***Abstract*—A fundamental problem when transmitting a significant message via a wireless connection in a wireless sensor network (WSN). Attackers can use this to get into the network and launch a few possible attacks to intercept or change actual data. As a result of network sensors' lack of routers, every node that is part of the network must use the same routing protocol to facilitate the transmission of packets. It presents some security challenges in compounded topology, where its unguided existence frequently leaves it vulnerable to attacks against protection, especially when unguided. The wormhole is a well known example of an attack that poses the most significant risk due to the difficulty in finding and stopping it. In this paper, a brand-new routing technique that aims to provide a secure path for data transmission is presented. Wormhole attacks are taken into consideration in research, and the method used to do so aims to find and stop attacks of the type that have been identified. The suggested procedure is validated using specific performance-related WSN parameters. The generated results are evaluated based on metrics such as energy efficiency, end-to-end delay, and packet delivery ratio. These results are then compared to those of other recent techniques in the same field, and it has been determined that the exhibited research is the most effective among the methods mentioned for the parameters under consideration.**

***Index Terms*—AOMDV, WSN, Cluster, LNCA, Detect, Prevent, Malicious Node.**

I. Introduction

In the WSN, a number of sensor nodes are used to monitor large geographic regions, and they are designed with features such as low bandwidth, storage, and power usage to sup- port environmentally friendly forecasting technologies. Sensor nodes collect data and are distributed to WSNs in different regions. When used within a WSN, sensor nodes can process signals, sync data with the base station, and verify routes using a minimum number of resources. Wireless sensor networks are thought to be helpful in various settings, including control overthe environment, defense and military applications, deployment of robotics, and many more. WSNs are now vulnerable to various assaults as a result. These threats are alleged to involve a wormhole attack, which is a type of denial-of-service attack that utilizes both in-band and out-of-band networks. Wormhole attacks are classified as harmful attacks in a wormhole link or tunnel is a type of connection in which malicious and attacker nodes are interconnected through a fast channel connection speed. Wormhole attacks involve at least two malicious nodes, also known as attackers. The attackers take control of the network to access the data, and intruders are able to monitor wireless activity. In Mobile Ad-hoc Networks (MANETs), all nodes are mobile and able to move, but because WSN nodes have a fix protection issue for mobile, Ad-hoc networks are still useful [1–4]. Network security is complex, while the sensor nodes mobilize their locations. In a MANET, a node is a device that communicates with other nodes without the use of a central base and often serves as a point of communication between nodes. These medium nodes function similarly to multi-hop radio networks when used with routers connected wirelessly and ad-hoc networks do not require pre-existing networking infrastructures in order to function.

II. Existing System

WSN clustering is essential to minimize energy usage and maintain the consistency of the device. Clustering is a well known and widely used technique in wireless sensor networks. Clustering is currently being implemented over a distributed approach to address problems such as network lifetime and resource availability. Clustering into sensor nodes is crucial to addressing many issues, including those with sensor networks' lifetime, scalability, and energy consumption.Algorithms that cluster data limit connectivity within domains and only sendnecessary data to the rest of the system via forwarding. A cluster consists of many nodes, and the local communication among the nodes are measured by the cluster's head (CH). The set typically interacts with its participant cluster to gather data. The cluster heads form one more layer of groups between themselves before they reach the drain [7,8]. The implementation of a cluster-based architecture requires extensive work. The benefits of clustering are numerous, but sensor networks also have their restrictions, issues, or challenges. In this section, we discuss some specific design and deployment issues that were addressed in the development of the network architecture based on clusters.

A. Node Mobility

Nodes in the network are often assumed to be stationary when the network is designed. However, frequently it becomes necessary to advertise the adaptability of base

DOI: rp-9788770040723.001

stations or CHs.As a result of node mobility, clustering is observed to be more complex because node membership can change dynamically [9].

B. Traffic Load

Sensors monitoring events can either be intermittent or persistent. Traffic will increase due to regular and continuous monitoring and tracking, which generates traffic when the relevant incident is observed. Events that occur intermittently forthe CH chosen from the sensor's population require. Loading of cluster members in an irregular manner and rotation of cluster member's position. However, intermittent events do not require periodic sensing, so the CH is not affected.

C. Overlapping Clusters

CH may have been pre-designed by the network's designer or selected by its sensors. If the eventual option is chosen,it is likely that one cluster member will join another CH. Cluster overlapping in architecture problems must also be considered. For optimal organization between groups, detecting overlap- ping clusters in order to develop the perfect structures is crucial to avoid gridlock, hunger, or unfairness during the competition for resources [10].

D. Load Balancing

It is crucial to balance the placement of sensors in sensor networks. Sensor nodes need to be distributed evenly among the available CHs, as malfunctioning CHs may overwhelm others and cause the S. Singh, H. S. Saini 1 3head loss. Creating equal-sized clusters in these situations is crucial fora good balance.

E. Dynamic Cluster Control

A node of a grouping device that is self-configured is required. Initial clusters are created by clustering processes and need to confirm their surroundings. They are produced based on various metrics, including the data's usefulness, nodes' capabilities, network bandwidth, etc. A significant challenge for any clustering Programme is the requirement that the cluster members evaluate each node's contribution asthe process progresses. According to [10], The CH should be selected in a new round of head elections when the target is outside its sensing range.

F. Inter-cluster Coordination

To achieve the desired outcome, CHs needed to connect. Toexchange knowledge and work as a team, they must cooperate.A different cluster head or base station in the network can request additional data collected by one cluster. The self- configuring grouping process must be able to accommodate coordination overheads between groups.

G. Data Aggregation

The cluster head must aggregate or transfer data from cluster nodes to the CH, which requires more resources.Therefore, due diligence should be exercised when deciding on the CH. Switching positions between various nodes regularly makes it possible to maintain the CH's energy. Another option is to obtain an effective node that can handle the additional energy requirement as the CH.

H. Failure tolerance

Failure tolerance can maintain uninterrupted sensor network functionality in the face of sensor node faults. Some sensor nodes may fail or become blocked as a result of power outages, physical harm, or environmental interference.Possible failed nodes include a CH or a piece of the cluster. Such failures shouldn't impact the overall mission or analyzing sensor performance network. Therefore, having a system that can react to these types of errors is crucial

I. Scalability

The number of member clusters in a cluster that was initially created should be changeable by CH, either increasing or de- creasing. The membership of a group can fluctuate fora variety of reasons. An environmental threat, for instance, could cause a cluster participant to fail. During this time, the CH can react to a drop in membership. Instead, under certain circumstances, the number of participants may increase in search of new nodes installation, the present CH may malfunction, etc. There must be consent from the sensor network. The number of clusters should be increased or decreased.

J. Number of Clusters

Cluster numbering, or the total number of clusters, is a crucial architecture problem that needs to be resolved. To maintain overhead control and minimise network complexity, the cluster count must be at its maximum. To create an energy- efficient network, the ideal number of clusters would be built.

K. Cluster Formation Time

The network's initial clustering time should be brief. Events like selecting the cluster count option, gathering CHs, and assigning cluster members to a CH should be completed as soon as possible.

L. Single hop vs Multi hops Network

Multiple-hop communication can be used in clustering as well as single-hop communication. Because transmitting energy varies by square size, a multi-hop network is also ideal for energy conservation. [11]. The Multi-Hop Network presents architectural issues with topology management and media access control.

M. Node Heterogeneity

Some sensor applications require deploying a complex mixture of different types and capabilities of sensor nodes. Networks may be subject to a variety of service quality constraints and follow a variety of data reporting models. Various sensors can produce data at varying rates. The heterogeneous model would be unable to cluster, making CH's task more difficult.

N. Cluster Formation

When forming the cluster, many factors must be taken into consideration, such as whether it will be centralized or decentralized, how many groups will be included, and more. Topics such with sensor network architecture can be resolved by routing protocols that Centre on clusters. Unexpectedly, every sensor in a group is now the cluster head, dividing the energy load equally among the sensors. A

DOI: rp-9788770040723.001

network's predetermined CH allocation is made by the builder.

O. Self-Configuration and Reconfiguration

One of the primary phases of cluster development is the self-organization process. Clusters ought to be able to adapt automatically to their environment. The ease with which the network can self-organize concerning the functional unit ispart of the wireless sensor network's main drawbacks. Tomaximize network lifetime, self-organizing process is expected to be energy efficient and reconfiguration or replenishment. The self-organizationmechanismis reconfigured. When new sensor nodes are added or removed [12].

III. Challenges in Existing System

Networks become vulnerable to wormhole attacks; it receives data packets without knowing their source, draining the node's power and interfering with packet delivery. Additionally,processing received packages to a node that has never been included in the network, the wormhole in the network impacts the WSN's overall performance. The system that can anticipate the wormhole path avoids the crucial need, and a hole-free route for data transmission is projected after studying the literature on wormhole assault detection and the clustered WSN. By creating wormholes in the network, packets are received without knowing where they hail from, consuming energy and interfering with packet delivery.WSNs suffer from performance problems caused by packages sent to non-WSN nodes that have never been included in the network. It is crucial to think of the system in a way that can predict the wormholes in the path and the hole-free path for data transmission.

IV. Literature Survey

Simulation results refer to the common EEHRCP that focuses on the wormhole, whereas the proposed EEHRCP targets the wormhole. The wormhole attacks employ the round path length and have been added to the EEHRCP algorithm, and the simulation results refer to the common EEHRCP that targets the wormhole. According to the simulated results, performance can be increased by[26]. The authors used distributed trust models to isolate the misbehaving nodes. Routing has been successful using a multi-facet routing scheme. The authors improved the energy effectiveness of the network. According to Mehetre et al., a trust-based routing method might be used to ensure secure routing by using encryption. [27]. A two-stage security system was used to secure the data packet at the node selected by the authors. A cuckoo search algorithm was used to choose stable routing routes. Based on the activation function,[28] suggested a reliable set of neighbors. The purpose of this plan was to increase network security. Based on energy restrictions, the authors evaluated the significance of confidence. An additive measure was used to estimate the node, preserving the reliability of nearby nodes as well for WSNs, Deepa and Latha [29]. A hierarchical secure routing protocol was proposed by him in a hybrid routing protocol focused on clusters. Selecting the coordinator's head uses an algorithm that considers a different hierarchical group. Using an algorithm to define negative nodes, the authors selected the coordinator's head or coordinating node. When danger nodes were detected, the data was transmitted along the shortest path. Energy-aware systems based on trust were proposed by Zahedi and Parma [30]. The authors enhanced the routing functions metrics by including the node'sindirect and absolute confidence values also the energy conservation issue. The authors distinguish between the malicious nodes and the regular nodes using the measured confidence values. Mohajeran and Gharavian [31] proposed a routing method derived from the imaginative optimization of an ant colony. The writers of WSN wanted the network to last longer. With this approach, the authors achieved balanced transmission, further enhancing the energy efficiency route. In their proposal to identify malicious nodes using a multi- attribute trust protocol, Ram Prabha and Latha [32] YurongXu proposes that neighboring nodes detect distributed wormhole attacks based on the number of leaps determined by the node by analyzing the importance of trust with measurements like accuracy, node elapsed time, and development in messages, etc. The quickest method is to build an auxiliary graph in that case. Local map deformation is set up in an attempt to identify the wormhole hazard. Define the black hole relation using the diameter feature. The wormhole pinpoints the threat automatically when the diameter of the network reaches a certain level. The simulation's conclusion indicates that the suggested technique's identification rate is only about 80% and is not very accurate [33]. In response to Rupinder Singh's hybrid wormhole detection model, a packet is used for every hope, drop, and delay. After estimating the node's packet loss probability using the deteriorating chance of existence, whichis calculated concurrently with path discovery, a probability of packet damage is calculated for the entire route. The type of attack through a wormhole is determined using these likelihood criteria [34]. Every node preserves information with the aid of the routing method protocol for almost every one of its neighboring nodes as part of the defence against wormhole assault, according to the suggestion by Parmar Amish et al. If the route information cannot be identified, the node drives a response packet while waiting for a response. Routing table is developed with the current route map, a target node determines a path that takes the same direction to reply to the sender of the data packets. If the sender receives multiple answer packets, it recognizes them:" Out there, there are many roads."When the round period (RTT) is less than the limit, the sender node defines a wormhole attack, estimates and compares the RTT to the limit, and drops specific routes [35]. A wormhole discovery approach using a critical methodology and packet leash was established by Mousam A. Patel et al. A promising method involves a watchdog node that continuously monitors the network, inspects packets submitted by a source, and then forwards them while covertly monitoring their transit. To assist the sender node in locating wormholes in the network environment, packet straps need to be aware of the node's spatial orientation and the node's way [36].

V. Methods and Proposed System

A. LNCA Outline

Phase I: Make a cluster where each step is finished through- out the study of a specific period

Step 1: Readings obtained from data interchange.

- Information is collected from the site by each node.

DOI: rp-9788770040723.001

- Notifies its nearby neighbors of the information. In return, the same node party sends data, which the node collects.
- A node evaluates its reading in relation to the receiving node when it has access to information from its immediate neighbours. When the measurements are comparable, the transmitting node increases the “degree of node” by one.
- The transmitting node id is kept in the neighbour node list by the receiving node.

Step 2: Graduation Node Exchange.

Each node informs the neighbours in its immediate area of its “remaining energy” and ”node degree”. In return, the node collects the data sent to the nodes in a group that is similar to itself. In the list of adjacent nodes, each node’s” node degree” matches that of the divisions. As the cluster’s representative, the node chooses itself. When a node chooses a CL as the cluster head, it has higher residual energy in G and shares its degree with the nearby node population (let’s say group G) ifit has the most significant degree of nodes (CH). Nearby nodes have the same residual power or full node degree if a tieis resolved by a node ID group. When a node has the lowest node ID, for instance, the cluster leader chooses itself.

Step 3: Statement from the cluster head.

- Announcements were sent by the cluster heads (CH) chosen for their local neighbours in Stage 2. In CH announcements, the TTL3 is set to a large number.
- If the “neighbouring node list” of the cluster head node contains the final hop node from which the package was created, the cluster head node receives the CH post.Node tests Receiving node: If the acquired CH note’s TTL is reduced by one if the last-hop node is found in its listof nearby nodes. If the TTL is less than zero, the node broadcasts the CH notification to its neighbours. Theparameter ”received” 4 has been verified
- If “Cluster - head Received” is set to false, the source node - a root node that generated the Cluster - head notice - is declared the cluster head, and “Cluster - head Received” is set to true. Messages the cluster header to finish the “registration” process. 5 If “Cluster - head Received” at a node’s endings for Step 3 is still ”wrong,” that node should be chosen as a ”directed cluster head,” rather than a Cluster - head.

Step 4: Cluster formation in the end:

In the event that a cluster is produced, the Cluster- Head adds the provided node ID to the “member node list” and receives a “registration” request.

B. *Proposed System*

This section discusses the recommended wormhole detection algorithm. The CH (Cluster Head) performs a crucial role inner the network. The two-layered approach is utilized to lessen the CH node’s load. Every node of a sensor is distributed randomly within the ocean. The sensor nodes’ job is to detect and convert the data to CH. The CH aggregates all the data it collects, which is subsequently sent to buoys on the ocean floor. The buoy on the ocean floor communicates with the base stations that analyse the detected data. LNCA is a possibility for cluster formation. The following might be used to explain LNCA clustering. A cluster head election process is achieved by randomly deployed nodes, regardless of size. Each node transmits a physical value to the number it is closestto. Node degree computation is the process of calculating all numbers of nearby neighbors. Sensor nodes with the highest node degree are designated as cluster heads.

C. *System Architecture*

We propose a specific method for the detection of the wormhole attack in the clustered network. Sensor nodes are immediately established, or various routes from the source to the AOMDV routing protocol are used to construct destinations. LNCA is one of the research methodologies that is frequently used to cluster the nodes for which similarity between the nodes is considered to be a significant concern. Additionally, at the initial phase of the node’s deployment, cluster formation is taken into consideration. The routing protocols table contains information such as RTT, ETD, Th, P Sent, P Received, etc., which is calculated using the hop countand some initializations. Each node in a cluster needs accessto this information. The system architecture shows howthe method operates in stages as it looks for network worm- holes.

D. *Steps of Proposed Technique*

Step 1: Organization of nodes; LNCA technique used for cluster formation.
Step 2: K numbers of paths are generated in accordancewith the AOMDV routing protocol.
Step 3: When the tp1 timer is triggered, a DP (Detection Packet) is sent from S to D
Step 4: P Sent is equal to P Sent plus 1.
Step 5: After receiving an assessment packet from D, S ends the timer by computing. To determine ETD, subtract tp1 from tp2.
Step 6: Each node maintains an estimate of the parameters such as RTT, ETD, Th, P Sent, and P Received in the routing protocol table.
Step 7: A timer td1 will be set once the link is established, and S will begin sending packets of data. The process starts at td2 and ends at that time, assuming the FP is received there.
Step 8: RTT is calculated as td2 minus td1.
Step 9: A RTT will occur if: the ETD follows.
Step 10: Then CH Using this formula, P = P Sent(S, D) -P Received(S, D).
Step 11: By dividing the average RTT by the total number of leaps, a threshold is determined.
Step 12: It follows that if P ¿ Th
Step 13: Alert CH to any malicious behavior
Step 14: CH advises S to take the alternate route by joining D and for going that path
Step 15: End.

