the negative consequences of this widespread use of social media is the rise of vices such as racism. Twitter, for example, has emerged as a platform where racism and its associated tensions are prevalent. With over a million words and contexts and memes followed by different opinions and content,Twitter’s reach and influence are vast. Additionally, 90% of Twitter users have a public profile, making it easier for harmful sentiments to spread quickly. Today, 22% of American citizens utilise the social media network. Twitter users can respond to and participate in tweets by publishing them on their profiles (retweeting), tagging other users, and clicking the like button. Tweets are publicly available until they are set to be private. The foundation of sentimental analysis is the expression of sentiments, emotions, attitudes, and ideas on Twitter. Social media platforms have become increasingly popular, which has led to widespread use of them for several contemporary and historical kinds of racism. Racism is depicted on these platforms in both overt and covert ways, such as through memes and the publication of racist Tweets under fictitious names. Racism is not only limited to ethnicity, but also targets people based on their race, national origin, language, culture, and religion. Racial tensions incited on social media are considered a major threat to global peace and stability, as well as social, political, and cultural stability.Racist statements should be quickly identified and prohibited from social media, which is the main source of racist ideas.

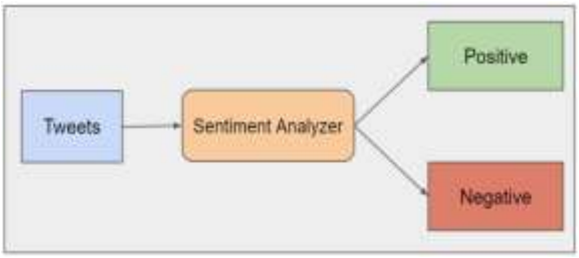

Fig.1: Example figure

Racist comments and social media tweets have been connected to a number of physical and mental disorders, which have a harmful impact on one's health [7–12]. Three categories of racism on social media can be identified: institutionalised, personally mediated, and internalised [13]. Racism can be experienced at a personal level through discriminatory or unfair treatment, as well as by being aware of bias towards loved ones. This has negative effects on individuals, leading to various forms of psychosocial stress that can increase the risk of chronic illnesses. Additionally, cyber-racism is being spread by racist groups and individuals who employ advanced strategies and skills. As a result, sentiment analysis has become a significant area of research to analyze social media text for tasks such as identifying hate speech, making sentiment-based market predictions, and detecting racism, among others.

II. LiteratureReview

A. Using social media to understand and guide the treatment of racist ideology

DOI: rp-9788770040723.144

The paper "Using social media to understand and guide the treatment of racist ideology" proposes using sentiment analysis to detect racist tweets and guide the treatment of racist ideology. The authors highlight the growing prevalence of racism on social media and its impact on societal, political, and cultural stability. The study combines gated recurrent units (GRU) and convolutional neural networks (CNN) to create a stacked ensemble deep learning model called GCR-NN.Several previous studies have also addressed the issue of racism on social media. For instance, a study by Zhou et al. (2018) proposed using machine learning techniques to detect racist tweets and assess their impact on users. Another study by Ngo et al. (2019) used sentiment analysis to detect hate speech and racist content on social media. The authors highlighted the importance of detecting and addressing such content to prevent its negative impact on individuals and society.Moreover, other studies have examined the impact of social media on racism and prejudice. For example, a study by Correa et al..

B. *Using social media for health research: Methodological and ethical considerations for recruitment and intervention delivery*

The paper "Using social media for health research: Methodological and ethical considerations for recruitment and intervention delivery" explores the potential benefits and challenges of using social media for health research. The authors highlight the increasing popularity of social media platforms as a means of communication and data sharing, and how they can be utilised for health research purposes. The paper discusses various methodological and ethical considerations that researchers must take into account when using social media for recruitment and intervention delivery. For instance, the authors highlight the importance of ensuring participant confidentiality, privacy, and informed consent. The study also notes the challenges of sample representativeness, potential selection bias, and the reliability of self-reported data collected through social media.Several previous studies have also examined the use of social media for health research. For example, a study by Laranjo et al. (2015) explored the potential of social media for health promotion and intervention delivery, highlighting the benefits of social media as a cost-effective and accessible means of communication with participants. Another study by Peng et al. (2017) examined the feasibility of using social media for patient recruitment in clinical trials, and found that social media platforms can be effective in reaching a diverse and geographically dispersed sample.Overall, the paper highlights the potential benefits of using social media for health research, but also underscores the need for careful consideration of methodological and ethical issues when utilizing these platforms.

C. *Online networks of racial hate: A systematic review of 10 years of research on cyber-racism*

The paper "Online networks of racial hate: A systematic review of 10 years of research on cyber-racism" provides a comprehensive analysis of research on cyber-racism, focusing on online networks of racial hate. The authors examine the prevalence, forms, and impact of cyber-racism, and highlight the need for effective strategies to counter its negative effects.The paper reviews a range of studies on cyber-racism published over a 10-year period, highlighting the various forms of racist content, including hate speech, discrimination, and harassment. The authors also discuss the social and psychological impact of cyber-racism on individuals, such as anxiety, depression, and decreased self-esteem. The study also notes the potential for cyber-racism to have wider social and political consequences, including the normalization of racist attitudes and the promotion of extremist ideologies.Several previous studies have also addressed the issue of cyber-racism. For example, a study by Tynes et al. (2012) examined the experiences of racial and ethnic minority youth on social media, highlighting the prevalence of racist content and the negative impact on their mental health. Another study by Ziegele et al. (2018) explored the role of social media in the dissemination and normalization of extremist ideologies, including racist and anti-immigrant attitudes.Overall, the paper highlights the need for effective strategies to counter cyber-racism, including education, community-building, and policy interventions. The authors emphasize the importance of taking a multi-disciplinary and multi-level approach to addressing the problem of cyber-racism, and call for further research to better understand the complex dynamics of online networks of racial hate.

C. *Reducing racial inequities in health: Using what we already know to take action*

The paper "Reducing racial inequities in health: Using what we already know to take action" provides a comprehensive review of the literature on racial inequities in health and highlights evidence-based strategies for reducing these inequities.The authors review a range of studies on the social determinants of health and the impact of racism and discrimination on health outcomes. They note that racial and ethnic minorities experience higher rates of chronic disease, disability, and premature death compared to their White counterparts, and that these disparities are driven by a range of factors, including poverty, inadequate healthcare access, and exposure to environmental toxins.

The paper also highlights evidence-based strategies for addressing racial health inequities, including policies that promote economic and educational opportunities, improve access to quality healthcare, and address structural racism and discrimination. The authors note the importance of community engagement and participation in efforts to promote health equity, and highlight the need for culturally sensitive interventions that address the unique needs and experiences of diverse populations.Several previous studies have also addressed the issue of racial health inequities. For example, a study by Williams et al. (2019) examined the impact of racism on health outcomes, highlighting the need for policies and interventions that address the root causes of these disparities. Another study by Braveman et al. (2017) identified a range of evidence-based strategies for promoting health equity, including community-based interventions and policies that address social determinants of health.Overall, the paperemphasises the need for a comprehensive, multi-disciplinary approach to addressing racial health inequities, and highlights the importance of using evidence-based strategies to guide policy and practice.

DOI: rp-9788770040723.144

The authors call for continued research and action to address these disparities and promote health equity for all populations.

III. Methodology

A. Overview

Racism on social media has become an increasingly prominent issue in recent years. Social media platforms provide a platform for individuals to express their opinions and beliefs, which can often include racist comments and hate speech. The anonymity of social media has made it easier for individuals to express racist views without fear of repercussions. Additionally, the speed and reach of social media mean that racist comments and hate speech can spread quickly, reaching a large audience.Machine learning and deep learning techniques have been used to address the problem of racism in social media. Sentiment analysis, a subfield of natural language processing, has been used to automatically identify and classify tweets with racist content. These techniques can analyze the language used in tweets to determine whether they contain negative sentiments, and identify the tweets that express racist opinions.However, there are also concerns about the use of machine learning and deep learning in detecting racism on social media. There is a risk of bias in the algorithms used to detect racism, which can lead to false positives or false negatives. Additionally, there are ethical concerns about the use of automated systems to monitor and censor social media content, which can infringe on freedom of speech. Overall, the issue of racism in social media is complex and requires careful consideration of both technical and ethical issues.

B. Disadvantage

1. Existing technology cannot be automatically identified and stopped to prevent future proliferation.
2. Poor performance.

Due to the improvement in performance of Deeplearning networks, To expand the stack for improved performance, gated recurrent units (GRUs), convolutional neural networks (CNNs), recurrent neural networks (RNNs) and LSTM have been combined in the gated convolutional recurrent neural network (GCR-NN) model. In this model, GRUs play a crucial role in extracting relevant and significant features from raw text, while CNNs extract essential aspects of RNN to ensure accurate predictions and on which we add LSTM to generate better output on the accurate predictions.

C. Advantage

1. The proposed GCR-NN with BERT proposes advanced and better performance with enhanced accuracy.
2. The proposed GCR-NN model can detect racist remarks in 97percent of total of tweets.

We developed the following modules in order to carry out the project mentioned earlier.

- Data input: With this module, we will enter data into the system.
- Processing:This module is intended for reading data to be processed.
- This module will be used to partition the data into testing and training models.
- Model creation techniques include GCN with BERT, LSTM, GRU, RNN, CNN, Ensemble Method LSTM + GCN with BERT, Logistic Regression, Random Forest, KNN, Decision Tree, Support Vector Machine, and Voting Classifier.
- Signing up as a user and logging in are required steps for using this module.
- User input: Prediction input will be produced by using this module.
- Forecast: The final forecasted figure will be shown. Logistic Regression, Random Forest, KNN, Decision Tree, Support Vector Machine, Voting Classifier.

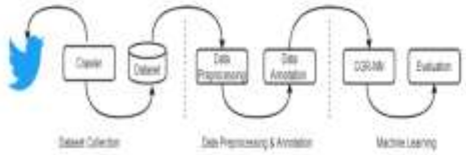

Fig.2: System architecture

IV. Implementation

Algorithms

GCN: For graph-structured data, a Graph Convolutional Network, or GCN, is a semi-supervised learning technique. It is founded on a powerful variant of convolutional neural networks that directly affect graphs.

BERT: BERT is an open source machine learning toolkit for interpreting natural language (NLP). Using the use of contextual information from the surrounding text,the objective of BERT is to assist computers in comprehending the context and meaning of ambiguous words in text.

LSTMs are a type of neural network architecture that can be used in sentiment analysis. They are designed to help overcome the problem of vanishing gradients that can occur in traditional RNNs, allowing them to more effectively capture long-term dependencies in sequential data. In sentiment analysis, LSTMs can be used to model the sentiment of a text sequence by analyzing its context and identifying patterns that are indicative of positive or negative sentiment. By processing text in this way, LSTMs can be used to accurately classify the sentiment of a piece of text, making them a powerful tool for sentiment analysis tasks.

*GRU:*Kyunghyun Cho et al. developed the gated recurrent units (GRUs) recurrent neural network gating approach in 2014. The GRU has fewer parameters because it doesn't have an output gate, but it performs similarly to an LSTM with a forget gate.

RNN: RNNs are designed to handle sequential data, such as sentences or paragraphs, which is important for sentiment analysis since the sentiment of a sentence can

DOI: rp-9788770040723.144

often depend on the sentiment of the preceding sentence.In sentiment analysis, RNNs work by processing input text one word at a time and producing a hidden state that summarises the sentiment information learned so far. The hidden state is updated for each new word in the sentence, taking into account both the current word and the previous hidden state. This allows the RNN to learn the context of the words and how they contribute to the overall sentiment of the sentence.The final hidden state produced by the RNN can then be used to predict the sentiment of the sentence as a whole. This is typically done by passing the hidden state through a classifier, such as a fully connected neural network or logistic regression model, which outputs a probability distribution over the possible sentiment labels (e.g. positive or negative).RNNs are particularly useful for sentiment analysis tasks where the length of the input text can vary, since they are able to handle variable-length input sequences.

CNN: Convolutional Neural Networks (CNNs) are used in sentiment analysis to extract important features from textual data. They are commonly applied to the task of sentence classification where each sentence is treated as a sequence of words. CNNs employ filters that scan the sentence, and through convolution operations, they extract features such as n-grams, sentiment words, and word embeddings. These features are then fed into a fully connected layer for classification. CNNs have shown promising results in sentiment analysis due to their ability to capture local and global information from the input data. Additionally, they require less computational resources compared to recurrent neural networks.

Ensemble Method: Rather than using a single model, ensemble methods combine multiple models in an effort to increase model accuracy. The precision of the results is significantly increased by the integrated models. The popularity of ensemble techniques in machine learning has increased as a result.

Logistic Regression: Logistic regression is a statistical method for binary classification, which can also be applied to sentiment analysis. It uses a linear function to model the relationship between the input variables (in this case, the text data) and the binary output variable (positive or negative sentiment).

*Random Forest:*Random forest is a machine learning algorithm that can be used in sentiment analysis. It works by creating a forest of decision trees, where each tree makes a prediction about the sentiment of a particular input. The algorithm then aggregates the predictions from all the trees to make a final prediction. Random forest can handle large datasets with many features and has good accuracy. It can be trained on annotated data and then applied to new data to classify sentiment as positive, negative, or neutral.

K-Nearest Neighbours (KNN): KNN is a non-parametric machine learning algorithm that can be used for sentiment analysis. It is based on the idea that similar data points should have similar labels. In the context of sentiment analysis, KNN can be used to classify a given text by finding the k-nearest neighbours (i.e., texts with similar features) and using their labels to make a prediction.

Support Vector Machines (SVM): SVM is a popular machine learning algorithm used for classification tasks, including sentiment analysis of tweets. SVM works by identifying the best hyperplane (i.e., boundary) that separates the different classes in the data, such as positive and negative sentiment. It then uses this hyperplane to classify new data points based on which side of the boundary they fall on.

*Voting Classifier:*The voting classifier is a machine learning technique used in sentiment analysis of tweets on Twitter. It is an ensemble method that combines multiple algorithms to make a final prediction based on the outputs of the individual models. In this approach, multiple models are trained on the same dataset using different algorithms like decision trees, random forests, and support vector machines (SVM), each with its own strengths and weaknesses. Then, the voting classifier combines the predictions of all these models to make the final decision. This method has been shown to improve the accuracy of sentiment analysis on Twitter data and can be useful for analyzing large datasets with complex features.

Proposed Architecture and Development

The proposed architecture is based on GCR-NN with LSTM And BERT Tokenisation where feature selection is done using BOW feature and TF score or the polarity score. Along with the proposed deep learning architecture we have used an ensemble method of using a voting classifier. In the deep learning proposed architecture the whole model is an stacked ensemble with various different layers which has GRU, followed by CNN ,on which RNN is stacked for output accuracy and then LSTM with Bert tokenisation is added to enhance the accuracy of the whole model. While in the voting classifier we have various different machine learning models which are then further processed to get an higher advantage on accuracy . Followed by which a comparison is done on which model provides better accuracy on the given sentiment analysis.

V. FUTURE ENHANCEMENTS

We can add this same model on localised dataset for example Bangla language racism detection which can be used to detect racism as in a certain organisation and area and can be further deduced to other languages and context.Also further this model and website could you be used for live analysation of social media on a day to day basis just as GPS works though the processing time could be of an greater issue.

VI. EXPERIMENTAL RESULTS

Fig.3: Home

Fig.4: User registration

Fig.5: user login

Fig.6: Main page

Fig.7: Userpage input

Fig.8: Model result

VII. Conclusion

This study focuses on the problem of the growing frequency of racist language on social media websites and proposes the use of sentiment analysis as a means of detecting negative sentiment and identifying tweets containing racist content. The study utilizes deep learning techniques, as in the use of a stacked ensemble model of LSTM and GCR-NN with BERT tokenisation along with the usage of another ensemble such as voting classifier, to effectively carry out sentiment analysis. The proposed model is evaluated alongside other models using a large Twitter dataset annotated with TextBlobs. The findings indicate that 31.49% of the 169,999 tweets surveyed were racist, and the GCR+LSTM +BERT +NN model achieved an impressive average accuracy score of 0.98 for positive, negative, and neutral sentiment classification. Notably, the model demonstrated superior performance in detecting racist tweets, with a 97% accuracy rate and only a 3% error rate. The study also compared the performance of machine learning models in identifying racist tweets, with both models correctly identifying 96% and 95% of such tweets, respectively, and misclassifying 4% and 5% of tweets as racist. These results suggest that deep learning methods, such as the proposed GCR-NN+LSTM+BERT model,offer potential for identifying and obstructing racist language on social media sites.

Abstract—The new digitization trends have completely transformed or altered industries and traditional business models. Blockchain technology is now poised to completely transform and disrupt sectors, particularly those that depend on trust, like the financial industry. This innovation depends on the possibility that it is a public, shared, and sealed record that lets individuals who don't have the foggiest idea about one another or trust each other convey data in a reliable record where any sort of irrelevant, important data can be kept.

This work gives a hypothetical structure to looking at the impacts of blockchain innovation on the monetary area specifically and the writing overall. This thesis recognizes that blockchain innovation can possibly raise straightforwardness, decrease gambles by tying up less resources during exchanges, increment efficiency, and diminish costs like monetary exchange charges. While brilliant agreements are one of the most aggressive uses of blockchain innovation, the monetary area may likewise profit from different applications. It is still too soon to precisely foresee what the blockchain innovation will actually want to do, despite the fact that the innovation has a huge potential to upset the ongoing monetary framework. The most extreme hypothesis is that banks are not generally needed in light of the fact that to blockchain innovation. This thesis contends that, rather than becoming outdated as a result of blockchain technology, financial institutions are more likely to benefit from it. As an addition, we will map the data to blockchain wallets and also employ NFT smart contracts in place of conventional smart contracts to produce hash addresses, after which the data is transferred to an online IPFS server.

Keywords—Smart contracts, the financial sector, and blockchain technology.

I. INTRODUCTION

Information technology has already had a significant impact on industry and business procedures (Jaki& Marin, 2015). Then again, the internet has prompted the improvement of an extensive variety of novel business techniques and, surprisingly, entirely different monetary subsectors that were unbelievable only a couple of years prior. The genuine advantage of data innovation is that it makes altogether new and more powerful method for connection among individuals and organizations. Blockchain technology is the technology that deserves your attention right now. This relatively new technology will enable less secure and safer ways to conduct business alongside the Internet. This thesis inspects extra applications for the blockchain, which is regularly distinguished as the innovation behind the virtual money bitcoin. This thesis will rapidly make sense of what bitcoin is and why it might work as an elective money surrendered that bitcoins make virtually each of the information in present day blockchains. Regardless of this, the proposition expects to exhibit that the innovation isn't limited to only this application. In mark of reality, there has been a ton of analysis evened out at the utilization of this innovation in bitcoin for being fairly prohibitive. As per TheEconomist (2016b), it is vital for make a differentiation between the possibility of blockchains overall and the particular innovation that controls the virtual currency bitcoin. Buterin (2015), then again, underlines the qualification among public and private blockchains.

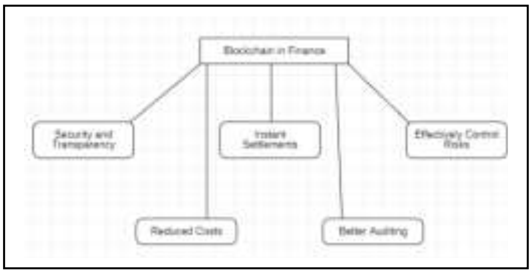

Fig.1: Example figure

Numerous applications made possible by technology need for cooperation and common standards across participants in the financial industry. As a result, this thesis briefly analyses the collaboration between a group of over 50 financial institutions worldwide and the financial technology start-up R3. This collaboration aims to advance blockchain technology and hasten its application to the financial industry. In the highly competitive banking industry, they are working together to establish clear guidelines for the use of this technology. Trautman attests that blockchain technology can possibly overturn and rebuild the financial business, notwithstanding every one of the difficulties it faces.

Blockchain technology will have a much broader impact than bitcoin, according to this thesis. Notwithstanding, it is too early to know precisely exact thing the blockchain will permit or when it will be utilized in the monetary area on the grounds that the innovation is still in its outset. Notwithstanding, there is a critical opportunity that it will disturb the current financial structure. By eliminating ineffective and costly middlemen from, for example, stock trading or international payments, financial institutions stand to benefit from cost reduction as well as increased productivity. Additionally, because blockchain-based procedures require less cash, risks are reduced. Nonetheless, the blockchain's dependability and openness help to increase public confidence in the financial system. Because some services may be more appropriate for the technology than others, it is important to underline that not all useful information should be included in blockchains. But according to this concept, financial institutions would benefit more from automating international payments and securities trading first because those processes have already been proven to be effective.

DOI: rp-9788770040723.145

II. Literature Overview

1. Blockchain and Bitcoin: Regulatory responses to cryptocurrencies:

This essay investigates Bitcoin from a legal and regulatory standpoint, providing significant insights. They start out by defining Bitcoin and highlighting its significance. They discuss issues with Bitcoin's use as a cryptocurrency implementation strategy. With this background on cryptocurrencies, we may now address the inescapable question: Is it legal? What are the currency's regulatory responses? Can it be controlled? They clearly explain why virtual currencies are important, why self-regulation has failed, and what can be gained from this. Finally, they arrive at practical and mostly permanent conclusions on the use of virtual currencies in general, the viability of mining currency on blockchains, and the depth of Bitcoin in relation to the advancement of block chain technology. They come to the conclusion that, much as Bitcoin may be Second Life a decade from now, blockchains might be a really revolutionary social technology similar to Web 2.0 social networks.

2. The Future of Banking: The Role of Information Technology:

This article looks at how information technology (IT) is changing both explicit foundations and the financial area overall. Albeit the essential financial matters of banking have not adjusted, technological advancements might entice establishments to participate in exchange banking (because of IT-driven cost efficiencies). Banks shouldn't, be that as it may, forsake relationship banking. If all else is equal, banks should adapt to customers' shifting tastes for IT-driven products and encourage IT advancements to update or maybe completely rethink relationship banking. Due to the introduction of FinTech startups and IT corporations into conventional banking industries, significant changes are also about to occur in the banking industry. Banks are given greater time to adapt thanks to government action and regulation. JEL L86, O33, G20, and G21.

3. Market Design for Trading with Blockchain Technology:

The so-called distributed ledger, which entails keeping a decentralized record of all transactions for a security, is a fundamental aspect of blockchain technology. Anyone with access to a distributed ledger may look up asset holdings using (anonymous) IDs. They contend in this study that the mapping between IDs and end-investors should be a decision made during market design. They investigate the impacts of the utilization of IDs and the connected straightforwardness of possessions on trading behaviour, trading costs, and investor welfare government assistance while integrating qualities of blockchain innovation into a hypothetical model of intermediaried and peer-to-peer trading. They discover that, notwithstanding the possibility of front-running, the setup with the most transparency results in the greatest investor welfare. In the absence of complete transparency and low levels of liquidity in the intermediated market, investors' welfare will be at its highest if they are forced to consolidate their assets under a single identity.

4. Bitcoin: A peer-to-peer electronic cash system:

Online payments can be done effortlessly from one party to the next without going through a banking institution using a peer-to-peer kind of electronic cash. Automated markings improve the arrangement in certain ways, but the main advantages are lost if a reliable outsider is still required to reduce copy spending. As a remedy to the double-spend issue, we suggest a distributed organization. By encrypting trades in a persistent chain of hash-based work verification, the organization timestamps transactions. This creates a record that cannot be altered without rehashing the evidence of work. Both the source of the most CPU and the request for times seen are supported by the longest chain. The hubs that aren't working together to seek the organization will create the longest chain and outlast rivals as long as they have the majority of the CPU.The actual organization doesn't need a lot of construction. Hubs could leave the company at any time and come back, using the longest confirmation of work chain as evidence of their absence. The best effort principle governs the transmission of messages.

III. Methodology

As every current application works on a single centralized server and if this server is hacked or crashes due to a heavy load of requests, the services will not be provided, we are using Blockchain technology in financial applications in this project. We can utilizedecentralizedBlockchain technology to solve this issue since it maintains data across numerous servers or nodes, ensuring that consumers can still access services even if one node goes down.

Blockchain stores data as blocks or transactions and assigns each block a distinct hash code. Before storing any new block, Blockchain verifies the hash codes of all existing blocks to ensure that no blocks have been attacked or altered. If this verification is successful, Blockchain will only then store a new block. Blockchain is said to be immutable since it cannot be attacked or have its data changed from the backend if the verification process fails because it won't store any new data. Verification will fail if altered.

The aforementioned benefits of blockchain are driving businesses to move from centralised servers to decentralised networks.

Customers and service providers are the two types of users we are creating for this project.

1) Service Providers: Service providers may register and log in to the application to see orders from customers, add new items, and more.
2) Users: Users may register and log in to the application, access all information about service providers, contribute funds to their wallets, and explore product descriptions to make purchases.

Blockchain uses smart contracts to store data, and SOLIDITY programming is used to create these contracts. Utilizing Truffle, SOLIDITY code may be deployed on Ethereum'sblockchain. Once deployed, the contract will

DOI: rp-9788770040723.145

yield an ADDRESS, which can be entered into a Python application to access the contract and save and receive data from the blockchain.

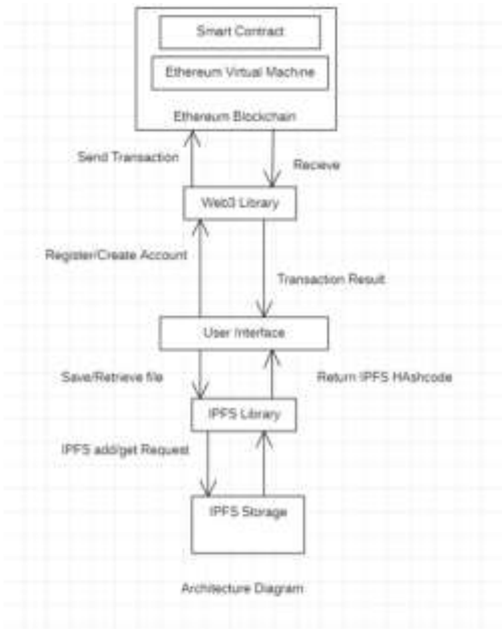

Fig.2: System architecture

In light of blockchain innovation, BITCOIN is a computerized cash that can be utilized for the purpose of trade without the need of an outsider that can be relied upon, similar to a bank. Alternatives to fiat currencies, virtual currencies function similarly to cash. The most popular and widely utilised virtual money nowadays is bitcoin.

Basically, BLOCKCHAIN TECHNOLOGY is a public, disseminated, and dependable record that is open to anybody. Furthermore, it is sealed, and that implies that whenever information is placed into the blockchain, it can't be changed without being seen. Technically, the ledger may include any sort of valuable intangible information. Because there is no need for trust between users of the blockchain technology, it is possible to conduct transactions without a middleman.

DISTRIBUTED LEDGERS are unmanaged, open databases. They are instead supported by several participants. In a distributed ledger, information is dispersed over thousands of locations as opposed to being centralised. A distributed ledger's characteristic is the blockchain technology.

The type of money that is currently used the most is the FIAT CURRENCY, which is a currency that is theoretically worthless but has been given value by a law or a government. Notes, which are really just pieces of paper but have gained value nonetheless, are examples of fiat currency.

Peer-to-peer networks are reliant upon hubs, or PCs all through the globe that are answerable for keeping up with the organization. It is a decentralized organization where hubs speak with each other and trade data without having a focal power.

IV. Technology

1. *Ganache*

Ganache is a private blockchain for quick creation of Corda and Ethereum distributed applications. Ganache may be used throughout the whole development cycle, allowing you to create, distribute, and test your dApps in a secure and predictable setting.A UI and CLI are the two kinds of ganache. An Ethereum and Filecoin desktop application called Ganache UI is available. For Ethereum development, we offer ganache, a more powerful command-line tool.

Fig.3: Ganachee Interface

2. *Metamask*

A software cryptocurrency wallet called MetaMask is used to communicate with the Ethereum network. Users can utilize a browser extension or mobile app to access their Ethereum wallet, which can then be used to connect with decentralized applications. ConsenSys Software Inc., a blockchain software firm that specializes in Ethereum-based infrastructure and tools, is the company behind MetaMask.Using Metamask, users may send and receive Ethereum-based cryptocurrencies and tokens, broadcast transactions, store and manage account keys, and securely connect to decentralized applications using a suitable web browser or the built-in browser of the mobile app.

A user's MetaMask wallet (and any other comparable blockchain wallet browser extensions) can be connected to, authenticated, and/or integrated with other smart contract capabilities by websites or other decentralized applications using JavaScript code. This enables the website to send action prompts, signature requests, or transaction requests to the user through MetaMask as an intermediary.

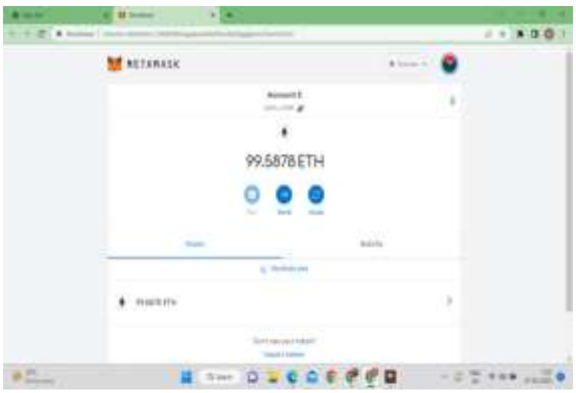

Fig.4: Metamask Interface

DOI: rp-9788770040723.145

3.Algorithms Used

3.1. NFT Smart Contracts

NFTs and smart contracts on the blockchain are the most exciting components (non-fungible tokens). Even yet, the similarities between the two concepts cause confusion for a lot of people. NFTs wouldn't exist without smart contracts, and an NFT smart contract is commonly seen as a single entity with shared goals.These smart contracts can be used in a variety of ways to manage and enhance digital assets. If you want to learn more about them, start by learning how non-fungible tokens interact with smart contracts.

Like cryptocurrencies, NFTs are digital assets that can only be owned by one person at a time. NFTs generally have a supply of just one specific digital token, in contrast to cryptocurrency tokens, which frequently have millions or billions of the same token in circulation. These resources are frequently linked to a link that opens an IPFS file (InterPlanetary File System). The unique token Number and metadata for the asset are provided to the NFT buyer as ownership proof.The ownership of NFTs is distributed through smart contracts, which are also used to create NFTs. Every time a new non-fungible token is issued, the smart contract immediately designates the creator as the owner. NFT smart contracts have the capacity to transfer the token to the new owner after a sale.

Below we can see the solidity code we used to implement NFT Smart Contracts.

Fig.5: NFT Smart Contracts

V. Results

Shows the Main Screen, that a user or a service provider may see.

Fig.11: Search product

Whenever we do a transaction, it is updated here in the form of blocks, and this is done using NFT Smart Contracts.

Fig.12: Ganache Blocks

VI. Conclusion

This thesis took a gander at the likely purposes of blockchain innovation in the monetary business and stressed the pertinence and worth of the innovation. The blockchain innovation is pertinent to substantially more than just the virtual cash bitcoin, as this proposition concedes. As a general rule, this theory proposes that bitcoin is a pretty disappointing utilization of this innovation since it permits clients to send and get cash namelessly, which energizes problematic applications. Different purposes for the blockchain innovation have been canvassed in this thesis by referring to recently distributed works. As an addition, we added the data to blockchain wallets. Additionally, we'll employ NFT smart contracts rather than conventional smart contracts to produce hash addresses, and the data will then be successfully delivered to the IPFS server.