DOI: rp-9788770040723.001

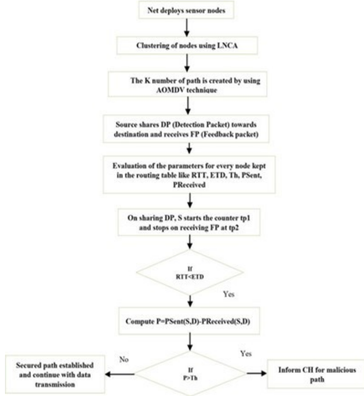

Fig. 1. Working architecture of the research methodology

VI. Results and Discussions

It predicts the hole-free data transmission method based on the path's wormhole. The network is vulnerable to wormhole attacks; it receives data packets without knowing the source, draining the node's energy and interfering with packet delivery.

Receiving packets are forwarded by the network wormhole to an outside node that has never joined the network, affecting the WSN's overall performance. In clustered WSNs, an essential requirement is to consider the literature just like that to avoid wormhole attacks. Using the wormhole present on the path, it forecasts the hole-free path for data packet transmission. Figures depict network formation following. The research methodology was simulated in NS2. The graphs represent the transmission of data between nodes orfrom a CH to lower-level nodes. Two different communication paths are shown in Fig. 5 and 6, and in Fig. According tothe methodology, the 1red line shows where a wormhole is located. As shown in Fig. 13, the packet considers path two after detecting a malicious or wormhole-containing direction. The blue line represents data transmission.

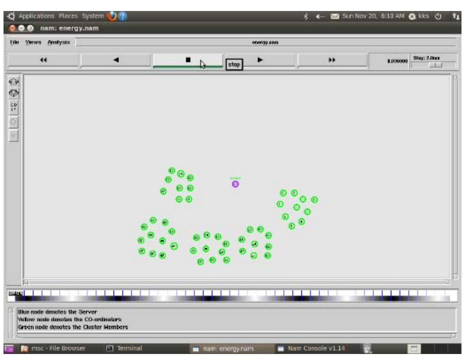

Fig. 2. Research methodology working architecture

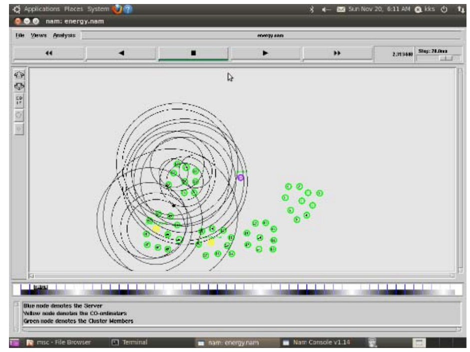

Fig. 3. CH Invention

Energy Consumption

Prior to choosing the best path, each free-path attacker's total energy must be calculated. In addition, the total energy in the attacker's free direction is calculated by adding theenergy levels at all intermediate nodes. This can be examined as.

Energy Consumption =Total Energy - Remaining Energy

Energy Efficiency = Remaining Energy Duration of the delay from beginning to end

The length of time it takes for each packet to leave the sender node and travel to the destination is defined as delay.

Delay = Received Time – Transmitted Time / Number of Packets

Fig. 4. Network communication between nodes

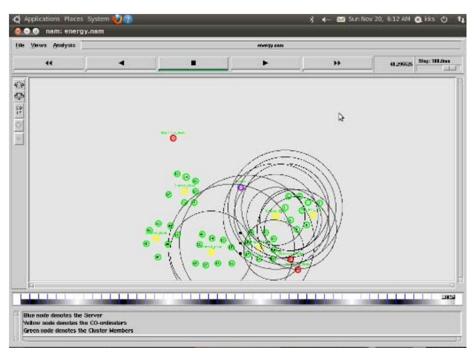

Fig. 5. Wormhole Detection

DOI: rp-9788770040723.001

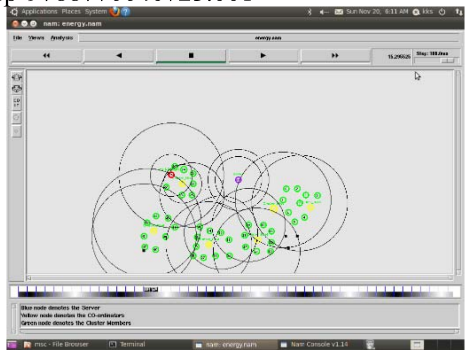

Fig. 6. Discover all Wormhole nodes

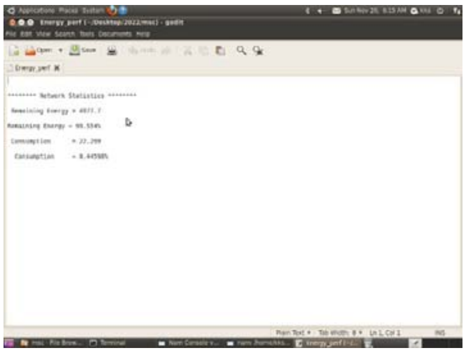

Fig. 7. Efficiency and Consumption Calculation

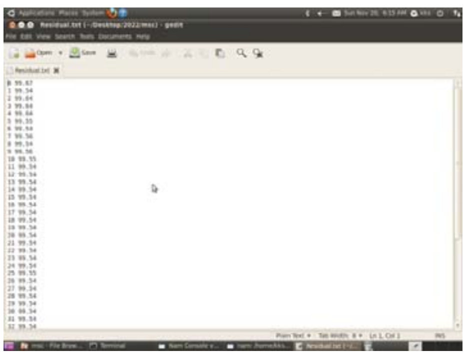

Fig. 8. Residual Energy of all Nodes

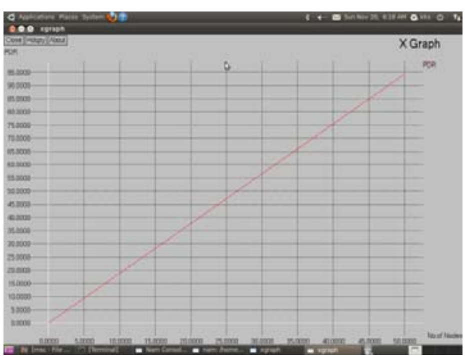

Fig. 9. Delay graph

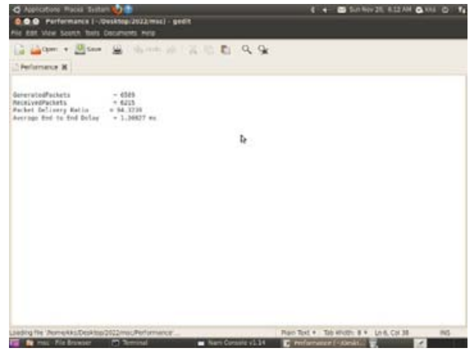

Fig. 10. Performance Calculation(PDR and Delay)

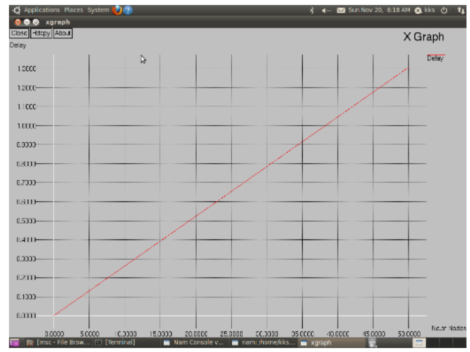

Fig. 11. PDR graph

Packet Delivery Ratio

The proportion of all packets created by the client node to all packets obtained by the end target.

PDR = Received Packets/Generated Packets * 100

When the comparison study considers both the EEHRCP and the AD-PSO in addition to the advisedmethod, and after results for all of the techniques taken into consideration were evaluated, it was found that the suggested technique (i- AOMDV) had a higher delivery rate for all network sizes.

VII. Conclusion and Future Work

A. *Conclusion*

The methodology is used here to detect wormhole attack on clustered networks. Sensor nodes and different routes are deployed in the early stages. AOMDV allows sending and receiving ways to be created. The LNCA technique, which organises the nodes into clusters, with the degree of similarity between the nodes being of paramount importance; is employed with regard to the study design, grouping the nodes during their initial deployment stage. Cluster formation is alsotaken into consideration at this stage. The performance assessments of the suggested technique based on variables like point-to-point delay are shown in graphs in the analysis section. Packet dropped ratio and energy consumption.

B. *Limitations of the Work*

- Prevention is a big challenge in this work.
- Wormhole detection is only possible.

DOI: rp-9788770040723.001

- We can't detect other attacks such as black-holes, vampire

C. Future Work

Integrate detection and prevention mechanisms to find malicious nodes and deliver more packets. Using the neighboring node's address as the bait's target address instigates RREP to bait the malicious node and respond, thereby tracking down the malicious node and preventing the attack. Use the Network Simulation Tool (NS2) to perform experimental simulations under various network conditions and evaluate performance metrics concerning packet delivery rate, delay, overhead, throughput, and energy.

***Abstract*—A Online Exams for the Blind is a software product that allows certain foundations of exam planning, administration, and administration to be done online. Either the Internet or your local network environment can be used for this. The exam software evaluates the answers given and results are available as soon as the exam is completed. The online exam system offers visually impaired students the opportunity to operate the system conveniently. Creating online exams is a big obstacle for individuals who are blind. The initiative created additional features to aid those who are visually challenged in their employment in order to prevent such issues. Here are the two types of languages he has implemented for creating questions. These are Tamil and English. The system allows traversing/navigating the stack of questions, makes it easy to submit answers, and maintains simplicity and confidentiality. Or, if desired, double-check all submitted responses prior to submission and using a voice synthesizer, the system will notify the candidate of the 'time left' increase. There is a lot of noise and confusion for other students when numerous visually impaired individuals take tests at the same time. Such disturbances will be reduced as much as feasible with the support of this project.**

Key Words: Visually Challenged, Examination System, Tamil, Traverse/ Navigate, Confidential, Voice synthesizer, Disturbances.

I. Introduction

Machines can be trained to interpret images in the same way that humans do, and to examine an image's features in greater detail than humans do. Face recognition on mobile phones and other apps to assure high level security, spotting and identifying objects and patterns in photographs and videos, and other modern technologies are all made possible by artificial image processing intelligence. Currently, image processing is widely used in a number of industries, including surveillance, law enforcement, gaming, biometrics, self-driving cars, and medical visualization.

Using visualization, which displays processed data in a way that is understandable to humans, provides visual representations of simple things that aid in decision-making, picture retrieval, which aids in image-based search, and image sharpening and restoration, which raise the caliber of processed images. Object detection, a technique for identifying things in images, Pattern recognition categorizes items, determines where they are located, and recognizes the hidden pattern in an image.

One of the necessities of daily existence is now the internet. The Internet is widely used by all people to access knowledge and information. However, accessing these text resources and using any online service can be challenging for those with visual impairments.

The development of computer-based accessible solutions has greatly expanded the range of opportunities available to those who are blind or visually impaired. The screen readers, an audio feedback- based virtual world, have greatly aided blind individuals in using online apps.

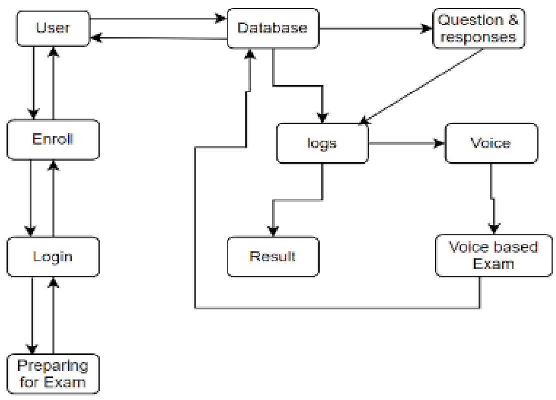

Fig: 1.1 Flow Diagram

The system is attempting to implement an exam system that would be beneficial for those who are visually impaired. It will prompt numerous questions and then obtain the response as the response with the help of keys that are integrated into the system. This will not only help each other to become more independent instead of relying on others' assistance. There are various systems like Voice Synthesizer (text-to-speech), image processing, Machine Learning with python which use the functions of Training Dataset, speech recognition (speech-to-text) and it will be necessary to get input from the students in the form of their voices in order to recognize the images for regulating and sustaining the system's flow. The key advantage of this system is that it only uses the user's voice when absolutely necessary, thus it won't need a strong or constant Internet connection. The user will be given voice prompts from the system asking them to carry out specific actions, and they will comply.

II. Literature Review

The pre-requisites for the proposed system have been predicted using current knowledge or approaches that may be appropriate after reviewing finished and ongoing research. The descriptions of the research publications would be as follows.

[1] **“**University Examination System for Students with Visual Impairments”Konstantinos Papadopoulos, ZisisSimaioforidis, KonstantinosCharitakis,andMarialenaBarouti - University of Macedonia, Thessaloniki, Greece

This paper “University Examination System for Students with Visual Impairments” by Konstantinos Papadopoulos, ZisisSimaioforidis, KonstantinosCharitakis,andMarialenaBarouti in this text is the creation of a web-based application, a complete application for university entrance exams. It is easy to use for visually impaired students and allows them to familiarize themselves with the established examination system with little effort. A user interface for those who are blind or visually impaired is built on the idea of intelligible text that students must read and write for tests. The N-print test dataset was used in this study to test 24 Greek lowercase letters and the numbers 1-9. Character and line breaks were also tested and assessed using it. The heads of 363 individuals were distributed in an unusual pattern and positioned 30 cm away from the screen

Advantages

1. Enables visually challenged pupils to choose from a variety of predefined settings for the presentation of digital text.
2. Depending on your preferences, you can choose what to do before the exam.

Disadvantages

1. Lacks timesaving, auto-tagging and reporting features.
2. A necessary part of rate grading and reporting, but also an administrative burden.

[2] “E-Examination Using Voice Interface for Visually Impaired Students” Aswathy M S, LijiSameulSree Buddha College of Engineering, Ayathil, Elavumthitta, Pathanamthitta, Kerala, India

This paper “E-Examination Using Voice Interface for Visually Impaired Students” is Aswathy M S, LijiSameul. This paper is all about developing an Open Distance Learning voice-based expert system for online tests for visually impaired students. It uses tools and methodology such as Java expert system, Shell, Voice XML, MYSQL, Voice User Interface and Voice Command Device, and K-Means cluster and shuffling Algorithm. Voice Xml is a key component of VUI systems and enables users to navigate a speech system. The database was updated using MySQL

Advantages

1. Accessible to all types of children, regardless of their handicap.

Disadvantages

1. ODL technology is entirely text-based and graphical. Thus, visually impaired individuals cannot do it.

[3] “Voice and Speech Recognition In Tamil Language” R. Kiran, K. Nivedha, S.Pavithra Devi, Subha.T Department of information Technology, Sri Sai Ram Engineering College, Chennai-44, Tamil Nadu.

This paper “Voice and Speech Recognition In Tamil Language” by R.Kirani, K.Nivedha,S.Pavithra Devi, T.Subha is a well-liked technological development that enables user contact with current technologies. It is often referred to as "computer speech recognition," "automatic speech recognition," and "speech to text". Tamil voice and speech recognition on smartphones has not received much attention. Automatic Speech Recognition (ASR) includes Dynamic Time Warping (DTW) Machine Learning techniques,Neural Networks (NN), Support Vector Machines (SVM), and Decision Trees (DT). Statistical Pattern Matching methods are divided into Gaussian Mixture Models (GMM) and Hidden Markov Models (HMM). ASR has achieved the highest word recognition accuracy possible, providing 86.5 and 92% during testing and training processes.

Advantages

1. Text messages make communication simpler for both sender and recipient, and audio data in Tamil is converted into Tamil text by mobiles' voice recognition systems.
2. Tamil is frequently used in speech recognition software, which raises its usage and raises public awareness of it.

Disadvantages

1. Indian smartphone users have found it difficult to use voice recognition software because of the lack of development in local languages. In this technical process, people who feel using these systems in a foreign country can be challenged instead of their own tongue.
2. The language barrier restricts the use of these applications, and there is no flexibility for native users.

[4] “Voice-based Online Examination System for Visually Impaired” ThajunNajaah, Samsudeen, ThowfeekAhamed Digital Mobility Solutions Lanka (Pvt) Ltd, Sri Lanka Institute of Advanced Technological Education (SLIATE) - 2021

This paper “Voice-based Online Examination System for Visually Impaired” by ThajunNajaah, Shamsuddin, ThowfeekAhamed is about information technology that has a great impact and life is easier in the development of fast-expanding technologies and applications. Voice-based online test systems enable students to take exams online using speech synthesis and speech recognition. This helps visually impaired people with developing their careers. The methodology used is the Correlation coefficient, which reduces the difficulty and increases the irony between visually impaired education and establishes the societal environment. The correction of spelling from the student answers is done using the generation of a word set together along with the production of raw and semantic vectors. The correction of spelling from the student answers is done using the generation of a word set together along with the production of raw and semantic vectors.

DOI: rp-9788770040723.002

$$Vi = Si * \mathrm{I}(mi) * I(ni)$$

mi - a word in a word set ni - the generation word in answers. I (mi) and I (ni) are the information content of mi and ni, respectively.

Advantages

1. It enables the student to attend the exams without disturbance from their surroundings. It is fully controlled by voice commands.
2. They can check for the answered and not answered questions.

Disadvantages

1. No noise filtering technique is added to this system.
2. Applicable only to the English language, not to other languages.

[5] "Development of an Examination Based System for the Visually Impaired Persons" Chukwuemeka[1], Ituma[2], Oyiga[3], Samson[4], Ebere[5], Department of Computer Science, Ebonyi State University, Abakaliki, Nigeria,Enugu State Polytechnic Iwollo, Enugu, Nigeria, Destinet Smart Technologies, New layout, Enugu, Nigeria

This paper, "Development of an Examination Based System for the Visually Impaired Persons" by Chukwuemeka, Ituma, Oyiga, Samson, Ebere, the main motive behind this paper is to make it easier for those who are blind or visually impaired to access high-quality education and in order to remove the barriers. The applications using this system are Examination Registration, Admin Registration, Training, Speech Recognition, Results. The dataset used here is the MySQL dataset and techniques like filters, photonic analyzers and voice synthesizers were used to achieve this. These were developed using universal modelling diagrams, and their implementation required MySQL and a Visual Studio Tool. Background noise hindered the overall system performance when it was examined. This performance is made possible by using an earpiece and mouthpiece to cancel out outside sounds. This resulted in students to able to successfully participate in the exam and getting the final score.

Advantages

1. The performance was hampered by background noise, but an ear and mouthpiece were employed to cut down on it while maintaining a high level of performance.

Disadvantages

1. Lack of independence.
2. Lacking the ability to compute results in real time, findings may be manipulated as a result of delays.
3. Lack of intellect or social skills to instruct the blind students on how to proceed, hence the mentor must be present during the exam to assist the student.

[6] "Online Examination System for Visually Challenged" MukulChowdary, ReshmaPriyanka, Srinivas, Rajesh, N. Leelavathy - Student, Professor, Department of Computer Science and Engineering, Godavari Institute of Engineering & Technology, Rajahmundry, AP

This paper "Online Examination System for Visually Challenged" - MukulChowdary, ReshmaPriyanka, Srinivas, Rajesh, N. Leelavathy is feasible on a local network or on the internet. The results are made accessible right away once the student submits their answers to the inquiries on their examination using a computer. This helps them to easily interact with the online system because of its accessibility features. For internet connection problems, this system has a feature which helps them to prevent them. Although it is possible to convert speech into text and convert text into speech, the capability currently available might be enhanced. Without the internet, this system's accuracy would be substantially lower. In this system, particular keys are employed to keep system flow in check. The student's voice should be given as input and that uses speech to text to sustain system flow. The system can navigate through the question stack and submit the answer with ease by integrating the keys, retaining simplicity and secrecy and students can relist to the question, alert the answers as needed using the designated keys. The tools and methodologies have the capacity to translate voice to text, and the ability to translate text to speech is constructed with the aid of libraries in Python to provide them with greater functional support. The applications included in this system are use of the keyboards and prompting the microphones.

Advantages

1. At the result of the test, the user may easily review all the questions they have already answered as well as any ones they haven't.
2. There is no need for a recorder during the examination

Disadvantages

1. No offline packages are available.
2. Users can't choose between the different sections - what they prefer to do.

[7] "Voice Operated Tool- Examination Portal for Blind Persons" - Akriti Vats, - Tandon, - Sinha, 2016

This paper ""Voice Operated Tool- Examination Portal for Blind Persons" by Akriti Vats, Tandon that the usefulness of speech recognition software is increasing these days. There are numerous interactive speech-aware programs. The need for embedded systems demands is growing, making the voice recognition system accessible on future embedded systems effective. In order to avoid the need for any support when administering a multiple-choice question test, the program for desktop computers is called the Examination Portal for Blind Persons. This system is a Web- based application and mobile application which is for native users. These system tools and methodology include computer speech recognition, Automatic speech recognition and the methodologies include Voice operated tool, Google voice and Siri. These applications include uplifting of blind users, handling different modules - question bank, candidate details, result analysis and the intelligence of blind people.

Advantages

1. One may simply control a computer network by speaking commands rather than clicking keys on keyboards.

DOI: rp-9788770040723.002

2. The people who can't use their hands or can't seem to give exams by just using their voices.

Disadvantages

1. No recognition of voice and speech is widespread as more and more applications are now being made using speech recognition tools.

[8] "A Voice-based E-examination Framework for Visually Impaired Students in Open And Distance Learning" Dr. Ambrose Azeta, ItorobongInam, Dr. OlawandeDaramola Department Of Information Technology Cape Peninsula University Of Technology Cape Town, South Africa

This paper "A Voice-based E-examination Framework for Visually Impaired Students in Open and Distance Learning" - Dr. Ambrose Azeta, Itorobong Inam, Dr. OlawandeDaramola. This system is a user's voice-based system that can access internet information through a voice interface. This Open Distance Learning e-examination system employs a speech interface but does not provide evidence of an intelligent type of evaluation. The framework that will guide the development of an ODL voice-based e-examination expert draws on the achievements of prior research. In order to determine the system's level of usefulness, this system is tested using datasets like user satisfaction survey questions, which is developed using a variety of technologies including rule-based reasoning, server-side scripting, voice-based system development, data administration, and system design. The algorithms include Fisher yates Shuffling and UML diagrams and the validation tools are Voxeo Prophecy - Speech Engine and HTTP Service. According to the usability test findings, the application achieved an overall usability rating of 3. 48 out of 5. This shows that perhaps the voice-based e-examination system may enhance the present web-based online assessment technique and provide them with considerable benefits with regard to distance.

Advantages

1. How to Create a Voice-Based App as a Verification Guide.
2. Enhance Examination Connectivity for Individuals with Visual Impairment Participating in Distance Learning.

Disadvantages

1. The program was not properly secured, and caller encryption using an email address and passcode was not used.
2. It lacks the capability of user voice recognition access control.

[9] "Online Examination System" Muna R. Hameed, Firas. A. Abdullatif Information Technology and Communication, Baghdad, Iraq International Advanced Research Journal in Science, Engineering and Technology (ISO 3297:2007 Certified Vol. 4, Issue 3, March 2017)

This paper "Online Examination System" Muna R. Hameed, Firas. A. Abdullatif is one that uses a computer system to administer exams online, either over an intranet or the internet. The benefit of this online test system is to thoroughly and efficiently evaluate the student using a fully automated method that not only cuts down on the required time but also produces results that are quick and precise.

It is a web- based application that uses web-based online applications like CBTS - Computer Based Text System and executed with inbuilt PHP packages and database. It also includes Student Management, Question Addition and Question deletion.

Advantages

1. More secure and more flexibility.
2. Demonstrating each system to overcome challenges framing the conduct of examination and to support the examination process.

Disadvantages

1. Each subsystem can't be handled separately without an influence on other systems.
2. It required more time to be programmed.

[10] "VQA-Machine: Learning How to Use Existing Vision Algorithms to Answer New Questions" Author: Anton van den Hengel, ChunhuaShen, Peng Wang, Qi Wu Year: 2017

This paper "VQA - Machine: Learning how to use Existing Vision Algorithms to Answer New Questions" by ChunhuaShen, Peng Wang, Qi Wu. In light of this, it is suggested that the latest VQA model expands the cross system to a higher level that can handle questions, visuals, and facts simultaneously. It has the capacity to flexibly combine a wide range of commercial CV techniques to get answers. Using these CV algorithms on the image, we can produce a range of data that we refer to as image facts. Naturally, a large portion of this data would not apply to the specific topic posed. This is implemented using VQA Visual Genome Dataset, which uses algorithms like Artificial Intelligence, Computer Vision and Natural Processing Language and Methodologies like Neural Turing Machine (NTM) and Validation tools like Joint Embedding and Modular Architecture with Memory Networks and these applications like Answer Prediction and Reason Generation.

Advantages

1. Even though the model is based on many data sources and activities, it advantages from employing a variety of off-the-shelf CV approaches.
2. The system functions better when more information is provided. It can use a CNN model that has already been built.

Disadvantages

1. By comparing the user factors with the prototype factors, the human approvals are calculated.
2. Only the best reason connected to the question being answered had to be chosen. They were instructed. Any of the reasons mentioned here may turn out to be helpful.

[11] "Cross-Modal Attention with Semantic Consistence for Image-Text Matching" - Author: Tan Wang, Xing Xu, YangYang Year: 2020

DOI: rp-9788770040723.002

This paper "Cross-Modal Attention with Semantic Consistence for Image-Text Matching" - Author: Tan Wang, Xing Xu, Yang Yang is one that uses Flickr30k and Microsoft COCO (MSCOCO). The benefit of this paper is that this online system is thorough and effective in the proposed CASC in preserving global semantic consistence along with local alignment.

And the datasets used here are two different datasets to do CASC. This is implemented using the Flickr 30 software, where it is a web-based application where it uses the application of Cross-modal attention for local alignment and multi-label prediction for global semantic consistence.

Advantages

1. It immediately extracts semantic labels from available sentences.
2. It also adds a global similarity constraint.

Disadvantages

1. Two datasets were the only ones used to test CASC. It was not tested whether CASC could operate with various datasets.
2. The key challenge in image-sentence retrieval is how to precisely gauge the semantic similarity between visual and textual input.

[12]"Embodied Question Answering"- AbhishekDas, SamyakDatta, Georgia Gkioxari[2], Stefan Lee, Devi Parikh, DhruvBatra

This paper "Embodied Question Answering" - AbhishekDas, SamyakDatta, Georgia Gkioxari, Stefan Lee, Devi Parikh, DhruvBatra, talks about an agent is randomly placed in a 3D environment and is then prompted with the question "What color is the car?" The agent must ask the question ('orange') and then intelligently navigate to explore the environment and gather data using egocentric first-person vision.

This is implemented using the algorithm of AI Skills – active perception, language understanding, goal-driven navigation, common sense reasoning, and grounding of language into actions. The dataset used is the EQA dataset. The applications used here are Question Answer Accuracy and Navigation Accuracy. It is used to construct the Embodied QA environments, end-to-end trained reinforcement learning agents, and evaluation protocols.

Advantages

1. The navigator (PACMAN+Q) suggested by the model performs best when compared to other baseline models by achieving
2. The smallest distance to target at termination (dT), which causes the model to achieve the highest answering accuracy.

Disadvantages

1. Most possible Embodied QA questions do not require a natural or "correct" navigation path to be answered.
2. The agent moves further away from the target than they did at the beginning. This demonstrates that Embodied QA is a challenging issue.

[13] "Learning Rich Image Region Representation for Visual Question Answering" Author: Bei Liu, Jianlong Fu, Zhicheng Huang, ZhaoyangZeng, Zheyu Chen Year: 2019

This paper "Learning Rich Image Region Representation for Visual Question Answering" Author: Bei Liu, Jianlong Fu, Zhicheng Huang, ZhaoyangZeng, Zheyu Chen to improve the representational capacity of both visual and text features as well as the ensemble of models in order to increase VQA by utilizing more potent feature extractors. Some detection methods are used for visual features to enhance the detector. We use BERT as the language model for the text feature and find that it can significantly enhance VQA performance.

The dataset used is Visual Genome as Object Detection, which uses the algorithm or validation tools known as NLP, BERT, GPT, ELMO& VQA Model. And the applications used here are Ablation Experiments and Comparison with Others and this requires that, using the input image, our model responds to.

Advantages

1. A single model is accurate to 72.79% on the test-dev split, and the ensemble of 20 models is accurate to 74.71% and 74.89% on the VQA test-dev.

Disadvantages

1. Performance is impacted by training large-scale datasets for feature extraction on object detectors.

[14] "Is an Image Worth Five Sentences? A New Look into Semantics for Image-Text Matching" Author: Ali FurkanBiten, Andres Mafla, Lluis Gomez Year: 2021

This paper "Is an Image Worth Five Sentences? A New Look into Semantics for Image-Text Matching" Author: Ali FurkanBiten, Andres Mafla, Lluis Gomez is about image-text matching. Representations from various modalities are mapped onto a single joint visual-textual embedding. The datasets used here are MSCOCO and Flickr30K are actually image captioning datasets that provide only a very small number of ground-truth and notations for relationships.

And the algorithms used here are Semantic Adaptive Margin (SAM) formulation and image captioning metric. Applications used here are the process of Effect of Temperature and Samplings. When using the entire training set, the performance on the annotated image-caption pairs is maintained while improving on other non-annotated relevant items. We'll release the code containing our metrics and our adaptive margin formulation.

Advantages

1. Evaluation of an item's semantic relevance is done separately from its annotated binary relevance.

Disadvantages

1. Image-text matching task is lacking in annotations. Only one image was deemed appropriate given a sentence query.
2. It's possible that the dataset also contains a large number of additional pertinent pictures or captions.

DOI: rp-9788770040723.002

3. The performance and efficiency are a little bit distorted because of the increased dataset requirement.

[15] “Roses Are Red, Violets Are Blue. But Should VQA Expect Them To? “- Author: Christian Wolf, CorentinKervadec, GrigoryAntipov, MoezBaccouche 13 Year: 2021

This paper “Roses Are Red, Violets Are Blue... But Should VQA Expect Them To?” - Author: Christian Wolf, CorentinKervadec, GrigoryAntipov, MoezBaccouche. It introduces distributional shifts in the test and validation splits that are specific to each question because they are based on question groups. We carried out large-scale research and we experimentally showed that a number of cutting-edge VQA models, even those created especially. This is done with the dataset known as GQA-OOD Training Dataset and the algorithm used here is LXMERT pre-training, LM hyper-parameters, Visual Studio. And it is used to train hyper-parameters, Question Diversity, Prediction.

Advantages

1. The advantages of the questions' synthetic nature far outweigh their drawbacks.
2. This specifically provides better control over the data and eliminates unmodelled external knowledge, which improves

Disadvantages

1. The proposed benchmark is based on the GQA dataset, whose questions were generated automatically.
2. As a result, the GQA dataset has a constrained vocabulary (covering only 70% of VQA2 answers), and it use synthetic syntax.

III. Drawbacks of Existing System

1. **Time delay** - Cased using speech-to-text for answering questions.
2. **Minimal accuracy**
3. A **Manual Monitoringprocess** is necessary.
4. **Independently** - Students who are blind must rely on others to acquire resources.
5. **Long word** - the student's long word is muted by noise suppression.
6. The voice entered in a seamless manner; these can be **discrepancies.**
7. They might not feel comfortable with the **assistance** of the blind people if they speak a unique language rather than English.

IV. Proposed System

The database network and Speech-To-Text conversions for this technology would be made feasible via internet access. With the support of text-to-speech, this approach was only recommended in order to lessen the pressure placed on the visually impaired students when writing an exam. Every component of the system has been integrated with it, and students can easily navigate through it with the help of the buttons and can choose their preferred language (Tamil or English) and even the codeword is provided to do the authentication process before the exam starts. The system also provides time alerts for students who want the most flexibility possible when taking exams.

VII. Conclusion

In this paper, we discussed how people who have trouble seeing could put in extra effort to test their internal aptitudes via a web exam. Navigating the question stack as the user interface for individual users. The initiative makes it possible for visually impaired people without any assistance of human intervention. It completely avoids voice synthesis, speech issues with recognition, noise suppression and mismatch errors. This system reduces ambiguity which prompts a given microphone. The user can hear alert messages that indicate "how much time is remaining" to submit the exam and can be easily navigable by users.

Before finishing the test, the users have the same access to all of the answered and unanswered questions that humans have. Due to the combination of activities offered by all of them, a blind person may now take a virtual test to determine their own skills.

The main goal of this project is to give users complete usability, supportability, profitability and feasibility to take an online test as a regular person. A person with a disability is permitted to take part in any competitions held by organizations through the internet. This could help to improve the percentage of visually impaired people who participate in any test that is competitive. Therefore, visually challenged impaired people can take exams just like any other person without any problem.

Acknowledgment

The authors would like to appreciate the efforts and cooperation of the staffs of Department of Computer Science Business Systems at Rajalakshmi Engineering College, Thandalam

***Abstract*—Medi-tracker is a web application using machine learning. Medi-Tracker serves doctors, medical representatives as well as patients to help understand their health condition after a blood test or after a diagnosis. Medi-Tracker was built with the intent to serve common people with an easy to access and understand user interface and reduce their cost to visit a doctor or stand in long queues to get the conclusion from their report. With an accuracy rate of 94% using Binary logistic regression Medi-Tracker is a python-based web application. According to a report even in 2022 many people can't afford a doctor's visit, so with the help of this just by undergoing a blood test they can have an AI based consultation at their fingertips. Our model is user-friendly and an end-to-end system for prediction. Our main purpose is to serve general people with easy medical assistance.**

Index Terms – Machine Learning, binary logistic regression, deep learning, .