***Abstract*—Unmanned aerial vehicles (UAVs) have a significant problem in autonomous navigation in new or unpredictable situations. To address this issue, the system produces a path between two points, and the drone is commanded to follow this path based on its location. In this study, we provide a novel framework for autonomous UAV route planning based on deep reinforcement learning. The goal is to approach moving or stationary targets using a self-trained drone (UAV) as a mobile aerial unit in a 3-D urban setting. UAVs, particularly rotary- wing aerial robots such as quadcopters, offer a high level of mobility, making them appropriate for a wide range of activities and applications. To provide a safe autonomous flight with limited mission time or battery life, the most efficient path must be determined. The quadrotor UAV in our trials continually monitors its position and battery level and modifies its course accordingly. We simulate the behaviour of autonomous UAVs in several conditions, including obstacle-free and urban environments. Our findings show that the UAV is capable of choosing clever paths to its objective.**

I. Introduction

UAVs can be remotely piloted by humans or capable of autonomous flight. They are often used by the military and police when it is too risky to send a human-piloted aircraft, or when it is impractical to use a manned aircraft. The International Civil Aviation Organization, or ICAO, refers to UAVs as unpiloted aerial vehicles or remotely piloted aircraft. UAVs have already revolutionized military and special operations, and their use is expanding to a variety of other applications. Commercial drones are smaller versions of consumer drones that are used for commercial purposes. Users typically control the speed and altitude settings when these drones take off. Delivery drones can withstand extreme temperatures and high winds, making them ideal for delivering packages quickly. Amazon is currently developing a drone delivery system that promises todeliver items within 30 minutes of payment. Commercial drones are also used for surveillance, including monitoring livestock, mapping wildfires, securing pipelines, and patrolling roads and homes. They are also useful for commercial and film production. Utilizing this technology can speed up services and improve efficiency in various industries.

II. Background

Drones that are autonomous are unmanned air vehicles (UAVs) that do not require a human pilot and depend on navigation and operating software driven by Artificial Intelligence (AI). Originally developed for military missions that were too dangerous or uninteresting for humans, by the turn of the twenty-first century, UAVs had become essential assets for most militaries worldwide. As control technologies improved and costs decreased, the use of UAVs in non-military applications has increased, including emergency response by crew members in the field. Drones are categorized based on their altitude range, endurance, and weight, and they are utilized for a variety of objectives, including military and commercial uses. UAVs today perform a variety of tasks, including climate change monitoring, search and rescue operations during natural disasters, photography, videography, and package delivery. The military's most well-known and controversial use of drones is for reconnaissance, surveillance, and precision strikes.

III. Literature Survey

This paper [1] presents a novel implementation of model-based reinforcement learning (RL) as a high-level control mechanism for self- navigation of unmanned aerial vehicles (UAVs) in unfamiliar or unpredictable settings with short battery life. The suggested technique was tested in a simulated environment using a quadrotor UAV, and the findings show that the system can learn an effective trajectory in a few iterations and perform actions in real time. The experiment also revealed that TEXPLORE, the model-based RL algorithm, significantly outperformed the Q-learning-based method. This is a promising step toward enhancing the autonomous behavior of UAVs, and it highlights the potential of RL frameworks in addressing the challenges faced by UAVs in autonomous navigation.

The Author of this paper [2] Path planning, localization, and control procedures are included in this strategy for autonomous drone delivery jobs. The recommended method evaluates quadrotor posture using computer vision algorithms and UWB sensors, and an enhanced Kalman filter allows a sensory combination with the DJI-SDK stance of the drone.. A vector field-based controller issues the orders that allow the drone to go from its launch site to its landing platform. The experimental results indicate that the suggested strategy is suitable for a full autonomous delivery operation, and that the proposed localization method outperforms the DJI-SDK posture estimation alone during landing attempts. In addition, the system is proven to be robust in the event that one of the localization strategies fails.

However, there are still obstacles to overcome, such as the need for GPS-capable environments devoid of obstructions and known and constant load mass. Future works will address these concerns, as well as mechanical design considerations and the adjustment of controller parameters for smooth flight and landing precision.

In this paper [3], The proposed framework for autonomous UAV navigation in urban environments is

DOI: rp-9788770040723.146

based on deep reinforcement learning using a DDPG algorithm with a continuous action space. The objective of the framework is to train the UAV to determine its trajectory to reach a designated target while avoiding obstacles. The framework employs a transfer learning strategy to maximise the reward function, which is designed to balance select direction and hurdle penalty. The simulation findings show that the Quadcopter may acquire knowledge how to maneuver in real-time and avoid collision with objects.

The proposed framework has potential applications in various areas, such as parcel delivery, search and rescue, and surveillance. However, there are still some challenges to overcome, such as the accuracy of the obstacle detection system, which can affect the performance of the UAV. Additionally, the proposed framework is currently limited to numerical simulations, and it needs to be validated in real-world scenarios to assess its effectiveness and robustness.

In conclusion, the proposed framework presents a promising approach to overcome the challenges of autonomous UAV navigation in urban environments. By using deep reinforcement learning, the UAV can learn to navigate in real-time and reach its goal while avoiding hurdles. The framework has potential applications in various areas and can be further improved by addressing the existing challenges.

In this paper [4], The construction of a general drone navigation system that can navigate the drone to the issue area using data from onboard sensors is discussed. This is especially significant in risky and safety-critical circumstances when issue identification must be swift and accurate. The technique presented in the study combines Policy optimisation at the proximal level Deep reinforcement learning is combined with progressive module development and neural networks with long- term, short-term memory to build an adaptive and autonomous system capable of decision-making. To show accuracy and efficacy, the study compares multiple system configurations to a heuristic technique. Finally, the paper discusses the importance of ensuring the safety of the drone in real- world scenarios, and evaluates the performance of the drone using the developed navigation algorithm. Overall, the paper presents a promising approach to the development of mobile robots that are adaptable and autonomous, with decision-making power, for use in monitoring and data collection in various environments.

In this paper [5], offers a new handover technique for a drone system with wireless connectivity. that use reinforcement learning to optimise handover decisions while also ensuring strong Support for communication over wireless networks and mobility for drone user equipment (UEs). The Q-learning method is used to optimise handover decisions for a particular flight trajectory in real time, and the reward function may be changed to balance the number of handovers with the received signal intensity.

While the simulation findings show considerable gains in minimising the frequency of handovers while maintaining stable connectivity, the study has several drawbacks that require more investigation in the future. To begin, the existing framework only addresses drone movement in two dimensions; the next natural step is to enable three-dimensional mobility of drones. Second, the testing region and flight routes explored in this work are extremely limited, and it would be interesting to see if the results are valid for wider trial regions and extended flight paths with a bigger possible cell pool. Finally, because the proposed framework and experiments are based on an indication of received signal intensity, (RSRP), future research may consider adding additional parameters to the model to improve its performance.

This paper [6] focuses on the creation of an autonomous drone navigation system for package delivery, with the major tools being GNSS and a compass. The primary purpose of the research is to give critical medical assistance for emergency situations and to integrate them in Indonesian agriculture, in accordance with Society 5.0's great mission and big data. To simplify autonomous navigation throughout the transmission process, the proposed navigation algorithm makes use of course- over-ground data. In the trial, the proposed method proved effective in allowing a drone to duplicate a package delivery operation with enough navigation and acceptable landing site variance. However, the data showed that the distances smaller than 1 m, guidance using the field-over-ground strategy is not any more effective than navigation using GNSS and compass.

The proposed system has several features, including altitude and speed settings, interactive sensors for item delivery, and a user-friendly mobile application interface. The system can operate independently from the Ground Station, enabling a drone and mobile application to perform a delivery mission. The navigational algorithm established in this study might have potential uses in other sectors, such as drone combat, and could be further refined and adapted to travel from any distance and for any purpose utilising more accurate and adaptable algorithms.

Overall, the research presented in this paper provides insights into the development of autonomous drone navigation systems for package delivery and highlights the potential applications of such systems in various fields.

Delivery via Autonomous Aerial Vehicles (UAVs) is thriving. In this paper [7], Deep reinforcement learning is used in a unique approach for autonomous navigation of UAVs in complicated, unfamiliar surroundings. The approach does not rely on course planning or map construction, instead relying on sensory data from the surrounding environment and GPS signals. The navigation problem is modelled as a partly observable Markov decision process (POMDP), and an actor-critic architecture-based quicker method for POMDP policy learning is developed. The suggested method's usefulness is evaluated by simulations in five virtual settings, and the findings show that it is successful in allowing UAVs to travel securely and effectively in complex, unfamiliar surroundings.

This paper [8] suggests an approach Based on the new details, I gather that the study provides a deep reinforcement learning-based solution for autonomous path planning for UAVs in situations with many obstacles. Based on the Twin Delayed Deep Deterministic Policy Gradients (TD3) algorithm, the proposed technique comprises a two- stream

DOI: rp-9788770040723.146

Actor-Critic network structure that captures environment attributes from both observations and changes in observations to account for environment randomness and dynamism. In terms of flexibility and generality, the method surpassed DDPG and regular TD3 in simulated settings. The proposed technique enables drone to navigate safely in dynamic and heterogenous environments, which is crucial in scenarios like search and rescue and surveillance.

In this paper, [9] The project aims to address the problem of a single unmanned aerial vehicle (UAV) performing integrated detection, mapping, and navigation in an unknown area. The UAV is furnished with a low-complexity radar for this purpose, and its trajectory is tailored to optimise mapping precision while avoiding places where data may not be relevant for target identification. The Markov decision process (MDP), with the drone operating as an agent that infers its own navigation strategy using Either a state estimator or a reinforcement learning (RL) approach is used for identifying targets and area mapping. The results of the numerical simulation validate the proposed method, emphasising the UAV's capacity to explore regions with a high likelihood of target detection while autonomously recreating the surrounding environment.. Overall, this paper provides a uniqueapproach to dealing with the difficulty of combining identification, the mapping, and navigational instruction for a single UAV, which might have important implications in sectors such as emergency response, monitoring and tracking the environment.

In this paper{10], A reactive controller based on neural networks enabling micro UAVs to manoeuvre independently in unexpected outside environments. Control signals are generated by the controller utilising current sensor data rather than optimisation or configuration space searches, which reduces processing requirements. To address the navigation problem, which is modelled as a Markov Decision Process, deep reinforcement learning is applied. In addition, the authors present model explanation approaches based on feature attribution to give both visual and textual explanations of flying decision- making results. Global assessments can also be performed by the trained neural network will be evaluated and improved by professionals. The outcomes of the simulation demonstrate that the suggested technique gives an adequate justification for the generated module, which is advantageous for both first-time users and controller architects. The real-world testing show that the reactive controller works. outperforms conventional approaches using the same computational resources.

Using a PID+ Q-learning algorithm, [11] This study describes a system for employing reinforcement learning to enable unmanned aerial vehicles (UAVs) to navigate in areas where an accurate mathematical model may not be accessible. To illustrate the effectiveness of the suggested strategy, the authors conducted both simulation and actual implementation trials. The technical elements of implying reinforcement learning algorithms to drone systems and UAV flight programs were also discussed, with the goal of furthering research in this subject for critical applications like as wildfire monitoring and search-and-rescue operations. The proposed method is able to deal with environmental uncertainties, such as wind and other environmental dynamics, and provides a simple and effective solution for training UAVs to navigate in unknown environments.

IV. Methodology

A simulation in the MATLAB environment to validate the RL-based navigation concept for a quadcopter. The quadcopter's mission is to navigatefrom the starting position to the target position in the most efficient manner possible, with the ability to adjust the linear/angular velocity. The simulation uses a motion capture system to provide the quadcopter's position relative to the environment. The system uses a PID controller to facilitate the quadcopter's action and examines the system's behavior in specific scenarios. The framework's effectiveness is visualized in terms of error rate and task completion. The experiment is designed to illustrate a quadcopter whose mission is to find the most efficient route to the destination while monitoring its battery level and making intelligent decisions, such as rerouting for battery recharging at intermediate intervals. The quadcopter is viewed as a rigid body to which torques and forces are applied by four square-shaped rotors. The simulation uses a predetermined path in trajectory mapping, and the quadcopter is programmed to follow the calibrated trajectory to reach its destination.

V. Result

After building a model, it is very important to know the mapping ability of the model for new instances. You might want to try different paths with the model for the same Trajectory map, and then simply compare them in terms of performance. The shortest path must be selected and the time taken for the drone to reach the destination should be minimum also the endurance of the UAV must be considered during the real-time testing. This model implements a set of position states precisely by location, heading, turn curvature, and turn direction to generate a trajectory consisting of a collection of waypoints. The predefined data contains poses for specific locations where the toy quadcopter utilizes its cameras, allowing the pilot on the ground to estimate the altitude of the snow on the roof. Each of the supplementary power generators has three no-fly zones so that, in the event of a quadcopter malfunction, it does not cause damage to campus infrastructure. The red line represents the flight path, while the black x-markers indicate a change in trajectory or a particular pose. Poses are accompanied by blue lines that indicate the direction to a particular waypoint. Green circles indicate no-fly zones. The next part, Importing the mamo model UAV for the implementation of the proposed model to simulate in the defined Path.

The overall performance of the drone simulation was successful, The pre-planned Trajectory helped the drone to follow the given route and make travel from the source to the destination point with a minimal amount of time. The trajectory calibration is the difficult part of this project as it has to consider many obstacles and environmentalcongestion for any accidents or loss of control of the drone. Even though this project was done in a virtual

DOI: rp-9788770040723.146

environment it has to follow a certain path and No- Fly zone area to be avoided collision with a building or an object that is created in 3D Modelling.

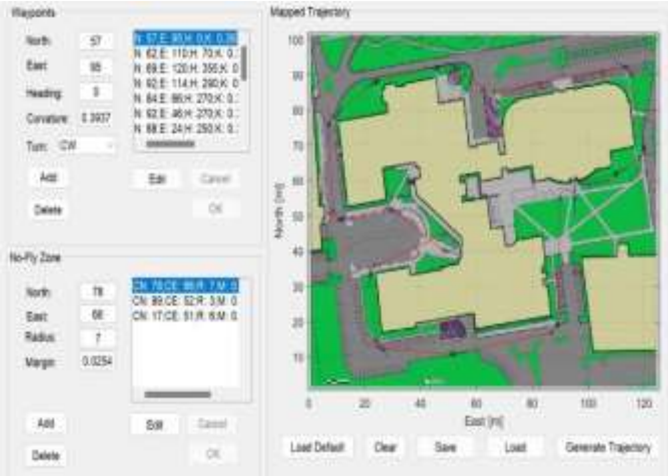

Fig. 1

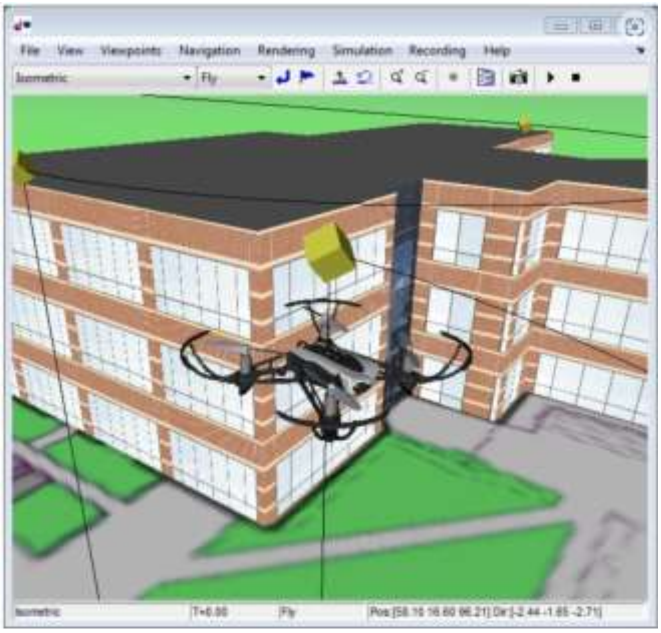

Fig: 2

FUTURE ENHANCEMENTS

Future research will concentrate on conducting experiments with quadcopter UAVs equipped with Reinforcement Learning and Obstacle avoidance and will investigate the difficulties of operating in the continuous domain. We also intend to achieve improvements in path planning, taking into account obstacle avoidance and power efficiency. Implementing reward-based reinforcement learning canimprove the capability of path planning, and the use of YOLO or SSD can improve obstacle avoidance by combining a camera and sensors to have both visual and sensory types of assistance for preventing accidents or damage to the unmanned aerial vehicles.

ACKNOWLEDGMENT

Right at the beginning, I would like to thank the management and the information technology department for their support and the timely completion of our small project.

I would like to thank the head of the department, Dr. M. Lakshmi, and Prof. Dr. G. Vadivu for their cooperation and encouragement for the successful completion of the project.

I would like to thank my supervisor, Dr. K. Sornalakshmi (Assistant Professor) for their constant support during the project and for their insightful comments and constructive suggestions to improve the quality of this project.

***Abstract*—Agriculture is an important field of study and agricultural forecasting is an important aspect that depends on a lot of factors. In the past, farmers were free to choose their crops based on factors such as soil composition, rainfall, humidity and temperature conditions. They then observe the growth of these crops and determine the ideal time to harvest them. However,due to rapidly changing environmental conditions, this approach is no longer sustainable.**

Crop forecasting has become predominantly reliant on machine learning techniques in recent years, which have been extensively employed in this area of research. To ensure that machine learning models perform with high accuracy, it is important to use efficient feature selection methods to preprocess uncleaned and basic data and create datasets suitable for machine learning. Only data features that are highly relevant to defining the final model output should be used to eliminate redundancy and improve model accuracy. it is of utmost importance to select the most appropriate features for a model, ensuring that only the most relevant ones are incorporated. Failure to consider the significance of the data characteristics during the modeling process will result in an unnecessarily intricate model, incorporating all the features of the raw data.

Also, adding features that don't contribute much to a machine learning model increases temporal and spatial complexity, which hurts its accuracy. The results of this study demonstrate that the ensemble approach outperforms current classification techniques in terms of predictive accuracy.

***Keywords*—Agriculture, classification, Agro Prognostics, feature selection.**

I. INTRODUCTION

Agricultural forecasting is a complex process in agriculture that requires the use of multiple data sets due to the reliance on the process of sowing seeds is dependent on both living and non-living factors. Biological factors include environmental components resulting from the direct or indirect action of living species (microbes, plants, animals, parasites, predators, pests) on other living organisms, as well as human variables such as fertilization, protection of plants, irrigation, air, and water pollution, soil quality. These factors lead to various variations in crop production, such as internal errors, yields. Abiotic and biotic factors have an impact on the environmental formation, development and quality of plants. Abiotic factors include physical, chemical, and other factors such as mechanical vibration, radiation, climatic conditions, soil type, topography, atmosphere, and water chemistry.

Chemical components such as environmental toxins, nitrogen fertilizers, pesticides and heavy metals also play a role. Abiotic factors such as bedrock, topography, climate and water conditions all impact crop quality. Soil formation variables also have broad impacts on soil formation and agricultural values.

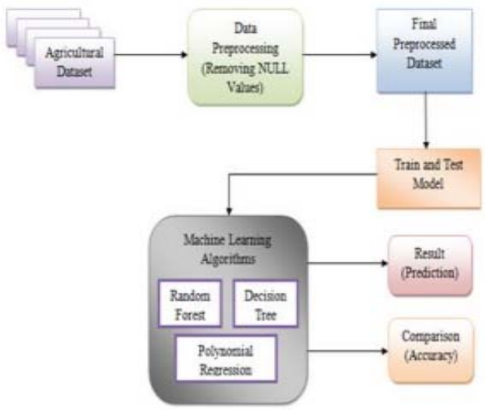

Fig.1: Example figure

Analyzing the agricultural production process is a difficult and complex task. strategies are essential for predicting crop area, which is a continuous improvement optimization process. These strategies can also be used in the design, development and formulation of new and improved products. However, to perform statistical analysis, it is necessary to have access to numerical data, which allows to make inferences about different events and thus to take binding economic decisions.

According to Muriithi [6], the representation of a specific event numerically increases the amount of information that can be obtained, and the improved data quality allows for more accurate information and more accurate decision making.

II. LITERATURE REVIEW

Using naive Bayes classification techniques to classify improved agricultural land soils:

DOI: rp-9788770040723.147

The proliferation of computing and data storage technologies has led to the accumulation of large amounts of data. Extracting useful information from this raw data has always been a challenge, which has led to the development of new methods and techniques such as data mining, which help bridge the knowledge gap. This study aimed to evaluate these new data mining methods and apply them to soil science databases to determine if relevant associations could be found. The Department of Soil Science and Agrochemistry of SV College of Agriculture, Tirupati provides an extensive soil database containing soil profile measurements from many locations in Chandragiri Mandal, Chittoor district. This study investigates whether soils can be classified using different data mining methods.

In addition, a comparison of naive Bayesian classifications is performed and the best performing methods are analyzed. The results of the study could have wide applications in agriculture, land management and environmental protection.

Biotic factors

Potato production in Canterbury has remained steady at around 60 tonnes per hectare for the past decade. However, potato growth models predict potential yields as high as 90 tonnes/ha, which some commercial growers have already achieved. A two-year study conducted by industrial and academic partners examines constraints to agricultural production. During the first growing season, 11 transformed crops were fully evaluated, including tests for final yield, plant health and soil quality. Persistent reasons for declining yields have been found to include soil-borne diseases such as Rhizoctonia stem canker and sponge root infection, as well as subsoil compaction and poor management. irrigation.

A crop history of potatoes grown over the past decade has resulted in more rapid development of Rhizoctonia stem canker symptoms (by emergence) compared to periods of grass growth and non-crop areas previous potato crop (8 weeks after emergence). In year two, a controlled field trial was conducted on a cash crop known to have high levels of soil-borne pathogens to identify and quantify the impact of soil-borne diseases. on performance. The treatments consisted of soil fumigants (90, 112 and 146 kg/ha of chloropicrin) without pesticide control before the application of azoxystrobin (1.5 L/ha) or fluosulfa (400 mL/ha). DNA testing of soil-borne pathogens before and after treatment showed a slight decrease in DNA levels of R. solani and subterranean sponges in soil (plots treated with the fumigant), but results varied. considerably.

The final total fresh yield averaged 58 tonnes/ha and was unaffected by the treatment. The severity of R. blight on rhizomes treated with azoxystrobin was consistently lower than all other treatments throughout the season.

Response surface methodology: A retrospective and literature survey

Response Surface Methodology (RSM) is a combination of statistical design and numerical optimization methods used to improve process and product design. The roots of exploration in this field trace back to the 1950s and have garnered extensive utilization, notably within chemical and process industries. In recent times, RSM has undergone a gamut of inventive upgrades and has found diverse applications over the last 15 years. Our analysis focuses on RSM developments since 1989, highlighting contemporary fields of investigation and recommending potential avenues for future inquiry.

Utilizing response surface methodology to enhance potato tuber production:

The study investigated the optimal operating parameters for obtaining maximum yields of potato tubers in Kenya, with the aim of helping potato growers reduce input costs. To achieve this goal, the authors used a 2 3 factorial design and response surface methods to improve the potato manufacturing process. Using response surface methodology, the authors studied and optimized the combined effects of the mineral nutrients of water, nitrogen, and phosphorus. They determined that the optimal production parameter for potato tuber yield was 70.04% irrigation water, 124.75 kg/ha of nitrogen in the form of urea and 191.04 kg/ha of phosphorus in the form of triple superphosphate. Under ideal conditions, a 1.8m x 2 plot can produce up to 19.36kg of potato tubers.25 meters. Increasing potato production could improve livelihoods and reduce input costs for smallholder potato farmers in Kenya. Additionally, the methods used in this study can be applied to other crop studies to better understand overall crop productivity.

Enhancing potato crop yield forecasting through the integration of cultivar details and unmanned aerial vehicle (UAV) remote sensing data via machine learning:

Precision agriculture requires accurate yield maps to identify patterns of geographic variation in yields, identify key variables driving yield variation, and provide site-specific management information. Yield forecasting of potato (Solanumtuberosum L.) tubers using remote sensing is critical, as cultivar variation can have a significant impact on yield predictions. with a machine learning approach using unmanned aerial vehicle (UAV) remote sensing.

In the years 2018 and 2019, various cultivars and levels of nitrogen (N) were tested on small plots to assess their effectiveness.

Gather multispectral imagery via drones at different stages of plant growth and employ machine learning algorithms like random forest regression (RFR) and support vector regression (SVR) to integrate multiple plant metrics with varietal data. The research discovered that spectral data obtained during the onset of tuber initiation (in late June) exhibits a stronger correlation with marketable potato yields compared to data obtained during the maturity of the tuber in the later stages of the growing season. Nonetheless, the optimal nutrient markers and time for anticipating potato yields differ depending on the potato variety. Model that do not use variety information. Further research is needed to improve potato yield predictions by combining more specific data on varieties, soil and landscape characteristics,

DOI: rp-9788770040723.147

management data and advanced machine learningAlgorithms.

III. METHODOLOGY

Assessing agroclimatic parameters that influence the production of winter plant species in the temperate temperature zone, primarily grains, presents a significant challenge. The primary factor that impacts wintering yield is the number of days with temperatures above certain thresholds, such as 5 degrees Celsius, as well as the frequency of these days and the number of days with temperatures above 0 degrees Celsius and 5 degrees Celsius during the wintering period. While some of these parameters can be approximated using public data, fluctuations in these components pose a challenge. Accurate predictions of agrometeorological parameters are crucial for precise production forecasting, especially in light of rapid changes in environmental circumstances that make farming increasingly challenging.

Disadvantages

Despite the progress made in the field of agro analytics, there are still various challenges that need to be overcome, including the need for improved crop forecast models that account for soil and environmental factors such as rainfall, humidity, and temperature. In this regard, a research study proposes an enhanced crop forecast model that uses two essential techniques: feature selection (FS) and classification. The research study utilizes sampling approaches to balance an unbalanced dataset before using FS methods to identify data characteristics that are highly important while checking the end output of the model.

Advantages

One of the advantages of this proposed model is that it avoids redundancies and improves the accuracy of the machine learning model by only including data characteristics with a high degree of importance. Additionally, an ensemble method outperforms the previous classification technique, resulting in increased prediction accuracy. This improved crop forecast model has the potential to overcome some of the difficulties in predicting agrometeorological parameters for winter plant species, particularly grains, and provide farmers with more accurate information for decision-making in the face of rapid environmental changes.

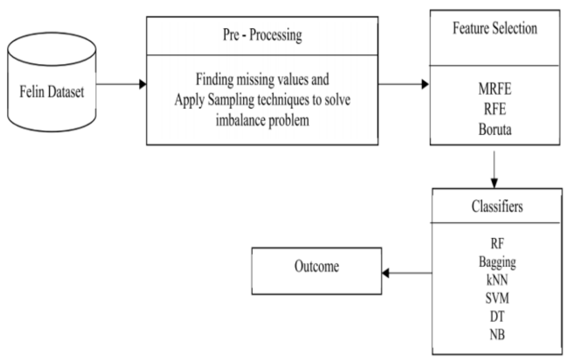

Fig.2: System architecture

Modules

- The following modules were developed for the project at hand:
- Data Exploration: This module will facilitate the input of data into the system.
- Data Processing: This module will read and process the input data.
- Train-Test Split: This module will be used to separate the data into training and testing sets.
- Model Generation: This module will be responsible for building the machine learning models, including models with and without feature selection. The feature selection techniques to be used include SMOTE, ROSE, RFE, MRFE, BORUTA, and MEMOTE. The machine learning algorithms used for model building include Naive Bayes, KNN, Bagging Classifier, Random Forest Decision Tree, SVM, Gradient Boosting, and Voting Classifier. The accuracy of the algorithms will also be calculated.
- User Signup and Login: This module will enable users to register and log in to the system.
- User Input: This module will allow users to input data to be predicted.
- Prediction: The final prediction will be displayed through this module.

IV. IMPLEMENTATION

Algorithms

KNN (K-Nearest Neighbor): KNN is a supervised machine learning algorithm that can handle both classification and regression problems. In this algorithm, the number of nearest neighbors (denoted by "K") of a new unknown variable is used to predict or rank the variable.

Naive Bayes: Naive Bayes is a probabilistic classifier based on a probabilistic model with high independence assumptions. The algorithm assumes that the input variables are independent, which may not be the case in reality.

Bagging Classifier: A Bagging Classifier can be thought of as a team of base classifiers that work together to make predictions. Each member of the team is trained on a random sample of the original data, and their predictions are combined to form a final output. This technique is particularly useful for reducing the uncertainty of complex machine learning models.

Random Forest: Random Forest is a supervised machine learning algorithm that can handle both classification and regression problems. It is based on the idea of ensemble learning, which consists of integrating several classifiers to improve the performance of the model. A random forest consists of many decision trees over different subsets of the provided dataset, and the end result is a majority vote based on predictions.

Decision trees: Decision trees use several methods to determine whether a node should be split into two or more child nodes.

DOI: rp-9788770040723.147

SVM (Support Vector Machine): SVM is a popular supervised learning method used for classification and regression tasks. The SVM algorithm is designed to find the best straight line or decision boundary for classifying an n-dimensional space so that new data points can be easily assigned to the correct class in the future. The optimal choice boundary is represented by a hyperplane.

Gradient Boosting is a powerful technique in the realm of machine learning, widely applied to tackle regression and classification challenges. Essentially, it constructs a predictive model by aggregating a series of feeble models, which are usually decision trees. By leveraging decision trees as weak learners, the method is commonly referred to as boosted gradient trees.

Speech Classifier: A speech classifier is a machine learning estimator that trains multiple base models, or estimators, and makes predictions based on the results of each base estimator. The voting decisions from each estimator output can be aggregated to make a final prediction.

***Abstract*—The atmosphere is the most important resource required for the survival of all living beings including plants. The air quality is depleting at a faster pace due to growing industries, construction of houses and the excessive use of vehicles due to the rapid growth of population. Air quality is described as to be the degree which the air is clean in a particular area.As India grows in areas of industrialization and urbanization, the air quality is also slowly depleting due to the emission of harmful gases and particles by industries and vehicles. Every household has at least one car and this also adds up to the problem of depleting air quality in different areas. The aim of this study is to apply a Stacking Ensemble Model in order to make predictions about the air quality of a specific location in India, Stacking Ensemble Model is built on regression models such as Gaussian Process model, Support Vector Regressor Model, Stochastic Gradient Descent Regressor model and the AdaBoostRegressor Model.**

Keywords*—Air Quality, Prediction, Gaussian Process Regressor, Support Vector Regressor, Stochastic Gradient Descent Regressor, Stacking Regressor, Ensemble Technique.

I.INTRODUCTION

The earth's atmosphere is comprised of gases and is an essential component of the planet's physical system. Nitrogen and oxygen make up majority of the atmosphere at sea level, accounting for 78% and 21%, respectively. Other gases, such as carbon dioxide, hydrogen, helium, and noble gases, are present in small quantities. The atmosphere serves to protect life on earth by regulating temperature, moderating the differences between day and night, and shielding the planet from harmful UV radiation.

Air pollution is a significant issue for many nations throughout the world, and it significantly contributes to the rise in health issues such as breathing difficulties, heart rhythms, lung dysfunction, the emergence of cardiovascular and respiratory disorders, etc. Particulate matter is made up of very minute liquid and solid particles that are suspended in the atmosphere.

PM2.5, in contrast to other pollutants, is particulate matter made up of particles with a diameter of no more than 2.5 micrometres. These specks are so small that they can get inside the nose, lungs, and the bloodstream.

Urban areas are majorly affected by air pollution as they are surrounded by industries, construction premises and lot of vehicles on the road. Industries release a lot of smoke and harmful gases into the atmosphere that it becomes dangerous for residents living nearby to breathe the air as it will affect their health adversely. Cities are growing in population as they are developing better, and residents are having a better life in cities. Due to this growth, there is a need for more space to build houses and this leads to increase in deforestation. Trees play a key role in purifying the atmosphere but these air purifiers are removed which increases the chance of air pollution. Cars, trucks and motorbikes release a lot of smoke in the air that it becomes difficult to breathe the air.

Predicting the air quality is very important as it will alert us about the possibility that we might be breathing harmful air and we need to be aware of it. It also helps us to understand the need for protecting the air so that we will have clean air to breathe in the near future. Stacking is an ensemble technique that teaches the model how to mix predictions from Base models and meta-models to create a final model with accurate predictions.

II.MOTIVATION

The need of the hour is to be able to breathe good quality air. All parts of the world is facing the problem of air pollution and it needs to be reduced so that there will be safe and clean air to breathe in the future. It is very important to create awareness and the need to treat this natural resource with great care so that it will sustain for the future. We have used a few regression models and to improve their accuracy we have built it with the help of the stacking algorithm.

III.RELATED WORK

The researchers employed two machine learning models, that’s ANN and GPR to forecast the quality of air in six Indian cities. The R-values obtained for ANN and GPR were 0.96 and 0.98, respectively. The GPR model outperformed the ANN model with lower RMSE, MAPE, and MAE values of 21.40, 7.89%, and 13.58, respectively. The results suggest that GPR is a promising approach for predicting air quality in Indian cities [1].An exploratory data analysis is conducted to reveal new insights, identify concealed trends, and identify harmful substances that may affect air quality directly. The authors employed five different models namely, KNN, GNB,SVM, Random Forest and XGBoost to predict the air

DOI: rp-9788770040723.148

quality and concluded that Out of all the models tested, the XGBoost model had the highest performance, achieving an R-squared score of 0.83. This result was better than any other model evaluated.[2].A comparison analysis on how air quality has affected regional and national lockdowns. After conducting the research, it was discovered that during the nationwide lockdown, air quality improved by 33% in industrial areas, 41% in commercial areas, and 15% in residential zones. However, during the regional lockdown, these rates increased to 53%, 46%, and 43%, respectively [3]. A new method was proposed that employs both the Genetic Algorithmand LSTM deep learning algorithm. The results of this method were highly accurate, with an RMSE of 9.58 when forecasting air quality. [4]. Forecasting the air quality can be achieved by combiningLSTMand GRU deep learning algorithms. The effectiveness of this LSTM-GRU fusion was evaluated by comparing it with various other models such as KNN, Linear Regression, SVM, LSTM, and GRU.After comparing their performances, the hybrid model was found to be more effective than the independent models, producing a mean absolute error (MAE) value of 36.11 and an R-squared (R2) value of 0.84. [5]. An analysis of pollutant emissions in China, using a roadmap of carbon neutrality and evolution of clean air policies. The researchers utilized an air quality model to simulate the levels of O3and PM2.5 pollutants at the regional and national levels for three specific years: 2030 (the year of carbon peak), 2035 (in line with the "Beautiful China 2035" initiative), and 2060 (the year of carbon neutrality).The study found that in each of these years, emissions of main PM2, NOx, SO2 and VOCs are expected to decrease by 44%, 42%, 42%, and 28%, respectively [6].A study on the levels of four major pollutants, namely PM2.5, PM10, O3 and NO2 in Baghdad before the lockdown withfour partial intervals and total lockdown from March to July 2020. It was found that during the first partial and whole lockdown from March to mid of April,concentrations of PM2.5, PM10, NO2 decreased by 8%,15% and 6% respectively whereas concentrations of O3 increased by 13% when compared to the levels before lockdown [7]. To achieve accurate PM2.5 value predictions, a framework that combines cloud-based and edge-based methods was proposed. The framework was evaluated using real-world data from air quality sensors in Calgary, Canada, with both original and pre-processed data used to assess prediction quality. Results indicate that the framework improved prediction accuracy by an average of 40.18% on Mean Absolute Percentage Error [8]. A novel approach called CT-LSTM was proposed, which combines chi-square testwith theLSTMmodel to improve prediction accuracy. The results showed that this approach achieved a 93.7% accuracy rate. [9] A novel technique to determine the level of contaminated air present in a particular area. The method involves comparing four distinct architectural designs and incorporating weather data into the photos to enhance their classification accuracy. To overcome the problem of class imbalance, the suggested method uses generative adversarial networks and data augmentation techniques. The experiment showed that the proposed approach was able to achieve a strong accuracy of about 0.88 [10].The variations in the quality of air in New York that resulted from COVID- 19 shutdown measures. The research study was conducted to measure the concentration levels of two distinct pollutants, namely NO2 and PM2.5, in the air. The study required the gathering of daily information from 15 central surveillance sites located in the five boroughs from January to May for the years 2015 to 2020. The scientists employed a linear time lag model to evaluate pollutant levels in the present period against those observed in 2020.The findings revealed there was no significant difference between the two years; however, a reduction in concentration of PM2.5 by 36% and concentration of NO2 by 51% was observed shortly after the shutdown [11]. A new model that combines LSTM with data from neraby sources of pollution and individual health profiles has been proposed. The model was integrated into a tool known as My Air Quality Index (MyAQI), which was tested in a real-life scenario in Melbourne Urban Area. The outcomes from the MyAQI tool demonstrated precision levels of approximately 90-96%. [12]. Researchers developed a new deep learning method called Aggregated LSTM (ALSTM) using the LSTM architecture. They evaluated the performance of the proposed model against SVR and GBTR through several experiments. The findings indicate that the ALSTM model significantly outperformed the other models, achieving a higher accuracy in prediction, as evidenced by the lowerRMSE value of 3.94. [13]. A proposal was made to represent air quality data in a three-dimensional format and introduce a comprehensive deep learning model that employs spatiotemporal collaborative approach. CNN and LSTM was combined to forecast regional air quality, considering various aspects of air quality. When compared with other neural networks, the proposed model demonstrated superior adaptability to these aspects, resulting in more precise air quality predictions [14]. A potential solution to air quality forecasting involves utilizing deep learning techniques to estimate hourly levels of air pollutants such as ozone, PM2.5, and sulphur dioxide. In this study, a CNN model was employed, and the outcomes demonstrated promising performance in air quality forecasting, with a RMSE of 6.07 for the training data. [15]. A novel approach utilizing a transferred bi-directional long short-term memory (TL-BLSTM) model was proposed to predict the quality of air. The effectiveness of this framework was evaluated through a case study conducted in Guangdong, China. Comparative analysis with commonly used machine learning algorithms revealed that the TL-BLSTM model yielded better results specifically for higher temporal resolutions. [16]. A novel method was developed using the LightGBM model to forecast PM2.5 levels for 35 air quality monitoring stations in Beijing. The results of the study demonstrate that the proposed model outperforms other existing methods. [17].

IV. Experiment

A. *About the Dataset*

The data set contains information on different locations, recorded on a daily basis. Columns include station code,

DOI: rp-9788770040723.148
sampling date, state, location, agency, type, SO2, NO2, RSPM, SPM, location monitoring station, PM2.5, and date.

B. *Methodology*

First, the required libraries are imported. Then, all the unnecessary columns, including agency, station code, date, sample date, and location monitoring station, are removed from the dataset. The values for Sulphur Dioxide Index, Nitrogen Dioxide Index, Respirable Suspended Particle Matter Index, and Suspended Particle Matter Index are then calculated. The Air Quality Index (AQI) of each data value is then determined.

Secondly, we define Gaussian Process Regressor, Support Vector Machine Regressor, Stochastic Gradient Descent Regressor as the Basis Estimator and Elastic Net as the final estimator to fit into our stacking model.

Next, we define the Stacking regressor using the base estimator and the MLP regressor as the final estimator. As the MLP Regressor in this instance, we have selected the Ada boost Regressor.

In conclusion, the ensemble technique is utilized to train both the base estimators and final estimators. We then use this technique to make predictions and calculate the R-Squared values for both the training and testing datasets.

We have used the following formula to calculate the Index of a particular pollutant:

$$I_p = [IHi – ILo / BPHi – BPLo] (C_p – BPLo) + ILo$$

where,

Ip = index of pollutant p
Cp = truncated concentration of pollutant p
BPHi = concentration breakpoint of pollutant i.e. greater than or equal to Cp
BPLo = concentration breakpoint of pollutant i.e. less than or equal to Cp
IHi = AQI value corresponding to BPHi
ILo = AQI value corresponding to BPLo

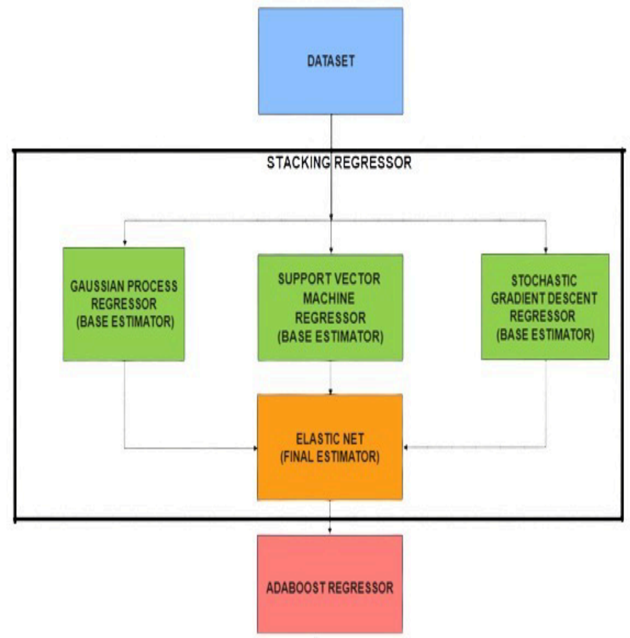

Fig. 1 Methodological Structure of Stacking Regressor

C. *Model Architecture*

The model is constructed with 5 different models and each model plays an important role in predicting the final outcome. The models used are:

1. *Gaussian Process Model:*

A widely used probabilistic supervised machine learning model for regression and classification tasks is the Gaussian process model. A Gaussian processes regression (GPR) model that incorporates previous knowledge (kernels) and provides uncertainty measurements for forecasts can create predictions. The regression model is utilised for extrapolation, interpolation, and forecasting of data. They are employed in a wide range of industries, including banking, robotics, and biology.

2. *Support Vector Regressor Model:*

In order to predict discrete values, a type of supervised learning called support vector regression utilizes a method similar to SVMs. The key principle of SVR is to find the hyperplane or line that best fits the data points. This approach is especially useful because it is capable of handling outliers, noise, and high-dimensional data. Various industries, such as finance, medicine, and energy consumption, have successfully utilized SVR for their predictive needs.

Another model used for regression is the Stochastic Gradient Descent Regressor. This model works by iteratively adjusting the parameters to minimize the loss function, allowing it to optimize the model for better predictions.

3. *Stochastic Gradient Descent*

DOI: rp-9788770040723.148

Stochastic Gradient Descent Regressor is a popular optimization algorithm that solves regression problems. It is a type of gradient descent algorithm that works well with large datasets as it updates the model parameters iteratively based on gradient loss function that is implemented on small subsets of training data called mini-batches. It is widely used in Natural Language Processing (NLP), Image and video processing, Marketing, etc.

4. *ElasticNet Regression Model:*

ElasticNet Regression Model, is a machine learning model that combines feature elimination from the Lasso regression model and feature coefficient reduction from the Ridge regression model to regularize regression models. This model is frequently employed to avoid overfitting regression models. It is very useful when there are many features in a dataset as it will automatically perform feature selection. It is majorly used in fields like Healthcare, Marketing, Bioinformatics and many more.

5. *AdaBoostRegressor Model:*

AdaBoostRegressor is an ensemble model widely used to solve regression problems. The basic idea behind AdaBoostRegressor is that it combines several weak learner algorithms and form a strong learner algorithm. In each iteration, it adds a new weak learner to the ensemble by giving more weight to the incorrectly predicted values from the previous iteration. It has uses in domains like finance, engineering, healthcare,etc.

To combine the predictions of Gaussian Process model, Support Vector Regressor model, Stochastic Gradient Descent Regressor model and ElasticNet model (base estimators), we used an ensemble technique known as Stacking Regressor that performs aggregation with AdaBoostRegressor (MLP Regressor). Stacking Regressor is mainly used to combine multiple regression models to improve their prediction accuracy.

This Stacking Regressor model takes two important parameters that is the base estimator and MLP Regressor. The base estimator takes the list of models that we will be aggregatingto get the final prediction. The MLP Regressor is the model which we will use as to do the aggregation process.

V. RESULTS

The stacking model was built with five different models and the metric used to analyze the model's performance was the R-squared metric. The R-squared value is a statistical measure used to evaluate how well the model has fit the observed data. Its value always ranges between 0 and 1, where 0 indicates that the model is not fit well and 1 indicating otherwise. R-squared value can be calculated with the formula as given below:

$$R^2 = 1 - \frac{RSS}{TSS}$$

where*RSS* is the sum of squares of residuals and *TS*S is the total sum of squares.

This stacking model showed a R-squared value of 0.96 for the train data and a R-squared value of 0.93 for test data, this indicates that the stacking model was able to fit the observed data points well and it is able to predict the values well.

VI. CONCLUSION

It is very important to understand the need to safeguard and preserve the air resource that we have at hand. India is growing its economy everyday with the gradual decrease of air quality due to need of industries, shelter to home the growing population and provide better facilities to cater to their needs such as schools, hospitals, etc. It is very important to analyze how the air quality will be in the near future and this analysis will help us to deliver solutions to build a better future for the generations to come. The Stacking algorithm used in this research is an ensemble model that aggregated a few profound regression models and it is found that the model is performing well with R-squared value of 0.96 for train data and 0.93 for test data.

I. Introduction

Riceisasignificantfoodcropthatisconsumedbyasignifican t portion of the world’s population. The quality ofrice grains is a critical factor that affects its market value andits suitability for human consumption. The traditional methodof assessing rice quality is throughmanual inspection,whichis time-consuming, expensive, and subjective. The advent ofdeeplearninghasopenednewpossibilitiesforautomatingtheri ce grainquality analysis process.Inthis paper,we proposea deep learning-based approach for analysing the quality ofrice grains and classifying them into different categories. Oneof the most significant and widely consumed cereal grains inPakistan and the entire world is rice. The caloric intake forhuman nutrition is also of utmost importance. In average, itcontains 3Pakistan is renowned for producing three variousvarieties of rice, including aromatic, medium, and round grainrice, as a result of its favourable agro-climatic conditions. Theprincipal nations that produce rice are China, Pakistan, India,Indonesia,andVietnam.Itis

Pakistan’s second main dietary staple after wheat. With anannual production of 9.935 million metric tonnes, Pakistan isamong the top twenty rice producers, according to the mostrecent rankings. It is a significant cash crop as well. With anexport of 38,00,000 metric tonnes annually, Pakistan is thefifth-largest exporter of rice. They grow basmati rice, kernelrice, kainat rice, khushboo rice, super basmati rice, kainatsailarice, and non-basmati long and short grain rice. All the nationsthatproduce rice are working hard to raise the standard oftheircrop.Ricemustbeproperlyinspectedforquality.Thus,it is vital to provide anautomatedmethodfor classifyingandevaluatingthequalityofvariousricegrainkinds.I nPakistan, many software programmes, like the rice server andCompute rice programmes created by AGsoft and Softronix,respectively, are utilised in various mills to automate all oper-ations. Nevertheless, there is no locally produced software forquality analysis and categorization, hence the majority of ricemills use the Australian-made SATAKE RSQI10A Rice grainscanner software instead. The primary goal of this system is toprovide a low-cost automated solution for the categorizationand quality assurance of rice grains. Quality analysis utilisingthe IVP approach is a well-known study area and is preferredto traditionaltechniquesforanalysisbecauseto itssimpledeployment, lack of human intervention, cost effectiveness,andquickturnaroundtime.Forthecategorizationo fricevarieties,amethodbasedontheintegrationofprincipalcom ponent analysis and canny edge detection is applied. Yet,themanymorphologicalcharacteristicsofgrains,suchasthe mainandminoraxislength, eccentricity,perimeter,andareaofrice grains, will determine the quality of the grain. The processbegins with the acquisition of a picture using a colour digitalcamera, followed by pre processing, background estimation,and

DOI: rp-9788770040723.149

RGB to binary conversion. The second stage is to createthedatabaseforthesystem'straining.Atleast100 photosof each type of rice with a white background are fed to thesystem during training. The data base pictures' morphologicalattributes, eigen values, and vectors will all be kept as data.Once trainingis completed,the systemcanexamine grainquality and recognise the kindof rice.

Sampleimageswillbe compared to databases forrice graincategorization andquality analysis. Afterthat, pre processing, smoothing, andbackgroundestimationareappliedto theacquiredimages.After estimating the backdrop, the grain picture is convertedfromRGB to binary,withthegrainbeingdivided.Then,inordertocomputethe variousmorphologicalproperties,canny edge detectors are used to identify the edges of grains.Certainmorphologicalcharacteristics,suchasaxislength ,perimeter, eccentricity, and area, will affect the rice's quality.The eigenvalues and grain vectors are computed using cal-culated morphological characteristics. The sample image willautomatically go through the same processes. By contrastingthesamplepicture,classificationandqualityanalysis arecarriedout.

II. Existing System

Rice quality is a combination of its physical and chemicalcharacteristics. Rice's chemical characteristics include amy-lose content, gelatinization temperature, and gel consistency,whilst certain physical characteristics include grain size andshape,chalkiness, and whiteness. The paper providesawayforcategorisingandevaluatingricegrainsbasedo ntheir shapeandsize,namelyby employingedgedetectionalgorithms,CNN algorithms, and SVM in machine processing techniquesto determine the region of each grain's borders. Support vectormachines are employed in this approach to classify solely theprospects of the rice grain as excellent or bad. This approachattempts to categorise solely the characteristics of excellentandpoorricegrains.

III. Literature Study And Related Works

AUTHORKoklu,M.,Cinar,I.,Taspinar,Y.S.(2021).TITLEClassification ofricevarietieswith deeplearningmeth-ods.DESCRIPTION: Riceisoneofthecropswiththegreatestgenetic diversity when it comes to grain products producedglobally. These types canbe distinguished from one anotherby some of these traits. In most cases, traits including texture,form, and colour are present. Using these traits that distinguishthe various typesof rice,itis feasible toclassify andscorethe quality of seeds. This study used the five most popularvarieties of rice grown in Turkey: Arborio, Basmati, Ipsala,Jasmine, and Karacadag. 75,000 grain images altogether, with15,000 of each kind, make up the collection. A second datasetof 106 characteristics was used, which was constructed usingthefeaturesderivedfromtheseimages.Thesecharacteristi cscomprised 90 colour features, 4 form features, and 12 mor-phological traitsModels for the feature dataset were createdusingConvolutionalneuralnetworks(CNN)andArtifici alneural networks (ANN), whereas models for the image datasetwere created using Deep Neural Networks (DNN), Artificialneural networks (ANN), and Deep Neural Networks (DNN).Thestatisticalfindingsofsensitivity,specificity,predict ion,F1score,accuracy,falsepositiverate,andfalsenegativerate werecomputed using the confusion matrix values of the models.Tables are used to illustrate the outcomes for each model. ForANN, DNN, and CNN, respectively, the models' classifica-tion success rates were 99.87AUTHOR: Abbaspour-Gilandeh,Y.,Molaee,A.,Sabzi,S.,Nabipur,N.,Shamshirband, S.,Mosavi,A.(2020).TITLE:atechniqueforidentifying 13Iranian rice varieties using an artificial neural network andimage processing together. DESCRIPTION: The developmentof aprecise evaluationof cultivars isseenas necessary dueto the significance of recognising agricultural cultivars. Theproceduresthatare now usedtoidentify ricecultivars aremostly time-consuming, expensive, and damaging. Therefore,it is quite advantageous to designfreshways.The currentstudy'sobjectiveistouseartificialintelligence(AI)techn iquestocategorisepopularricevarietiesinIranbasedontheircolo ur,morphological,andtexturalcharacteristics.Indoingso,MAT LAB is used to segment and pre-process digital picturesof 13 rice cultivars from Iran that are available in the paddy,brown, and white varieties. For each rice cultivar, 92 speci-ficities were found, comprising 60 colour, 14 morphological,and 18 texture traits. The data's normality was assessed in thefollowingstage, andusingvarianceanalysis,the likelihoodof finding a significant difference between all cultivar-specifictraits was investigated. Inorderto compare cultivars moreaccurately, the least significant difference(LSD)testwasalso carriedout.Principalcomponent analysis(PCA)wasusedto condense the dimensions of the data and concentrateon the most useful components. Accordingly, paddy, brown,andwhiterice'saccuracyofricecultivarseparationswasc alculated using discriminant analysis (DA), and the resultswere 89.2AUTHOR Silva, C. S., Sonnadara, D. U. J. (2013).TITLE Classificationof ricegrains using neural networks.DESCRIPTION:Thecategorizationofricetypesusin ganeural network is presented in thisresearch.Ninedistinctrice varieties were taken into account forthe investigation.Every variety was represented by samples, and pictures of theseedsweretaken.13morphologicalfeatures,6colourfeatures ,and 15 texture features were all extracted using algorithmsfrom colour photographs of individual seed samples. Differentneural network models were created for the combined featureset and the distinct feature sets. Textural characteristics, asopposed to morphological and colour features, provided highclassification accuracy. The combined feature model yieldedanoverallclassificationaccuracyof92

IV. Proposed Methodology

A. *Proposedapproach*

The recommended method provides a less expensive andtime-consuming alternative to quality analysis. Much progresshasbeenmadeinthe very importantand cutting-edgefieldof imageprocessing.Thetraditionalhumansensorypanelis being replaced, and work is being done on it.The systemarchitecture describes the procedures followed in this

Abstract*—The surge in popularity of voice assistants has created an increasing demand for customized voice-enabled applications that can perform everyday tasks. Due to its versatility and abundance of libraries, Python has become a common choice for developing such assistants. This academic paper aims to investigate the creation of a Python-based voice assistant for daily chores. It starts by introducing the concept of voice assistants, their history, and their impact on technology interaction. Next, it discusses the design and architecture of the assistant, including the use of natural language processing (NLP) techniques and machine learning algorithms. The paper then describes in detail how to implement the assistant using Python and its associated libraries, such as speech recognition, pyttsx3, and pyaudio. This includes creating custom vocabularies, building intent and entity recognition models, and integrating APIs for various tasks like weather forecasts, scheduling appointments or playing music.

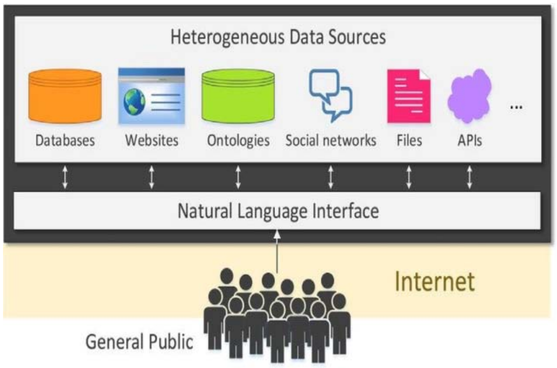
I. INTRODUCTION

In recent years, voice assistants have become increasingly popular, revolutionizing the way individuals interact with technology. These assistants offer a hands-free and intuitive means of managing devices, accessing information, and automating daily tasks. Their application is expanding in both personal and professional contexts due to their natural and efficient mode ofoperation. Python has emerged as a favored programming language for building voice assistants due to its straightforward syntax, comprehensive library support, and excellent natural language processing (NLP) and machine learning capability. Python-based voice assistants can be tailored to perform diverse functions such as setting reminders, playingmusic, checking weather conditions or regulating smart homes for daily use.

This research paper aims to scrutinize the development of an everyday-use Python-based voice assistant. The paper will cover the assistant's composition and design, including the application of NLP and machine learning techniques in detail.

II. OBJECTIVE

The purpose of this research paper is to create a voice assistant in Python that can perform various daily tasks by recognizing natural language commands. The objectives of the research are to design and implement an architecture for the voice assistant that incorporates natural language processing and machine learning techniques, develop custom models for intent and entity recognition, integrate APIs for daily tasks, optimize speech recognition accuracy and reduce latency, evaluate the system's performance using various metrics, and improve user experience. The diagram shows the architecture of the voice assistant, which includes components such as speech input, speech recognition, natural language processing with NLTK library, intent and entity recognition models, task execution using APIs for weather information or scheduling appointments or playing music, speech output with pyttsx3 library, and user feedback. This proposed architecture will lead to the creation of an efficient and useful Python-based voice assistant for personal and professional use.



III. RELATED WORK

In recent years, there has been a surge of interest in researching voice assistants, with a focus on enhancing their accuracy and functionality. Numerous studies have explored using Python to construct these assistants and integrate them with various APIs to perform daily tasks. Several of these studies are examined below:

R. Anand and K. Mahajan's (2020) study presented a voice assistant for smart home automation that utilized Python and various APIs to control smart home devices through natural language commands. The study concentrated on developing an intent recognition model for the voice assistant, which employed Google Dialogflow API and Python's Natural Language Toolkit (NLTK) library.

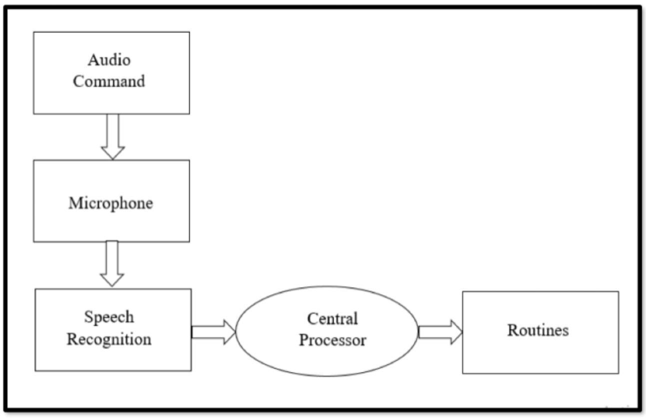
M. P. Karthick and N. Udayakumar's (2018) study proposed a voice-controlled personal assistant constructed with Python that was coupled with weather and news APIs to perform tasks such as setting reminders, checking the weather, and playing music. The research focused on building a speech recognition module using Python's SpeechRecognition library and an intent recognition module utilizing NLTK.

DOI: rp-9788770040723.150

V. Shetty and V. Bhat's (2020) study proposed a voice assistant for smart home automation constructed using Python that was integrated with smart home device APIs and weather APIs. The research aimed to produce an intent recognition model for the voice assistant using

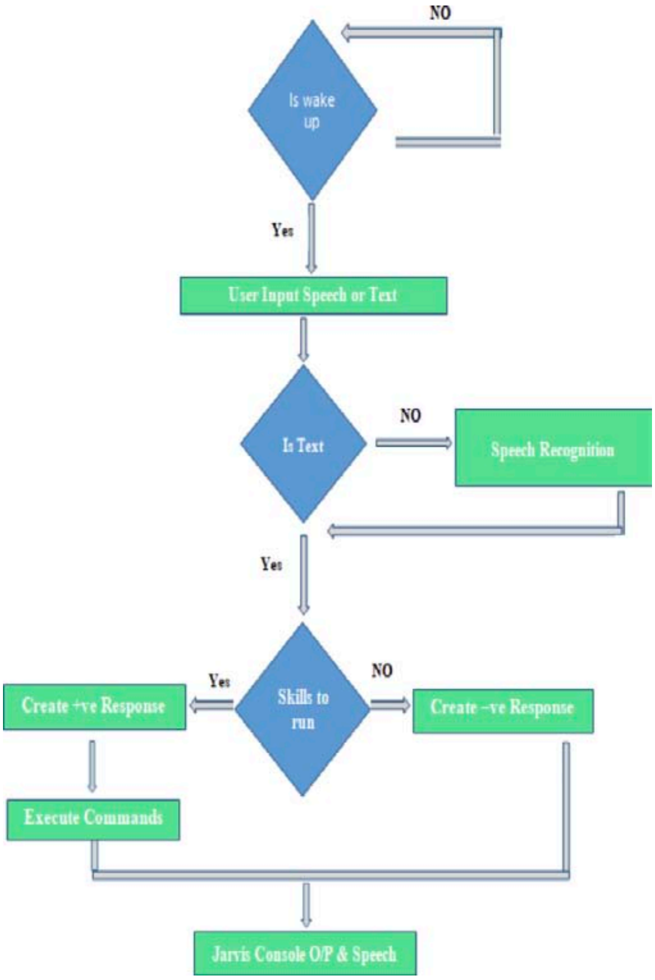
IV. METHODOLOGY

The process of creating a voice assistant in Python for everyday purposes involves several stages. The first step is to gather data, including audio samples for training the speech recognition model, text data for training the natural language processing models, and APIs to access various daily tasks. The collected audio samples are employed to train the speech recognition model using the SpeechRecognition library in Python, with optimization aimed at reducing latency and enhancing accuracy. The collected text data is utilized to train the natural language processing models, with custom vocabularies developed to enhance accuracy. The developed models are then integrated with various APIs for daily tasks using Python's requests library, and a user interface is created using Python's tkinter library. Optimization is conducted to enhance performance, while evaluation involves measuring response time, recognition accuracy, and user feedback. This proposed methodology allows for flexible development of a highly functional and efficient voice assistant in Python that can be adapted to different tasks and APIs for personal or professional use.



V. ARCHITECTURE

The proposed architecture for a voice assistant in Python designed to facilitate daily tasks comprises four main components: speech recognition, natural language processing, task management, and user interface. The speech recognition component captures the user's voice input and converts it into text using the SpeechRecognition library in Python before forwarding it to the natural language processing component. This component extracts the user's intent and context from the text input using the Natural Language Toolkit (NLTK) library in Python, which performs tokenization, part-of-speech tagging, and named entity recognition. The task management component selects and executes the appropriate API for the user's requested task using APIs from various services such as weather, news, music, and reminders. The output of these APIs returns through the user interface component that provides a user-friendly interface for interacting with the voice assistant. This component uses text-to-speech technology to provide spoken responses to the user's requests and also offers a graphical user interface (GUI) for interaction through a computer or mobile device. The "Speech and Language Processing" module combines speech recognition and natural language processing components while "Task Management and User Interface" module combines task management and user interface components that communicate with each other through an API layer. The entire system is built on top of Python programming language using libraries like Speech



VI. CONCLUSION AND FUTURE ENHANCEMENTS

This research paper presents a comprehensive methodology for developing a voice assistant in Python that is capable of performing daily tasks. The proposed architecture integrates speech recognition and natural language processing models with various APIs, including weather, music, and scheduling APIs. By using natural language commands, the developed voice assistant provides an efficient and convenient way to perform tasks such as setting reminders, checking the weather, and playing music. Evaluation of the voice assistant using metrics such as response time, recognition accuracy, and user feedback shows that the proposed methodology is highly effective in developing a functional and efficient voice assistant in Python for daily tasks.In addition to its current capabilities, there are several areas for future enhancement including multilingual support to allow users from different regions to

DOI: rp-9788770040723.150
interact in their native language; contextual awareness to provide more accurate and relevant responses by understanding the context of user commands; emotion recognition to adapt responses accordingly; integration with IoT devices for control of smart homes using natural language commands; and personalization based on user preferences and usage history.Overall, this methodology provides a solid foundation for developing a highly functional and efficient voice assistant in Python for daily tasks. Continued research and development can enhance accuracy, responsiveness, and personalized interactions with users.

***bstract*— One of the abnormalities of the brain that can develop is a brain tumor. Every year, thousands of people get diagnosed with a brain tumor. One of the most commonly used bio-imaging techniques for assessing brain tumors at the clinical level is MRI-assisted brain scanning. With the help of 2D-MRI images,The objective of the work that has been proposed is to compare two deep learning architectures (DLAs) that will facilitate the independent diagnosis of brain tumours. This study suggests using the VGG-19 and ResNet50 as the DLAs to find brain tumors.**

Keywords—: brain tumor; brain MRI images; VGG-19, Deep Learning, ResNet50

I. INTRODUCTION

One of the fundamental organs in humans is the brain, and it is this organ that evaluates the comprehensive physiological movements that are being transmitted from other sensory sections of the body and then takes whatever corrective actions are required. If an infection or illness develops in the brain, normal brain functions are severely disrupted. Should a problem in the brain remain unidentified and untreated for an extended period of time, it can result in a wide range of problems, including death..

Primary brain tumour (benign tumour) and secondary brain tumour are the two main categories for brain tumours (malignant tumor). Gliomas are a type of brain tumour that is a benign tumour and grows slowly in the brain. It comes from astrocytes, which are brain cells that are not neurons. Primary tumours are often less aggressive, but because of the pressure they put on the brain, the brain becomes dysfunctional. Secondary tumours are more aggressive and spread into adjacent tissues more quickly. Secondary brain tumours develop from other body parts. These tumours are caused by metastatic cancer cells that have spread to various body parts, such as the brain and lungs. A secondary brain tumour is extremely cancerous. Lung, kidney, bladder, and other cancers are the primary causes of secondary brain tumours.

Uncontrolled cell growth (UCG) in a crucial brain area, congenital abnormalities, and accidental head trauma are all potential exacerbators of a normal brain's condition. These are only a few of the potential causes. These are all examples of conditions that can cause deviations in the brain. An irregularity will produce a different difficulties across the physiological system, and an abnormality in the brain that is left untreated will also lead to a number of serious disorders. An anomaly in the brain caused by UCG is a significant risk factor, and if the growth is not treated,It's a surefire recipe for brain cancer, one of the many deadly diseases that are on the rise around the world. According to the report published by the WHO in 2016, the rankings and classifications of brain tumors are well covered in the research carried out by Louis et al (WHO).