I .INTRODUCTION

A. Artificial Intelligence

Artificial intelligence is the human-made intelligence for devices and machines. AI works as a helping hand for humans to perform tasks and help keep track of day-to-day activities in their lives. The term artificial intelligence was coined previously to defy machines that could mimic and perform human-like activities like "decision making" and "problem- solving". Artificial intelligence has come a long way in the present world of technology. Just giving a simple task to a machine and letting it finish the task with the desired output has saved a lot of time and manpower. Today a lot of sectors use artificial intelligence as their helping hand. From traffic control to weather prediction, vehicle manufacturing to cruise control, and autopilot in vehicles. From assembling small parts in a mobile device to making calls or setting reminders artificial intelligence has come a long way.

B. Machine learning

Machine learning, as illustrated in Fig.1, being a subset of AI (artificial intelligence) that deals with training a machine to perform a set of tasks based on the training data. Machine learning is a process to help machines to learn and provide solutions by predicting and performing simple statistical calculations. Machine learning is crucial in training machines and computers based on datasets and lets them perform actions and predictions based on the data. A machine is first trained with a dataset and after the training period is over the machine is given inputs and based on the training it can predict the output for the input received. In several fields machine learning algorithms are employed to execute tasks that would be difficult or impossible to perform with conventional techniques.

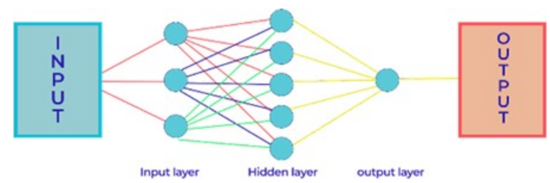

Fig. 1. Machine Learning

C. Deep Learning (DL)

DL or deep structured learning, as illustrated in Fig.2, is a broader part of machine learning. Where machine learning simply works with one hidden layer of the trained dataset, deep learning has more than one layer of the dataset to predict and perform tasks precisely. Deep learning is machine learning using artificial neural networks and representation learning.

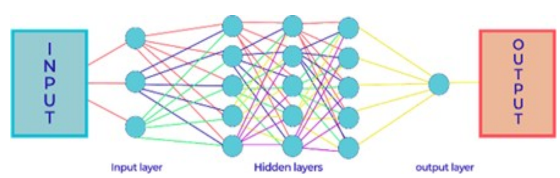

Fig. 2. Deep Learning

D. Artificial neural network (ANN)

ANN consists of a connection formed by interconnected nodes similar to neurons of animals(humans). As neurons transmit data from one part of the body to the brain and direct output to the preceptors an artificial neural network performs a similar task by sensing the environment and transmitting the data from the sensors to the processing unit and then from the processor back to the actuators to perform the output. An artificial neural network forms a network of interconnected nodes to share information and perform specific tasks layer by layer. Each layer is responsible for different tasks and duties. An artificial neural network is a neural network made artificially, these are a group of multiple preceptors or neurons at each layer that solves the tabular data, Image data, and testdata.

An Artificial neural network is capable of learning non-linear functions, it uses universal function approximations.

An ANN faces a few challenges such as -

- The number of trainable parameters increases, so does the size of the image.

DOI: rp-9788770040723.003

- It shows vanishing and exploding gradients.

AI is powering personal devices in our homes and offices similarly to electricity. AI will be the next big thing after the electricity that will hugely impact our daily life.

E. Medi - Tracker

The name of the project is **Medi-Tracker** as its main function is to track and predict whether a patient is having or has the chance to get a particular disease or not. This project uses Binary Logistic Regression to forecast the likelihood of disease in various organs of the body like the liver, kidney, heart, etc.

This project uses the datasets from Kaggle and other sources to train and link users via HTML forms and landing pages.

- Breast Cancer: Wisconsin Breast Cancer Dataset
- Diabetes: Pima Indian Diabetes Dataset
- Liver: Indian Patient Liver Records
- Heart: Heart Disease Dataset
- Kidney: Chronic Kidney Disease Dataset

II. Related Work

Patients have to consult a doctor each time they undergo a blood test or they have been through a diagnosis. Normal people are not able to understand what all these readings mean and how they are normal or not. So after each step or regular blood test patients or their family members have to consult a doctor just to understand the report. The existing process of undergoing a predicting diagnosis was a bit tiring and costly. Also, other patient diagnostic systems are not user-friendly, and accessing them for normal people is nearly impossible. The end-users so far were always doctors and medical representatives. Still, in 2022 many people will not be able to get proper healthcare services because of not the wide reach of doctors and hospitals. Using AI people can have a personal doctor at home. There is a scarcity of professionals like technicians, nurses, doctors and infrastructure. According to a World Health Organization report (WHO), there is only a 0.76:2.09 doctor to nurse ratio per 1000 people. Thus it can be said that there is an acute shortage of hospital beds is being faced by Indian Healthcare. Physical access to hospitals remains a significant barrier to both preventive and curative health care. High medical costs are incurred in India by approximately 63 million people and they face poverty due to the same. Using technology in a better way, healthcare can be made affordable for everyone.Previously, various studies were conducted for disease detection based on specific symptoms using various ML algorithms. Montoet. al. developed a SAS Statistical Analysis Software version 6.12 for influenza disease prediction [1]. A study of influenza patients with fever and at least two additional flu symptoms was conducted in the clinical trial, which involved a total of 3744 unvaccinated adults and adolescents. Eventually, the lab found that 2470 of the 3744 individuals were infected with influenza.. The model's accuracy rate was 79 percent. Karayilan et al. [2] devised a model for the heart disease pre- diction based on ANN and Backpropagation Neural Networks, two of the most prevalently used ANN learning techniques. 13 clinical features were fed as input and then trained with the help of backpropagation algorithm in order to decipher any heart disease with an accuracy of 95%. Chen et al. [3] streamlined a number of ML algorithms to accurately assess the chronic outbreak of disease. The amount of data gathered for training purposes was grossly inadequate. A latent factor model was being used in order to overcome this. A new multimodal disease risk prediction model (CNN-MDRP) based on convolutional neural networks was created. The algorithm's accuracy was roughly 94.8%. This study makes use of the actual hospital data taken from the hospital dataset. Chae et al. [4] analysed 80 infectiousdiseases using four different DL models: DNN, OLS, LSTM and ARIMA. All other models tested were outperformed by the DNN and LSTM models. Resul et al.[5] built an ensemble-based methodology to diagnose heart disease using SAS enterprise miner 5.2 in their study. Experiments on the heart disease dataset were carried out in order to fully automate the diagnosis of heart disease. Three independent neural network models were taken into consideration in order to create the ensemble model. There was an increment of neural network nodes of ensemble model, but further performance improvement wasn't noticed. The results of the experiment can be used to diagnose heart disease with an accuracy rate of 89.01%. Four ML algorithms are employed to process the input dataset: Naive Bayes, Random Forest, SVM and Simple CART. A classifier model is trained and tested for each algorithm, and the results obtained from them are compiled. SVM has the highest precision value of 0.784, while Random Forest has the lowest precision value of 0.756. With a higher accuracy of 79.13%, the SVM model outperformed the other methods in [6]. In this case, the "Pima Indians Diabetes Database", obtained from the "National Institute of Diabetes and Digestive and Kidney Diseases", is the dataset under consideration. Khourdifi et al. [7] employed the KNN model to predict and classify heart diseases. He used the UCI heart disease dataset and an accuracy of 99.7% was achieved. Sriram et al. [8] achieved a 90.26% accuracy with the in- corporation of the Random Forest model. The "Parkinson's disease voice dataset" was obtained from the "UCI Machine Learning repository at the Center for Machine Learning and Intelligent Systems". Parthiban et al. [9] applied automatic learning methods to diagnose cardiac related diseases present in patients diagnosed with diabetes. WEKA has been used to implement the Naive Bayes and SVM algorithms. The Chennai Research Institute's data set of 500 patients has been used. The Naive Bayes algorithm has an accuracy 74% whereas SVM has the highest accuracy of 94.60%. To detect heart disease, Chaurasia et al. [10] proposed using data mining approaches. The algorithms used in this case are bagging, Naive Bayes and J48. A data set on heart disease with 76 attributes is available from the UCI machine learning laboratory. Prediction is based on only 11 attributes. Naive Bayes achieved an accuracy of 82.31%. J48 provides an accuracy of 84.35%. Bagging yields an accuracy of 85.03%. Thus, on this data set, bagging has been able to provide a higher classification rate. Vembandasamy et al. [11] made use of the Naive Bayes algorithm for detection of cardiac diseases. The information used came from one of the Chennai's most renowned and

DOI: rp-9788770040723.003

leading diabetes research institutes. The dataset consisted of 500 patients. WEKA tool is used and 70% of the Percentage Split performs classification. Naive Bayes has an accuracy rate of 86.419%. A study waspresented by X. Liu et. al. [12] using a hybrid classification system devised upon the RFRS method in order to help in heart disease diagnosis. There are two subsystems for the proposed system: an RFRS featured selection system along with an classification system with an overall classifier. The maximum classification accuracy for the given model is of 92.59%. Maniruzzaman detected the diabetes disease by using certain ML algorithms [13]. The diabetes risk factors were identified using the Logistic Regression (LR). The model performed with an accuracy of 90.62%. Mohan et al.[14] put in place an effective heart disease prediction system. An accuracy of 88.4% was achieved using the HRFLM upon The Cleveland dataset. Daghrir et al. employs three ways to arrive at a conclusion on a given system: KNN, SVM, and CNN. Because of its efficiency and versatility, it outperforms KNN. Although an SVM classifier performed quietly, the CNN is regarded as a more strong and resilient classifier, giving an accuracy of 85.5%.

III. PROPOSED METHOD

Here we are proposing the solution to overcome long hospital cues and cut the costs of doctor visits just to know your health status after a blood test or diagnosis. Nowadays a blood test is easily available at the doorstep and the results are delivered via email or door to door. But reading and understanding the result data. We proposed a solution where anyone can easily access our web application for free and check for any potential harm they possess as per the blood report or not.

Our webpage is simple with an easy user interface. Any user with a little bit of knowledge can check the status of a patient or even the patient can check the status of his/her health via our web application.

Patients just have to put their data in their respective fields and click on predict to get their results in simple language. Our model is much more user-friendly than the previous models. Our model is an end-to-end system for prediction. Our main purpose is to serve general people with easy medical assistance. Our backend does not store the data of any patient so we don't ask users for their names or mobile number. The sole purpose is to help people and that is served through this model. By making use of web technology and AI people in remote areas can also get access to health care. Using technology in a better way, healthcare can be made affordable for everyone. We have used a light ML model that can load within no time without compromising the accuracy of the prediction. Light models quickly load which helps in better response to the page. This Web-App provides a wide range of predicting the contamination of multiple infectious diseases as in Diabetes, Kidney disease, Liver Infection, Heart Disease & Cancer. Though this app provides a wide rangeandhighspeedtheaccuracyhasnotbeencompromised.

Hyper-parameters have been selected very carefully so that the accuracy is not hampered.

As shown in Fig.3, Our system is always active and patients need not wait for doctor's visits or wait in queues. They can easily put in their report values and get the prediction for their health.

[start
{
Read details from html form
Process the details and check with the machine hearing model.pkl
Predict it is '0' or '1'
Check the value for '0' or '1' Send the output via html static
}
end]

Helping others is the only goal, and this methodology does that. People in faraway locations may now receive healthcare thanks to web technologies and AI. Healthcare may be made more accessible and inexpensive for everyone by utilising technology effectively. We have employed a quick-loading, lightweight ML model without sacrificing prediction accuracy. Light models load rapidly, improving the page's responsiveness.

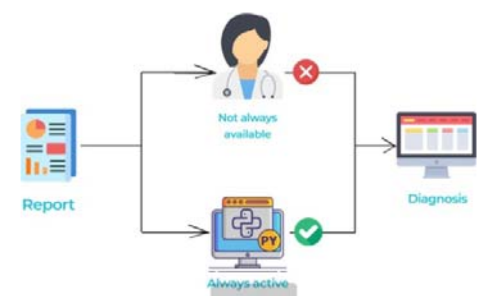

Fig. 3. Our model ideation

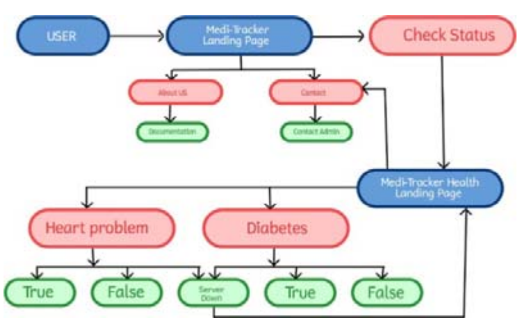

Fig. 4. Working of Model

We are using binary logistic regression, as shown in Fig. 4, to predict our patient's and user's health status.

In binary logistic regression, the predicted outcome has only two values (1 or 0) or (Yes or No)

It is the most utilized regression model where the value is either 1 or 0. Unlike fuzzy logic it has only 2 discrete outcomes.

If 32◦C is considered to be hot and any temperature below that is termed as cold then binary logistic regression would distinguish it as -

- 29◦C - Cold
- 31◦C - Cold

DOI: rp-9788770040723.003

- 31.9◦C - Cold
- 32◦C - Hot

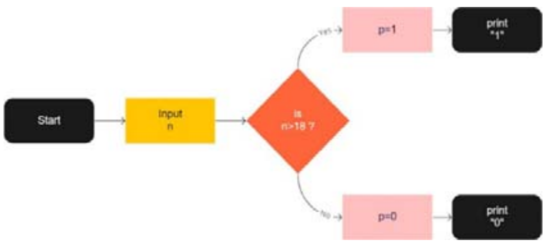

Fig. 5. Flow of Work of binary logistic regression

B. *Accuracy*

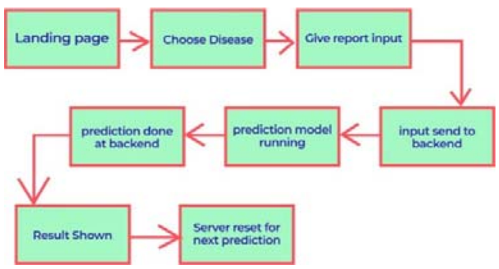

Fig. 6. Flow of Model

IV. Experiments

A. *Training Details*

The Patient Diagnostic System, that is, Medi Tracker, was trained using logistic binary regression which gives discrete results as True or False, we gather data to and forth an HTML page in the form of a form, connected to the Python virtual environment in the background.

B. *Metrics*

1) *Accuracy:* The accuracy of the model is calculated by comparing the prediction of the model to the ground truth. The mathematical calculation of the overall accuracy is done using True Positives, True Negatives, False Positives, and False Negatives as the parameters.

$$Accuracy = (TP+TN)/(TP+TN+FP+FN)$$

C. *Experimental Results*

The dataset used was extracted from Kaggle to train the prototype, based on the trained process. When the input is given, the data has been successfully validated for the potential occurrence of the diseases with an accuracy of 96.97%.

V. Conclusions

All the previously developed machine learning algorithms and models could predict only one disease and had a low accuracy rate. In our study, we have attempted to retain a high accuracy while removing one significant flaw seen in earlier models used for the diagnosis of patient diseases- the low accuracy rate of predicting the patient's disease. We have incorporated one singular platform for all the diagnosis of a wide range of diseases, which increases the efficiency and convenience of use by regular people, with an accuracy of 95.62%.

***Abstract*—Purpose- Artificial intelligence (AI) is growing at an exponential rate in healthcare, and a variety of applications have been created to help solve some of the biggest challenges facing health organizations. Some of these applications include artificial intelligence in diagnostics and treatment planning, while others are designed to improve communication and collaboration between health professionals. Virtual assistants that are powered by AI in healthcare applications can help people to live healthier lives, learn more about topics they're interested in, and change their behavior if needed. Artificial intelligence (AI) is a software that emulates human psychological development. This is being done through the use of healthcare information and advanced analytics techniques. This is having a major impact on healthcare, as it allows for better care for patients. Artificial intelligence (AI) is used to help doctors make better predictions about the health of patients who are having surgeries. This helps to reduce the amount of time needed for them to make a decision about what to do next. This information is used to improve the quality of care for patients. This includes techniques like natural language processing for unstructured data, current deep learning, and machine learning algorithms for structured data, like support vector machines and neural networks. AI is used for illnesses like cardiology, neurology, and cancer. Health authorities need to be aware of the current state of AI technologies and the potential applications they could be used for in the healthcare industry. This would allow for better value-based care to be achieved.**

Design/Methodology- For the research work, five cities were chosen, Delhi, Mumbai, Kolkata, Chennai, and Hyderabad. These cities were selected as a study focus primarily because these cities attract both international and local visitors because of their highly qualified doctors and excellent medical facilities that use AI technology. These cities are home to top-notch healthcare facilities, super-specialty hospitals, and research and diagnostic centers, making them the fastest-growing locations for receiving medical care.