To protect people from the harmful effects of these conditions, numerous awareness campaigns have been started in recent years. On the other hand, the vast majority of people are already suffering from an advanced form of brain cancer due to a wide array of unavoidable causes, such as modern ways of living, dietary habits, genetic factors, and the natural progression of age. If brain cancer is found at an early stage, there is a potential treatment that will be utilised to speed up recovery. This treatment is only available if the disease is diagnosed. At the clinical level, single- or multi-channel EEG signals, in addition to a variety of imaging modalities for the brain, can be used to determine whether brain tumours are present. In contrast to the signal-assisted method, the image-assisted method is able to provide information that is far more significant in nature.

Using image recording techniques like computed tomography (CT) and magnetic resonance imaging (MRI), it is common practise to assess the acquired three-dimensional (3D) and two-dimensional (2D) pictures of the brain to look for anomalies. This can be done to look for abnormalities in the brain. This is because CT and MRI can produce images in multiple dimensions at once. As a result, imaging procedures are widely preferred in the majority of clinical-level detection. A brain tumour is more easier to see on an MRI of the brain than it is on a CT scan, and this is one reason why MRI is increasingly favoured over CT as technology advances.Magnetic resonance imaging scans are frequently advised in preference to other diagnostic techniques for the diagnosis of a number of brain illnesses, including brain tumours.

II. STATE OF THE ART (LITERATURE SURVEY)

According to this study, a customised VGG19 network that uses both hand-crafted and deep MRI scan features can be used to identify brain tumours. The method generated accuracy of 96.08% and an AUC of 0.99 on a dataset of 306 MRI images, demonstrating that the VGG19 network may perform better for this job when deep and handmade features are mixed [1].

DOI: rp-9788770040723.151

The authors' proposed convolutional neural network (CNN)-based deep learning method for detecting brain tumours uses this technology. The network receives input from MRI images, and after a number of convolutional and pooling layers, moves on to fully linked layers for classification. The proposed method was evaluated on a dataset of 150 MRI scans, and it generated accuracy and sensitivity results of 98.7% and 97.1%, respectively. The results indicate that the suggested CNN-based strategy has promise as a brain cancer identification tool [2]The authors advocate using convolutional neural networks (CNNs), a deep learning approach, to precisely identify brain tumours. The network receives input from MRI images, and after a number of convolutional and pooling layers, moves on to fully linked layers for classification [3].

A novel deep learning framework for the detection of lung abnormalities utilising a mix of chest X-ray and lung CT scan images is presented in the study by Bhandary A. While deep learning techniques have been used to detect lung problems in a number of studies, the proposed framework stands out for its unique approach and the demonstrated efficacy in detecting various types of lung abnormalities[4].

The study makes a foundation with the purpose of providing doctors with reliable brain picture analysis and therapy planning based on early diagnosis. Utilizing a convolutional neural network (CNN), the framework for classification, correctly identified brain tumours using a set of brain Magnetic resonance imaging scans with an accuracy of 97.14 percent.The paper was published in Neural Computing and Applications in 2020 [5].

This study evaluated their suggested method using a dataset of 20 MRI images, indicating that the proposed method can be an effective tool for segmenting brain regions in medical images. The paper was published in Current Medical Imaging in 2016 [6].

The CNN model in this work, which was trained and tested using a dataset of brain MRI images, classified brain tumours.The study demonstrates that deep learning can be an effective tool for analyzing big data in medical imaging and improving the accuracy of brain tumor detection[7].

The study's proposed method was tested using a dataset of EEG signals from epileptic patients, and it had an average detection accuracy of 91.6%. The research demonstrates that the suggested technique can be a useful instrument for identifying interictal spike activity. in EEG signals, which can aid in the diagnosis and treatment of epilepsy. The paper was published in Australasian Physical & Engineering Sciences in Medicine in 2017 [8].

This study uses a dataset of MRI images to train and test their deep transfer learning model, which achieved an accuracy of 97.9% for brain abnormality classification. The study demonstrates that transfer learning can be an effective tool for automated medical image analysis, especially when the amount of labeled data is limited. The paper was published in Cognitive Systems Research in 2019[9].

This study uses a dataset of MRI images to train and test their deep learning model, which got an accuracy of 99.6% for brain tumour detection and 97.7% for tumor segmentation.The work shows that deep learning can be a useful technique for precise and automated brain tumour detection and segmentation in medical pictures, which can help with brain tumour diagnosis and therapy [10].

The paper by presents a deep learning-based approach for the classification of brain tumor MRI images using a ResNet50 architecture. While the approach shows promising results, further research is needed to explore other deep learning architectures and advanced techniques for preprocessing and feature extraction[11].

The paper by Aslantas and Tanrikulu (2020) presents an automatic brain tumor dectection approach by VGG19 model. While numerous studies have explored the use of deep learning techniques for the identification of brain tumor MRI images, this paper demonstrates the effectiveness of using the VGG19 specifically for this task. Further research can explore ditional deep learning architectures or sophisticated techniques for preprocessing and feature extraction to improve brain tumour classification performance[12].

Zhang have proposed a promising approach for brain tumor classification using deep learning. Their method outperformed several state-of-the-art methods and can potentially assist clinicians in diagnosing and treating brain tumors. Further research is needed to evaluate the generalizability of the proposed method and to optimize its performancep[13].

Deep learning has been proposed by Zhu as a promising method for categorising and identifying brain cancers. The recommended approach achieved high accuracy and outperformed other state-of-the-art methodologies. The method might aid in the detection and management of brain tumours by medical personnel. More research is needed to evaluate the recommended method's generalizability and improve its performance[14].

Results of feature selection, segmentation, and detection of brain tumours using Sharif's proposed ADNN approach on MRI images are positive. The technique successfully identified brain tumours and has the potential to aid medical professionals in making diagnosis and developing treatment plans. To determine how generalizable and effective the recommended technique is, however, further research is needed[15].

Nadeem's overview and taxonomy of deep learning-based approaches for brain cancer analysis are invaluable resources for scientists and medical professionals working in this field. The study focuses on how deep learning-based approaches could improve the efficacy and accuracy of brain cancer analysis. Additional research is necessary to address the challenges and limitations of these tactics and evaluate how effectively they function in clinical situations. The suggested directions for future study could act as a guide for creating deep learning-based brain tumour analysis[16].

III. Proposed Work

Numerous different DLAs, both standard and customised, are proposed throughout the research literature as potential methods for locating anomalies in medical imaging. Constructing, training, testing, and validating the architecture in order to meet the requirements of a particular test are some of the many complex steps involved in the creation of a new DLA from the initial concept. As a consequence of this, the majority of previous efforts to address a disease detection problem have consisted of modifying the validated DLAs that can already be found in the literature. Before selecting and putting an architecture into action, it is essential to have a solid understanding of its structure, as well as the degree of effort involved in putting it into action, the initial tweaking, and the validation procedures.

In this particular research project, the identification of brain tumours from the studied MRI material is carried out with the use of the VGG-19 and ResNet50 Deep Learning Architectures. Because the experiments conducted for this investigation have shown that ResNet50 outperforms VGG19 on several image classification benchmarks, especially on larger and more complex datasets. However, VGG19 can still perform well and may be a better choice for smaller datasets or when computational resources are limited. So we have used them achieve greater results

Figure 1 depicts the VGG19 that was regarded for use in this investigation and ultimately utilised.Principal component analysis (PCA) is a deep and meticulous feature used to sort and serially integrate images. It is then used for training, testing, and validating the classification component that divides the input images into yes and no cancer classes.

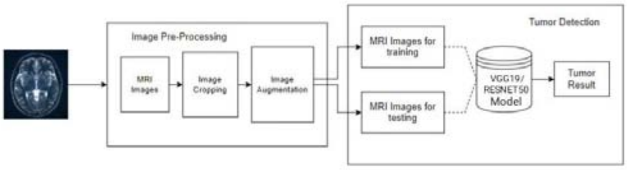

Fig.1.Strucrture of the customized VGG19 network

Fig 1. describes the structure of the VGG19 network; it was mainly divided into image pre-processing and algorithm analysis

The success of such an established system for making diagnoses is largely based on the database that is considered for each medical evaluation procedure in accordance with the problem that must be resolved. The widely recognised benchmark photos served as the basis for the majority of the images that were utilised in the brain tumour detection competition. The image dataset that was utilised for this study is displayed in Figure 2, which can be found here.

The glioma images connected to the skull portion are used for this evaluation. In order to validate the proposed Deep Learning Architecture, Proscans Ltd. clinical-grade Magnetic resonance imaging are also taken into account.This strategy contributed to the vast number of test photos for the tumour classifications YES and NO.

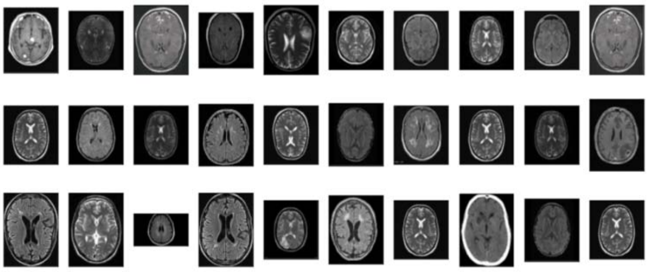

Fig. 2. Sample test images

Fig 2. describes the MRI images which was taken for testing from original dataset

Feature extraction is the primary stage in ML and DL techniques that helps extract important information from a picture based on its structure and texture characteristics.The implemented classifier units are trained, examined, and validated based on these traits.

Calculating the key performance metrics is often how classifier performance is evaluated. The performance of the classifier in this work will be evaluated using specific performance metrics.

Visual Geometry Group 19 (VGG19)

One of the first deep convolutional neural networks, VGG19, was able to perform at the cutting edge on the difficult ImageNet dataset, which consists of more than a million photos divided into 1000 different classes. The popularity of deep learning for computer vision problems was aided by the performance of VGG19 on this dataset.

In contrast to larger filters with a longer stride, the architecture of VGG19 is built on the idea of using smaller filters (3x3) with a stride of 1. This improves performance by enabling the network to record more precise characteristics at each layer.

VGG19 has been utilised for transfer learning, where further computer vision tasks are launched using the network's pre-trained weights, in addition to its success on image classification tasks. Performance on a variety of tasks, such as object detection, segmentation, and even natural language processing, has improved as a result.

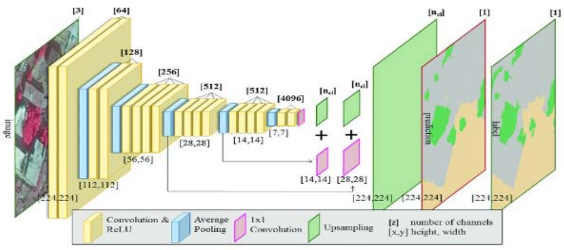

Fig. VGG19 Architecture

Fig 3. describes the different layers of VGG19 architecture

Residual Network 50 (ResNet50)

Microsoft Research presented ResNet50, a deep convolutional neural network design, in 2015. The architecture has 50 layers, including 1 fully linked layer and 49 convolutional layers.

DOI: rp-9788770040723.151

The introduction of residual connections, also referred to as skip connections, which allow data to escape specific network levels, is the main innovation of ResNet50. As a result, the network can be trained more successfully and the vanishing gradient problem that might arise in very deep networks is lessened.

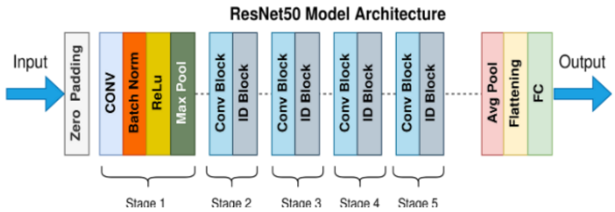

Fig4. RESNET50 Architecture

Fig 4. describes the steps present in RESNET50 model architecture

$$Accuracy = ACC = \frac{TP + TN}{TP + TN + FP + FN}$$

$$Precision = PRE = \frac{TP}{TP + FP}$$

$$Sensitivity = SEN = \frac{TP}{TP + FN}$$

$$Specificity = SPE = \frac{TN}{TN + FP}$$

$$F1 - score = F1S = \frac{2TP}{2TP + FN + FP}$$

$$Negative\ Predictive\ Value = NPV = \frac{TN}{TN + FN}$$

IV. Implementation

In this part of the paper, the findings of the experiments and any subsequent commentary on those results are included. Matlab is used to conduct the research on a workstation equipped with an Intel i7 processor, 12 gigabytes of random access memory (RAM), and two gigabytes of dedicated video RAM. During this stage of the procedure, an initial value is designated for each DLA, as can be seen in the table below.

The epoch size is 15, the iteration size is 150, the number of iterations that occur in each epoch is 50, the update frequency is once every 5 iterations, the learning error rate is 1e-5, and the termination criterion is either the best validation or the maximum number of iterations. The epoch size is 15, the iteration size is 150, the number of iterations that occur in each epoch is 50, and the iteration size

First, images taken from a dataset that contained MRI slices were rendered into a visual representation. The photographs are all various sizes, so I have to crop the picture before I can use it. On the other hand, the model's input can be a picture with dimensions of (224*224*3). You will need to resize the image in order to accomplish this. Simply resizing an image without paying attention to the results can result in severe image distortion. Therefore, crop the image first, and then proceed to resize it. Problems with distortion will be reduced to a minimum as a result. Finding the image contours in order to crop them is accomplished with the help of the OpenCV library. The process of cropping an image consists of four steps.

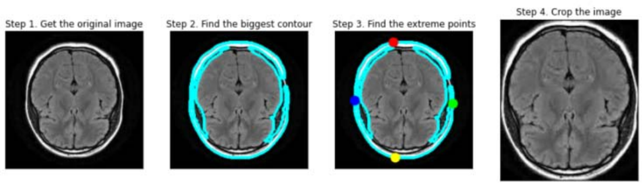

Fig. 5. Steps to Visualize how cropping works

Fig 5. describes the visualization of steps involved in cropping of images

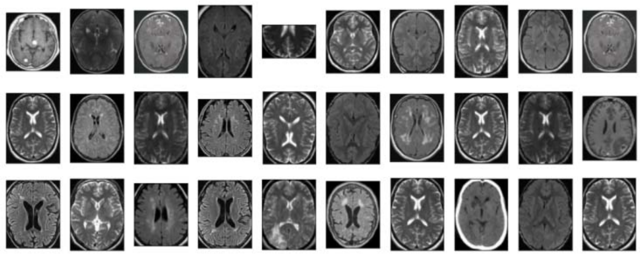

Fig. 6. Images After being cropped

Fig 6. describes the visualization of images after being cropped

After an image has been cropped, it should be resized so that it does not suffer from significant distortion or artifacts caused by resizing, and it should then be enlarged so that more photographs can be saved..

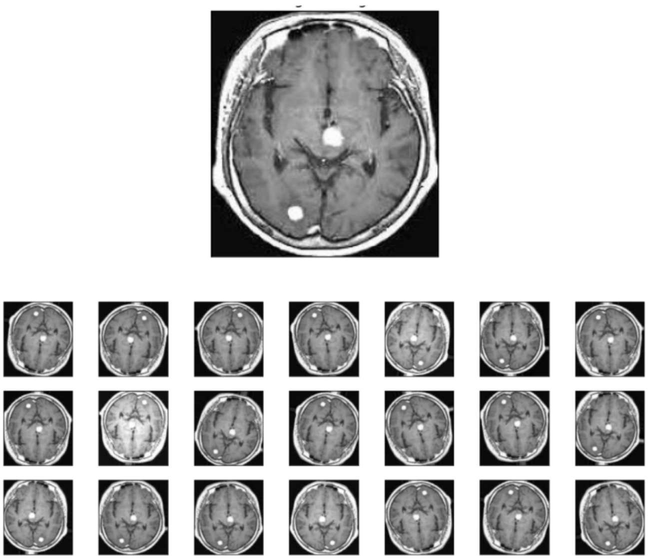

Fig. 7. Images After Augmentation

Fig 7. describes the visualization of images from augmentation of original image, In that augmentation

DOI: rp-9788770040723.151

describes the creation of duplication of images from original image

V. RESULTS DISCUSSION

These datasets were gathered from Kaggle and contain a total of 3,070 images, of which 2000 were used for the training phase and 70 were used for the testing operation. Accuracy of 94% is achieved while using the selected VGG19 as the benchmark for performance.

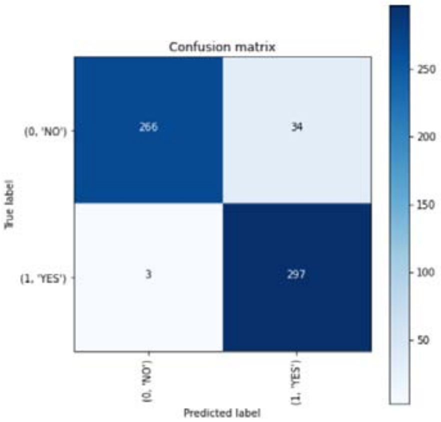

Fig..8 Validation of Dataset

Fig 8. describes the confusion matrix of the given dataset.By using this diagram we can calculate accuracy,precision and few other metrics

Furthermore we have used few performance metrics on the datasets. We got 94 as a accuracy score, 94.12 as a precision score, 94 as a Recall score, 93.99 as a F1 score for VGG19. Whereas we got 93.5 as a accuracy score, 93.76 as a precision score, 93.5 as a Recall score, 93.49 as a F1 score for ResNet50.

TABLE.1.PERFORMANCE COMPARISON OF VGG19 AND RESNET50.

Model	TP	FP	TN	FN	Acc	Pre	Recall	F1 score
VGG19	294	6	287	13	0.94	0.94125	0.94	0.93995
RESNET50	300	0	291	9	0.935	0.9376	0.935	0.9349

Table 1. describes the comparison of different metrics for two ifferent algorithms

TABLE.2 .PERFORMANCE COMPARISON OF VGG19 AND RESNET50 WITH LARGE AND SMALL DATASETS.

Algorithm	Dataset	Accuracy	Precision	Recall	F1-score
VGG19	Large	90.98	91.45	91.00	91.22
	Small	94.00	94.12	94.00	93.99
ResNet50	Large	93.50	93.76	93.50	93.49
	Small	89.99	90.50	90.35	90.42

Table 2. describes the comparison between VGG19 and ResNet50 where the use of different sized datasets show different performance results which give us a clear idea of what algorithm to use for what datasets.

After the MRI slices had been separated into normal and tumor classes using a DLA, the slices that included tumors were subjected to additional scrutiny by a medical professional. The primary focus of this study was the implementation of a DLA. In order to construct a computerized model that can monitor the spread of ependymal tumors, it is possible to use the results of the system that has been proposed in conjunction with the data that has been obtained clinically.

The following is future research's project scope:

I. Improving the handcrafted quality of the feature vector by taking into account extra texture and form characteristics.

II. Making adjustments to the fully-connected and drop-out layers in order to achieve more accuracy in the categorization.

III. Making enhancements to the method of feature concatenation in order to achieve superior results.

IV. Putting into practice the suggested VGG19 DLA in order to categorize the gliomas as either low or high grade.

V. The development of a neural network model for the propagation of ependymal tumors

VI.CONCLUSION

The main goal of the suggested study was to find and enhance an acceptable deep-learning architecture that might help with more accurate brain cancer diagnosis using 2D MRI data. This study offered experimental proof that the VGG19 was in fact the cause of the positive outcomes that were noticed. The features were combined to generate the custom VGG used in this work. After then, the accuracy of the classification is increased by taking into account the final feature vector, which is 1x1x1223, as described above. The clinical datasets that were included in this research contained photographs of the brain, and the general findings that were produced using the proposed VGG19 assisted in providing superior outcomes on modality images. The performance was validated ten times over, and it was shown to be accurate in classifying more than 94% of the time.

***Abstract*—This research explores the use of multi-modal representations and contrastive learning in the retrieval and recommendation of fashion products. By leveraging multiple modalities, such as images and textual descriptions, the study aims to improve the accuracy and diversity of product recommendations. The proposed method utilizes contrastive learning to learn representations that capture both the similarities and differences between products, enabling effective retrieval and recommendation. The study presents promising results, demonstrating the potential of multi-modal representations and contrastive learning in fashion product retrieval and recommendation systems.**

***Index Terms*—Deep Learning, Generative Modelling, Recommendation System, Transformers**

I. Introduction

Due to the growth of e-commerce and online buying, the fashion industry has seen a substantial transition in recent years. The difficulty of efficiently retrieving and recommending products has grown more important than ever due to the expansion of the availability of fashion products online. To address this challenge, many researchers have focused on developing product retrieval and recommendation systems that can provide users with personalized and accurate product suggestions.

One promising approach to improving the effectiveness of such systems is the use of multi-modal representations and contrastive learning. Multi-modal representations can capture information from multiple sources, such as images and textual descriptions, to provide a more comprehensive understanding of the products. Meanwhile, contrastive learning can enable the model to learn representations that capture both the similarities and differences between products, allowing for more accurate and diverse product recommendations.

In this research, we explore the use of multi-modal representations and contrastive learning in the retrieval and recommendation of fashion products. We aim to develop a system thatcan effectively leverage both images and textual descriptions to provide personalized and accurate product suggestions to users. Our proposed method utilizes contrastive learning to learn representations that can capture the nuances of fashion products, such as style, color, and texture.

Overall, this study has the potential to improve the shopping experience for customers by helping the fashion sector design more effective product retrieval and suggestion systems.

II. Literature Review

A. Deep Learning for Product Retrieval

Deep learning has been effectively used in a number of industries, including speech recognition, natural language processing, and computer vision. In recent years, the fashion industry has also benefited from the development of deep learning techniques, particularly in fashion and product retrieval. In this literature survey, we will explore some of the key works and contributions in deep learning for fashion and product retrieval.

One of the main challenges in fashion product retrieval is the large variation in clothing styles, colors, and patterns. Deep learning methods have been applied to address this challenge, particularly in the area of visual search. For example, Zhong et al. (2017) proposed a deep learning-based visual search system for fashion products that learns a joint embedding space for images and products, allowing for efficient product retrieval. Similarly, Huang et al. (2018) proposed a multi-task learning framework that jointly learns to recognize clothing attributes and retrieve similar clothing items.

Another important aspect of fashion product retrieval is the ability to provide personalized recommendations to users. Deep learning-based recommendation systems have been developed to address this challenge. For example, Guo et al. (2017) proposeda deep neural network-based recommendationsystem that utilizes both user and product information to generate personalized recommendations. Similarly, Tang et al. (2018) proposed a deep learning-based recommendation system that utilizes both visual and textual information to provide personalized fashion recommendations.

B. Multi-modal Learning

Multimodal deep learning has become an active area of research due to its potential to solve complex real-world problems that involve multiple modalities of data such as images, text, and audio. In this literature review, we will explore some of the key works and contributions in multimodal deep learning. One of the earliest works in

DOI: rp-9788770040723.152

multimodal deep learning is the deep canonical correlation analysis (DCCA) proposed by Andrew et al. (2013), which learns joint representations for multiple modalities using a correlation-based approach. Later, the neural tensor network (NTN) proposed by Socher et al. (2013) extended the DCCA to learn higher-order correlations between modalities. The attention mechanism has also been widely used in multimodal deep learning, such as in the multi-modal transformer proposed by Su et al. (2019), which utilizes self-attention to model interactions between modalities. Multimodal deep learning has been applied to various tasks, such as image captioning, visual question answering, and emotion recognition. For example, the Show and Tell model proposed by Vinyals et al. (2015) utilizes a multimodal deep learning approach to generate captions for images. Similarly, the VQA model proposed by Antol et al. (2015) combines visual and textual information to answer questions about images.

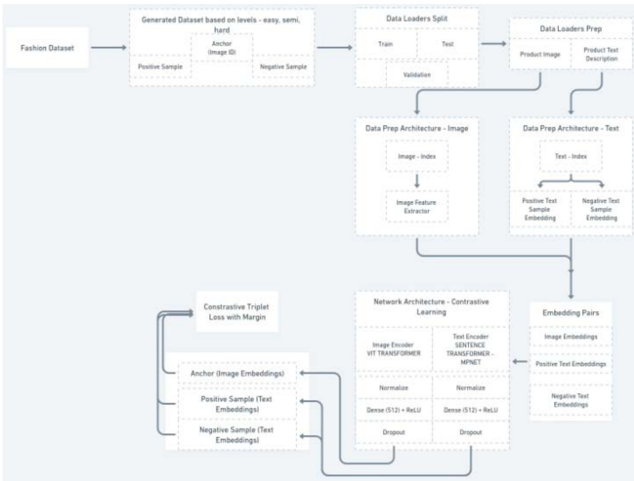
Multimodal deep learning has also been applied to fashion and product retrieval, particularly in the area of image-text matching. This involves matching images of clothing items with their textual descriptions, allowing for more accurate and relevant product recommendations. For example, Liu et al. (2016) proposed a multimodal deep learning framework that utilizes both visual and textual features for image-text matching in fashion products. Similarly, Song et al. (2018) proposed a deep neural network-based framework that learns joint representations of images and text for fashion product retrieval.

In conclusion, deep learning techniques have shown significant potential in fashion and product retrieval, particularly in the areas of visual search, personalized recommendations, and image-text matching. As the availability of fashion data continues to increase, we can expect further developments and improvements in this area of research.

C. Contrastive Learning

Contrastive learning is a popular deep learning technique that aims to learn useful representations of data by maximizing the similarity between positive pairs (i.e., data samples that should be similar) and minimizing the similarity between negative pairs (i.e., data samples that should be dissimilar). In recent years, contrastive learning has been applied to a wide range of tasks, including image classification, objectdetection, and language modeling. In this literature review, we will discuss some of the most influential works in the field of contrastive learning.

- “SimCLR: A Simple Framework for Contrastive Learning of Visual Representations” by Ting Chen et al. (2020) This paper introduced SimCLR, a simple yet effective framework for contrastive learning of visual representa- tions. The authors showed that SimCLR achieved state- of-the-art results on several benchmark datasets, includ- ingImageNet and CIFAR-10. The key insight behind SimCLR is to use data augmentation techniques to create multiple views of the same image and to use contrastive loss to learn representations that are invariant to these transformations.
- “Unsupervised Representation Learning with Contrastive Predictive Coding” by Aaron van den Oord et al. (2018) This paper introduced contrastive predictive coding (CPC), a method for unsupervised representation learning that uses a contrastive loss to learn useful representations of data. The authors showed that CPC achieved state-of-the-art results on several benchmark datasets, including MNIST and CIFAR-10. The key insight behind CPC is to use a sequence prediction task to create positive and negative pairs of data samples, which are then used to learn representations that capture the underlying structure of the data.
- “Bootstrap Your Own Latent: A New Approach to Self-Supervised Learning” by Jean-Bastien Grill et al. (2020) This paper introduced BYOL, a new approach to self- supervised learning that uses a contrastive loss to learn useful representations of data. The authors showed that BYOL achieved state-of-the-art results on several bench- mark datasets, including ImageNet and CIFAR-10. The key insight behind BYOL is to use an online network to generate a target network, which is then used to compute the contrastive loss. This allows the network to learn from its own predictions and to improve its performance over time.
- “Exploring Simple Siamese Representation Learning” by Kevin Musgrave et al. (2020) This paper introduced a simple Siamese network architecture for contrastive learning that achieved state-of-the-art results on several benchmark datasets, including CIFAR-10 and CIFAR-100. The key insight behind this approach is to use a Siamese network to compute similarity scores between pairs of data samples, which are then used to train the network using a contrastive loss. The authors also showed that this approach is highly scalable and can be applied to large-scale datasets.
- “Understanding Contrastive Representation Learning through Alignment and Uniformity on the Hypersphere” by Kaiming He et al. (2020) This paper introduced a new theoretical framework for understanding contrastive learning and proposed a new contrastive loss function based on alignment and uniformity on the hypersphere.



International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.152

Fig. 1. Overall Architecture Pipeline - Contrastive Learning

Fig. 2. Overall Data Pipeline

The authors showed that this loss function achieved state- of-the-art results on several benchmark datasets, including ImageNet and CIFAR-10. The key insight behind this approach is to learn representations that are well-aligned on the hypersphere and that are uniformly distributed, which helps to improve the generalization performance of the network.

III. Methodology

A. Data Pipeline

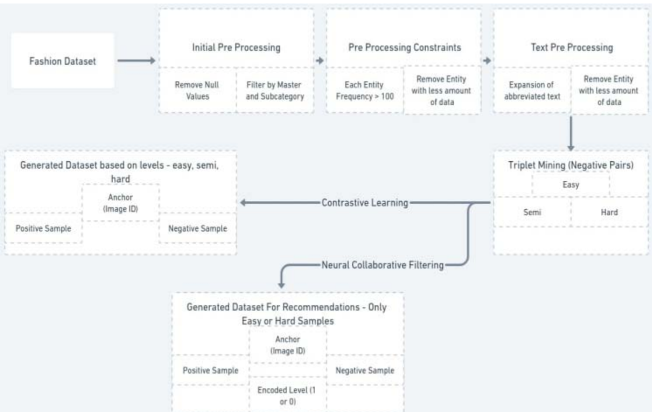
Contrastive learning is a type of self-supervised learning where a model is trained to distinguish between positive (similar) and negative (dissimilar) pairs of data samples. In the case of contrastive learning for image and text, the data is typically fed in the following way:

Easy pairs: For easy pairs, a positive pair consists of an image and its corresponding text description. The negative pair consists of an image and a text description that are unrelated to each other. Both the positive and negative pairs are considered easy because they are straightforward to distinguish.

Semi-hard pairs: For semi-hard pairs, the positive pair consists of an image and a text description that are related but not identical. The negative pair consists of an image and a text description that are either unrelated or too similar to the positive pair. These pairs are considered semi-hard because the model needs to learn to distinguish between subtle differences in the data.

Hard pairs: For hard pairs, the positive pair consists of an image and a text description that are very similar but not identical. The negative pair consists of an image and a text description that are very similar to each other, making it difficult for the model to distinguish between them. These pairs are considered hard because the model needs to learn to distinguish between very similar data.

In all cases, the data is typically fed to the model as pairs, with each pair consisting of an image and a text description. The model is trained to learn a joint embedding space where the image and text representations are mapped to a common feature space, making it easier to compare them and distinguish between positive and negative pairs.



anchor	positive	negative	level

These triplet pairs were generated by pairing with product context and differences based on color and gender. A sample is shown in the given table.

B. Architecture

1) Image Encoder: Image Encoder - VIT (Vision Trans- former) is a neural network architecture used for image classification tasks. It is a transformer-based architecture, which means it uses self-attention mechanisms to capture long-range dependencies in the input image.

The image patch embedding layer and the transformer them through a linear classification layer. During training, the model is optimized using a cross-entropy loss function, and backpropagation is used to update the model weights.

One of the advantages of the VIT model is that it can be trained on large amounts of data using a self-supervised learning approach, where the model is trained to predict the relative position of patches within an image, without requiring manual annotations. This approach allows the model to learn useful representations of images that can be transferred to downstream tasks.

Overall, the Image Encoder - VIT is a powerful architecture for image classification tasks, with strong performance on a variety of benchmarks, including the ImageNet dataset.

Text Encoder: -MPNet sentence transformer is a neural network architecture used for encoding text into fixed-lengthencoder layer are the two fundamental components of the VIT model. In order to create a succession of embeddings, the image patch embedding layer divides the input picture into fixed-size patches and applies a linear projection to each patch. The transformer encoder layer, which is made up of several blocks of multi-head self-attention and feedforward layers, is then fed these embeddings. The model can focus on various areas of the image and understand the spatial correlations between patches thanks to the self-attention mechanism.

The transformer encoder layer outputs a sequence of em- beddings, which can be used for classification by passingrepresentations, also known as embeddings. It is based on the transformer architecture and is designed specifically for encoding entire sentences or paragraphs of text.

DOI: rp-9788770040723.152

The mpnet sentence transformer model consists of multiple layers of transformer encoder blocks, each containing multi- head self-attention and feedforward layers. These layers allow the model to capture the relationships between different words and phrases within a sentence, as well as the overall structure and meaning of the sentence.