In order to conduct this research study, structured questionnaires were used. The data was gathered using the convenience sampling method. The sample size for the data collection was 500, and it included men and women from a range of age groups, economic levels, and occupational backgrounds.

Findings - From the study, four factors emerged which have been labelled as "Perceived awareness", "Perceived accuracy", "Anonymity", and "Convenience". Furthermore, it has been found that factors "Perceived awareness", "Perceived accuracy" and "Convenience" have a significant influence on Consumer Trust. This study examines the acceptability, potential benefits, and challenges of using artificial intelligence (AI) in healthcare, as well as the potential implications on the healthcare system as a whole.

Keywords — Artificial Intelligence, Healthcare Service, Chatbot, Convenience

I. INTRODUCTION

Artificial intelligence (AI) is described as machine intelligence as opposed to the intelligence of individuals. [14]. Artificial intelligence refers to any agent or piece of technology which can reconstruct human behavior in educating, reasoning, and decision-making by observing and understanding its environment and implementing the measures required to optimize its possibilities of success. AI and associated technologies are becoming more popular in business and society [8]. It is bringing a radical transformation to healthcare because of its ability to harness the power of big data. An AI system extracts relevant information from an extensive clinical setting to assist in the development of real-time inference for potential risk detection and health diagnosis [16]. And enhance evidence-based clinical decision-making [5], and deliver value-based care that can be utilized to enhance the efficiency, safety, and access of health services spurred by increased accessibility of healthcare data and the speedy proliferation of analytics tools [10]. Supporting the digital transformation of healthcare is prompting a public dialogue over why AI will potentially substitute healthcare professionals [15]. We suspect that robots, will not surpass medical professionals in the coming years [11]. AI will enhance the effectiveness of healthcare provision by facilitating the lives of patient practitioners, and nursing personnel by undertaking jobs that would generally be performed by individuals, with less effort and for a significantly lower price [4].

Artificial Intelligence can support practitioners in making optimal clinical judgments and potentially replace verdicts in certain areas of healthcare [6]. That enables healthcare systems to deliver more effective treatment to more patients and helps doctors improve the workflow of healthcare practitioners enabling them to devote greater effort to delivering personal attention to patients and reducing burnout by taking human judgment into account in specific healthcare areas, including radiography, and by making better clinical judgments overall and minimizing the unavoidable diagnostic and treatment blunders that occur in human clinical practice [19].

DOI: rp-9788770040723.004

The feasibility, possible advantages, and difficulties of using artificial intelligence (AI) in healthcare are examined in this paper, along with any potential effects on the healthcare system as a whole. The goal of healthcare is to become more interactive, anticipatory, customized, and proactive.

II. Review of Literature

Recently, there have been a lot of advances in data science and artificial intelligence. There's a new phase of AI that's different from earlier ones, but research in artificial intelligence for a variety of applications has been ongoing for a few decades. This is because recent AI applications and technologies, like healthcare, are more efficient because of the way they use computers, have a lot of data, and are populated by a large number of skilled people [12].

There is general agreement that artificial intelligence (AI) tools will help to improve human labor in healthcare settings, rather than replacing healthcare professionals. Healthcare workers may benefit from AI's ability to assist with a range of activities, from operational processes to hospital records and patient contact. Specialized services like image processing, medical equipment management, and patient monitoring may be especially well-suited to AI [2]. There are many different opinions about the best ways to use artificial intelligence (AI) in the healthcare industry. The most crucial sectors, according to Forbes, would be administrative processes, image processing, telerobotics, chatbots, and making decisions about patient care [13].

AI is desperately needed in the medical field to diagnose diseases. A number of fascinating advancements in this area have made it possible for medical professionals to detect a variety of ailments earlier and with greater accuracy [18].

There are many potentials uses for artificial intelligence (AI) in diagnostics. AI can help doctors diagnose colorectal cancer more quickly and with better accuracy. This can help improve a patient's chances of surviving the disease. Additionally, various limits of ML in diagnostics have been discovered by scientists and they've made recommendations on how to lessen the impact of these downsides [7]. As a result, AI still has a lot of potential in diagnostics.

Natural language processing (NLP) is the study of how computers can understand and respond to human language. This can involve things like chatbots, which are computer programs that can talk to people like a human [9]. Healthcare chatbots may help make doctor-patient and clinic-patient interactions more accessible, help people keep track of their medication adherence, or help people have teleconsultations with doctors. This technology is still in its early stages of development, but there are many potential benefits to be had [3]. The chatbot technology helps you do things like surveys about your health, create reminders for you, communicate with healthcare teams, schedule appointments, access and analyze health data, or translate diagnostic patterns based on what you know about your health [1]. In spite of the fact that the majority of doctors in a US survey of 100 doctors thought chatbots might help with making doctor's appointments, finding medical centers, and delivering information about medications, more than 70percent also said they couldn't cater to all patients' requirements, displayed emotion and may put patients at risk owing to improper self-diagnosis [17].

III. Objective of the Study

To identify the factors influencing Consumer Trust toward Artificial Intelligence in healthcare.

IV. Figures And Tables

KMO and Bartlett's Test

Kaiser-Meyer-Olkin (KMO) measurements of sample adequacy have a scale from 0 to 1, with values closer to 1.0 being considered ideal and values less than 0.5 being considered inadequate. A Kaiser – Meyer – Olkin value of 0.887 was obtained from our findings. This indicates that there is a substantial quantity of data overlapping or that the variables have a high coefficient of determination. As a result, factor analysis is possible. The results of Bartlett's Test of Sphericity is substantial since the significant value is less than 0.05. (0.000). These tests provide the minimum conditions that must be met before doing factor analysis when taken into consideration.

Total Variance Explained

Each component represents a quality score, known as an eigenvalue underneath the title 'Total' of 'Initial Eigenvalues.' Parameters having an eigenvalue higher than one are selected for deeper examination as they solely reflect actual value.

Factor 1 which has been classified as **"Perceived awareness"** reports 38.748% of the total variances.

Factor 2 which has been classified as **"Anonymity"** reports 16.031% of the total variances.

Factor 3 which has been classified as **"Convenience"** reports 6.515% of the total variances.

Factor 4 which has been classified as **"Perceived accuracy"** reports 5.400% of the total variances.

Rotated Component Matrix[a]

From Rotated Component Matrix, we have labeled factors:

Factor 1: Perceived Awareness

The Variables associated with the factors are as followed.

V1: AI is being used in healthcare in the development of predictive models- **(.785)**, **V2**: AI has the potential to enhance patient outcomes while lowering costs and boosting productivity- (**.769)**, **V3**: Healthcare professionals make better decisions about patient care by using artificial intelligence to develop personalized treatment plans- (**.753)**, **V4**: AI is being used in healthcare is in medical imaging- (**.721)**, **V5**: An artificial intelligence algorithm can analyze medical images to detect potential health issues- (**.713)**, **V6**: The complexity of AI technology and the jargon used to describe it can be

DOI: rp-9788770040723.004

a barrier to its widespread adoption in healthcare- (**.690)**, **V7**: Many people don't know what AI terms mean, and it can be difficult to understand how they're being used in healthcare-(**.644)**, **V8**: There is a potential for AI to reinforce existing biases in healthcare, which could lead to increased inequality-(**.641)**, **V9**: AI algorithms are merely as good as the training data they are given, and if the training data is prejudiced or uneven, the algorithms may end up confirming those prejudices- (**.637)**.

Factor 2: Anonymity

The Variables associated with the factors are as followed.

V10: AI can be used in healthcare while protecting the privacy of patients by anonymizing data-(**.872)**, **V11**: The researchers and healthcare professionals are working together to use AI without compromising the privacy of patients-(**.816)**, **V12**: One way to protect patient anonymity is by using secure data transmission and storage practices- (**.814)**, **V13**: Healthcare providers and researchers can use secure data transfer protocols and encrypted storage to protect patient data from unauthorized access-(**.813)**, **V14**: AI is used in healthcare to help patients, but it is important to make sure that their privacy is protected-(**.728)**, **V15**: Healthcare providers can use artificial intelligence (AI) to help them diagnose and treat patients while maintaining their privacy-(**.699)**.

Factor 3: Convenience

The Variables associated with the factors are as followed.

V16: The automation of repetitive tasks, faster medical diagnosis and treatment, and more individualized care are all possible with AI-(**.795)**, **V17**: Chatbots and virtual assistants can provide access to medical advice and support, such as symptom checking and medication reminders, 24/7-(**.726)**, **V18**: AI can be used to monitor patients remotely and provide real-time updates to healthcare professionals-(**.672)**, **V19**: AI can be used to analyze patient data and predict potential health risks or complications-(**.666)**.

Factor 4: Perceived Accuracy

The Variables associated with the factors are as followed.

V20: AI algorithms can often perform at a level comparable to, or even better than, human experts-(**.833)**, **V21**: AI algorithms are properly developed and trained to avoid biases or inaccuracies-(**.784)**, **V22**: AI has the potential to improve the accuracy of healthcare diagnosis and treatment by providing training and oversight-(**.665)**.

H0: There is no relationship between Consumer Trust and the factors, “Perceived Awareness”, “Anonymity”, “Convenience”, and “Perceived Accuracy”.

H1: There is a relationship between Consumer Trust and the factors, “Perceived Awareness”, “Anonymity”, “Convenience”, and “Perceived Accuracy”.

TABLE 1: MODEL SUMMARY

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.82[a]	.66	.659	.6910

Predictors: (Constant), Perceived Accuracy, Convenience, Anonymity, Perceived Awareness

The above Table 1 shows that the R-square value is 0.66 indicating 66% of the total variation in Consumer Trust which can throw light by the factors, “Perceived Awareness”, “Anonymity”, “Convenience”, and “Perceived Accuracy”.

TABLE 2. ANOVA[a]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	199.148	4	49.787	104.275	.000[b]
	Residual	400.266	495	.477		
	Total	599.414	499			

Dependent Variable: Consumer Trust

Predictors: (Constant), Perceived Accuracy, Convenience, Anonymity, Perceived Awareness

Table 2 shows that the p-value is less than 5% which came as 0.000 in the results which means that the model is acceptable.

TABLE 3. COEFFICIENTS[a]

Model		Standardized Coefficients Beta	t	Sig.
1	(Constant)		69.188	.000
	Perceived Awareness	.785	19.651	.000
	Anonymity	.055	1.389	.166
	Convenience	.140	3.511	.001
	Perceived Accuracy	.163	4.085	.000

Consumer Trust = 3.268 + 0.785*Perceived Awareness + 0.163*Perceived Accuracy + 0.140*Convenience.

The impact of the factor **Perceived Awareness** is found to be the highest. And the factor **Perceived Accuracy**, and **Convenience** has a significantly low impact compared to **Perceived Awareness**.

V. CONCLUSION

Artificial intelligence (AI) has brought in many changes in medical practice, which include digitalizing data acquisition and analyzing the treatment techniques of various diseases and finding out possible ways to prevent them. Artificial intelligence systems are used to help doctors make better decisions about patients' health. They are used to help diagnose problems, train health workers, and research new ways to improve health care. Over time, AI systems will become better at doing all of these things on their own, without our help. Furthermore, the main challenge we are facing is not the lack of technology itself, as it is rapidly evolving and uncovering various new areas of its use, more so the legal framework requires appropriate regulation and political and financial transformation in the healthcare sector.

***Abstract*—Using the Web's inherent link structure, the Hyperlink-Induced Topic Search (HITS) algorithm identified and ranked sites based on their relevance to a search query. However, it solely considered the hyperlink structure and overlooked the contents of web sites and the reality that various hyperlinks on the Web may have varying degrees of value. In this research, we offer a unique page ranking method that integrates the hyperlink using the triadic closure theory, considering both the Vector Space Model (VSM) as well as the TrustRank algorithm, in an effort to counteract the aforementioned subject drifts. The approach initially determined the degree of relevance between two arbitrarily selected websites by comparing their subject matter and the number of references they shared. Then, a new eigenvector was built on top of that model to iteratively determine each page's authority and hub value. Following this, we used the trust-score technique to determine how trustworthy each page in the first group actually was. With our proposed Web page ranking algorithm against three traditional HITS-based methods, including the Web Page Topic Resemblance, Conventional Benchmark Degree, and Trust-degree algorithm. Based on the experimental findings, it is clear that our suggested method is superior than the other four traditional enhanced techniques and the HITS methodology.**

***Keywords* — HITS, trust degree, vector space model, hub value, web mining.**

I. Introduction

The usage of a web search is ubiquitous in the pursuit of knowledge on the Internet. Search engines take a user's keyword input, then utilise ranking algorithms to order results and send them to the user.Three common approaches are used to categorise the relevant information for search engine page rankings.Two well-known algorithms are used to analyse the structure of hyperlinks [1].

They leverage the interconnected network of links between pages to its maximum potential, abstracting the relationships into a knowledge graph and iteratively determining a rating for each page.In order to determine how these search engine results pages are ranked, page rank as well as HITS are extensively used metrics.Using a combination of co-link analysis, social network analysis, and a semantic clustering algorithm, Yang presented a Web site ranking model for identifying subject communities among academic websites (SNA) [2].

Page Rank as well as HITS algorithms have flaws that are becoming more obvious as they are used more widely in search engines.To address these issues, researchers have developed several enhancements for HITS.Using a vector space algorithm to determine the resemblance between the web links and the user requests, Jones's probability ranking and an ontological selection ranking model determined the cardinality for internetpages of search engine results [3].An all-encompassing probabilistic framework for WPSS (web page scoring systems) has been created.

To rank websites for Web crawlers, we used the cell-like transmembrane computing optimization technique (CMCFC), which considered not only the main text of each page but also the content of any anchor links, page titles, and paragraphs immediately around them.Combining the hyperlinks and the word distribution across online pages, using formal concept evaluation to build the concept context graph, and then rating the web sites based on this, is what the semantic ranking does.

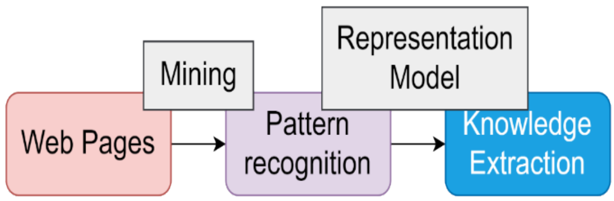

Fig. 1. Overview of web mining process

By examining the semantic relationship between Web sites, a relevance context graph was built from link (hyperlink) context graphs, allowing URLs with the same subject to point to each other.The rankings values for the specified webpages may be predicted using the relevance context graph.In order to direct Web crawlers, the idea context graph coupled the interlinking of web sites with the addition to online pages to create a concept ranking of web pages.HITS, a traditional scoring method, is widely used and successful websites between them. Overview of web mining process is shown in Figure 1.

In this case, the content material on the hub sites is relevant to the authority website that is directed to by those hub pages.The authoritative websites are linked to using hypertext from the hub page.In the HITS method, the values of the hub and authority pages are positively correlated; that is, a high-quality hub page will link to many high-quality authority sites, and a high-quality authority page will be linked to by many high-quality hub pages [4].

The HITS algorithm, on the other hand, simply uses the internal and external link counts of the correspondingly ranked web pages to determine rankings.

As a result, the symbiotic nature of host- and topic-drift connections will become problematic.Some studies and methods have been developed to address the issue.By giving website content from the same server significantly less weight, they suggested the BHITS(Bharat's enhanced HITS) algorithm.The issue of mutual reinforcement was nearly fixed.

To improve their capacity to anticipate the relevance of web sites, Zong et al. devised the P-HITS (Probability-based HITS) method, which uses probability to choose URLs from a list of URLs and incorporates the meta data of hyperlinks.They proposed the SALSA algorithm, which combines the query-related features of the HITS algorithm with the random walks employed by PageRank.The XHITS model was suggested on the basis of the HITS-hub and authority degrees of web sites, both of which allow for the concealment of semantic knowledge within hyperlinks [5].

The model introduced a unique machine learning technique for calculating web page rank scores, extending previous work on hubs and authority to include additional feature ideas.These techniques, however, rely only on the structure of the links themselves.Some integrated methods based on hyperlink and content analysis were developed to address topic drifts.Results show that including semantic text into the HITS algorithm improves its performance.In contrast, there are additional algorithms that make use of data gleaned from things like user comments or Web server logs.

In this paper, we present a unique ranking algorithm on the basis of HITS by combining the harmonic progression convergence theory with the TrustRank algorithm, which considers both the page content and the links between pages (R-HITS).The testing findings confirmed the efficacy and superiority of our suggested algorithm, demonstrating a decrease in topic drifts and an improvement in the quality of retrieval [6].

II. Literature Survey

Web page rankings are determined by HITS and HITS-based algorithms. Three issues that these algorithms have yet to address are the filtering of irrelevant hyperlinks, the prevention of subject drift, and the existence of mutually reinforcing ties across Web pages [7]. Here, we introduce the original HITS method and various updated versions of the algorithm for ranking Web sites, and then we critically examine their performance. HITS is an algorithm that just analyses links; it does not consider the text of web pages and cannot determine whether connections are more important than others.