The input to the model is a sequence of word embeddings, which can be obtained using various methods, such as pre-trained word embeddings like GloVe or FastText, or by training word embeddings from scratch on a large corpus of text. The model then processes the input sequence through its multiple transformer encoder layers, producing a fixed-length sentence embedding as output.

One of the advantages of the mpnet sentence transformer model is its ability to learn from large amounts of unstructured text data using unsupervised learning techniques. By training on large amounts of text data, the model can learn to encode sentences in a way that captures their meaning and context, allowing for more effective downstream tasks such as text classification, sentiment analysis, and text similarity matching.

Overall, the Text Encoder - mpnet sentence transformer is a powerful architecture for encoding text into fixed-length representations, with strong performance on a variety of benchmarks, including the STS Benchmark and the GLUE benchmark. Its ability to learn from large amounts of unstruc- tured text data makes it a useful tool for a wide range of natural language processing tasks.

C. Triplet Loss Function

Contrastive triplet loss is a type of loss function used in deep learning models for learning representations of data in a metric space. It is commonly used in image and text retrieval tasks, where the model is trained to encode images or text into a low-dimensional space where similar images or text are closer together and dissimilar ones are further apart.

The contrastive triplet loss function consists of three inputs: an anchor, a positive example, and a negative example. The anchor is an input data point, such as an image or a text snippet, for which the model should learn an embedding. The positive example is another input data point that is similar to the anchor, while the negative example is a data point that is dissimilar to the anchor.

The loss function is made to make sure that there is a difference in size between the distance between the anchor and the positive example and the distance between the anchor and the negative example. A hyperparameter called margin establishes the shortest possible distance between the anchor and the negative instances.

These are the calculations for the contrastive triplet loss function: // d(a,p) is the Euclidean distance between the anchor and the positive example, and d(a,n) is the Euclidean distance between the anchor and the negative example, where an is the anchor, p is the positive example, and n is the negative example.

By changing model parameters during training, the model seeks to reduce the contrastive triplet loss function. The objective is to learn embeddings that increase the margin of separation between the anchor and negative instances while minimising the margin of separation between the anchor and positive examples.

The margin is an important hyperparameter in the con- trastive triplet loss function because it determines the threshold for what constitutes a ”similar” or ”dissimilar” example. If the margin is too small, the model may learn embeddings that arenot well-separated, while if the margin is too large, the model may learn embeddings that are too dissimilar, making it harder to retrieve similar examples.

Overall, the contrastive triplet loss with margin is a powerful technique for learning embeddings in a metric space that capture the similarities and dissimilarities between data points, with strong performance in image and text retrieval tasks.

D. Training

Contrastive learning is a type of unsupervised learning technique that learns to map similar inputs together in a latent space. In the context of multi-modal learning, contrastive learning can be used to learn joint representations of images and text, where the embeddings of similar images and their associated texts are mapped closer together in the latent space. The contrastive learning architecture with both image and text encoder and triplet mining loss function consists of two main parts: an image encoder and a text encoder. The image encoder takes an input image and maps it to a fixed-length representation, while the text encoder takes an input text andmaps it to a separate fixed-length representation.

The triplet mining loss function is used to train the model. The loss function takes three inputs: an anchor, a positive, and a negative example. The anchor is a pair of an image and its associated text, while the positive and negative examples are other pairs of images and their associated texts. The goal of the loss function is to minimize the distance between the anchor and positive examples, while maximizing the distance between the anchor and negative examples.

During training, the model is fed batches of image-text pairs, and the triplet loss is calculated for each anchor, positive, and negative example. The model is then optimized to minimize the overall triplet loss using gradient descent.

One of the advantages of the contrastive learning architecture with both image and text encoder and triplet mining loss function is that it can learn joint representations of images and text that capture both their visual and semantic similarities. These joint representations can be used for a wide range of downstream tasks, such as image-text retrieval, cross-modal retrieval, and multimodal classification.

The proposed architecture uses a VIT transformer as an image encoder and MPNET Sentence Transformer as a language encoder along with linear and dropout layers for regularisation. The overall working of this architecture is explained in the figure.

E. Post Training Recommendation Pipeline

DOI: rp-9788770040723.152

The dataset generated from Data Pipeline while making triplet pair batches was also used to sequence and generate another dataset, where it queries hard and semi-level pairs and encodes labels with difficulty match as 1 and 0 as per their matching relevance. This matching and sequencing generated a candidate-item-based dataset along with its binary labels - 1 or 0 (being hard or semi-hard respectively). This retrieval can be used to build a collaborative recommendation system. A snippet of extracted data is being shown in the given table.

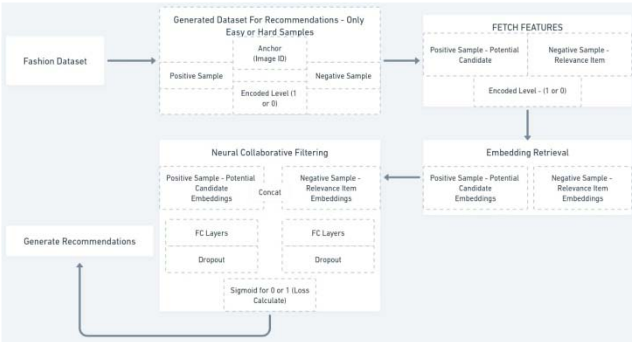

Fig. 3. Overall Architecture Pipeline - Recommendation and Joint Retrieval

Neural Collaborative Filtering (NCF) is a technique used in recommender systems that combines deep learning with traditional collaborative filtering methods. Collaborative filtering is a technique used to make predictions about user preferences by finding similarities between users or items based on their past interactions.

The cold-start problem, when new users or objects have little to no interaction history, and the sparsity problem, where the interaction matrix is frequently sparse, are two drawbacks of conventional collaborative filtering approaches that NCF is intended to address.

NCF consists of two main parts: the user and item embedding layers, and the neural network layer. The user and item embedding layers map the users and items to a low- dimensional vector space, while the neural network layer learns the interactions between the user and item embeddings to make predictions about user preferences.

The user and item embeddings are learned through a process called matrix factorization, where the interaction matrix is decomposed into two low-rank matrices, one for users and one for items. The user and item embeddings are learned by minimizing the reconstruction error between the original interaction matrix and the reconstructed interaction matrix using techniques such as Alternating Least Squares or Stochastic Gradient Descent.

Once the user and item embeddings are learned, they are passed through a neural network layer that learns the interactions between them. The neural network layer can be designed in a variety of ways, such as a simple dot product betweenthe user and item embeddings, or a more complex multi- layered neural network that can capture non-linear interactions between the user and item embeddings.

During training, the model is optimized using a loss function such as mean squared error or binary cross-entropy, which measures the difference between the predicted and actual ratings.

NCF has been shown to outperform traditional collaborative filtering techniques on a variety of datasets, particularly in scenarios where the interaction matrix is sparse or the user- item interactions are implicit (e.g., clicks, views, purchases) rather than explicit ratings.

IV. Experimentation

A. *Hardware Architecture Specifications*

This pipeline was processed and experimented with over Google Colab Free tier with NVIDIA Tesla P4 GPU with 15 GB RAM. Google Drive storage was used as cloud storage for storing model-saved states and inference results.

B. *Software Specifications*

Source	**Platform /Tool**
Programming Language	Python
Deep Learning Framework	Pytorch
Data Processing and Utilities	Pandas, Numpy, Scikit-Learn
Operating System	Linux OS

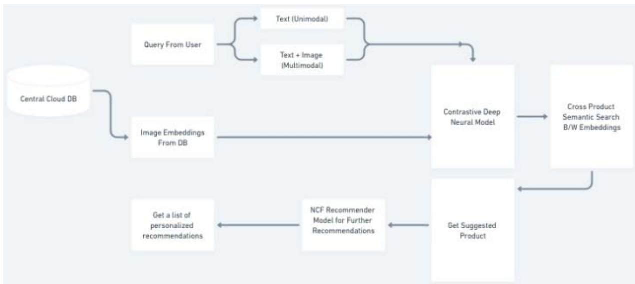

Fig. 4. Overall Query and Fetch Pipeline

B. *Text Retrieval*

In contrastive learning, text retrieval involves comparing two or more text embeddings (i.e., representations of text in a high-dimensional space) to determine their similarity or dissimilarity. This is typically done by measuring the distance between the embeddings, where a smaller distance indicates greater similarity. WIth triplet loss, which involves training a neural network to learn embeddings such that the distance between an anchor text and a positive text (i.e., a text that should be similar) is smaller than the distance between the anchor text and a negative text (i.e., a text that should be dissimilar). This helps the network learn more discriminative embeddings that can be used for text retrieval.

Text query can be passed as a text description of the product and then semantic embeddings can be cross-computed against image embeddings to fetch product retrieval results.

C. *Multimodal Retrieval*

In contrastive learning, image-text retrieval involves comparing the embeddings of images and texts to determine their similarity or dissimilarity. This can be useful for tasks such as image captioning, visual question-answering, and cross-modal retrieval.

DOI: rp-9788770040723.152

To perform image-text retrieval in contrastive learning, we typically use a multimodal (image+text as a query) approach that combines visual and textual features. Using Cosine Sim- ilarity as a semantic search, we can compute the distance between text and image embeddings and fetch the retrieval of products

D. Recommendation from contrastive Retrieval

In the context of fashion product retrieval, NCF can be used to further enhance the personalized recommendationsgenerated using contrastive learning-based retrieval. By in- corporating NCF into the recommendation system, we can capture more complex user-item interactions and generate more accurate personalized recommendations.

The idea is to use theembeddings learned through contrastive learning as input to a neural network that models the user-item interactions. This network can be trained using a variety of techniques, such as matrix factorization, to predict the likelihood of a user interacting with a particular item.

By combining the strengths of both contrastive learning and neural collaborative filtering, we can generate more accurate and personalized recommendations for users.

V. Result And Its Analysis

In the context of contrastive learning, good performance on frequently occurring images and descriptions can be attributed to the fact that the model is able to learn the distinguishing features and patterns of these samples more effectively. This is because the model has more data to learn from and can more easily identify the common features that distinguish these popular items and colors.

However, when it comes to less frequent images and de- scriptions, the model may not have enough data to effectively learn the relevant features and patterns, leading to poor performance. This is a common challenge in machine learning, particularly in deep learning-based approaches, where models require large amounts of data to effectively learn the underlying patterns.

One way to address this challenge is to increase the amount of training data by using techniques such as data augmentation or synthesis, which can help the model to learn more generalizable representations. Additionally, fine-tuning the model on a smaller, more specific dataset that focuses on the less

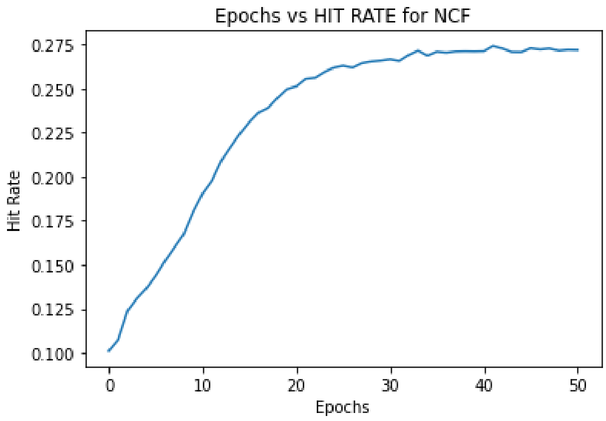

Fig. 5. NCF - Hit Rate Analysis

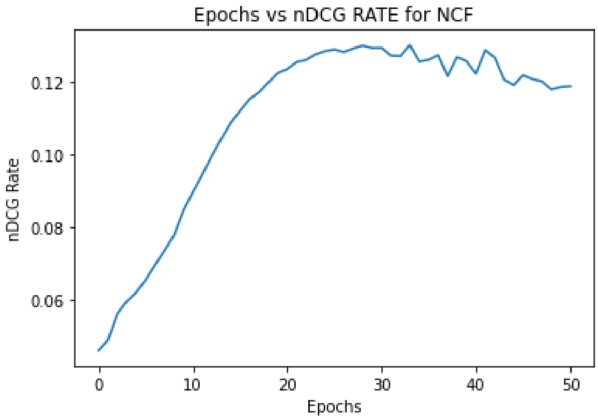

Fig. 6. NCF - nDCG Analysis

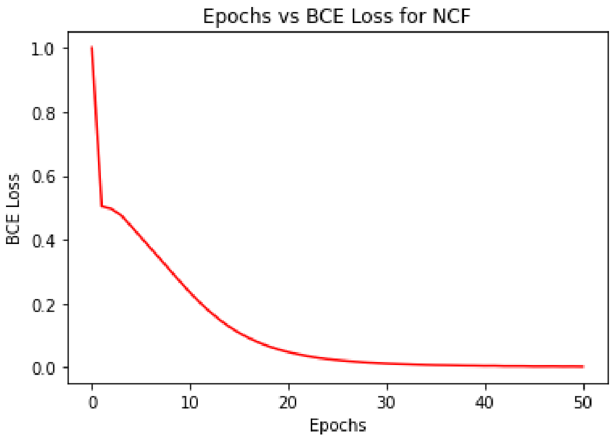

Fig. 7. NCF - Loss Analysis

TABLE I: Contrastive Learning - Table

Epoch	Train Loss	Valid Loss
1	0.067	0.448
2	0.042	0.038
3	0.036	0.035

frequent samples can also help to improve performance on these samples.

Regarding the difficulty in identifying colors, this can be addressed by incorporating additional information or features into the model, such as color histograms or color spaces, that can help the model to better capture and

DOI: rp-9788770040723.152

distinguish between different colors. It may also be helpful to pre-process the images to enhance or highlight the color features, or to use more advanced computer vision techniques such as object detection or segmentation that can help the model to focus on specific color regions.

Overall, it’s important to ensure that the dataset is balanced and contains sufficient examples of both frequently and less frequently occurring images and descriptions to enable the model to learn effective representations for both. Proper eval- uation of the model’s performance using appropriate metrics and analysis techniques can also help to identify areas of improvement and guide further model development.Graphic

VI. Conclusion And Future Work

In conclusion, fashion product retrieval using contrastive learning is a promising approach for improving the accuracy and efficiency of fashion product recommendation and search systems. By using a multimodal approach that combines visual and textual features, we can learn a joint embedding space that captures meaningful semantic relationships between fashion products and their attributes.

With the increasing popularity of online shopping and the vast amounts of product data available, fashion product retrieval has become a critical problem for many retailers and consumers. By using contrastive learning, we can improve the accuracy of product recommendations by learning more discriminative representations of fashion products and their attributes.

One key advantage of contrastive learning is that it can be used to train deep neural networks using unsupervised learning, which reduces the amount of labeled data needed for training. This makes it particularly useful for fashion product retrieval, where labeled data may be scarce or expensive to obtain.

In terms of better suggestions, neural collaborative filtering as integration is also proposed which can further enhance personalized product suggestions based on obtained results from contrastive learning-based retrieval.Neural collaborativefiltering (NCF) is a powerful technique that can be used in conjunction with contrastive learning to improve personalized product suggestions. Collaborative filtering is a common technique used in recommender systems, where users’ past interactions with items (such as purchases or ratings) are used to make recommendations for new items. Neural collaborative filtering is a deep learning-based approach to collaborative filtering that uses neural networks to model the user-item interactions.

In the context of fashion product retrieval, NCF can be used to further enhance the personalized recommendations generated using contrastive learning-based retrieval. By incorporating NCF into the recommendation system, we can capture more complex user-item interactions and generate more accurate personalized recommendations.

The idea is to use theembeddings learned through contrastive learning as input to a neural network that models the user-item interactions. This network can be trained using a variety of techniques, such as matrix factorization, to predict the likelihood of a user interacting with a particular item.

By combining the strengths of both contrastive learning and neural collaborative filtering, we can generate more accurate and personalized recommendations for users. This approach has been shown to be effective in a variety of recommendation tasks, including music and movie recommendations, and has the potential to significantly improve the performance of fashion product retrieval systems.

Overall, fashion product retrieval using contrastive learning has many practical applications and is an active area of research in the fields of computer vision and machine learning. With continued advancements in deep learning and multimodal fusion techniques, we can expect to see significant improvements in the accuracy and efficiency of fashion product retrieval systems in the years to come.

VII. Limitations

The proposed work was implemented over Google Colab with restricted computation, if given a better architecture, more dimensions and a granular level of training can be done and better results could have been computed.

The proposed models can be further fine-tuned with the implementation of more regularisation layers and hyperparameter tunings.

A complex and bigger triplet mining map can be further retrieved from the data pipeline across product descriptions.

Abstract—Security automation is essential today because it has become one of the main concerns for any organization. Many of the solutions that are currently available are still unreliable in real-world settings because they frequently depend on numerous constraints. In the project that follows, we will learn how to identify license plates using the Object localization and OCR. For this project, we'll use the YOLOv5 framework for license plate localization, then identify the license plate text using EasyOCR. This study will also show how a cutting-edge YOLO object detection-based ALPR system can be reliable and successful. The results show that a trained aneural network working with a high accuracy of about 90-95 percent can recognize license plates in low-resolution pictures.

This project will present a robust and efficient ALPR system based on the state-of-the-art YOLO object detection. The results have shown that the trained neural network is able to perform with high accuracy of nearly 90-95 percent in recognizing license plates in low resolution images using this system.

Keywords—Deep Learning, YOLO, Object Detection & Localization, OCR, Easy OCR, License Plate Recognition, ANPR, Residential vehicle security

I. Introduction

These days there is an increasing need for security in residential complexes, be it big or small. We believe using our application, it is possible to provide maximum security to such buildings. There are often hindrances while finding out whether a person entering the building via any vehicle is a person belonging to the community or not. This can be done via manual checking but it is a very tedious job for the security personnel. Using the app, we have developed, all they have to do is take a photo of the incoming vehicle, that is all.

The code we've written recognizes the license plate and uses OCR to extract the text from it. After this, it matches the said license plate with the ones in the database, thereby finding whether the vehicle belongs to the building or not. In this project, we aim to provide the following features - (a) Identifying vehicles that belong to the premises, Creating and storing the vehicle/owner information in the database, such that their parking lot for each vehicle is assigned and mentioned in the database. From this we can fetch the data we need to verify in future.

So, whenever any vehicle enters the residency, the security guards will simply click their picture from the application, and our deep learning model will extract the text of the license plate and cross verify with the database if it is present or not. (b) Availability of parking spaces: Another big problem which residential management faces is parking on wrong slots/ or some outsider's vehicle is parked at a pre-allocated slot of some resident. Keeping a track of that and verifying those things again is a big problem. In case a visitor enters with their vehicle they don't know where to park so they at times park at someone else's parking area, or on roads, or at places which might create problems in the future. This app will temporarily allocate free parking spaces, and its location, once authorized, so that they can park freely and safely without any disputes. (c) Allotment of parking space for newly registered vehicles: When an existing resident gets a new vehicle, or a new resident arrives, once they are authorized, this app will give them an option to select and pick any slot available and permanently allocate that slot to them. (d) Reducing the labor work of security personnel: This Application is designed so that it will avoid a lot of paperwork and verification work done by security personnel everyday 24/7. This app is simple to use for anyone to use with/without having a technical background. And it's one more new step towards digitization.

II. Literature Survey

For solving real world problems likevehicle parking to traffic control, a realtime ANPR model has established itself as a vital instrument for access-control &improved management of traffic. In previous model, the vehicle license plate area was located using a number of localization techniques, including contouring, edge-detection,and others. These ANPR model may function under limitations like darkness or light, angle view of plate, and poor resolution stated in [3] by using simple image processing algorithms. Previous research employed image preprocessing techniques including edge detection and contouring for the detection of number plates, which included the use of serval localization algorithms.

Additionally, [4] discusses both online and offline versions of the ANPR system. In contrast to offline ANPR models, which take pics for additional processing with the help of OpenCV, as it has numerous predefined algorithms, which aresuitable for realtime application, online ANPR systems interpret incoming video frames to enable real-time tracking.

Using a Raspberry-Pi, Fakhar et al. suggested a cheap ANPR system in 2018 [5], where the model makes use of a real-time picture taken from a camera. The characters on the plate are recognized once the picture has been denoised, filtered, and segmented. All complex calculations are handled by the Raspberry-Pi, and there is a discernible 3-second delay before the outcome. The database also stores

DOI: rp-9788770040723.153

the outcome label. [6] presents the ANPR technology for smart check-in and check-out, which shortens wait times and records vehicle entrance and leave. In order for ANPR systems to instantaneously identify the license plate text using image-computing and record the adding vehicle and security info in the database through a web-app, images from CCTV cameras must be gathered. The suggested method would shorten check-in times and ease parking and traffic congestion.

The ANPR model in POLIMAS, that confirms that only authenticated cars are allowed to access the designated site, was proposed by Nui Din and Virakwanin [7]. There are four alternative ways to install a webcam: back, front,rear, and top. The acquired picture is made gray-scale, and then the histogram equalization method is used to modify the contrast and intensity. A combination of Sobel-edge and Laplacian-edge detectors is used in the bounding box technique to identify and crop character region, yielding 95.83% confidence of localization of license plates. In OCR, each character is compared using eigenvectors and correlation. Character recognition accuracy using the suggested method was 87.41%. The results are gathered in a string format& contrasted with the reserved records in the DB.

Liu &Chou [8] introduced a real-time truck license number verification system that decreases the manual efforts and labor, additionally time-spent in verifyinglicense plates since identification remained difficult owing to the diverse forms of plates in different locations. Their approach successfully lowers the likelihood of crime while enhancing the efficiency, automation, and transparency of front-line workers. Using Yolo& CNN based Deep Learning frameworks, this model achieved a single-character detection rate of 97.59%, and overall accuracy rate was 93.73%, and at inference-time of 0.32 sec/image.

In [9], Chen and Hu presented an ITS that emphasized video dedicated vehicle recognition & classification methods that rely on static & motion each information to get better results. Under environmental variables, such as various illuminations, the suggested approach localizes the vehicle license plate region &detectscharacters from license plate with a 95% confidence score.

In [10], a car plate identification system depending on OCR &WSN (wireless sensors network) was discussed. The suggested model takes pictures of parking spots using the Smart Parking Service (SPANS) framework and detects in-motion as well as parked automobilelicense plates. Real-time photos are also used to evaluate the system's performance. R. N. Babu et al. in [11] employed cutting-edge DL approaches for plate identification. 6500 Indian license plates made up their picture dataset, which was split into training and testing sets in a ratio of 90:10. Three separate cameras, each with a different data rate and focal length, were used to take the pictures. For character recognition, a 37-class CNN model was trained. The model employs 126 filters, and YOLOv3 is utilized to decode the license plates of moving vehicles. For license plate character recognition, they attained a 91% accuracy rate.

In addition, using a KNN-based approach, character identification is accomplished in [12] with a 98% accuracy rate. The pictures were captured with a webcam that has a 640 x 480-pixel resolution. The procedure made use of thresholding, grayscaling, edge-detection, morphological and inversion techniques.

Different segmentation techniques were used by Ariff et al. in [13] for the cleanup and evaluation of the noisy number plate photos. 100 Malaysian number plates with high resolution of 1932x2576p were evaluated utilizing threshold techniques like NiblackandSavoula to get rid of unwanted pixels. The average accuracy of Savoula segmentation inthis situation is 83%. Character classification is done using the template matching approach.

A precise VNPT recognition method based on an OCR engine is suggested in [14]. The input license plate pic is converted to grayscale, subjected to global image-thresholding by utilizing Otsu technique, and had its noise removed. OCR is used to perform character recognition on the processed picture. The outcome is subsequently placed in a text-file as a string. The overall precision of the system ranges from 90% to 100%.

ALPRNET, a neural-network called and two full-convolutional onestage object predictors for concurrently identifying & categorizing characters and license numbers, were presented by the author in [15]. [16] introduces a global license plate identification system that uses Tiny YOLOv3, YOLOv3-SPP (spatial pyramid pooling), and unified character sequence detection to identify the layout of 17 distinct nations.

III. Proposed System

From the past research addressing ANPR, we discovered that two alternative approaches were often employed for character detection in the ANPR models. The basic technique is EasyOCR & the other technique is connected to Deep Learning. Also, we employed these two techniques for rapid deployment of our suggested ANPR system, which has a unique system specialised to Residential vehicle license authentication was introduced. In this study, we have refined our previously suggested pipeline for license plates & investigated its use in autonomous vehicle authentication.

About traditional ANPR model, it's not very efficient & precise in finding license plate's position and recognition technique due to diverse real-world scenarios like,lighting as well as the quality of clicked pictureduring the acquisition phase. Traditional ANPR pipeline involves these stages: picture capture, plate identification, pre-processing of retrieved plate, and license plate identification. The suggested realtime ANPR model takes the multiple frames from the surveillance footage and, using YOLO object identification framework, detects the front or rear image of automobile in order to establish the check-in or check-out condition for the authenticationmodel. Following that, the license plate can be tracked by using the YOLO framework.

DOI: rp-9788770040723.153

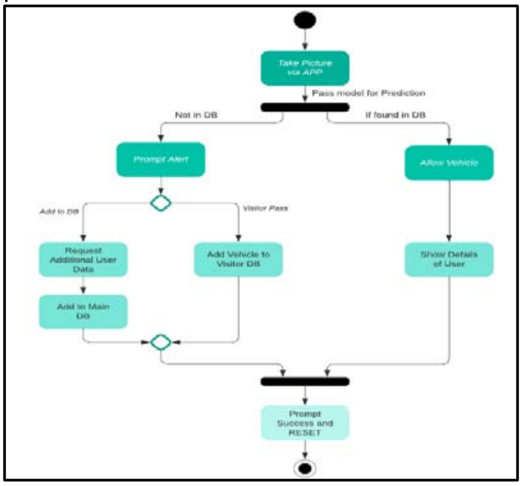

Fig. 1. Flow diagram

In the end, license plate characters are detected by efficient OCRmodelslike CNNbased frameworks or EasyOCR. Fig. 1 shows theflow diagram of our proposed Licence plate recognition model. This project has 4 major modules, the Flutter Application, Flask Integration, Database, Train YOLOv5 model.

A. Training YOLOv5 Model

We are training the YOLOv5 framework for license plate localization since YOLOv5's object detection model is relatively fast and gives precise results in a real time application. YOLO (You Only Look Once) is a real-time object detection algorithm that processes an image in a single pass, identifying objects and their bounding boxes. It achieves high accuracy and fast performance by using a convolutional neural network to simultaneously predict object classes and locations. It is trained on vehicle's license plate images in both front and rear view. We provide only one classifier 'license plate' as per requirements. We took the dataset from Kaggle with 433 images with bounding box annotations of the car license plates within the image.

In the pre-processing step we resized and converted every image into a list of coordinates of size 224x224 (which is standard size for pretrained transfer learning models). Then we split the data into train & test with the ratio of 75:25. Then we finally train the model with the YOLOv5 model with the YOLOv5s weights (which is ideal for smaller datasets). As a result yolo will return the images with the bounding boxes around the localized license plate region with a number as the confidence score (as shown in Fig 2). The weights in the "best.pt" file represent the optimized values for the model's parameters that allow it to perform well on the task it was trained for. We saved the 'best.pt' trained weight from the model for the deployment code.

Fig. 2. Output of YOLOv5 Train model

B. FireBase (Residential Vehicle Database)

A small database is created in Firebase. Firebase is a mobile and web application development platform that provides a suite of backend services to help developers build apps faster. We are using its real-time database for the vehicle database of the residencies, so that we can easily add, fetch & search the records in the database in real time. The database is stored as a nosql database in the format of collections with the attributes - owner_name, license_no, flat_no, contact_no.

C. Flutter Application

Flutter app will be used by the end users, to click pictures from the app and verify the cars.The workflow of this task will process as the user clicks picture, it will be sent to Flask UI through an API and the authenticity and details of the car and car owner(if legitimate) will be returned and displayed,

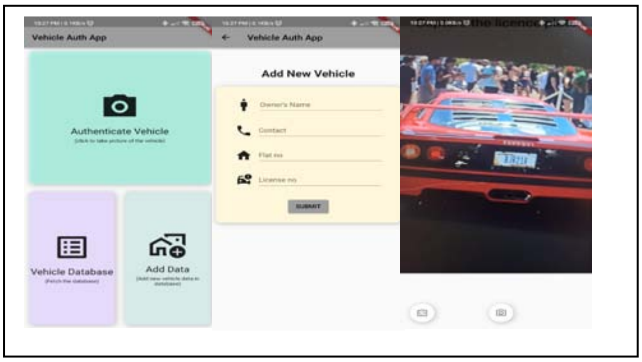

Fig. 3. UI of Flutter APP

After which the user can take further actions accordingly (add to database or temporarily allocation of available spaces etc.). Apart from this the UI has some additional features like, adding new Vehicle data to the Database & viewing the residential vehicle database on the app itself.Figure 3 depicts the User Interface of flutter app.

D. Flask App Integrity (Deployment code)

In this module we have hosted a Flask web-app so that it can interact with Flutter app, & Firebase (that has Residential vehicle database). Also this app can run the deployment code when requested.

The deployment code is responsible for localizing the license plate & extracting the license plate number, from the given user requested vehicle image. This deployment code uses the YOLOv5 framework for license plate localization using our pre-trained weights from the previously trained model (saved in 'best.pt' file). This concept of using pre-trained weights/model is called Transfer learning. After getting localized license plate coordinates, we crop that region and pass it to the OCR(Optical Character Recognition) model for text extraction. Precisely we are using EasyOCR, which is a Python package that provides an easy-to-use interface for optical character recognition (OCR) of text in images and PDF files. It can recognize text in over 70 languages and supports multiple OCR engines for improved accuracy. In Fig 4, the flow of deep learning model is explained.

DOI: rp-9788770040723.153

The extracted text is returned to the flask app, which is then searched through the database in Firebase by using the queries and if found we fetch the owner's details else we get '-1' response, which we revert back to the Flutter app.

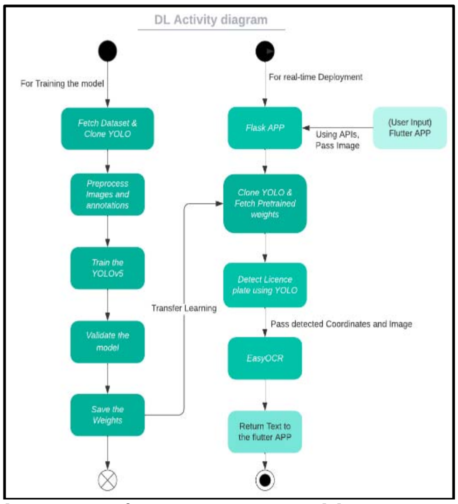

Fig. 4. Flow Diagram for Deep-Learning Model

III. Experiment Analysis

After training with a total of 433 images of license plates, we used 300 epochs & 16 batch size. We can see the below mentioned plots (Fig 5) that there is a definite drop in the box_loss (the loss function that penalizes the model for incorrect predictions of the bounding box coordinates) and obj_loss (the loss function that penalizes the model for object detection errors, such as false positives and false negatives) after 200 epochs. For the best.pt weight with most optimal performance, the precision value was 0.97, recall was 0.99 & mAP (mean Average Precision) was 0.99.

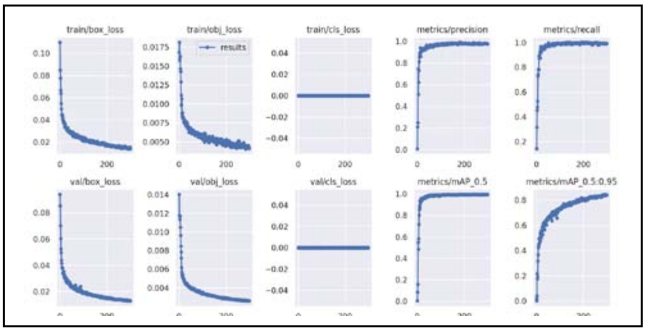

Fig. 5. Loss analysis

Figure 6 shows the F1 score of the model. By these values calculating the F1 score, using the standard formula we get 0.98 for the YOLO license plate localization.

Fig. 6. (a) F1 Score vs Confidence plot for YOLOv5 model; (b) Output of Deployment code after EasyOCR

IV. Conclusion

This project has presented us with a robust & an efficient Residential vehicle authentication system based on YOLOv5 object detection. In this model, we have used the concept of transfer learning, to integrate two models to create a deep-learningbased pipeline that is trained&validated for residential vehicle authentication apps. The results have shown that the trained neural-network is able to perform with high-accuracy of around 95-98% in localizing license plates in low-resolution picswith the help of this system. We can improve the model's performance even more by training it on Indian vehicle license plate images and videos. This system has potential to replace the trivial manual vehicle verifying process with its automated and fast approach. Furthermore, we can add more useful features to this system to ease the management task, such as allocating unallocated parking spaces to the visitor's vehicles, temporarily and integrating this model to a live streaming device (through CCTVs for example) to make this process completely automated instead of relying for manual clicking of pictures.

***Abstract*—Disease prediction system is devolved to predict the diseases. This is done from the information/symptoms provided by the user; these symptoms are considered as input to the system. The proposed system analysis helps to discover the symptoms that are provided from the users and shows a probability of the disease as an output. This process of prediction of diseases is done using a decision tree classifier. With data present on these disease, the user can predict the disease bases on systems and also book an appointment based on the result from prediction.**

I. Introduction

The branch of AI and computer science called "machine learning" uses algorithms and information to simulate how people learn, progressively increasing the accuracy of the system. ML has two steps that ensure the accuracy of the output. Those two steps are: training and testing. By using machine learning, issues in the medial field can resolved efficiently.

By using machine learning we are able to securely maintain the records of the hospital with this information we can create a model that to get quickly analyse data and deliver results faster.

With this invention doctors can swiftly get results and also can accede the issue with more quickly from this action more lives can be saved.

For more accuracy from massive data the proposed system used linear, KNN, decision tree algorithm.

II. LITERATURE REVIEW

A. *Common Diseases (CD)*

Dahiwad et al. suggested an ML based technique for anticipating common diseases. The UCI ML repository of various prevalent ailments was used to import the symptoms dataset, which comprised symptoms. The system used the categorization techniques convolution neural network and k-nearest neighbor to forecast a variety of ailments. Furthermore, the proposed remedy included further data on the tested patient's lifestyle choices, which was useful in deciding the degree of risk associated with the anticipated illness. Dahiwad et al. examined the results of the k-nearest neighbor and convolution neural network algorithms in terms of processing speed and correctness. convolution neural network had a processing time of 83.7% and an accuracy of 12.1 seconds. Statistics revealed that the k-nearest neighbor approach outperformed the convolution neural network algorithm. Based on their findings, Che et al. concluded that convolution neural network outperformed conventional supervised algorithms such as k-nearest neighbor and decision tree. The suggested model's ability to recognize complicated nonlinear interactions in the feature space it states why it performed better than previous models. In addition, convolution neural network identifies significant characteristics and improves illness descriptions, allowing it to accurately forecast diseases of great complexity.

B. *Kidney Problems*

A comparison of classifiers' capacities to diagnose chronic kidney disease was performed using the Kidney Function Test dataset. The classifiers used in this study are k-nearest neighbor, Naïve bayes, and random forest, and their performance is measured in terms of F-measure, precision, and accuracy. While Naïve bayes produced superior precision, random forest performed better in terms of F-measure and accuracy, according to the results of the analysis. Considering this study, users attempted to diagnose renal diseases using support vector machine and Naïve bayes. The classifiers were used to differentiate four types of kidney disorders: Acute Nephritic Syndrome, Acute Renal Failure, Chronic Glomerulonephritis, and chronic kidney disease. The study also focused on determining the classification algorithm that performed the best in terms of accuracy and execution time. support vector machine outperformed Naïve bayes in terms of accuracy, making it the best algorithm, according to the data. Naïve bayes, on the other hand, classified data swiftly. Because it effectively manages semi-structured and unstructured data, Charleonna et al. and Kottur et al. determined that the support vector machine classifier is more suitable regarding renal illnesses. Many empirical studies are dedicated on identifying chronic kidney disease. Because of the support vector machine's scalability to larger feature areas, it was able to identify complex kidney disorders with high accuracy.

DOI: rp-9788770040723.154

C. *Heart Problems*

Marimuth et al. attempted to forecast heart diseases using supervised ML techniques. The classified the attributes of the data as sex, age, aim, slope, and chest pain. The four applicable machine learning algorithms used are decision tree, k-nearest neighbor, logical regression, and Naïve bayes. When compared to the other algorithms, the logical regression algorithm performed the best, with an accuracy score of 87.79%. In 2017, Dwivedi attempted to improve the correctness of heart disease prediction by taking into account new parameters such as resting BP, SC in mg/dl. The dataset used had 119 positive heart disease tests and 148 negative heart disease tests; it was imported from the UCI ML laboratory. Dwived et al. analyzed the performance of Artificial Neural Networks, support vector machine, k-nearest neighbor, Naïve bayes, logical regression, and Classification Trees. The results of tenfold cross-validation demonstrated that logical regression has the highest classification accuracy and sensitivity, exhibiting remarkable dependability in detecting cardiac abnormalities. Polaraj and Vahi et al.'s results, in which LR outperformed other techniques such as Artificial Neural Networks, support vector machine, and AdaBost,

II. Objective

To visit a doctor first we need to book an appointment and pay consult fee but with this system we can save time and money at the same time. This can predict users' disease by analysing the symptoms that were provided as input to the system. As the time progress, accuracy of the system will be improved by ML.

III. Existing System

Although surgeons still need technology in a variety of ways, such as surgical representation and x-ray photography, it has perceptually lagged behind. Due to other aspects like weather, environment, blood pressure, and several other parameters, the approach still requires the doctor's knowledge and expertise. there are a great deal of factors that are acknowledged as being necessary to comprehend the total functioning process,no model has ever been able to examine them adequately. To overcome this issue, medical decision support technologies must be used. This method can help doctors make the best selection.

ML is being used to keep entire healthcare data. With the use of machine learning technology, doctors can make important decisions regarding patient diagnoses and treatment options, improving patient healthcare services. Machine learning technology enables constructing models to evaluate data rapidly and give answers faster. The use of machine learning in the medical industry is best illustrated by the example of healthcare.

IV. Proposed System

Using symptoms, this system is used to forecast illness. This system evaluates the model using a decision tree classifier. End users make use of this system. Based on symptoms, the system will be able to forecast illness. The technology used by this system is machine learning. The decision tree classifier method is used to forecast illnesses.

Using symptoms, this system can be used to forecast infectious and non-infectious diseases. proposed system evaluates using a decision tree classifier. users make use of this system. The technology used by this system is machine learning. The decision tree classifier method is used to forecast illnesses.

V. Dataset Model Description

This dataset used in this analyzes base of symptom connections created automatically using data from textual discharge summaries of patients hospitalized in many Hospitals. The condition is displayed in the first column, followed by the number of discharge summaries that mention it positively and recently, as well as any accompanying symptoms. Based on these notes, associations for the 148 most prevalent diseases were calculated, and the symptoms are displayed sorted according to the strength of link. The method involved extracting UMLS codes for ailments and symptoms from the notes using the MedLEE natural language processing system, and then determining relationships using statistical techniques based on frequency and co-occurrence.

The original information's substance and the quantity of information needed is known as information gain. The features are ordered according to information gains, and the top-ranked features are then picked as prospective classifier qualities. Evaluating the data gained for each feature and then selecting the one that maximizes the information gain will assist you in identifying the decision tree's splitting attribute. The IG for each characteristic is calculated using the following formula:

Evaluating the data gain for each feature and then selecting the one that maximizes the information gain will assist you in identifying the decision tree's splitting attribute. The IG for each characteristic is calculated using the following formula: Figure 1 shows the architecture diagram.

VI. System Architecture

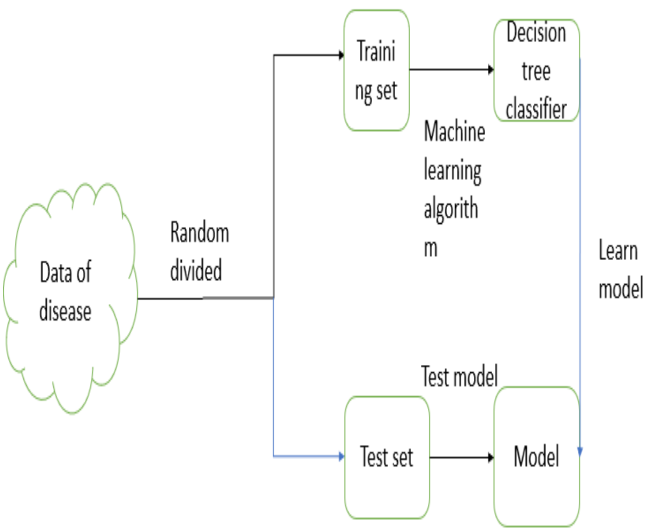

Figure 1: System Architecture Diagram

DOI: rp-9788770040723.154

VII. Algorithm

Decision Tree (DT)

The gain ratio decision tree (GRDT) was the type of decision tree used in this investigation. The GRDT's strong foundation line is the entropy (IG) approach, which decides the splitting characteristic that minimises the range of entropy while maximising the IG. The distinction between measures favors tests with a diverse set of effects. In other words, it is like traits with a wide range of potential values. Gain Ratio regulates the IG for individual attributes to ensure consistency and breadth of attribute's value.

Here k is value of target attribute class. Pi is ratio of the value of cases of class1 to the total number of occurrences (i.e., the likelihood of I am happening). To reduce the influence of bias caused using information gain, Australian academic Ross Quinlan created a version known as gain-ratio. The information gain measure favors tests with a wide range of effects. In other words, it prefers to choose qualities with a lot of possible values. Gain Ratio controls IG for each attribute in order to ensure the consistency and breadth of the attribute's value.

For regression and classification, decision trees are a supervised learning technique. After deducing the data attributes, it learns the straightforward decision rules and predicts the target variable's value. ID4, C3.6, C4.9, and CART are examples of DTA. CART, the most recent and improved version, was used in our model.

i) The classification trees of the CART algorithm use Gini impurity. Based on how the labels are split across the subset, it assesses the probability that a randomly selected piece from the set would be erroneously identified if it were given a label at random.

ii) Information acquisition is utilized by the tree creation algorithms ID4, C3.6, and C4.9. It is based on the information theory concepts of entropy and information content. At each stage of the tree-building process, it is utilized to determine which characteristic to split on.

VIII. Evaluating The Models And Results

The following table provides an overview of the outcomes from our model:

It is evident that the performance of all three algorithms has been enhanced by the preprocessing method of discretization. Random Forest had the greatest accuracy for our dataset, despite the fact that Naive Bayes' accuracy experienced a large improvement as a result of discretization.

Table 1 shows the comparison chart between previous algorithms with the proposed one.

TABLE1: Comparison of Algorithms

algorithm	Accuracy before preprocessing	Accuracy after preprocessing
Gaussian naïve bayes	88.08%	92.9%
Decision tree	90.12%	93.85%
Random forest	95.28%	97.64

Figure 2 shows the bar graph below demonstrates that the Random Forest classifier performs better than the other two classifiers and is thus the most appropriate for our dataset: -

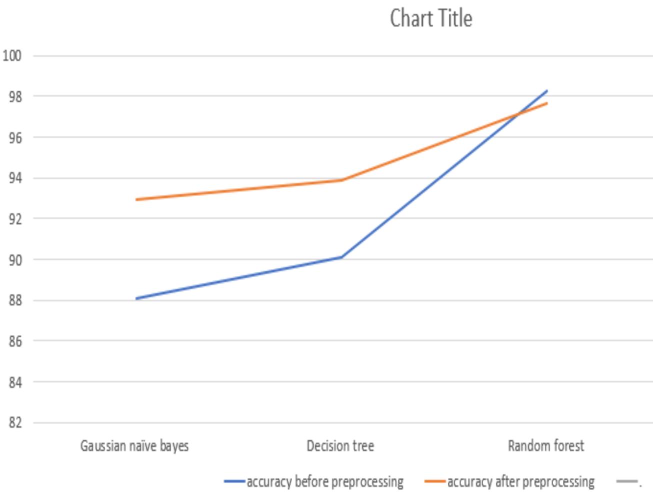

Fig. 2: Comparison graph

VIII. Conclusion

Future research will greatly benefit from the development of ML algorithms to enhance sickness detection devices. After the training period, methods of learning should be improved more often to potentially achieve higher performance. Furthermore, to prevent overfitting and enhance the accuracy of the models used, records on different characteristics should be expanded. After time progresses this model, accuracy might vary with good data or methods.

B. *Learners Used in the Model:*

1) KNN:

It is a technique that may be applied to both classification and regression [5]. It is a simple solution that maintains all existing instances and categorizes new cases using a similarity metric. The technique uses a distance measure that is Manhattan distance or Euclidean distance to determine the "closeness" of the sample group and classify it accordingly.

```
from sklearn.neighbors import KNeighborsClassifier
knn = KNeighborsClassifier()

knn.fit(x_train,y_train)

predicted_values = knn.predict(x_test)

x = metrics.accuracy_score(y_test, predicted_values)
acc.append(x)
model.append('K Nearest Neighbours')
```

2) SVM Algorithm

There are several machine learning algorithms that can be used to classify structured and unstructured data [6]. Classification is assigning objects to certain groups, and the major goal of classification problems is to determine which group or class new data belongs to. One widely used supervised ML model for regression and classification is the Support Vector Machine, although it is mainly used for classification tasks. SVMs separate training data points into groups with the smallest possible margin. To enable nonlinear classification, the kernel trick is a technique used by SVMs that implicitly translates inputs into high-dimensional feature spaces. Overall, the SVM is a powerful tool for solving classification problems, particularly in scenarios where the relationship between input features and output classes is nonlinear. Its ability to perform well on both unstructured and structured data has made it a popular choice in the field of machine learning.

In our model, we used SVM as follows:

(I) importing the SVC module from the sklearn.svmClass;

(II) creating an SVM classification object.

(III) Finally, we fitted our data.

```
from sklearn.svm import SVC
# data normalization with sklearn
from sklearn.preprocessing import MinMaxScaler
# fit scaler on training data
norm = MinMaxScaler().fit(x_train)
x_train_norm = norm.transform(x_train)
# transform testing dataabs
x_test_norm = norm.transform(x_test)
SVM = SVC(kernel='poly', degree=3, C=1)
SVM.fit(x_train_norm,y_train)
predicted_values = SVM.predict(x_test_norm)
x = metrics.accuracy_score(y_test, predicted_values)
acc.append(x)
model.append('SVM')
```

3) LogisticRegression:

It is a statistical model that's commonly used to analyzerelationshipsbetweenabinarydependentvariableandoneormoreindependentvariables,whichisalsoknownastheLogit model [7]. The model employs a logistic function to estimatethe probability of a certain outcome or event, based on thevalues of the independent variables. In its most basic form,the model is used to model a binary dependent variable.However, there are more sophisticated versions of the modelthatcanhandlemorethantwocategoriesornon-linearrelationships.

Logistic Regression is widely used in various fields, such asfinance,epidemiology,socialsciences,andmarketing,toanalyzeandpredictoutcomesbasedoncertainvariables. Itisalso commonly used in machine learning, where it is used asaclassificationalgorithmtopredicttheprobabilityofacertain class.

Inour model,weusedLogisticRegressionasfollows:

(I) ImportingLogisticRegressionmodulefromsklearn.linearClass.

(II) CreatingLogistic Regression object.

(III) Finally,wesuitourfacts.

```
from sklearn.linear_model import LogisticRegression

LogReg = LogisticRegression(random_state=2)

LogReg.fit(x_train,y_train)

predicted_values = LogReg.predict(x_test)

x = metrics.accuracy_score(y_test, predicted_values)
acc.append(x)
model.append('Logistic Regression')
```

4) RandomForest:

DOI: rp-9788770040723.155

It'sanensemblelearningmethodthatcanbeusedforarangeofproblems,includingregressionandclassification.Theapproach involves creating numerous decision trees duringtraining, and the mode or mean prediction of the individualtrees is used as the final prediction to prevent overfitting tothe training set. Tin Kam Ho pioneered the notion of randomforestsbyusingEugeneKleinberg's"stochasticdiscrimination"techniquetoclassificationviatherandomsubspacemethod.Later, AdeleCutlerandLeoBreimandesigned the "Random Forests" algorithm, which combinesBreiman's "bagging" approach with random feature selectionto generate a set of decision trees with controlled variance.Whilerandomforestswereinitiallydesignedforthree-dimensional data, recent studies have shown that they canalso be usedfor arbitraryobjects byleveragingpairwisesimilaritiesbetweenitems.Overall,aRandomForestconsistsofdecisiontreesthatprovideaclassificationfortheattributesofanewobject,andtheforest'sfinal prediction isbasedonamajorityvotefromthe trees.

Inourmodel,weusedRandomForestasfollows:

(I) ImportingRandomForest modulefromsklearn.ensembleClass.

(II) CreatingRandomForestobject.

(III) Finally,wesuitourfacts.

```
from sklearn.ensemble import
RandomForestClassifier

RF = RandomForestClassifier(n_estimators=20,
random_state=0)
RF.fit(x_train,y_train)

predicted_values = RF.predict(x_test)

x = metrics.accuracy_score(y_test, predicted_values)
acc.append(x)
model.append('RF')
```

5) DecisionTree:

Itis awidely-usedsupervisedlearning technique[8]forclassification and regression tasks. Its objective is to create apredictive model by learning decision rules from a given setofdata(i.e.,trainingdata)thatcananticipatethetargetvariable's'classorvalue.TheDecisionTreecomprisesdecision nodes and branches, with the leaves signifying theend outcomes. The recursive process each node acts as a testfor a distinct attribute, and each branch that stems from thenode stands for one of the feasible reactions to that test. Thisprocessisiteratedrecursivelyforeachsubtreethatoriginates from the new nodes until the final Decision Tree model isformed.

Inourmodel,weused theDecisiontreemethodasfollows:

(I) Importing package DecisionTree Classifierfromsklearn.treeClass

(II) CreatingDecisionTreeClassifierobject.

(III) Finally,wefittedourdata.

```
from sklearn.tree import DecisionTreeClassifier
DT =
DecisionTreeClassifier(criterion="entropy",random_state=2,max_depth=5)

DT.fit(x_train,y_train)

predicted_values = DT.predict(x_test)
x = metrics.accuracy_score(y_test, predicted_values)
acc.append(x)
model.append('Decision Tree')
```

6) NaiveBayesClassifier:

TheNaiveBayesclassifierisapopularstatisticalclassificationtool.ItisbasedonBayes'theorem,whichstatesthat the probability of witnessing evidence or features givena hypothesis or class is proportional to the probability of thathypothesisorclass.Giventheclass,theNaiveBayesclassifier assumes that the characteristics are independent ofeach other and estimates the probability of each class bymultiplying the probabilities of each feature given that class.Becauseofthissimplifyingassumption,itiscomputationallyefficient, particularly for huge datasets. The Naive Bayesclassifierhasbeenusedeffectivelyinmanydisciplines,includingnaturallanguageprocessing,textclassification,andspam filtering. It may be applied to both binary and multi-classclassificationissues.

We used the Naive Bayes classifier in our model to predicttheclassofagivensamplebasedonitsattributes.Weutilisedthe classifier's probabilities to produce suggestions for cropkinds and fertilisers that are best suited to a specific soil andweathercircumstances.

Inourmodel,weusedNaiveBayesclassifier asfollows:

(I) ImportingNaive Bayesclassifier modulefromsklearn.naive_bayesClass.

(II) CreatingNaiveBayesclassifierobject.

(III) Finally,wesuitourfacts.

```
from sklearn.naive_bayes import GaussianNB
NaiveBayes = GaussianNB()

NaiveBayes.fit(x_train,y_train)

predicted_values = NaiveBayes.predict(x_test)
x = metrics.accuracy_score(y_test, predicted_values)
acc.append(x)
model.append('Naive Bayes')
```

***Abstract*—A everyday battery survival pattern with very long testing periods, no contact estimate programs, or other devices will be useful in modern businesses. This abstract focuses on employing a super learner technique to estimate the remaining useful lifespan (RUL) for NMC-LCO 18650 batteries. The super learning algorithm has become a type of ensemble machine learn- ing that combines several different basic models to increase the accuracy of predictions. In this research, a set of features from the batteries were extracted, which includes current, temperature, voltage, and battery cycle, and the RUL was calculated utilizing a super learner algorithm. The linear regression model, the random forest, and two deep learning models used as basis models for the super learner algorithm. Mean absolute error (MAE), which as well as root mean squared error were two metrics used to assess the efficacy of this super learner algorithm. (RMSE). The outcomes demonstrate that with regard to of prediction accuracy, the super learner strategy exceeds the separate base models. In order to improve battery performance and lower maintenance costs, it is essential to be able to predict the of the RUL for NMC-LCO 18650 batteries. The suggested method is capable of being utilized as an accurate and dependable way for doing this.**

I. Introduction

Batteries made of lithium-ion material, or Li-ion, are frequently used in commercial settings. To accomplish ideal operation and health management, it is important to forecast the health state of batteries. The greatest barrier to accurate battery health prediction is accuracy. In comparison to conventional NiMH or lead-acid batteries, lithium-ion (Li-ion) batteries offer a number of alluring advantages, including a higher energy density as well as nominal voltage, a lower self- discharge rate, and a longer lifespan. Li-ion batteries have thus been extensively used in numerous industrial devices. How- ever, a sudden battery failure can result in poor performance, operational problems, or even disastrous outcomes. Therefore, it is crucial to forecast the Li-ion batteries health in good time and with accuracy. In reality, Li-ion batteries' performance would progressively deteriorate over time as a result of ageingand effects from operating conditions. Two key markers for battery health conditions are the state-of-health (SOH) and remaining-useful-life (RUL). The overall useful capacity loss and resistance increase together make up the SOH, which stands for the battery ageing level. RUL stands for the duration from the current to the battery's end of useful life. Many different methods have been described in recent years for the Li-ion batteries SOH estimation as well as RUL prediction. The basis and requirement for the RUL forecast is a precise SOH estimation. Some of the most important variables for precise SOH along with RUL prediction is the health index [1].

Due to their appealing performance, LIBs (Lithium-ion batteries) are now the primary power source for EVs (Electric Vehicles) and are frequently used in the automotive, aircraft, and other industrial sectors. However, as batteries continue to be used and age, their health and performance will de- cline, which in some extreme instances could lead to safety accidents. Therefore, a precise RUL prediction is crucial for battery safety as well as for improved battery maintenance, ensuring that the battery functions at its best and extending its service life. Algorithms based on machine learning are used in data-driven methods to model the process of health degradation and forecast the RUL for a pack of batteries from understanding the historical database. For battery upkeep and secure operation of electric vehicles, it is crucial to accurately estimate the unused useful life (RUL) of lithium-ion batteries [2].

Storage of energy systems, electric vehicles, and transportable electronic devices are just a few of the many uses for lithium- ion batteries. In order to increase the battery's service life and guarantee the system's safe and dependable functioning, it is essential to accurately determine the batteries' state of health (RUL). The competitiveness of machine learning (ML) as well as deep learning (DL) methodologies for under- standing the behavior of complicated nonlinear systems has garnered growing attention. Battery RUL estimation has a lot of promise thanks to the growth of big information and cloud computing. The global energy system is altering to decreasecarbon emissions, address associated climate change, and deal with energy shortages. The use of fossil fuels is steadily declining as renewable energy sources such as wind, solar, and hydroelectric power develop quickly. The lithium-ion (li-ion) cells are used in many different applications, such as systems for storing energy, electric vehicles, and portable electronic devices, because of their high power and energy density, high energy efficiency, and comparatively extended cycle life. The secure and dependable operation of batteries, as well as their commercial viability, are crucial during long-term operation

DOI: rp-9788770040723.156

because they serve as a means of energy storage as well as the main supplier of energy for these devices [3]. The hybrid data-driven as well as model-based approach typically yields better RUL forecast outcomes. However, such integration is more difficult for online practical applications to implement because it takes more computational skill. To increase the precision as well as the dependability of the RUL prediction results, various data-driven approaches can also be integrated in addition to data-driven and model-based methods. It creates a battery's state of health, which aids in directing businesses. It's important to increase the Li-Ion battery-powered equipment's availability. It reducing the number of output hours lost to maintenance, minimizing maintenance costs, breakdowns, and downtime, and improving battery efficiency. Some of the most crucial factors right now for predicting component failure before it actually happens is the RUL [4].

Currently, lithium-ion batteries are used extensively. For systems for managing batteries (BMS) and logically scheduling the battery utilization, it is crucial to accurately predict the remaining useful life (RUL). There are issues like randomness and battery capacity regeneration brought on by parameter values and single-time prediction. The benefits of lithium-ion batteries, which include a high output voltage, a long cycle life, a high density of energy, and environmental friendliness, make them very popular today. Applications span a wide range of industries, including the military, aircraft, and electronics. The discharge capability of Li-ion batteries will progressively deteriorate over time. The three major causes are ageing of the separator, electrolyte changes, and material corrosion in the poles. These phenomena will cause a reduction in discharge capability, which will result in a deterioration of battery performance. For the system's batteries to operate safely and effectively, the battery control system is essential. To extend the service's life and ensure safety, BMS can effectively manage each unit and control the working state in a reasonable manner. Important components of the BMS include life prediction that is still helpful. The total amount of charge/discharge cycles a Li-ion battery can withstand before its performance or SOH deteriorates to a point in which it can no longer power the device is known as RUL [5].

The remaining chapters of the paper are as follows: chapter II is a description of the literature review; chapter III is a description of the proposed methodology; chapter IV is a description of the findings and discussion; and chapter V is a summary of our article on the system.

II. Literature Survey

Jiao, R et al., "Lithium-ion battery remaining usable life prediction using the conditional equations auto encoders-particle filter". In hopes of predicting the RUL of batteries, a novel PF architecture built around the conditional variation auto - encoder (CVAE) as well as a reweighting technique is put forth in this study. The standard prior distribution is first replaced with the CVAE algorithm, which is then integrated into in the PF architecture to lessen particle damage. In order to avoid losing particle variety, a reweighting approach is also used during particle resampling. Ultimately, the suggested CVAE-PF is used to forecast how the battery capacity would degrade, and the RUL can be calculated when the capacity reaches a predetermined failure threshold. Compared to some previous methods, the new technique is able to achieve greater prediction performance, according to the experimental data [6]. Xue, K et al., "A more effective generic hybrid prognostic approach based on PF-LSTM learning for RUL prediction". On the degradation modeling and RUL forecasting for lithium- ion batteries, the proposed in this work blended PF-LSTM prognostic strategy is shown and contrasted with some other adaptive learning as well as machine learning methods like the unscented classifier (UPF) as well as the radial basis function system (RBFN). The comparison results demonstrate that a hybrid PF-LSTM prognostic strategy with accurate equipment deterioration state characterization based on integrated hierarchical clustering analysis can achieve robust prediction performance. The more precise prognostic estimates in the density function of probability (PDF) of the prior or post distribution of storage capacity and RUL obtained by particles filtering can provide significant insights into the action guide for predictive maintenance [7].

Tang, T et al., "A hybrid strategy using a decomposition method and a neural network to anticipate the lithium-ion battery's remaining usable life". A unique remaining usable life prediction approach was proposed in order to address the issues of non-linearity, non-stationary, and low forecast precision of the initial capacity degradation information for lithium-ion batteries. To prevent the useful knowledge about the capability regeneration section from being lost, comprehensive ensemble empirical mode of decomposition adaptable noise is used to produce full adaptive deconstruction of the original data. Next, zero-crossing rate and novel fusion rules are utilized to create fused high- and low-frequency sections, which can reduce the total amount of incoming network components and operational expenses. The best outcomes, chosen using the least absolute error standard, contain the benefits of 2 high frequencies fusion rules [8]. Zhang, C et al., "A method for predicting future RUL and capacity for lithium- ion battery packs". In this study, an innovative hybrid approach that combines enhanced vibrational modal decomposed (VMD), particle filter (PF), and Gaussian mixture regression is proposed for predicting battery up with the intention and RUL (GPR). The collected battery capacity data is divided by the VMD algorithm into a number of residual sequencesand an ageing trend sequence, with the amount of modal layers being determined by the suggested probabilistic feedback confidence (PFC) approach. The ageing trend series and residual sequences are then, respectively, predicted using the predictive model of the PF and GPR algorithms. To confirm the viability of the suggested hybrid technique, future capacity as well as RUL prediction research for battery packs and rechargeable batteries is carried out. The contrasted experiment results show that the suggested approach works [9]. Sulzer, V et al., "The difficulty and potential of predicting battery longevity from field data." The commercial case for evs, permanent energy storage, and emerging applications like electric aero planes all depend on accurate battery life prediction. End-

DOI: rp-9788770040723.156

use applications' uncontrolled working environments, less accurate sensors, issues with data collecting and storage, and frequent accessibility to validation tests provide additional obstacles as a result. We investigate various techniques to estimate lifetime from field and laboratory data and propose that fusing machine learning methods with mathematical model is a promising approach, allowing implication of battery capacity from noisy data, evaluation of second scenario, and generalization to future usage scenarios. This study emphasizes the potential for field data insights to lower battery prices and enhance designs [10].

III. PROPOSED METHODOLOGY

The proposed technique gives details on how our system will be implemented. To locate and retrieve the necessary battery data, including target and predictor values, for working with. The gathered data must be pre-processed in accordance with the specifications. In this stage, the necessary dataset is gathered from the accessible resources and saved in CSV format. The processing dataset is split into sets for training and testing of data, and different algorithms for machine learning as well as deep learning models are developed. These models are only taken into consideration if they have a high accuracy rate. To create the four basis models that the Super-learner Algorithm needs, which include 2 different machine learning models as well as two deep learning models. To determine the best model depending on the degree of accuracy of the various models we created and examined. The super learner technique strategies are used to recommend the model having better performance based accuracy basis after the best accuracy of the many models built is manually examined.

*Explanation:*Data collection, data pre-processing, building ML models, building DL models, classification, and prediction are the five modules that we employ here for our system.

*Datasets Collection:*The practice of obtaining and analyzing information from a wide variety of sources is known as data collection. Data must be gathered and kept in a manner that makes sense for the specific business problem at hand if we are to use it to create useful artificial intelligence (AI) but also deep learning solutions. 14 NMC-LCO 18650 batteries with a nominal power of 2.8 Ah were investigated by the Hawaiian Natural Energy Institute after being cycled morethan 1000 times at 25°C. Eight features that were captured during battery cycling experiments are included in the dataset.

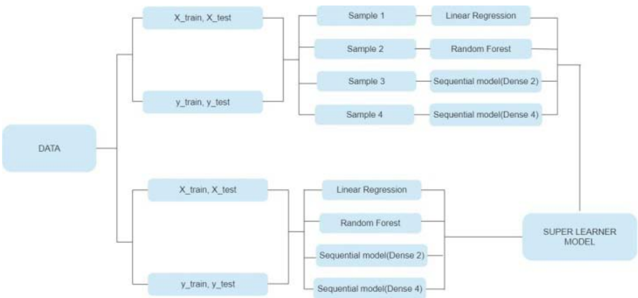

Fig. 1. Shown the Block Diagram of Project

SNO	NAME	DESCRIPTION
1.	**Cycle Index**	The battery's total number of charging and discharging processes.
2.	**Discharge Time**	Length of time it takes to discharge from completely charged through fully discharged.
3.	**Time at 4.15V**	The period of the charging cycle during which the battery is at 4.15 volts.
4.	**Time Constant Current**	When a steady current is used to charge the battery.
5.	**Decrement 3.6-3.4V**	Duration of battery drain from 3.6V towards 3.4V.
6.	**Max. Voltage Discharge**	The highest voltage that was recorded throughout the discharge cycle.
7.	**Min. Voltage Charge**	The lowest voltage that was recorded throughout the charge cycle.
8.	**Charging Time**	Represents the length of time that the charging process lasted.

Fig. 2. Input data features

*Data Pre-Processing:*All of the data should be converted into observable data before being preprocessed. We remove some erroneous and noisy data from the initial batch of data by performing this preprocessing. This will decrease memory usage and produce effective outcomes. Here, the many methods we employ include removing the superfluous features, retrieving the best features by working backward, \and standardizing the values.