For this reason, once Kleinberg published the HITS algorithm, several academics investigated it and offered many enhanced algorithms for addressing the various application criteria. HITS calculate a page's hub value as the total of the authority values of all pages that connect to it. A page's authority score is calculated by adding the hub scores of all the pages that link to it. For this reason, a hub page that links to numerous low-authority pages would have a larger hub weight than one that links to fewer high-authority pages [8].

Borodin et al. presented the Hub-Averaging method to address this shortcoming. At first, Lempel and Moran attempt to merge the best features of Page Rank with the HITS algorithm, creating a system that takes use of HITS's strengths where they pertain to the user query's topic and also incorporates Page Rank's random walk model. In reality, several experimental data demonstratethat SALSA provides superior search results to Page Rank and HITS [9].

Today, it ranks high among the most effective algorithms for link analysis. The Hub-Averaging algorithm is a combination of the HITS and SALSA procedures. This is an operation that can be performed using the algorithm. The purpose of ARC is to collect quantitative a set of credible web sites on any subject [10]. The core of the system is an algorithm that analyses text and links locally before reaching a "global agreement" on the finest resources available.

The HITS algorithm has been implemented by a wide variety of systems for the purpose of categorising websites. As a result, Teoma was able to apply a similar method to rank websites. It has been claimed that these methods can produce more relevant results in a search than either text-index search engines like AltaVista or directory-index search engines like Yahoo. Despite the fact that several trials have demonstrated that HITS yields useful search results over a broad spectrum of query topics, this approach may run into the following issues due to its utter disregard for textual contexts throughout its implementation [11]. It is often accepted as true that a website's pages and links are all the work of a single contributor or group.

A single "user's" opinion on quality is all that should be reflected in them. But HITS algorithm doesn't take that into account when determining a page's importance and authority. Unfortunately, it is not uncommon for many pages on the first host to all refer to the same page on the second site, p1.In each of the examples above, one "person's" perspective lends disproportionate weight to the respective website.Tools that create web pages sometimes include extraneous hyper connections like navigation links, commercial links, and other regularly created useless links.However, HITS do not include in how closely the page's content relates to the subject matter of the user's inquiry.Furthermore, it gives equal weight to all hyperlinks, despite the fact that the relevance of numerous hyperlinks may vary [12].

As a result, the HITS algorithm unfairly prioritises the less-relevant or irrelevant hyper link (links).The most popular authority (hub) websites have nothing to do with the subject matter of the user's search [13].Distraction from the

DOI: rp-9788770040723.005

original topic might occur for two main reasons.There are a couple of possible explanations for this: first, it's possible that the basic set B was obtained by include irrelevant or less relevant web page(s) in the root set R expansion process, and second, hub web sites contain several themes [14].

HITS algorithm might give more weight to the TCK page if it detects a cluster of unrelated web sites.In this research, we use HITS and the traditional HITS-based algorithms to propose that the degree of subject similarity between web sites, the degree to which they share references, and the degree to which they can be trusted are all crucial in determining where on the web each page should be ranked [15].Web page concept resemblance is a semantic feature used to prevent subject drift and filter irrelevant pages; a higher degree of shared reference can increase the value added by a common web page(hyperlink) while decreasing the impact of a mutual hyper link on a page's rank.A higher trust level may eliminate certain unhelpful connections [16].

I. PROPOSED SYSTEM

A targeted crawler's primary objective is the rapid indexing of as many relevant web pages as feasible. We need to give a more efficient means of locating pertinent websites. The adjacency matrix's building blocks are believed to be these connections that have some level of significance. In this research, we examine how three factors - web page subject similarity (brief as PTS), common reference degree (brief as CRD), and Trust Rank of Web Page - affect the relevance between any two given web pages.

Crawled websites need to be analysed so that keywords may be extracted from the complete text, title, anchor text, and surrounding paragraph language. There is now widespread usage of the Vector Space Model (VSM) in the conventional information retrieval sector, and manysearch engines utilise similarity calculations relying on this approach to rank websites. The following is a breakdown of how VSM is used to determine the degree of similarity between a web page's content and the subject matter of a user's search query as:

$$\vec{e_y} = (x1j, x2j, x3j \ldots\ j), \vec{r_k} = (r1, r2k, r3k \ldots\ rnk) \quad (1)$$

where$\vec{e_y}$ represents the web page and $\vec{r_k}$ defines the query initiated by the particular user. $xnj$and rnksuch that $1 \leq l \leq n$where these are the relative importance of the terms ulon web page $ej$and subject rkin the user's query, and $n$refers to total elements on script $ej$and topic rk. The Maximum - likelihood Document Frequency formula is used to assign relative importance to individual words in a corpus such that:

$$x_{lj} = ueg_{lj} . je\ lj\ \frac{gl}{gmax} . log\ \frac{O}{ol} \quad (2)$$

Where $O$is the cumulative quantity in documents over$C$regarding the manipulatorrequest discussion, olrefers to quantity of scripts such as ul, ugl. and$jeglj$. are the term intensity and reversetext recurrence of the descriptor ulin ejor a request response issuerk, respectively, and $gl$is the happenings of the term ulin web page ejor the query response context rk. User query subject phrase weights are also calculated.

Cosine likeness is used to calculate the degree of similarity between the topics covered on the web page $ej$and also the user's query subject rksuch that:

$$S(\vec{e_y}, \vec{r_k}) = \cos(\vec{e_y}, \vec{r_k}) = \frac{\sum_{i=1}^{n} xlj.xlk}{\sqrt{\left(\sum_{i=1}^{n} x_{lj}^2\right)\left(\sum_{i=1}^{n} x_{lj}^2\right)}} \quad (3)$$

If page Phas a link to page Qthat reads $qP \rightarrow qQ$, then page $Q$is being promoted by page P. Furthermore, it indicates that the writer of qPendorses the ideas expressed in qQ. As a result, we may conclude that the contents of $qP$and $qQ$are highly comparable if there is a hyper connection $qP \rightarrow qQ$between them. Let's suppose that the likeness among $qP$and $q$is $tP$and that the resemblanceamong$qQ$and manipulatorrequestissue$q$isqQ.

We may therefore interpret the sum of $qP$and qQas the degree to which propositions $P$and $Q$are same in terms of q. In this work, we refer to this similarity as the subject similarity between websites. It's seen as a potential component that impacts the significance of a pair of seemingly unrelated pages. The significance of the hyperlink $qP \rightarrow qQ$increases as the degree of topic similarity between the two web pages increases. Without such context, the connection is irrelevant.

So, thelikenessamong web pages $qP$and qQbuilt overrequest$r$is derived as the result of multiplyingtjandtk, where $tj$and $tk$are the similarities of web pages tjandtklinked to the query q. The similarity between web pages is represented as follows:

$$S(qP, qQ) = \begin{cases} tj\ .\ tk\ ,\ if qP \rightarrow qQ (qP \neq qQ) \\ 1, & qP = qQ \\ 0, & otherwise. \end{cases} \quad (4)$$

Here, we'll incorporate the concept of triadic closure into our study on social networks. Please begin by explaining and critiquing the concept of triadic closure. There is a higher chance of friendship between two people in a social network if they share a friend or two in common. This is the first and foremost rule of triadic closure.

When two nodes Y and Z share a friend X, the resulting edge between them forms a triangular shape in the social network, with edges coming from and connecting all three nodes X, Y, and Z. This triangle "closes" at its third edge, which connects points Y and Z. If we take two pictures of a social network, one after theother, we will often uncover many new edges connectingpeople who had a shared neighbour in the first image dueto triangle-closing.

DOI: rp-9788770040723.005

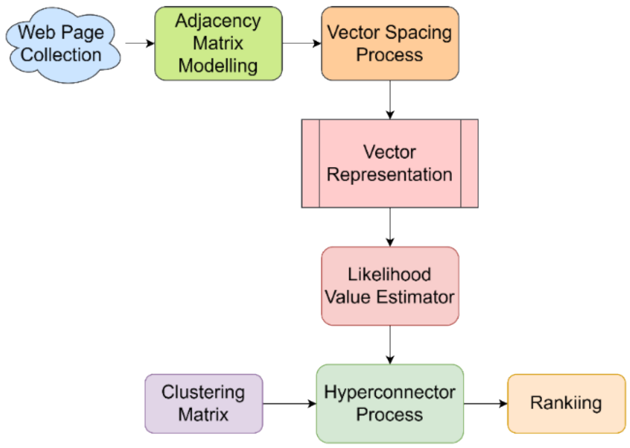

Fig. 2. Process flow of proposed model

The theory of harmonic progression is extended by two theorems. The initialleewaydeduction may be stated as follows: if a set of people has a large number of mutual friends, then it follows that the chances of those people becoming friends themselves increase. There are only two people who both person X and person Y know in common. All three of Yand Z's mutual pals are named A1,B1, and C1. The following inferences can be made with little effort.

The likelihood of A1 and B1 becoming friends in the imminent is developed that of A and B. As an illustration of the second extension theorem, we may say that the likelihood that two people will become friends increases if their common friends have deeper ties with one another. The web itself may be seen as a directed graph, as is common knowledge. Hyperlinks between websites are represented by edges in a directed graph, while nodes represent individual pages.

We already established that if page P has a hyper link to page Q, then P endorses Q. By including a link to another work, the author of work P implicitly endorses the work in question. If we think of the Internet as a social network and each webpage as a person, then the friendship between two websites is analogous to the friendship between two people. In particular, if two nodes P and Q are connected by an edge may both signify the friendship between the two people in the social network, and the hyper link between the two web pages in the web network. The process flow of proposed model is shown in Figure 2.

Because of this, the theorem proving the applicability of triadic closure theory in social networks may be applied to the World Wide Web. Here's a more in-depth explanation: Web sites P and Q seem to be more likely to expound on the same topic if the ordinary in-degree between them is bigger and the unusual in-degree between them is lower. The evidence suggests that websites P and Q may be more pertinent. Consequently, the degree of common reference is another aspect that impacts the significance of any two pages chosen at random.

In order to identify spam websites, the TrustRank algorithm described by Gyongyi et al. was implemented. A website's credibility on the Internet is determined by the algorithm. The basic premise of this technique is that more trustworthy pages will have their trust scores slightly lowered but remain extremely high if they are linked to from a page with a higher TrustRank. The TrustRank algorithm was at first created to help identify spammy websites. However, TrustRank was more commonly utilised in the search engine ranking algorithm. Websites' overall rankings are frequently impacted by this.

Values of TrustRank are often calculated at the level of the domain in the search engine ranking algorithm. The more the host's trustworthiness, the greater the aggregate ranking's strength. Like the PageRank algorithm, the TrustRank algorithm relies on a massive amount of information available on the World Wide Web. For this reason, Asano et al. suggested a trust-score method based on the TrustRank algorithm. A trust-score is assigned by the trust-score algorithm to every page in the HITS basic set Q.

For the vast majority of user query themes, Asano et al. conducted exploratory studies, discovering that more than half of the root set of web pages are credible and relevant to the particular algorithm also relies on this premise: This leads to numeroussides in the underlyingcause set v is a trustworthy; and if page v is connected from many dependable, then page v is a dependable authoritative web page. Denote these sets by their initials: $R$for the collection of roots, Was vertices, and $F$for the edges.

We present a ranking system that considers a web page's trustworthiness in addition to its topical similarity and degree of shared referencing. The suggested approach offers two improvements over the HITS algorithm. By merging the page topics that are comparable and the degree of common reference, a new clustering matrix is formed. The updated adjacency matrix is then used to calculate the core and authority values. The second is calculating the credibility of each website in the B. To determine a page's rating, we consider both its core or credibility value and its trust-degree. First, we create the new transformation matrix B by linearly combining the matrixes article theme resemblance and common evaluation level. Also, we can denote as:

$$B = \mathrm{P} + \gamma \text{where } 0 \leq \mathrm{P} \leq 1, 0 \leq \mathrm{P} \leq \gamma \text{ and } \mathrm{P} + \gamma = 1. \quad (5)$$

In this approach, the parameters and define how adaptable the resulting adjacency matrix $B$is, whereBmn = $\mathrm{P}mn$ + $\gamma mn$is a matrix element. Next, the new transitive matrix $B$is used to determine hub and authority values. Also, the entire technique of calculating is identical to that used by HITS. This is how the new iterative formulae are written:

$$b = B^T i \quad (6)$$

$$i = Bb \quad (7)$$

$$bj = \sum k \in (j)\ Bnmik = \sum k \in JK(j)(\mathrm{P}mn + \gamma mn\ )ik \quad (8)$$

$$ik = \sum k \in (j)\ Bnmbk = \sum k \in PM(j)(\mathrm{P}mn + \gamma mn\ )bk \quad (9)$$

In this approach, the parameters and define how adaptable the resulting adjacency matrix $B$is, whereBnm =

DOI: rp-9788770040723.005

$Pmn + \gamma mn$is a matrix element. Next, the new transitive matrix $B$is used to determine hub and authority values. Also, the entire technique of calculating is identical to that used by HITS. This is how the new iterative formulae are written.

II. Results and Discussion

Here, we examine the proposed system to three traditional advancing algorithms based on HITS and choose a large number of subjects with MAP, F-Measure, and DCG to evaluate the algorithm's performance. The experimental data shows that compared to three competing algorithms, our suggested approach for ranking web pages yields much better results.In our trials, we compare our proposed method to the HITS algorithm and three other well-known enhancement algorithms (BHITS, SALSA, the Hub-Averaging, and ARC).You may shorten their names to HITS, SAHITS, and ARCHITS.

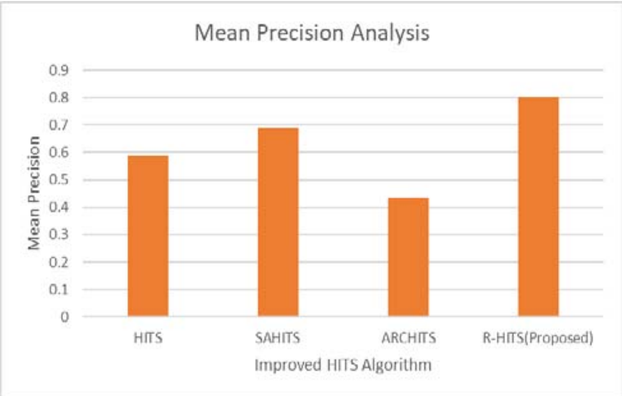

Fig. 3. Mean Precision Analysis

Virtualization, wall climbing, drinking, the Olympics, the railroad, the kayak, the yard, cheddar, Hepatitis, and the Kabuki theatre are only ten of the numerous categories from which we selected user query topics to showcase the experimental outcomes.Our investigations make use of root sets Bs that are composed of the top 200 results from a subject.For example, the ARC method's group B includes webpages that are link-distance three separate or less from at minimum, but in the HITS algorithm this was done just once.

We discovered that 20 iterations is a good number to utilise in tests since iteration quickly converges.Using indices such as MAP (Mean Average Precision), F-Measure, as well as DCG, the effectiveness of the aforementioned six algorithms may be assessed (Discounted Cumulated Gain).For each algorithm, in particular, the average value across all user query subjects represents its precision.

Accuracy is how many highly relevant results an algorithm returns in comparison to how many results are found in the top 10 for a given algorithm.The recall measures how many of the most relevant results returned by an algorithm are included in its top ten list.If the VSM-calculated similarity among the page's subject and the query response topic is more than the threshold value of 0.5, then the page is considered relevant.DCG's key notion is that a page's score should be deducted if it has a better grade than one that is higher in the ranking.

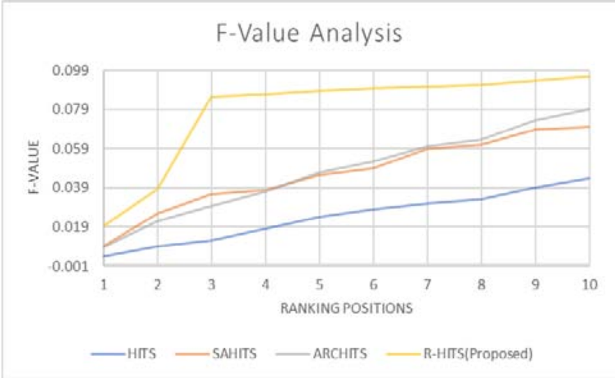

Fig. 4. F-Value analysis

First, the proper relevance degree is assigned to the website that falls inside the Top10 websites discovered by each algorithm.In particular, the page receives a score of 0 if the likeness between the homepage and the user querytopic falls within the range [0.0, 0.25]; if the range [0.25, 0.5] is crossed, the page receives a score of 1; if the range [0.5, 0.75] is crossed, the page receives a score of 2; and if the range [0.75, 1.0] is crossed, the page receives a score of 3.In this case, n is set to 10, which indicates that we are analysing ten different web sites for this result rank.

We calculate themes for each method in the tests.It's easy to spot similarities between the three figures:Compared to the other five methods, the values of the proposed method are clearly greater.In particular, the HITS method has a MAP of 0.6716, the BHITS algorithm has a MAP of 0.5107, SALSA has a MAP of 0.8258, Hub-Averaging has a MAP of 0.7043, and the suggested approach has a MAP of 0.9609.