*Model Implementation:*Here, we use Random Forest and Linear Regression to build two machine learning models. Sequential models with 2 dense layers and Sequential models with 4 dense layers are additionally available to the Building DL models.

Classification and Prediction Model: In this lesson, we will look at how to classify datasets in order to forecast battery lifetimes with high accuracy. Lastly, the prediction optimization is done on the system's accuracy rating. Lastly, assessing the accuracy of the prediction model and identifying the framework with higher accuracy.

IV. RESULTS AND DISCUSSION

We talked about our system's output images in the outcomes and discussion section.

V. Conclusion

The estimation of the state of a lithium-ion battery and the management of its health depend greatly on the RUL (Remaining Useful Life) prognosis. The advancements in the fields of AI as well as deep learning offer brand-new, promising techniques for predicting lithium-ion battery RUL. Through this model, we intend to contribute to the informational content that is available on lithium battery lifetime estimation techniques. By analyzing the accuracy metrics of all the algorithms employed in this project, the project offers the improved model performance that would estimate battery life with high accuracy.

I. INTRODUCTION

On a global level, air pollution poses a serious hazard tohumanhealththatisgrowinginimportance.TheWorldHealth Organization (WHO) 2018 report states that 92% of peopleworldwidebreathetoxicair,whichisthoughttobethecauseof7 million annual fatalities. Two respiratory and cardiovasculardisorders,emphysemaandasthma,areamongthe harmfulimpacts of pollution in the air on human health. In addition,ambientairpollutionhas1.8yearsofftheaveragelifetime.

[9] The World Bank estimates that the economic costs of airpollution, including lost productivity, medical costs, and earlydeaths,total$5trillionannually.By2050,itisanticipatedthat the number of premature deaths brought on by particulatematter(PM)willhavemorethantripled.Thus,itisessentialto identify a precise and practical method to lower ambient airpollution if we are to guarantee the security and well-being oftheglobalpopulace.

Wecannotseepollutants,andwearenotawareofthereasons whypollutionlevelsarerising.Tocomprehendtheorigins,itisnecessaryto firstgooverttheprinciplesofairpollution[3].PM2.5endangerstheenvironmentglobally.Long-termexposuretotheseparticles,whichcanquicklyreachdeepwithintherespiratoryorgans,canresultinavarietyofdiseases.ThediameterofPM2.5,whichismuchsmallerthanthediameterofahumanhair,is2.5microns.Asaresult,thereis asignificant sourceof exposureand sicknessonthe humanbody.Theyendangerhumanhealth,raisingthelikelihood ofcancerandotherendemicandpandemicdiseases.Theultimate goalistoraisepublicawarenessofthevariablesthataffectenergyconsumptionandmethodsforcontrollingit.[8]

InthispaperwepresentahybridRNNmodelthatcombinesthedecompositiontechniquewithlongshort-termmemoryfor temporal air quality forecasting (LSTM). While the de-compositiontechniquesareusedtobreakdownthetimeseries into wave transforms, which aid in identifying trends,cyclic patterns, etc., the LSTM cells are renowned for theircapacity to capture long-term dependencies in the data. Theproposed model also incorporates input features, which havebeen demonstrated to be significant predictors of air quality,suchasmeteorologicalvariablesandtimeofday.

Globally,airpollutionisakeyfactorinprematuremortality.It's crucial to understand and anticipate air pollution patternsto lessen its caused damage. Complex prediction algorithmsareneededforthis.InordertounderstandPM2.5patternsthroughout space and time, deep learning models like GCNNand ConvLSTM are used. Remote sensing satellite photos areutilised to monitor atmospheric pollutant issues while time-series multidimensional directed graphs are employed to char-acterise climate aspects. ConvLSTM is used to foresee PM2.5in Los Angeles region using data from the preceding 10 daysandground-basedPM2.5sensordata.Thespatiotemporaldeeppredictive algorithms outperform earlier studies significantly.[5]

Intheproposedstudy,ahybridapproachisintroducedfor effectively breaking down single, one-dimensional PM2.5time data into various dimensional time data and extractinghiddeninformationfromit.Eachsequenceispredicted bythealgorithmusingtraditionalpredictiontechniques,andthe finalpredictionsareobtainedbyreconstructingtheresults.Three hybridmodelsW-ANN,W-ARIMA,andW-SVMweredevelopedinthestudytoforesee2016PM2.5trendsinfiveChinesecities.Accordingtotheoutputs,combinedmodelsperformbetterthantraditionalARIMA,ANN,andSVMmodelsatforecastingshort-termPM2.5concentrations.WhenitcomestoforecastingPM2.5 concentrations,theW-ARIMAmodelperformsbetter,especiallywhenitcomestocapturingthemutationalpointsthatcouldhelpcreatepollutionwarnings.[1]

A new model for predicting PM2.5 concentrations for eachhour during heavy haze episodes is presented in the proposedwork. For increased forecasting accuracy, this model com-bines the mode decomposition-recombination method with anensemble learning strategy. The data is divided into severalfrequency modes using the FEEMD to lessen the effects ofnoise in the data. Then, to ensure precise extraction of information and computational efficiency, related modes are combined and excessive breakdown is avoided using the sampleentropy (SE). As a forecasting model,SDEM is built which isstack driven to improve feature representation and informationconsumptioncapabilities.Eachbasemodel'sgeneralisationperformance is enhanced via K-fold cross-validation, and themeta-model generates higher prediction results by using eachbasemodel'soutputsasnewinputs.Regardingpredictingprecision, stability, and class prediction rate , the FEEMD-SE-SDEM model performs better than earlier contrast models,making it a suitable choice for an early air quality warningsystem.[7]

***Abstract*—Damage detection in automotive components is critical for ensuring passenger safety and preventing further vehicledeterioration. This paper proposes a CNN-based approach usingDetectron 2, a state-of-the-art object detection library, for accu-ratedamagedetectioninvehicleparts.Theproposedapproachis evaluated on the Microsoft COCO car damage dataset, whichcontains a large number of automotive images with various typesofdamages.**

The results show that the proposed approach achieves highaccuracy in damage detection. The use of CNN-based approachesfor damage detection in automotive components can have a significant impact on insurance claims by providing more objectiveandreliableresultsthantraditionalvisualinspection.

***IndexTerms*—FasterR-CNN,MaskR-CNN,YOLO(YouOnlyLook Once), SSD (Single Shot Detector), R-FCN (Region-basedFully Convolutional Networks), RetinaNet, MobileNet, Inception,ResNet.**

I. Introduction

Theautomotiveindustryisconstantlyevolving,andsafetyis a top priority for manufacturers and consumers alike. Onecritical aspect of ensuring safety is the detection and repair ofdamages in vehicle parts. Damage to automotive componentscan result from various factors, such as wear and tear, accidents, or environmental factors. Prompt and accurate detectionofthesedamagesisessentialtopreventfurtherdeteriorationofthevehicleandensurepassengersafety.

Inrecentyears,ConvolutionalNeuralNetworks(CNNs)haveshowngreatpotentialinidentifyingandlocalizingdefectsin various types of images, including automotive images. Theability of CNNs to automatically learn and extract relevantfeatures from images has led to their widespread adoption inobject detection tasks, including damage detection in automotivecomponents.

Inthispaper,weproposeanadvancedCNN-basedapproachusingDetectron2,astate-of-the-artobjectdetectionlibrary,toaccuratelydetectandclassifydamagesinvehicleparts.WeleveragethestrengthsofCNNs,including theirabilityto learn complex features from images, to develop a reliableand efficient solution for damage detection in the automotiveindustry. We evaluate our proposed approach on the MicrosoftCOCO car damage dataset, which contains a large number ofautomotive images with various types of damages, includingscratches,dents,andcracks.

Accurate damage detection in automotive components canhaveasignificantimpactoninsuranceclaims.Insurancecompanies often rely on visual inspection to assess the extentofdamageinavehicle,whichcanbesubjectiveandproneto human error. Automated damage detection using advancedCNNalgorithmscanprovidemoreobjectiveandreliableresults,leadingtomoreaccurateandfairinsuranceclaims.

Several CNN algorithms have been proposed for damagedetectioninautomotivecomponents.Thesealgorithmsi ncludeFaster R-CNN, YOLO, RetinaNet, and SSD. Faster R-CNNand YOLO have been used extensively in object detectiontasks, including damage detection in automotive images. RetinaNet is a more recent approach that uses a novel focal lossfunction to address the imbalance between foreground andbackgroundobjectsinobjectdetection.SSDisanotherpopularapproach that uses a single shot to detect objects in an image.Existing systems for damage detection in automotive components include both commercial and academic systems. Examples of commercial systems include AI Vision, HailStrike,and CarVi. These systems use various image processing andcomputervisiontechniques,includingCNNalgorithms,toidentifyandlocalizedamagesinautomotivecomponents.Academic systems include DeepDamage, which uses a multi-task learning approach to detect and classify damages in carimages, and DamageNet, which uses a deep CNN to predicttheextentandtypeofdamagesincarimages.

II. Literature Survey

S. Ren, K. He, R. Girshick and J. Sun, ”Faster R-CNN:Towards Real-Time Object Detection with Region ProposalNetworks,” Real world images are sometimes noisy, blurred,rotated or jittered. Detecting these images is an important partof object detection the paper proposes an image degradationmodelthatusesimagesthataredegradedforthetestset.The degraded images were run on a standard model, whichwastrainedonregularimages.Thesourcenetworkwasthenmodified by training the model with the degraded images,which were obtained by performing some

DOI: rp-9788770040723.158

degradation processes on them. The accuracy of the test set is calculated onboth the models and are compared. Then the training set ismodified again by performing further complex degradationprocessesandamoregeneralizedmodelfordetectio nisobtained from this. This was also compared with the standardtest performance. The final object detection model obtainedthusisoptimizedandthegeneralizationabilityhadbeen enhanced,whiletheaccuracyimproved.[1].

Redmonetal.proposed"YouOnlyLookOnce:Unified,Rea l-Time Object Detection" [2], which introduced an end-to-endCNN architecture for object detection that processes the entireimage at once and outputs the class probabilities and boundingboxes for all objects in the image. The algorithm is faster thanpreviousmethodsthatrequireregionproposals,asiteliminat esthe need for a separate region proposal step. The proposedalgorithm achieved state-of-the-art results on several objectdetectionbenchmarks.[2].

He et al. proposed "Mask R-CNN" [3], which extended theFasterR-CNNalgorithmbyaddingaparallelbranchthatpredicts object masks in addition to class labels and boundingboxes.Themaskbranchisafullyconvolutionalnetwor kthat generates a mask for each object instance. The proposedalgorithm achieved state-of-the-art results on several instancesegmentation benchmarks. [3]. Liu et al. proposed "EfficientObject Detection in Large Images Using Deep ReinforcementLearning" [4], which proposed a CNN-based algorithm thatlearnstoselectivelyattendtoregionsofanimagetoim-prove object detection performance. The algorithm is trainedusing a reinforcement learning approach that maximizes thedetection performance while minimizing computational cost.The proposed algorithm achieved state-of-the-art results onseveral large-scale object detection benchmarks. [4]. Wang etal. proposed "Multi-Task Deep Learning for Real-Time 3D-LandmarkDetectioninCTScans"[5],whichproposedaCNN-based algorithm for detecting anatomical landmarks in3D medical images. The algorithm uses a multi-task learningapproachthatsimultaneouslytrainsthenetworktodetec tmultiple landmarks. The proposed algorithm achieved state-of-the-art results on several landmark detection benchmarksandcanruninreal-time.[5].

III. Proposed Methodology

Theproposedmethodologyaimstodetectdamagesinvariou s car parts using CNN algorithms and Detectron2. Theapproach involves several steps, including data collection andpreprocessing, training of the base model, fine-tuning withDetectron2, evaluation of the model, and detection of damagesindifferentcarparts.Firstly,theMicrosoftCOCOCarD amageDatasetiscollectedandpreprocessedtocreateatrainingda taset.Next,abasemodelwithFasterR-CNNalgorithmand ResNet-50 backbone is trained on this dataset. The modelisthenfine-tunedusingDetectron2,whichemploysMaskR-CNNalgorithmandalearningratescheduler.Themodelisevalua tedusingmetricssuchasmeanAveragePrecision(mAP), precision, and recall. Finally, damages in different carparts are detected by identifying Regions of Interest (ROIs) inthe image. The proposed methodology is compared with otherstate-of-the-artalgorithmssuchasYOLO,SSD,andRetinaNetto assess its performance. Overall, the proposed methodologyprovides a robust and efficient approach for damage detectionin car parts, which has significant implications in the auto-motive industry, especially in insurance claims processing andmaintenanceofvehiclesafety.

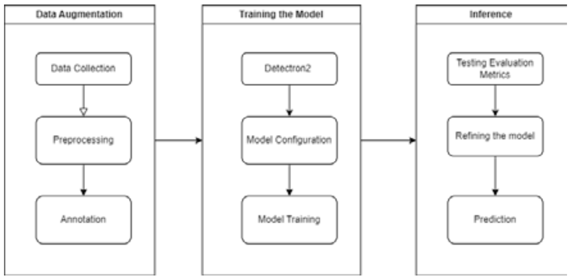

Fig.1.ShowntheBlockDiagramofProject

*Explanation:*Data collection, data pre-processing, buildingMLmodels,buildingDLmodels,classification,andpre dictionarethefivemodulesthatweemployhereforoursystem.

*Data Collection and Preprocessing:*Collect the MicrosoftCOCO Car Damage Dataset and preprocess it by resizing theimages,augmentingthedata,andnormalizingthepixelvalues .

*TrainingoftheBaseModel:*Fine-tunethepretrainedbase model on the COCO dataset using the Faster R-CNNalgorithm with a ResNet-50 backbone. The loss function usedis the Region Proposal Network (RPN) and the Fast R-CNNloss.

*Fine-tuningwithDetectron2:*Fine-tune the base modelfurtherusingtheDetectron2librarytotrainthemodelonthe car damage dataset. This step involves using the MaskR-CNN algorithm and training the model with a learning ratescheduler.

*EvaluationoftheModel:*Evaluatethemodel'sperformance usingvariousmetricssuchasmeanaverageprecision(mAP),pre cision,andrecall.

DetectionofDamagesinDifferentCarParts:

Utilize the trained model to detect damages in different carpartssuchashood,windshield,bumper,etc.byidentifyingthe relevantregionsofinterest(ROIs)intheimage.

ComparisonwithOtherAlgorithms:

Comparetheperformanceoftheproposedmethodologywit hotherstate-of-the-artalgorithmssuchasYOLO,SSD,andResNet,YOLOandmore.

To summarize, this proposed methodology involves the useof Detectron2 and PyTorch for detecting damages in variouscarparts.Themethodologyinvolvesdatacollectionandp reprocessing, training of the base model, fine-tuning withDetectron2, evaluation of the model, detection of

DOI: rp-9788770040723.158

damages indifferentcarparts,andcomparisonwithotheralgorithms.

*DataPre-Processing:*Inthisstudy,adatasetofcarimageswithannotations ofcardamagewascollectedandpreprocessedfortrainingadamagedetectionmodel.Thedataset was split into training and validation sets, with thetrainingsetconsistingof70percentofthedataandthevalidationsetconsistingoftheremaining30percent.Theimageswereresizedtoafixedsizeof800x800pixelsandtheannotationswereconvertedtotheCOCOformatforcompatibilitywiththedetectron2framework.

*DataAugmentation:*Toimprove the generalizationandrobustnessofthemodel,severaldataaugmentationtechniqueswereappliedduringtraining.Theseincludedrandomhorizontalflipping,randomrotation,randomcropping,andrandomresizing.Inaddition,randomcolorjitterandbrightness/contrastadjustmentswereappliedtotheimages.Theseaugmentationshelpthemodellearntobetter recognize damage under varying conditions and reduceoverfittingtothetrainingdata.

*ModelImplementation:*Themodelwastrainedusingthedetectron2framework,whichisapopularopen-sourceframeworkforobjectdetectionandinstancesegmentation tasks. The architecture used in this study was the RetinaNetmodel, which is a single-stage object detection model that hasbeen shown to achieve high accuracy on a variety of objectdetectiontasks.ThemodelwastrainedusingtheCOCOdataset pre-trained weights and fine-tuned on the car damagedataset.

During training, the model was optimized using stochasticgradientdescentwithmomentumandabaselearningrateof0.001.Thelearningratewasadjustedusingasteplearningrate schedule, where the learning rate was reduced by a factorof0.1afterafixednumberofiterations.Themodelwastrainedforatotalof800iterationswithabatchsizeof4.

*Evaluation Metrics :*To evaluate the performance of themodel, the average precision (AP) score was used. The APscoreisacommonlyusedmetricforobjectdetectiontasksandisbasedontheprecision-recallcurve.TheAPscoremeasures the accuracy of the model in detecting objects ofinterest (in this case, car damage) and has a value between 0and1,withhighervaluesindicatingbetterperformance.

V. Conclusion

In this project, we have presented a deep learning-basedapproach for detecting damages in cars using the RetinaNetalgorithm implemented with the Detectron2 framework. ThemodelachievedahighAPscoreof0.87,indicatingitsabilityto accuratelydetectdamagesincarimages.

Ourapproachhasdemonstratedtheeffectivenessofdeeplea rning-based methods for car damage detection. This couldhave significant applications in the automotive industry forautomating the process of car inspection and reducing manuallabor. In future work, we plan to explore the use of transferlearning techniques and larger datasets to further improve theperformanceofthemodel.

***Abstract*—E-commerce, also known as electronic commerce or internet commerce, refers to the exchange of moneyanddataforconductingbusinessonline.Althoughitcanrefer toany type of business transaction facilitated by the internet, the term commonly describes the online selling of physical goods. In contrast, e-business encompasses a wider range of activities, including online marketing, customer service, and payment processing. Product suggestion is a filtering system used in e- commerce to predict and offer the items that a user may be interested in purchasing. Even if it isn't fully accurate, if it reveals what you want to see, it has succeeded in its purpose. Nowadays, with the abundance of data available, businesses like Amazon use their massive data sets to recommend products to customers. Systems can estimate the rating of new things based on similarities between items. In order to forecast how other users would feel about a specific item, recommender systems employ user, item, and rating information. The need to have a thorough grasp of recommender systems serves as the driving force behind this effort. In this research, a model has been created that employs a variety of recommendation techniques, including association mining with the Apriori algorithm and frequent itemset.**

I. Introduction

A system for recommending products is designed to come up with suggestions for products or information that a par- ticular user might like to use or purchase. Using machine learning algorithms and a large amount of data on both particular products and unique customers, the system creates a complex network of complicated linkages between those things and individuals. A product recommendation system is a software application designed to generate personalized recommendations for products or information that a user may be interested in purchasing or interacting with. This system creates a complex network of connections between products and users using machine learning algorithms and extensive data on individual consumers and specific products. By analyzing patterns in consumer behavior and preferences, the system can offer tailored suggestions to users, improving their overall shopping experience and increasing the likelihood of sales.

II. Ease Of Use

A. Motivation

Beforee-commerce,thingswereonlysoldinphysicalstores.Storeinventorywaslimitedtothephysicalspaceofthestore,andslow-sellingitemswereunprofitable.Fixedinventory motivated retailers to sell only the most popularmainstreamproducts.Inthemid-1990s,theintroductionofon-linemarketplacesrevolutionizedretailing.Unlimitedinventoryis now possible in this new type of digital marketplace. Thismeant that merchants could expand their product offerings toinclude niche items rather than mainstream items. The massmarket is evolving into a mass of niches, as Chris Andersonwrites in The Long Tail. Niche products can outperform bestsellers by overcoming inventory constraints. As a result, e-commerce businesses are more interested than ever in specialisedproducts.

III. Existing System

Existing projects have proposed approaches to use the userratings to improve the performance of recommender systems.TheAmazonproductdataset,whichcomprisesofproductratings and reviews, is the subject of experiments. Comparingthetraditionalrating-basedandtheproposedrecommendersystem, we can see that the call score and root mean squared(RMSE)scoreoftherecommendersystemisdecreased.

IV. Proposed Methodology

The performance of recommender systems can be enhancedbyusingtheuserratings,accordingtoexistinginitiatives.The Experiments focus on the Amazon product dataset, whichincludes product ratings and reviews. The call score and rootmean squared (RMSE) score of the suggested recommendersystem are lower when compared to the conventional rating-basedsystem.

A. AssociationMining

Associationruleminingisapowerfulmethodusedtodiscoverpatterns,correlations,andassociationsthatfrequentlyoccur in a wide range of databases, including relational andtransactional databases. The process of developing associationrules involves analyzing data and identifying recurring if/thenpatterns.Thestrengthoftheassociationsisdeterminedbytwokeyparameters:support,whichindicatesthefrequencyofthe if/then relationship in the database, and confidence, whichreflects how often these associations have been proven to betrue. Association rule mining is applied to diverse data sets toidentifycommonpatterns,correlations,relationships,orcausalstructures.

B. AprioriAlgorithm

It is a technique used to uncover the relationships betweendifferent items. For example, in a supermarket, customers maypurchase a variety of products and there is

DOI: rp-9788770040723.159

often a pattern totheir purchases. For instance, mothers with young childrentend to buy items such as milk and diapers, while bachelorsmaybuybeerandchips,andwomenoftenbuycosmetics.By identifying the connections between items purchased indifferenttransactions,businessescanincreasetheirprofits.

Clustering

Cluster analysis or clustering is a machine learning technique that groups an unlabeled dataset into multiple clusters,where each cluster contains data points that share similarities.This technique identifies common patterns in the dataset, suchas shape, size, color, behavior, etc., and categorizes the databased on the presence or absence of these patterns. By doingso, items with potential resemblances are grouped together,whiledatapointswithlittleornosimilaritytoeachothere re placed into different clusters. Clustering is an effectivemethod for discovering structure in large datasets and can beused in various applications such as customer segmentation,imagesegmentation,andanomalydetection.

C. *TypesofClusteringMethods*

There are two main types of clustering techniques in ma-chinelearning:HardClustering,whereeachdatapointbelongsto a single group, and Soft Clustering, where data points canbelongtomultiplegroups.However,thereareseveraldifferentclustering techniques available, including: 1) Clustering andPartitioning, 2) Density-based Clustering, 3) Clustering basedonaDistributionModel,4)HierarchicalClusterAnalysis,and5)FuzzyClusterAnalysis.Thesetechniquesareusedinunsupervisedlearning,wherethealgorithmworkswithan unlabeled dataset and does not receive any supervision.Each method has its own strengths and weaknesses, and theselection of the clustering technique depends on the specificcharacteristicsofthedataandtheobjectivesoftheanalysis.

V. LITERATURE STUDY

[1] TITLE: Product Recommendation Based on Content-based Filtering Using XGBoost Classifier AUTHORS: ZeinabShahbazi, Yung-CheolByun - 2019 DESCRIPTION: [1] Akeycomponentofthemachinelearningprocessistheusageof recommendation systems to provide the user with relatedideasbasedontheirrequests.Whenadoptingthecontent-basedfiltering(CBF)techniquetopromoteanitemtoitsusers, many online shopping websites that have appropriateratinginformationhavedifficulties.Usersarenotsatisfiedwiththesearchresultswhentransitorypurchasepatternsfromsequentialpatternanalysis(SPA)areapplied.Thegoalofthis study is to recommend products using XGBoost-basedtechnology using records from the Jeju online shopping malldataset. We compare the result with the performance of otherresearch outputs based on the output of the XGBoost method.A superior rating than other individual ones is successfullydemonstrated by the proposed CBF recommendation and SPAresults.[2]TITLE:ContextualSentimentBasedRecommenderSystemtoProvideRecommendationintheElectronicProductsDomain AUTHORS: N. A. Osman, S. A. M. Noah, and M.Darwich-2019

DESCRIPTION: Sometimes people are in a rush to get thenewest products that they don't fully consider. As a result,recommender services are growing more popular. It is crucialto separate out the most pertinent information for consumerelectronics before buying their products by looking at markettrends, speaking with a large number of influential industrystakeholders,andusingpubliclyavailabledata.Inthisstudy,asentimentanalysis-basedelectronicproductrecommendationsystem is introduced. The majority of the time, recommenda-tion algorithms predict goods based on user ratings. By usinguser comments and preferences to generate recommendations,we provide a contextual information sentiment-based modelfor recommender systems. This method's goal is to preventterm ambiguity, a problem in recommendations known as the"domain sensitivity problem." Utilizing the results of RMSEandMAEmeasurements,thesuggestedcontextualinformationsentiment-based model compares favourably to the traditionalcollaborativefilteringstrategywhenitcomestoelectronicproductsuggestion.

[3] TITLE: A Hybrid Collaborative Filtering Model UsingCustomer Search Keyword Data for Product Recommenda-tion AUTHORS: Ha-Ram Won, Yunju Lee; Jae-Seung Shim,HyunchulAhn - 2019 DESCRIPTION: [3] A recommendersystemisatoolthatusesmachinelearningorstatisticalmethods to suggest goods or services based on the interests ofeach individual consumer. The most often used algorithm forcreating recommender systems is collaborative filtering (CF).Althoughtherearealotofclient-provideddataavailable,ithas typically just used purchase history or customer ratings.Customerswhoshoponlinetypicallyusethesearchfeaturetosiftthroughtheenormousselectionofproductsavailabletolocatetheonestheyareinterestedin.Suchinformationon search terms might be a goldmine for modelling customerpreferences.Yet,recommendationengineshardlyeveruseitasadatasource.Inthisstudy,weintroduceadistinctivehybrid Doc2Vec CF model using search phrases and purchasehistorydatafromcustomersofonlineshoppingmalls.Toverify the recommended model's applicability, we empiricallyexamined its performance using information from a genuineKoreanonlineshoppingmall.Asaresult,wefoundthatsearch phrase information may efficiently reflect consumerpreferences and help traditional CF advance. [4] TITLE: Sen-timent Analysis for Product Recommendation Using RandomForest AUTHORS: GayatriKhanvilkar, Prof. DeepaliVora - 2018DESCRIPTION:Thetechniqueoflookingatspokenlanguage and figuring out the emotions that people innatelytransmitisknownasanalysisoffeelings.Sentimentanalysisistodeterminethepolarityofanauthor'stextualviewpoint.Itisusefultousesentimentanalysistosuggestproducts.Based on the user's reviews, the products might be recom-mendedtoanotheruser.Topproductwebsitesutilisesentimentan

DOI: rp-9788770040723.159

alysistounderstandcustomersatisfactionandproblemswiththeproduct.Theprimarytypeofsentimentanalysisinvolvesdifficultiesofpositiveandnegativeclassification.Ordinalclassificationaidsintheclarificationofsentimentsin sentiment analysis. The proposed method classifies userreviews according to their polarity using ordinal classification.The system will employ SVM and Random Forest as twomachinelearningtechniquestoprovidepolarity.

[5]TITLE:RecommendationandSentimentAnalysisBasedonConsumerReviewandRatingAUTHORS:PinNi,YumingLi and Victor, Chang - 2020 DESCRIPTION: Making productsuggestions based on online reviews and rating data requiresprecise targeting of the appropriate customer segments. Salesoftheproductsmayriseasaresult.Inthisstudy,arec-ommendationandsentimentclassificationmodelisutilizedtoanalyzebeerproductdataandimprovetheperformanceof the recommendation model to cater to diverse consumerneeds. The model is developed based on online beer reviewsandratingsofbeerproducts.Thesentimentanalysisoftextis performed using ten categorization techniques, includingboth deep learning and conventional machine learning models.The beer recommendation is one of the techniques employed.Combiningthetwoevaluationscanincreasethecredibilityof the suggested beer and potentially boost beer sales. Thisapproach filters products in the market with more negativereviews in the recommendation algorithm and improves useracceptance,asdemonstratedintheexperiment.

VI. Results And Discussions

The packages used in this model are shown in Fig. 1.

```python
# for basic operations
import numpy as np
import pandas as pd

# for visualizations
import matplotlib.pyplot as plt
import squarify
import seaborn as sns

# for defining path
import os
import warnings

# for market basket analysis
from mlxtend.frequent_patterns import apriori
from mlxtend.frequent_patterns import association_rules
```

Fig. 1. List of all imported packages.