Based on these results, it can be concluded that the suggested method has a higher MAP value than the HITS algorithm (by 43.0%), the BHITS algorithm (by 88.2%), the SALSA algorithm (by 30.9%), the Hub-Averaging algorithm (by 16.3%), and the ARC algorithm (by 36.4%).Overall F as well as DCG scores of the proposed method show clear superiority over the RC algorithms over a range of search engine rankings.When x = 0.5, they display how the proposed algorithm's values vary with varying.Each of the three characters shares some traits with the others.

Nonetheless, the MAP (F and DCG) values develop at varying rates, with the highest rates occurring when = 0.On the other hand, when = 0, the values are practically identical.Furthermore, the smallestvalues occur at = 0, while the largest occur at = 1.Examples like these shows how subject similarity across web pages may significantly improve a page's position in search results.When = 0.5, they illustrate how the suggested method performs in terms of MAP, F, and DCG.

DOI: rp-9788770040723.005

Fig. 5. Performance analysis for different ϑ values

The values of MAP (F and DCG) in all three figures tend to decrease as x increases, which indicates a common denominator.When going from x = 1 to x = 1, however, the rates at which the values decrease are quite large.Values are also maximal at x = 0 and minimal at x = 1.These examples show that t(vi), the trust degree, had a minor impact on the ranking of websites.Indicating that the suggested algorithm is superior in its capacity to place high-quality websites at the top of search engine results.In addition, they validate our contention that the subjectsimilarity of websites is a significant factor in the suggested website rank.

III. Conclusion

Using harmonic progression closure concept, vector space models, and the TrustRank algorithm, we provide a new page ranking system in this study. Subject similarity, degree of sharedorientation, and are all defined. To iteratively determine authority and hub values, a novelmodel is built according to the subject similarity of web pages and the sharedorientationgrade. In addition, by integrating the trust-score method, we establish the degree of confidence we have in each website in the baseline collection. Last but not least, the score has been derived by combining thehub value along with degree of trust. Experimental findings reveal that our suggested page ranking method locates higher-quality Top10 websites than the HITS, BHITS, and ARC algorithms. In the past, there may have been some theme drifts, but HITS can help fix that. In conclusion, we have created a HITS-based algorithm that successfully returns the top 10 web sites that best answer user query subjects.

***Abstract* — Skin cancer is one of the most dangerous types of cancer. Deoxyribonucleic acid (DNA) damage left unrepaired in skin cells results in genetic flaws or skin cancer. Early diagnosis of the condition is essential due to the rise in skin cancer cases, high mortality rate, and pricey treatments. Researchers have created methods for the early identification of skin cancer after realizing the severity of these issues. From the detection of skin cancer and melanoma, different factors like symmetry, color, size, and shape are understood. This study offers a thorough, systematic discussion of machine learning methods for skin cancer early detection. We examined research on the detection of skin cancer that was printed in credible peer-reviewed journals. This paper offers a summary of a computer-assistedanalyticalmethodfordiagnosingmelanoma.Itwillalsointroduceanoverviewofautomaticskincancerdiagnosisbyimageanalysisusingimageprocessingtechnologybasedonmachinelearning.This review's objective is to give researchers whodecidedtoimplementmachinelearningforcancerdiagnosticsas anopportunitytolearnthelatestdevelopmentsfromscratch.**

I.INTRODUCTION

Skin cancer is one of the most dangerous varieties of cancer. Skin cancer is as a result of unrepaired deoxyribonucleic acid (DNA) in pores and skin cells, inflicting genetic defects or mutations with inside the pores and skin Due to the growing range of pores and skin most cancers cases, excessive mortality,and comfort treatment, early analysis of the circumstance is necessary. Recognizing the seriousness of these problems, researchers have advanced techniques for the early detection of pores and skin most cancers. Different parameters alongwithsymmetry, color, length and form are acquainted to pores and skin most cancers detection and cancer identification. In this paper, we provide a detailed systematic review of machine learning techniques, a prominent area of research aimed at building devices that mimic human intelligence for fitness maintenance. The application of ML in fitness does not currently update doctors, but it can provide a better path to health issues. So take a look at these work Specific strategies for early detection of cancer are mentioned correct diagnosis of this disease Skin cancer that develops inside melanocytes is known as melanoma ,which can be cells inside the outer layer of pores and skin (epidermis). Melanocytes produce a pigment known as melanin, which offers color to pores and skin. Melanin offers the pores and skins its tan or brown color and protects the pores and deeper layers of the pores and skin from the dangerous consequences of the sun turns out to be anomalous, developsout of control, and actively invades the surroundings organization. Melanoma can also affect the pores and skin, or spread to other organs and bones through the blood and lymph flow. Melanoma is the most prominent form of most cancers of the skin. Melanoma can be cured if treated early, but if left untreated, most melanomas expand to different components of the body. Surgical intervention and early detection to eliminate cancer and successfully cured the largest number of cancer cases. However, it is often irreversible in later stages. Melanoma can be diagnosed using four parameters (ABCD).

A very accurate system that can identify skin lesions was created by Hassan El-Khatib et al. [5] using a deep learning-based approach. They suggest brand-new classification schemes based on a variety of classifiers, including neural networks and feature-based approaches. Depending on its computed accuracy, each classifier (method) assigns a specific weight to the final decision system, enabling the system to make better conclusions. First, they developed a neural network (NN) that can tell benign from malignant melanoma. During the training process, evaluation is used to analyse the NN architecture. Some biostatistics parameters, such as accuracy, specificity, sensitivity, and Dice coefficient are calculated and classification was done by using a support vector machine

According to Teck Yan et [6] dermoscopy images were used to predict the prognosis of skin cancer using a modified version of the Particle Swarm Optimization (PSO) set of rules for function optimization. The proposed PSO set of rules is used for function optimization because determining the most significant distinguishing characteristics between benign and malignant skin lesions plays a significant role in the diagnosis of strong skin malignancies. It now also includes multiple matrix representations to prevent premature convergence of the original PSO set of rules, in addition to subswarms, nearby and mutation-predicted nearby exploitation. To put it another way, distant swarm that show health but low function proximity are utilized to guide the subs warm-based search and to enable the investigation of more different look for areas. It is also suggested to use modified speed updating techniques to allow the debris to follow multiple swarm bellwethers and avoid the local and ecumenical worst individuals, partially (i.e. in arbitrarily designated sub-dimensions) and (in each dimension), with the goal of searching for ecumenical optima. Use probability distributions and dynamic matrix representations to diversify your hunting strategy. The UCI database, several unimodal and multimodal reference functions, and proposed PSO variations examined with multiple skin lesions point to superiority.

An artificial neural network classifier (ANN) classifier that categorises specific datasets as malignant and non-cancerous based on their attributes was proposed by Christo Anant et al. [9]. Malignant melanoma can be distinguished from benign melanoma by specific characteristics. Using feature extraction techniques, these features are extracted. The 2D wavelet transform and 3D designated by K feature extraction techniques are employed. An procedure known as back propagation is used to train the ANN. You will receive the feature estimate and its actual output in this way. Initialization of inputs is random. The inputs are adjusted throughout each cycle in an effort to reduce the error between the desired output and the actual yield. The application of predicted ANN classifiers to decision-making and pattern recognition is effective.

DOI: rp-9788770040723.006

Enakshi Jana et al. [10] focus on different methods that can be used for segmentation. Commonly used segmentation algorithms include feature extraction from the segmented image, such as k-means, histogram thresholding, and image of the feature set extracted from the segmented image. there is. Various demotion algorithms are available for this purpose. The latest skin cancer detection techniques descend using machine learning and deep learning based algorithms. The most commonly used demotion algorithms are support vector machines (SVMs), feed forward artificial neural networks, and deep convolutional neural networks. This paper provides a study and analysis of current skin cancer detection techniques and a brief comparison between state-of-the-art algorithms.

The deep CNN model proposed by Neema M et al. [11] can classify melanoma types into benign or malignant classes. In this work, a less complex model was used and an accuracy of about 70% was achieved. Future extensions of this work include modifying the prediction accuracy by adjusting parameters and redesigning the network for cases with multiple classes that can detect different categories of skin lesions. The proposed system is a highly effective tool that contributes to timely and diverse assessment of disease. The system also has a built-in use cordial, using her GUI in explainable form.

Barataet al.[12]revealed that a great deal of work has gone into developing a diagnosis tool for the most deadly type of cancer, melanoma. The Global system, local feature, and bag-of-feature are the two separate systems that are discussed in this research for melanoma detection in dermoscopy images. Skin lesions are categorized using a global approach. Melanoma is classified using a classifier that uses either a bag-of-features or a local feature. Additionally, it contrasts the colour and texture features in lesion classification to see whether set of features is more discriminating. Both strategies produce excellent results when the colour feature is used alone

Satheesha, T. Y. et al. [13] highlighted the use of artificial neural networks, receiver operating characteristics (ROC), and non-invasive computerized dermoscopy to evaluate images and diagnose melanoma. Melanoma, a dangerous illness, currently has a greater fatality rate among skin cancer patients. The highest death rates are among the middle-aged and elderly. Due to the fact that it has developed notably past the dermis of the skin, it has been judged to be dangerous. The algorithm consists of these three steps: The initial lesions are obtained using a Self Generating Neural Network (SGNN). Using the feature extraction formula, the second feature description of the tumor's size, texture, and boundaries is extracted. Using a support vector machine, portions of the third lesion are categorized according to their phases (SVM). Images from non-invasive computerized dermoscopy display lesions that are visible due to their size. Due to its improved sensitivity and precision, the recommended system will be more efficient than the present computerized dermoscopy method. Compared to the current system, the suggested one is more accurate. Using multiple photos, the algorithm was successfully tested and delivered accurate segmentation.

III. CONCLUSION

Early detection of melanoma allows for effective treatment. Dermoscopy image processing and machine learning methods will be extremely affordable and widely accessible. Some dermoscopy equipment for computer analysis can be utilized in clinics and even at home. Getting the right diagnosis and treating the anomalies at the key stage of skin cancer requires expert advice and the use of the appropriate techniques. For a person's well being, proper consideration should be given to identify the disease using classification, feature generation, lesion segmentation, and feature segmentation

***Abstract*—During these modern days everything revolves around technology, thus everything is getting digitized. From teenagers to working age groups use technology, so it is important for computers to classify digits based on handwriting. Many of them have different handwriting which sometimes cannot be identified by humans themselves, so what we have to do is by using machine learning we could make the computer read with an accuracy of 95%. This will surely benefit the process of storing old documents without retyping everything as it will consume a lot of time, instead they can take a picture of the documents and upload into the system which will in turn go through it and show it in text form. On this topic we have done our share of research, and also we have implemented it practically. All types of handwritten documents can be read with a high percentage of accuracy, which makes many people's lives easier. The project is still in its development and early stages, but once it reaches its destination it could be very useful.**

***Keywords*— Artificial Intelligence, MNIST Dataset, convolutional Neural Networks, digital reading, Machine Learning, Deep learning**

I. INTRODUCTION

MNIST digit classification using a machine learning algorithm for handwritten digit recognition has a great importance in recognition of the optical character , not only that this digit classification can also be used in theories as a test case and not only that they can also be used for machine learning algorithms. The digits that are handwritten are first preprocessed, which includes both normalization and segmentation So that it is possible to compare recognition results on some common basis and reduce their work for the researchers.Not only machines but even humans have a problem reading few types of handwriting as they are unique and different but nowadays everyone are opting for the digital technology.Retyping all the handwritten documents manually into the computer is a very difficult and tiring job .Artificial intelligence computer vision techniques had made it very easy because of which everything can be digitized and not only that, it will also make it easy for the teachers as students answer script can be corrected directly with the help of machines, just by uploading the scripts and marks. Also can be easily updated in the computer with ease .That is why conventional neural networks was developed so as to read whatever type of

\

handwriting more than 95% accuracy.This type we can see in google lens that is currently used by many people .This

also can be implemented in account and finance department for both private and public sectors in which they can upload a number of querie. This will be of tremendous benefit to us as it reduces the chance of human error and also can reduce time consumption and make our lives easier .So it reduces human error and also saves time. One more thing is that it as the main method in schools are paper and pen mode there will be many documents from which they are supposed to be digitized every year and manually doing that will take them forever so the best method would be to upload it and that should be digitized by the help of AI which will make their work easier . Our final goal is to make as much as accuracy while predicting handwritten dataset with the help of Convolutional Neural Network and machine learning. One of the most essential data sets for evaluating the effectiveness of the convolutional neural networks and learning algorithms is indeed the MNIST handwritten character recognition classification data set. Learning algorithms such as k-nearest neighbors (KNN), random forests, svm (SVM), and simple neural network models may easily achieve 97%-98% accuracy on a test set of 10,000 photographs when using 1 million photos as the training set. Convolutional neural networks (CNN) improve this accuracy to over 99% with fewer than 100 misclassified photographs in the test set. The last 100 photographs are becoming more difficult to correctly identify. More complex models, careful tuning of hyperparameters such as learning rate and batch size, regularization methods like batch normalization anddropout, and so on. augmenting of training data are required to enhance accuracy after 99%. We obtain a model capable of achieving extremely high precision on the MNIST test set without the requirement for sophisticated structural elements or learning approaches. One of the most frequent model designs is a collection of convolution layers followed by a completely linked layer at the end. We employ fundamental data augmentation strategies such as translation and rotation. We train three different models with comparable architectures and use majority vote to choose the best model.The final forecast The designs of the three models are identical, but the kernel sizes with in convolution layers change.Experiments demonstrate that merging images with various kernel sizes

DOI: rp-9788770040723.007

improves precision more than mixing models with a similar kernel size.

II. Literature Review

[20]MNIST (Modified National Institute of Standards and Technology) is a classic dataset used in the field of machine learning for the task of image classification. It consists of 70,000 images of handwritten digits from 0 to 9, with each image being a 28x28 grayscale image. The MNIST dataset has been widely used as a benchmark dataset for evaluating the performance of various machine learning algorithms, including deep learning models, for image classification tasks.

In this literature survey, we will review some of the recent studies on MNIST digit classification using machine learning algorithms.[19]Authors compared the performance of various deep learning models, including Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and Autoencoders, for MNIST digit classification. They found that CNNs outperformed the other models, achieving an accuracy of 99.35%. The authors also showed that data augmentation techniques, such as rotation and translation, could improve the performance of the models.[2]Few other authors have also investigated the effectiveness of transfer learning for MNIST digit classification. They compared the performance of various transfer learning approaches, including fine-tuning and feature extraction, using different pre-trained models. The authors found that transfer learning could significantly improve the performance of the models, achieving an accuracy of up to 99.7%. Usage of some deep learning and neural networks for us to get a image representation is high on demand in this modern era.Image processing has a huge number of publications already.In our paper we are going to show how to classify images based on using CNN. The fashion domain also uses classification of digits and it has a lot of benefits .It also has a lot of work that was published on it. All humans have a different handwriting which is very unique so the computer finds it very difficult to understand each type of handwriting.For us to improve the accuracy to over 99% then we have to view complex methods like some careful tuning For some like learning rate and batch size which have few regulations such as training data augmentation and normalization of batch is need for hyperparameters .MNIST test accuracy is approximately 98% accurate on a few papers .In this paper we will produce a model that can be achieved which has a higher accuracy on MNIST test which will also be very simple.The model also uses convolution layers which have fully connected layers at the end. ,these are one of the commonly used model architectures .Basic data augmentation schemes,translation and rotation are used .Three models which have similar architectures and also use majority voting between the models to obtain some final prediction .They have architectures which are similar but have different kernel sizes .we can give better accuracy by combining different kernel sizes more than combining different models.We present a model that achieves very good precision here on MNIST testing sample without the use of sophisticated structural elements or learning approaches. One of the most frequent model designs is a collection of convolution layers followed by a completely linked layer at the end. We employ fundamental data augmentation strategies such as translation and rotation. We train three models with comparable architectures and then use majority vote to get the final prediction. The designs of the three models are identical, but the kernel sizes in the convolution layers change.Experiments demonstrate that combining models with different kernel sizes improves accuracy more than combining models with the same kernel size.

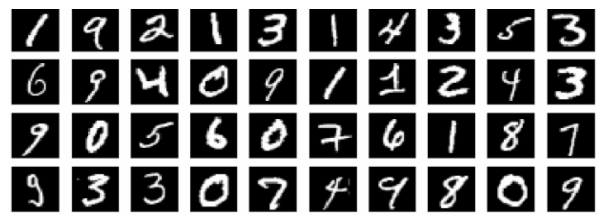

Fig. 1. Image used for testing the digit classification

III. Previous Advancement

This section discusses the most modern strategies for handwritten numeric digit categorization, as well as the benefits and drawbacks of each methodology.

Shulan et al. introduced a cascade CNN which has two stage with outstanding performance. Here a cascade CNN approach is based on complimentary differentiation of few objectives between Stage I and the consecutive next stage. By feeding directly poorly recognised training samples, learning is little discriminative which is added to train Stage II. Experiments were carried out on the highly competitive MNIST handwritten digit database. Their cascade model outperformed all others in terms of performance. The drawback of this approach is that it takes more time than other procedures.