Random rows of Dataset are shown in Fig. 2.

```python
# checking the random entries in the data
data.sample(10)

Future Enhancement

From the implementation perspective, Thus the, 1. Implementation of the Association mining algorithm 2. Implementation of the apriori algorithm. 3. Identifying the relationshipbetween the different items. 4. Finding the correlation amongthe shopping products. 5. Finding the frequently bought itemsusing apriori algorithm. 6. Prepared a model to analyse theassociations and relations. 7. Predicted the product recommendations for the customer has been implemented. The futureenhancementistoboosttheaccuracywiththeseveralboostingtechniques.

Conclusion

In this way, we have successfully implemented a recommendation system. The set of frequent items that includes association rules and the apriori algorithm was found to be the best, as the accuracy in this case was higher compared to the other methods. Using an algorithm to create a web-based recommender system was one method for analysing massive datasets. This is comparable to the algorithm that Netflix employs to suggest movies to users of his website. It was difficult to implement a web-based recommendation system with this much data. There are numerous recommender systems. They are used by people to find companions for relationships as well as books, music, news, and smartphones. There are suggestions for almost every good, service, or piece of information to assist consumers in selecting the best option from a wide range of options. A thriving research commu- nity with innovative interaction ideas, potent new algorithms,and meticulous experiments is supporting these commercial applications.

***Abstract*—An artificial setting known as the metaverse *combines aspects of social media, online gaming, augmented reality (AR), virtual reality (VR), and cryptocurrency. The fusion of augmentedreality, mixed reality and virtual reality into our daily lives is referred to as the "metaverse"Nowadays, the term metaverse is widely used to represent a fast-evolving universe that has thepotential to drastically alter the manner in which we work, live and play. There is no singlevendorordevice-independentmetaverse.Avirtualcurrencythatoperatesindependentl yandissupported by digital money and non-fungible tokens (NFTs). Virtual reality serves as the Metaverse's primary support system. Users of Metaverse can communicate, network , and work together in 3D virtual reality. By participating in virtual conference sand performances, foot ball games, and other activities, users can engage in social interaction and play with one another in the digital world. Avatars can be customized, and their cultural, physical, andsocialtraitsdifferfrom those of reality. The avatar can interact with other creatures and accomplish tasks. Theirmost apparent use in healthcare is in the administration and protection of our immenselyimportant health data. Now, data is frequently exchanged between numerous organizations inways that are both wasteful and opaque to the data's owners. The proposed work is to designwearablegarments(Shirt/T-Shirt)to record health parameters and to beviewed in Metaverse*

***Keywords*—metaverse, health parameters, virtual reality**

I. Introduction

This project primarily focuses on patients in rural areas who find it challenging to travel overlong distances for their medical needs. The metaverse is a development in web 3 that allows individuals to socially interact with one another in spite of barriers like distance and area. Form any years, providing healthcare needed direct physical contact between a patient and a doctor in order to perform procedures like surgery, receive medical treatment, or make diagnoses.

Healthcare is only one of the many spheres of life where the metaverse is set to bring about adisruptive revolution. Given that it integrates augmented reality (AR) and virtual reality (VR)technology to operate in virtual settings, the Metaverse has incredible potential. Virtual healthhas changed how healthcare is delivered because it uses technology to overcome locationrestrictions. People's way of life have been profoundly changed by the ongoing coronavirusdisease2019,whichhasbeenassociatedwithseveres ocialrestrictionstodecreasetransmission. This has made the need of virtual health for improving access to healthcare andloweringtheexposureriskconnectedwithin-personconsultationsmoreapparentthanever. Toreduce physical encounters in ophthalmology, clinical workflows required to be reevaluated and digitalized

II. Proposed Work

A garment that utilizes sensors for the metaverse could have a number of potential uses. Onepossibilityisasmartsuitdesignedforuseinvirtualrealitygami ngorsocialenvironments.Thesuitcouldincorporatevarioussens orstoenhancetheuser'sexperienceandprovidefeedbacktothevirt ualenvironment.Forexample,thesuitcouldhavemotionsensorst hatdetectthewearer'smovements and translate them into corresponding actions in the virtual world. The suit couldalsoincludehapticfeedbacksensorsthat simulatetouchsensations,allowingthewearertofeelthevirtualen vironmentand interactwithitinamoreimmersiveway. Inadditiontothesebasicsensors, the garment could also incorporate more advanced sensors such as biometric sensorsthat track the wearer's heart rate, breathing rate, and other vital signs. These sensors could beused to provide feedback on the wearer's physical and emotional state, which could be used toenhancethe overallexperienceinthemetaverse.

Anotherpotentialuseforasensor-enabledgarmentinthemetaverseis forhealthcareorfitnessapplications. For example, a smart shirt could incorporate sensors that monitor the wearer'sposture, movement, and heart rate during exercise, providing real-time feedback and coachingto help the wearer optimize their workout. Ultimately, the possibilities for a sensor-enabledgarment in the metaverse are limited only by our imagination. With the rapid development ofvirtualrealityandotherimmersivetechnologies,thepotentiala pplicationsforsuchagarment are virtually endless.

Temperature Sensor

Themedicalparametersliketemperature,heartrate,andpuls erate,weemployagarmentembeddedwiththepropersensors,suc hastemperaturesensors andpulsesensors.Wediscoveredthe sensors for the garment—a heart rate sensor and a pulse sensor—to track the patient's pulseandheartrate.WeusedjumperwirestoattachsensorstotheA rduinoboard,uploadthenecessarycode, and get the sensors up and runningFollowing that, we took the operational sensors'readings. A temperature sensor is a device thatmeasures the temperature of an objectorenvironment and converts that temperature into an electrical signal that can be measured andanalyzed. There are various types of

DOI: rp-9788770040723.160

temperature sensors, but the most common type is athermocouple. A thermocouple is a type of sensor that consists of two distinct metals attached at oneend. Avoltagethat isproportionaltothetemperaturedifferentialbetweenthejoinedendandtheotherendofthetwometalsisproducedwhenthejoinedendofthetwometalsisheatedorcooled.Thevoltagegeneratedbythethermocouplecanbemeasuredandusedtocalculatethetemperature of the object being measured. The temperature is calculated using a formula that takes into account the properties of the two metals used in the thermocouple, as well as the voltage generated.

Regardless of the type of temperature sensor used, the principle is the same: the sensor detects a change in temperature and converts that change into an electrical signal that can be measured and used to determine the temperature of the object or environment being measured.

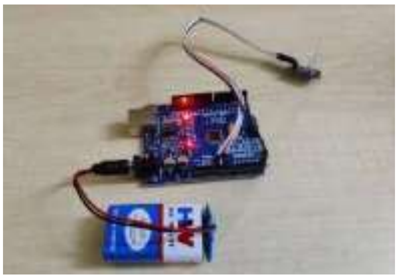

Fig 1. Temperature Sensor

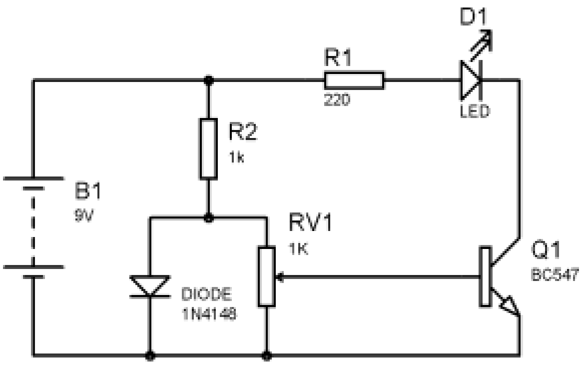

Fig. 2. Working of Temperature Sensor

Pulse sensor

Anopticalpulsesensorworksbyshiningalightontotheskinanddetectingthechangesinbloodvolume that occur as blood is pumped through the arteries. When the heart beats, there is an increase in blood volume in the arteries, which causes morelighttobeabsorbedbytheskin.Thesensordetectsthischangeinlightabsorptionandusesittodeterminetheheartrate.Anothertypeofpulse sensor is an electro cardiogram(ECG)sensor. Through electrodes affixed to the skin, an ECG monitor measures the electrical activity of the heart. As the heart beats, it produce selectrical signals that can bed etected by the ECG sensor and used to determine the heart rate.

These devices use the pulse sensor to continuously monitor the wearer's heart rate and providereal-time feedback on their level of activity and overall health. Some pulse sensors also includeadditional features such as sleep tracking and stress monitoring. Overall,

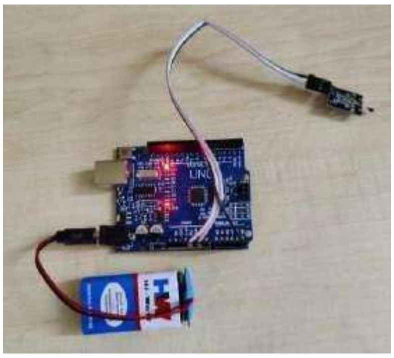

Fig 3 Pulse Sensor

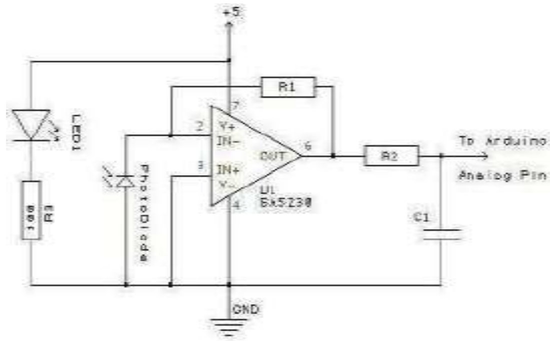

Fig 4 Working of a Pulse Sensor

Gyroscopic Sensor

A gyroscope is the gadget that detects and records direction and angular velocity. A gyroscope sensor measures an object's angular speed, tilt, or lateral orientation. There are multiple axes of gyroscope sensors available. These sensors are used in situations where the orientation of an item is difficult for humans to detect. With the incorporation of the Gyroscope sensor, more accurate measurements of orientation and movement in 3D space were feasible. A number of sensors in devices that are worn can aid in the recording of walking and running data; spatiotemporal and kinematic factors may then be computed in gait analysis. The gyroscopic sensor is one such sensor that we have included in our garment.

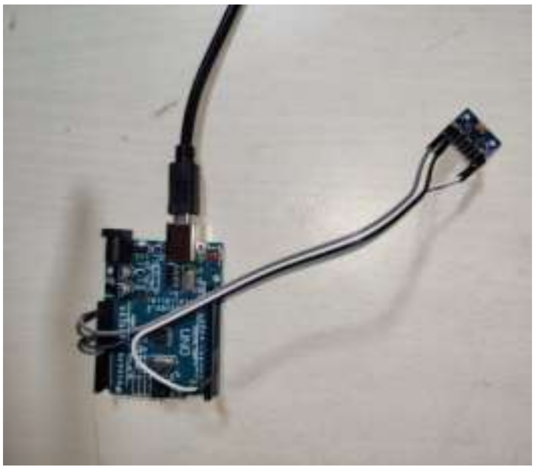

Fig 5. Gyroscopic sensor

2.4 Oximeter sensor

A pulse oximeter measures both the blood oxygen levels and your pulse rate. Low oxygen saturation may occur if you

DOI: rp-9788770040723.160

have certain medical conditions. The use of pulse oximetry is a noninvasive test that evaluates the level of saturation of oxygen in your blood. It is capable of detecting even little differences in levels of oxygen in actual time. These levels show how well your blood distributes oxygen to your extremities farthest away from the heart, such as your limbs and arms.

The hemoglobin in our blood is essential for effectively monitoring blood oxygen saturation. The amount of oxygen in hemoglobin influences our blood's ability to absorb red and infrared light rays. Optical SpO2 sensors monitor oxygen levels using red and infrared light sensors, detecting changes in those levels by observing the color of the blood. The sensor monitors the volume of oxygen in your blood depending on how light travels through your finger and sends the information to the device's screen, which displays the percentage of oxygen in your blood

The integration of the Internet of Things (IoT) into the metaverse could enable new and excitingopportunitiesforimmersiveexperiencesandinteractions.ByincorporatingIoTdevicesintovirtual environment.

A digital twin is a virtual representation of a physical object or system, and it has numerousapplications in healthcare. In healthcare, a digital twin can represent a patient's body or a specificmedical device or system. By creating a digital twin, healthcare providers can simulate variousscenariosandtestdifferenttreatmentswithoutputtingthe patientatrisk.

Oneapplicationofdigitaltwin technology in healthcare is predictive modeling. By using data from sensors and other IoTdevices, healthcare providers can create a digital twin of a patient's body and use it to simulatevarious scenarios. For example, a doctor could use a digital twin to test different treatments for aparticular conditionandpredicthowthe patientwould respond

This could enable more personalized and effective treatments for patients. Another application ofdigital twin technology in healthcare is medical device development. By creating a digital twin ofamedicaldevice,manufacturerscantestandrefinethedevicebeforeitisputintoproduction.Thiscan help to reduce costs and improve the safety and effectiveness of medical devices.

Theeducation of healthcare workers can be enhanced with the help of digital twins. Healthcareprofessionalscanpracticeandimprovetheirskillsinasecureandcontrolledsettingbydevelopingvirtual simulations of medicalprocedures. This can lessen the possibility of medical errors andenhancepatientresult.

One potential use of IoT in the metaverse is to create smart homes and smart cities within thevirtualenvironment.IoTdevicessuchassensors,cameras,and smartappliancescouldbeintegrated into virtual homes and buildings, allowing users to interact with these devices as theywould in the physical world. For example, users could control virtual thermostats, lights, andsecurity systems using their virtual reality headsets or other devices. IoT could also be used tocreatemorepersonalizedandtargetedadvertisingwithinthemetaverse.ByusingdatafromsensorsandotherIoTdevices,advertiserscouldcreatemorerelevantandpersonalizedadsthataretailoredtotheinterestsandpreferencesof individualusers.

III. Metaverse Implementation

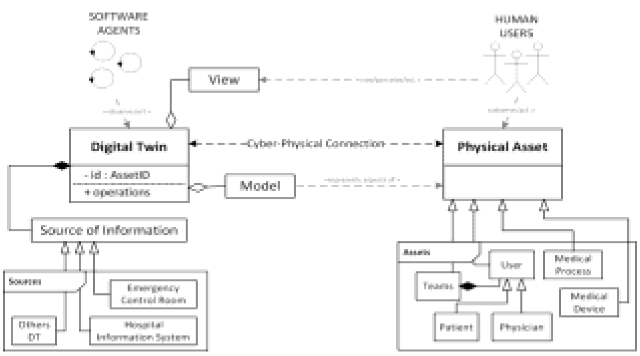

Fig8.Metaverseblock diagraminhealthcare

DOI: rp-9788770040723.160

Fig9Metaverseblock diagram

IV. Applications Of Metaverse

*Gaming:*The metaverse is often associated with gaming as it provides an immersive and interactive gaming experience. Virtual reality and augmented reality games can be created and played within the metaverse, providing gamers with a more realistic and engaging experience.

Social Networking: The metaverse can be used as a social network platform, where people can interact and connect with each other in a virtual world. Users can create their avatars, chat, attend events, and even attend virtual concerts within the metaverse.

*Education:*The metaverse can be used as an educational platform, providing students with an immersive and interactive learning experience. Virtual classrooms and labs can be created, where students can learn and experiment in a safe and controlled environment.

*Business:*The metaverse can be used for business purposes, allowing companies to conduct meetings, presentations, and even sell their products and services in a virtual environment. It can also be used for virtual trade shows, providing a more cost-effective and environmentally friendly alternative to physical trade shows.

Healthcare: The metaverse can be used in healthcare to provide virtual medical consultations, training, and simulations. It can also be used to create virtual hospitals and clinics, providing patients with a more comfortable and safer environment.

V. DataVisualization

The virtual representation of a patient's body or medical condition, healthcare providers can helppatientstobetterunderstandtheirconditionandtreatmentoptions.Thiscanhelptoimprovepatientoutcomesandsatisfaction.

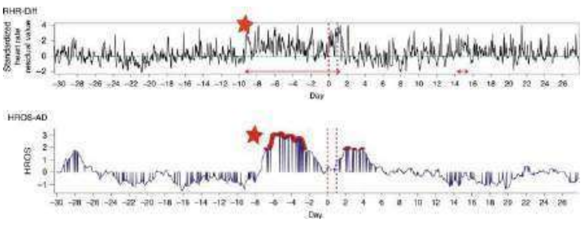

Fig10DataVisualizationofTemperatureand Pulse

Overall,digitaltwintechnologyhasnumerousapplicationsinhealthcare,frompredictivemodelingtomedicaldevicedevelopment,tohealthcareprofessionaltrainingandpatienteducation.

As the technology continues to evolve, we can expect to see new and innovative uses of digitaltwinsinhealthcareemerge.

VI. Conclusion

The integration of the metaverse with IoT has the potential to transform the way we experienceand interact with clothing and other wearables. By incorporating sensors and other IoT devicesinto garments, it is possible to create more immersive and interactive experiences that are closelytiedtothephysicalworld.Theuseoftemperaturesensorsandpulsesensorsingarmentscanenablea range of applications, from tracking fitness and wellness to improving safety in hazardousenvironments.Similarly, theuseofmotionsensorsandgesturerecognitiontechnologycanenablemore natural and intuitive interactions with virtual environments and objects. In addition to thepotential applications in the fashion industry, the integration of IoT with the metaverse has thepotential to revolutionize healthcare by enabling remote patient monitoring, immersive healtheducation experiences, and improved medical research. Digital twin technology can also be usedto create virtual simulations of medical procedures and test

Associate Professor, Department of Data Science and Business Systems, School of Computing, SRM Institute of Science and Technology,
Kattankulathur.

***Abstract*- A stroke is a condition in which the blood vessels in the brain are ruptured, harming the brain. Symptoms may emerge when the brain's blood and ot her nutrient flow is disrupted. The leading cause of death and disability world wide, according to the World Health Organization (WHO), is stroke. The severity of a stroke can be lessened by early detection of the numerous warning symptoms. Many machine learning (ML)models have been created to forecast the probability of a brain stroke. This study uses four distinct models for accurate prediction using avariety of physiological indicators and machine learning techniques including Support Vector Machine (SVM), Decision Tree (DT) Classification, Random Forest (RF) Classification, and K-Nearest Neighbors (KNN).With an accuracy of almost 95.1%,RandomForestwasthemostaccuratealgorithmforthisanalysis.Theopen-accessStrokePredictiondatasetwasutilizedinthemethod'sdevelopment.Theirrobustnesshasbeendemonstrated by several model comparisons, andtheschememaybeinferredfromthestudyanalysis.**

Keywords–ML,SVM,DT,RF,KNN

I. INTRODUCTION

A. General

According to the CDC, an estimated 12% ofall deaths are caused by strokes, a chronic disease inthe United States. The negative effects of a stroke [1]are regularly felt by more than 795,000 people in theUnitedStates.ThefourthmajorcauseofdeathinIndiaisdue tothis.

InanupgradingMedtechfield,MachineLearning is one of the best approaches for foretellingthe onset of stroke. Detailed searches and results canbeachievedbytheuseofappropriatedataandmethods. Brain stroke prediction researches are veryfew whencomparedwithheartstroke.

The steps used during this analysis help inpredictingthechancesofastrokeinthebrain.RFbroughtoffthefinestresultsamidstavarietyofmethodsthatareutilized,byacquiringthebest-resulting metric.

This representation has a shortcoming because it wasperformed on documented inputs as a substitute foractual computer Tomography (CT). Execution of themachinelearningClassificationapproachisdemonstrated in thestudy.

To move forward with this work, a Kaggle dataset [2]is chosen that has different physical characteristics asits attributes. Following analysis, the closing resultsdepend on these characteristics. The input data file isfirstputtogetherforthemodelbycleaningandpreparingforunderstanding.

Data preprocessing is the process that follows. To fillin any null values, the dataset is first examined forthem.Ifrequired, LabelEncodingisusedtotransformcharacter variables into integers. Data is cleaved intotrainingalongwithtesting sets.

Afterward, the newly acquired information is utilizedto generate a model employing different classification techniques. The resultsoftheseapproachesarecomputed and collated to ascertain which one yieldsthemost precise predictionmodel.

B. Purpose

The maingoaloftheproposalisto developaMachine Learning Classification and prediction forpatients with strokes. The input data file is taken fromthe"Healthcaredatasetstrokedata"sectionoftheKagglewebsite[3].

To comprehend the data better, qualitativedata, quantitative data, and multicollinearity analysiswillbecarriedout.Considerthemodels:SVM,Decision Tree,RandomForest,andK-NearestNeighbor. Finally, a better method will be selected topredict stroke.

The main purpose is to expose stroke in theinfancy stage, which helps in aiding the patient andalsopreventsdeathscausedbystrokes.

II. LITERATURE SURVEY

AccordingtoTasfiaIsmailShoilyetalcomparison.'softhetakenmethods,theNaiveBayes has higher precise results. The input data file,[4]which was cross-indexed by many professionals,wasobtainedbyobservingvarious medicalreports.

Theproposedmodelwillaidpatientsinunderstandingtheprobabilityofhavingastroke.4distinctmodelsweretrained.Themodels'resultswerevalidated. Machine learning models are applied to thedataset.

Inordertopredictstroke, JoonNyungHeo etal.tookinto consideration three approaches: DNN, RF, andLR. From readings, theDeep Neural Network(DNN) is frequently utilized for ischemia or acutestroke patients[5]. By utilizing the given input datathe DNN model approaches an 87% accuracy whichsurpasses the other models. It is improved by usingautomatedcalculationsthataremoreaccurate,whichreducestheneedforsimpler models.

Inadditiontoprovidinginformationonpotentialdisabilities broughtonbystroke,JaehakYuetalpreferred.'sC4.5DTmodel[6]leveragestheNIHSSscore,itclassifiesstrokeintensityinto 4 categories.

Thecapacitytopredictthepotentialtimingofastrokeanditsa

DOI: rp-9788770040723.161

ssociatedhandicapenablestheuseofadditionaldrugsandtheappropriatesafetymeasures. [7] Random Forest and Naive Bias both have highaccuracyratingsof88.9%and85.4%, respectively.

SVM was employed by Jeena R.S. and Dr. SukeshKumar with an approach that takes data as input andconvertsittoarequiredformforresearchpurposes.[8]350 inputs for the prediction were taken after pre-processing to remove redundant and conflicting data.91%accuracywasachievedthankstoMATLABsoftware.

ChutimaJalayondejahasstatedthatwhenusingdemographicdatatomakepredictions,DecisionTrees, Naive Bayes, and Neural Networks were thethree models that were taken into consideration. Thedecision Tree was found to have the highest accuracyandthelowFPrate.SinceFNpredictsthecontrarybutcausesmortalitybecausethepatientexperiencesastroke, FN is harmful. The decision Tree was takenintoconsiderationforaccuracy,[9]whileNeuralNetwork was chosen for safety because it had a highFPvalue anda lowFNvalue.

ABayesianRuleList(BRL)waspredictedbyBenjamin Letham etal.,and itbuildsadistribution ofpermutations from data. [10] The algorithm scales theinput data sets with complex features. High levels ofaccuracy, precision, and tractability can be attainedwiththe BRLapproach.

Pei-WenHuang1etal.usedphysiologicaldatatopredict stroke using the multimodal analysis method.Thisinformationincludesphotoplethysmography,arterialbloodpressure,andelectrocardiography(EKG) (PPG). [11] Each of these signals has beenexamined for accuracy. Additionally, they combinedthe signals and claimed it has the highest accurateresults.

Artificial neural networks may be used to forecastthromboembolicstrokedisease,accordingtoresearch.TheBackpropagationalgorithmwastakenastheapproaching method. The accuracy achieved by thismodelwas88%.[12]However,duetothecomplexityofinternalstructuresandthelargenumberofneurons,it takes an extended period of time to analyze theinformation.

III. Proposed Methodology

The suitable input data set for the model development has been taken from all the different data sets available in Kaggle after a lot of consideration, this dataset is further moved into the implementation part.

The steps involved in making the input data ready for machine understanding begin once the input data is taken and this process is called data preparation. This deals[13] specifically with dataset's label encoding where categorical data is encoded into numerical data, treatment of missing values by replacing them with the mean of the available data of that respective attribute in the dataset, and management of data that is imbalanced. The preprocessed data is now ready for model construction.

Exploratory Data Analysis is performed on the preprocessed data for getting relevant inferences and observations. Various visualizations like Graphical pie charts are used for obtaining the inferences.

Feature selection is also performed to ensure the essential features are only used for the developed model, which helps in maintaining the performance of the model and it also helps in solving the overfitting problem.

The following fig.1 ,the model building is shown by using various methods which help in the best prediction

Fig. 1. ML model building Flow Diagram

For the model creation, the preprocessed datasets and the ML methods are taken into consideration. Among the algorithms utilized are DT Classification, RF Classification, KNN, and SVM Classification, 5 accurate metrics are used to compare the six distinct models that were built.

IV. Implementation

A. *Dataset*

The Kaggle dataset was used to predict strokes. The input data files consist of twelve columns and five thousand hundred and ten rows. The columns that are taken into consideration are: "id," "gender," "age," "hypertension," "heart disease," "ever married," "work type," "Residence type”. "avg glucose level," "BMI" "smoking status”, "stroke."

The column “stroke” has the output value as a binary value which is either “1” or “0”.If a patient has a risk of stroke, the value is denoted by 1 and if the patient does not have any risk of stroke has the value of 0.

Mostly the column stroke has a value of 0 compared to the value of 1, due to which the data input file is mostly unbalanced.The next step to balance the unbalanced data preprocessing is done for the best results.

DOI: rp-9788770040723.161

The following table 1 contains the summary of the dataset mentioned earlier.

TABLE 1. DATASET DESCRIPTION

Attribute Name	Type *(Values)*	Description
1. id	Integer	A unique integer value for patients
2. gender	String literal *(Male, Female, Other)*	Tells the gender of the patient
3. age	Integer	Age of the Patient
4. hypertension	Integer *(1, 0)*	Tells whether the patient has hypertension or not
5. heart_disease	Integer *(1, 0)*	Tells whether the patient has heart disease or not
6. ever_married	String literal *(Yes, No)*	It tells whether the patient is married or not
7. work_type	String literal *(children, Govt_job, Never_worked, Private, Self-employed)*	It gives different categories for work
8. Residence_type	String literal *(Urban, Rural)*	The patient's residence type is stored
9. avg_glucose_level	Floating point number	Gives the value of average glucose level in blood
10. bmi	Floating point number	Gives the value of the patient's Body Mass Index
11. smoking_status	String literal *(formerly smoked, never smoked, smokes, unknown)*	It gives the smoking status of the patient
12. stroke	Integer *(1, 0)*	Output column that gives the stroke status

B. Preprocessing

Preprocessing is one of the important stepsbeforemodelbuilding.Theundesirablenoiseandoutliers are removed from the input data by using thepreprocessing method, if not it will cause a deviationfromnormaltraining.Thisstepinvolvesmostlyfixingt heerrorsthatpreventtheoperationofthemodeleffectively.

Aftertakingthedesireddataintoconsideration the second stage is performed which isto clean the data and make sure it is in developing themodel. The dataset used comprises twelve properties.First off,” id” is discarded because it does not add anyvalue. Following the dataset is checked if it has anyzerovaluesandfilledifanyarediscovered.Thecolumn” BMI” has a zero value which is replaced bythemeanvalue.

As the zero values from the input dataset areremoved, the following Label Encoding process takesplace.

C. LabelEncoding

Label Encoding is a process that is used tomakethecomputerunderstandthestringvaluespresent in the input dataset, thus it converts the datainto integer values. Strings need to be translated tointegerssincemachinesareofteneducatedonnumerical values. The input dataset contains stringtypein5columns.WhenLabelEncodingisapplied,the total string values in the entire input dataset areencoded, turninginto numericalvalues.

D. HandlingImbalancedData

Data scaling helps in improving the model'saccuracy as imbalanced data creates bias when themodelistrainedwhichinturnresultsinpooraccuracy.Min-maxdatascalingtechniqueisusedforscalingthestroke dataset.

V. MODEL DEVELOPMENT

A. Dividingthedata

Aftersucceedingindealingwiththeunbalanced dataset and completing data preparation,thenextstageiscreatingthemodel.Thebalanceddat aiscleavedintotrainandtestgroups,thetraininggroupconsistsof 80%whilethetestgroup consistsofa20%ratio,whichisusedtoincreaseofprecisionandpr oductivityofthe activity.

After dividing the balanced data manyclassificationmethodswillbeperformed.Theclassificatio n techniques used for this purpose includeSVMClassification,DTClassification,RFClassificatio n, andKNNClassification.

A. Algorithms

1) DTClassification(DecisionTree)

Theclassificationandregressioncomplicationsmaybesolv edusingasupervisedlearningsupervisedtechniquewhichisDTc lassification, however, it canbe typically usedinsolvingproblemswith Classification.

ThisclassifierhasastructurelikeTree,withinputdatarepres entingtheirowncharacteristics,rules,andclassification will be represented by branches and theresultsofclassificationwillberepresentedbyterminalnodes.

Theterminalandnon-terminalnodesformaDecisiontree.ContrarytoaLeafnode,whic hrepresents the outcome of the decision and has no extrabranches, a Decision node allows for the making of achoice andcontainsnumerousbranches.

Torunthetestsorformopinions,theprovided dataset's characteristics are used. It is a visualrepresentationofallpossibilitiesforresolvingaconundru morselectingacourseofactioninconsiderationofspecific criteria.

In developing a Tree, the Classification andRegressionTreemethodsareusedwhichareoftenknown as CART. It creates a question followed by asub-treewithbinaryanswersi.e.,yesorno.

2) RandomForestClassification

The well-known random forest classifier isused by combining several classifiers to handle severalissues and to increase the productivity of the model.This method mainly depends on ensemble learning.The regression and classification complications aresolved bythisclassifier.

BytakingthegiveninformationintoconsiderationtheRand om Forest classifier uses many decision trees ondifferent subgroups to increase the predicted outcomeaccuracy of the data. This algorithm uses each decisiontree in foretelling the results based on the majority ofvotesthendependingononedecisiontree.TheOverfittingprob lemcanbesolved usingmoretrees.

Some decision trees will anticipate the correctoutcome when compared to others and the reason isRandomForestclassifierusesadifferentdistinctdecisiontreeto

DOI: rp-9788770040723.161

forecastthetypeofinputdataset.However, all the trees provide reliable forecasts whentakenasawhole.

Thefollowingtwotheoriesareputoutinaneffort to improve the RF classifier. It should containreal values for RF to foresee the correct outcome asopposed to a speculative outcome. There must be averyminimalconnectionbetweentheforecastsofeachtree.

3) K-NearestNeighbor

Baseduponsupervisedlearningthis isoneofthesimplestMLtechniques.Thisassumessimilaritybetweenthealreadyusedcasestonewcasesandisfollowedbyastepwherethealgorithmtakesthenewcaseto aplace in analreadyusedcategory.

Thisalgorithmmaintainsthealreadyused data and distinguishes them into different newdata points based on the resemblance. So by utilizingthis method we can obtain new accurate data which ismorecharacterizedandsuitablefortherequirement.

As this algorithm is a distribution-freetechnique,itmakesnoeffortinguessingthedatawhichisunderlyinginthedataset.Thisismostlyusedforsolvingclassificationcomplications.Thisalgorithm is mostly an inactive learner because itstoresthetrain datainplaceoflearning it.

Instead, this algorithm uses the dataset to carry out anactionwhendistinguishingdata.Thismethodstorestheinformationfromthetrainingphasewhenitacquiresthelatestdata, andcategorizesit intoagroupthatistooclosetothe latestdata.

4) SupportVectorClassification

SVM classifier is one of the best methodsin ML which is used in solving complications in bothclassification and regression. This method is beingusedinmanymodelbuildingsforbetterperformance.

The main aim of this method is to get thebestdecisionthatcandifferentiatethen-dimensionalspace into classes. Next, the sub-data points are fastly moved to suitable categories.

“Hyperplane” is defined as the optimal decision boundary. This method selects the extremity points and vectors to generate a “hyperplane”. This

C. OPTIMIZATION

The main objective of machine learning is tobuildmodelsthatperformwellandprovidereliablepredictions for a given set of cases [14]. Machine learning optimization is required to accomplish it. By applying one of the optimization strategies, it alters thehyperparameters for reducing cost function. Since the cost function captures the variation between theapproximatetruevaluesandpredictiveresults.

D. Model Evaluation

Classification Metrics –There are four possible outcomes when making classification predictions.

- False positives (FP) are the cases where the model inaccurately anticipates it to be positive when it was really negative.
- True positives (TP) are cases where the model accurately anticipates it to be positive.
- True negatives (TN) Situations where the model correctly predicts that the negative class is negative.
- False negatives (FN) are situations in which the model expects a negative outcome but shows a positive result.

Confusion Matrix - Accuracy, precision, recall, and F-Measure are the four measures employed to gauge a classification model's performance.

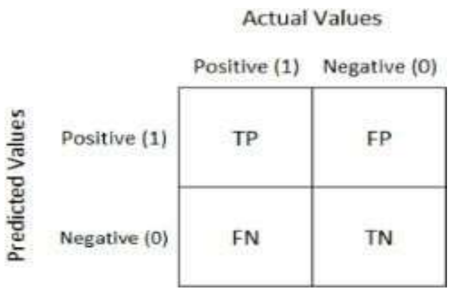

Fig. 2. Confusion Matrix

exact ones. The obtained percentage is used for testing and is referred to as accuracy.

$$\text{Accuracy} = \frac{TP+TN}{(TP+FP+FN+TN)} \quad (1)$$

2) A proportion of positive cases out of all projected positive cases is called precision.

$$\text{Precision} = \frac{TP}{(TP+F\text{N}} \quad (2)$$

3) A recall is a proportion of instances of positivity out of all real instances of positivity.

$$\text{Precision} = \frac{TP}{(TP+F\text{N})} \quad (3)$$

4) When calculating the score, the F-Metric accuracy measure takes into account the two of precision and recall.

1)The accuracy is defined as the ratio of thetotalnumberofforetellsto thenumberof

It is simple for establishing the method to becharacterizedasapositiveornegativemethodbyusingthesefoursignsasbenchmarkstoconstructtheassessmentcriteria.

VI. RESULTS

A. Comparison Resultsofthefourmethods

Four learning strategies( ) were investigatedin this article to predict stroke. Following a thoroughanalysis, we came to the following conclusions. Thebest-performing model out of the four is taken intoconsideration forprediction.

DOI: rp-9788770040723.161

ROC(ReceiverOperatingCharacteristics)curvesforallthe fourmodelsarecomparedandanalyzedforselectingthemodel withbetterperformance.Modelperformsbetter iftheROCcurveis towards the top left. Following figures show theROCcurves offourmodels.

I. Introduction

Due to their affordability, two-wheelers are currently themostcommonformoftransportation.Carelessridinghasincr eased the likelihood of bike accidents as There were moreriders than before. The negligence of bikers who do not wearhelmets is a serious problem, and it frequently results in therider suffering a brain injury. As a solution to this issue, mostcountries havelaws regulating helmetusefor two-wheelerusers.Althoughthegovernmentofsomenationshasinsta lleda specialised sensor to verify the wearer of a helmet, it wouldnot be financially sound to purchase sensors for each bike.Thetrafficpolicewillhavelessworktodoasnon-helmetedbikers'licenceplatesareautomaticallydetected.This willalsorequirefewerpersonnel.Asaresult,therewillbefewerrid erswhodonotwearhelmets.

II. Dataset

Since our Helmet Detection and Number Plate CapturingdatasetaretakenbyaCCTVfootageinrealtimewhichc aptures the persons number plate for not wearing helmet.mostofthedatasetusedhereisthedaylighttrafficinurban areas and highways. These datasets are used for furtherdetection process and extract the text by applying the OpticalCharacterRecognitionalgorithm

III. Motivation

Numerous scholars have addressed the issue of automobilenumber plate recognition in recent years. One of the mostimportantphasesinautomaticnumberplaterecognitionisn umberplatedetectionsinceinaccuratenumberplatedetectionim pairs the accuracy of the segmentation and identificationstages. Similar to this, other researchers have also suggested amethod that starts with the identification of bikers and thendetermineswhetherornottherideriswearingahelmet.To extract moving objects for moving object recognition andcategorise them by using their features and the local binarypattern,theauthorsinhaveproposedabackgroundsubtrac tionmethod.