Hubert Cecotti studied the influence of several parameters and pre-processing methods of a distance based on picture distortion models on accuracy. One major problem is to lower the processing time of closest neighbor classification by taking rejection criteria and adaptive distances into account. The author evaluated the efficacy of this single character identification algorithm on three datasets of Indian handwritten numbers, one for each common Indian plot: Bangla, Devanagari, and Oriya. The authorsdemonstrated that extracting information relating to four orientations improves accuracy significantly. This method makes use of GPUs and high-performance clusters to deliver cutting-edge results.

The clustering algorithm used gives great performance but takes longer to cluster the input and construct the feature.Khedidja and Hayet studied the application of various differentiators or as we say classifiers which help in the identification of printed digits by describing the digits in a novel manner utilizing hybrid feature extraction. The study comprised three separate features estimated from extraction,cavities, zonal extraction, and retinal representations, and also nine distinct predictors, K-Nearest Neighbor - KNN - with varied distance measurements, SvmClassification - decision tree, and linear svm

DOI: rp-9788770040723.007

classification - LDA.-. Majority Voting takes into account classifier combinations. Experiments were done out on a dataset of printed numbers with multiple fonts and sizes. This approach has only been assessed for printed databases; it has yet to be analyzed and reviewed for handwritten digit databases.

Few people suggested a novel hybrid classification strategy for identifying printed numerals in their paper .To extract features, object region perimeter assessment, Fourier Descriptors, and a Chained code-based approach were utilised. A unique curve tracking Chain code based approach (CTCC) was introduced to recover curve knowledge from digit photos. Few multi layer and Dynamic programming employing a back propagation approach were used to achieve recognition (MLP-BP). The accuracy was increased to 99%. Although confined to printed digits, the proposed methodologies were simple, with higher identification accuracy and decreased time complexity.

Gattal et al. studied the use of several statistical and structural factors in the detection of solitary handwritten digits, a classic pattern recognition challenge. By merging multiple representations of non-normalized handwritten numbers, the authors attempted to enhance identification rates.

Some of these characteristics include statistical information, moments, feature and projection-based characteristics, and features derived from the contour and skeleton of the digits Some of these characteristics are taken from the whole picture of the digit, while others are retrieved from various sections of the image after the image has been subjected to uniform grid sampling. One-against-all SVM is used for classification. Experiments on the CVL Single Digit Database yielded high recognition rates similar to state-of-the-art approaches in this field.

Alkhateeb and Alseid introduced a Handwritten Arabic digits multi-class classification approach utilizing Dynamic Bayesian Network (DBN), with technological details provided in 3 parts: pre-processing, feature extraction, and categorization. The digits are first pre-processed and their sizes are standardized. Then, using the discrete cosine transform (DCT) coefficients technique, features are reconstructed from each normalized digit, and even a set of additional handwritten characteristics are added. digits are provided. Finally, theseTo develop a deep neural network for classification, attributes are employed. The proposed method was successfully evaluated on a Handwritten arabic digit database (AD Base), which had 70k digits produced by 700 different authors, as well as the results were encouraging and promising.

El et al. compared the efficiency To capture discriminative characteristics of handwritten digits, four feature extraction techniques based here on Discrete Cosine Transform (DCT) were developed. Upper left corner (ULC) DCT coefficients, zigzag DCT coefficients, and block-based DCT ULC coefficients and block-based DCT zigzag coefficients are the techniques. To assess the performance. The parameters of the each DCT variation are used as data input for the Svm Classifier. Their objective was to identify the optimum feature extraction strategy for enhancing classification accuracy while speeding up learning algorithms. The data demonstrated that perhaps the block-based DCT zigzag extraction of features performed well in terms of accuracy in classification and reduction rate. outperforms its competitors.

Babu et al. introduced a novel solution to off-line handwritten digit detection based on structural characteristics that eliminates the need for thinning and size normalization techniques. For digit identification, they employ four distinct kinds of structural features: number of openings, water tanks in four directions, optimum profile distance in 4 directions, and fill-hole density. To identify minimal distances, a Euclidean minimum distance criteria is utilized, and a k nearest neighbor classifier is used to categorize the digits. The MNIST database is used to train and test the system. A total of 5000 numerical pictures are evaluated to validate the suggested approach, with a high identification rate.

Singh and Lai [9] proposed a method for digit recognition based on a single layer neural network classifier and Principal Component Analysis (PCA). The created model minimizes the characteristics in order to decrease computing needs while accurately classifying the digit into ten groups (0 to 9). The developed system is a backward propagation (BP) neural network that has been trained and tested on the MNIST dataset of handwritten digits. On the MNIST 10K test dataset, the suggested approach achieved good accuracy. They took into account not just accuracy, but also training time, recognition time, and memory needs for the whole process.

They have also discovered the digits that the system misclassified.

IV. Algorithm

The CNN is a learning technique which is deep and where it automatically classifies input . The past few years CNN has been good at classifying images and also it is being used in many domains like healthcare and academic domain . One of the most reliable algorithm was indicated that it was CNN which is good at automated prediction from start to end. CNN also extracts very important features from the given input that makes it easy for us.Data entry professionals devote hundreds of hours to typing handwritten data into computers. It is a very time-consuming activity that also necessitates a high level of precision and fast typing due to the large number of entries that must be input.Various organizations spend tons of money transferring their documents from one format to another.Deep learning and machine learning are critical components of computer technology and artificial intelligence. Deep learning can minimize human effort in identifying, learning, predicting, and many other areas. As a result, we developed a Convolutional Neural Network System capable of automatically converting handwritten pictures to digital format with a 93% accuracy.

DOI: rp-9788770040723.007

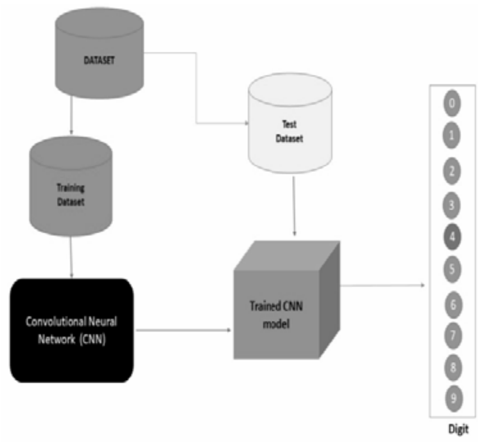

Fig. 2. CNN model

[1] It has very high features from few input data which are passed onto the other layer which is a feature map. This is the conventional layer.

[2] The data dimensions are reduced by feature map pooling,where dimensions are reduced by generating new feature maps.PL takes average or it might take maximum,this is done at Pooling Layer.

[3] FC layer completes the task of classification.Softmax function is where for each class the Probability scores are calculated and labeled a popular activation function.

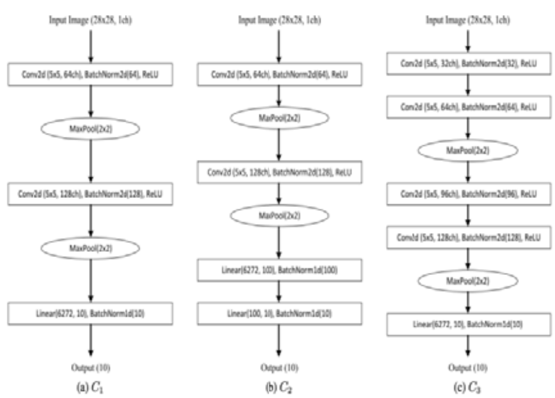

Fig. 3. Network model used for classification

V. Dataset

MNIST digit classification dataset is being used .The keras is in Python and MNIST as an API which is a dataset that is provided by the API. 60k -10k training images are available in it. This is a great way to individuals who need to go through pattern recognition just in a minimal amount of time.

The Keras API have four values returned namely- *x_train, y_train, x_test, and y_test*.

VI. Loading Dataset

The language used here is python. We used googlecolab for doing this python code. We can also use jupyter notebook or vs code

The steps that we followed :-

1. Add and create a googlecollab notebook.
2. Then we load the necessary libraries, we must load the MNIST dataset

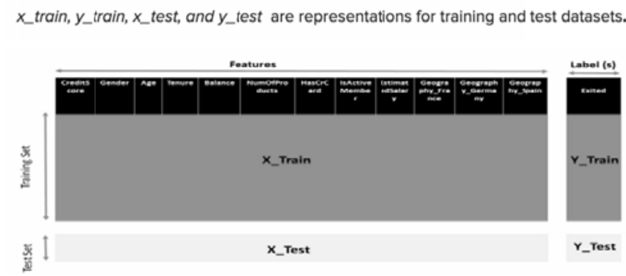

Fig. 4.dataset into training and test set

VII. Processing the Dataset

To improve the quality of the data it should be rectified,cleaned and processed .The best form of dataset has no null values and all numeric values are scaled.So in order for the data to be good for CNN we will be training the dataset .If we write X_train[0] we get images between 0-255. The output is a 2-dimensional matrix. writey_train[0] we will get 5 as output. The 0th image of this training dataset represents the number 5. Training and test datasets .we convert the 2-d matrix to a 1-d array after scaling.

VLII. Convolutional Neural Network Being Trained and Created

For the above code the input layer follows two hidden layers and a output layer.The activation function make key decisions if they should move forward or not.In CNN it has many neurons which are based on activation functions,the neurons fire up and the network moves forward. 'relu' is a activation function.The model is compiles and fit after it been created.The relations are viewed in the dataset during fitting. They will learn throughout the process as many times as has been defined. For every mistake it makes it learns and gets better accuracy each time.At the end of the epoch it gets the highest form of accuracy .A image has three dimensions: width, height, and channel. The MNIST dataset is a monochromatic image with the dimensions 28x28. In the shape parameter, we set the sample size to -1 so that it adopts the form of both the attributes ["x"]. The advantage is that the batch size may be tuned to hyperparameters. The first convolutional layer seems to have 18 filters also with kernel size of 7x7 with equivalent padding. The same padding has the same height and width for both the output and input tensors. TensorFlow then adds zeros to the columns and rows to guarantee that they are of the same size.Following the convolutional is the pooling process. This pooling computation will shorten the data's extension. With a dimension of 3x3 and a stride of 2, we can employ the max pooling2d module. We use the previous layer as input. The output size of the second CNN is precisely 32 filters. The convolution operation has the same size as before, and output shape is [batch_size, 14, 14, and18].to define the completely linked layer Before combining with the thick layer, the feature map must be compressed. With a size of 7*7*36, we may utilize the module reshape.

The thick layer will link neurons. We can and will implement an activation feature for Relu. A dropout regularization term will be added which has 0.3 as its rate, implying that 30percent of the weights are 0. Dropouts occur only during the training time. The mode input to the classification algorithm fn() function specifies if the model should really be trained or evaluated.

TABLE 1: OTHER ALGORITHM

4	Efficient CapsNet	0.16	99.84	Efficient CapsNet: Capsule Network with Self-AttentionRouting	2021
5	SOP CNN	0.17	99.83	Stochastic Optimization of Plain CNN with Simple Methods	2020

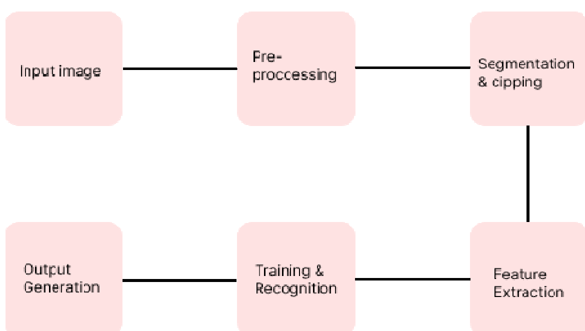

Fig. 5. Architecture of CNN

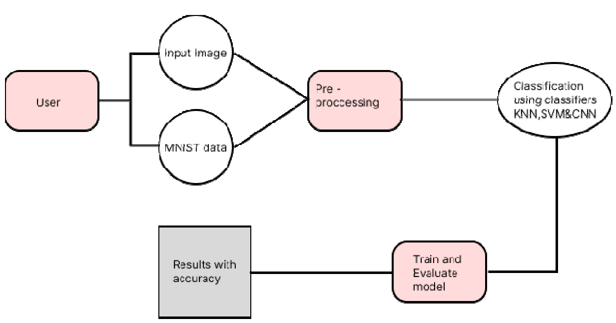

Fig. 6. Data flow Diagram of the system model

IX. MAKING PREDICTIONS

The test dataset has some predictions that are made and then they are stored in the data frame which is called the y_predicted_by_model . Calculation will be done for each dataset to see the probability score. The prediction made by the model is the highest probability score. We must define a tensor with the data's shape. We may accomplish this by using the reshape module. Here we must specify the tensor in order to shape it. The first for this argument is a data characteristic that is defined in a function argument.

X. CONCLUSION

In this paper we see how a dataset is divided and trained.MNIST was taken to make predictions using CNN algorithm and TensorFlow .The predictions were made to train the model and make an accuracy to upto 99% for digits 0-9.Using an aggregation of heterogeneous and homogeneous network models might improve performance up to 99.91percent of overall test accuracy, which is among the best available.

Studies using diverse configurations reveal that great performance is attained by a combination of approaches such as batch normalization, data augmentation, and ensemble methods, rather than by a single methodology or model design.

***Abstract*—In today's hectic lifestyle, over time, has arisen the need of looking after one's mental well being. However, many medical, social, financial and personal issues have turned out to be obstacles in timely detection and treatment of mental health diseases which may even cost the life of the sufferer. The presented work proposes a transformer-based mental health condition classification model and a sentiment-oriented response system to interact with the patient, giving human-like replies. Although numerous chatbots have been developed, very few have concentrated on the issues of mental health but that too with irrelevant responses. This approach aims at delivering positive chat system to the patients, using specific Reddit datasets for each category. The classification model resulted in an accuracy upto 93% and the response system has proven to be quite sensible and relevant.**

***Index Terms*—mental health, artificial intelligence, natural language processing, chatbot, transformers, sentiment analysis**

I. Introduction

During and after the Covid-19 pandemic, the social media caught its attention on a topic existing much before people knew about it and has been more important than people have believed it to be - mental health. While depression and anxiety are the two known conditions, there exist many more mental conditions which may arise due to emotional or psychological reasons and even due to irregularities in habits and lifestyle. Due to very less awareness about mental health issues and their signs and symptoms, the people suffering from many such diseases often become preys to prolonged mental illness, disorders and even suicides.

Due to such reasons, it is quite important to make people aware of their mental well being and so far it has been done by psychiatrists and psychotherapists. However, due to un- availability of a sufficient amount of professionals in this field and the unaffordable consultation fees and treatment charges have restricted people to get a cure of their mental issues andillness. Hence, in this running world of an hectic race, there is an urgent need of educating people about their own psychology and protecting them from the abstract wounds in a feasible manner. With the evolution of Artificial Intelligence and the introduction of chatbots, many individuals and organizations have aimed at providing aid to tensed people who have got a place to put their thoughts down without hesitation and feel a lot relaxed with their problems. However, there are several limitations with the response systems of these chatbots.

Firstly, almost all of them are oriented towards tackling depression and anxiety, putting no light on other mental health conditions. This leaving out leads to low efficacy of these chatbots and the users may get irrelevant responses which may not help them with their issues. Secondly, the way chatbots are designed becomes an obstacle in an interactive conversation and gaining actual feelings out of the users. As mentioned in the Wired article [1], chatbots like Woebot and Wysa though have claimed of being compassionate response systems, do not hold any proper survey report in the first place. Woebot is based on a guided chat system, does not allow the user to type his own words and instead provides input options. Although it is designed well, lacks human inputs and personalized response to each message. Wysa, on the similar ground, presents two different approaches of treatment- self-care and online consultation with a doctor, charging fees for both. Hence, although there are interactive chatbots to tackle mental health patients, their medical accuracy and user satisfaction turn out to be the major limitations. The presented approach, as shown in Figure 1 first classifies the patient into one of the 8 chosen mental health categories and then asks the user for inputs and giving them responses based on their categorized condition as well as the specific message, with a positive sentiment.

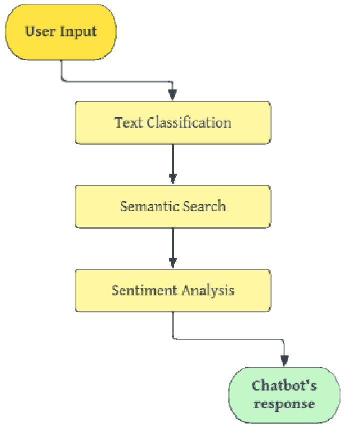

Fig. 1. Structural flow of the proposed work

II. Related Work

As rightly said in the Medical Device Network article [2], most of the mental health chatbots, instead of doing good, turning out to be harmful for their users, their market is unregulated and they do not have government's approval due to the lack of empirical evidence to back their efficacy and usage. The review paper by Alaa et.al. [3], concludes that the majority of the chatbots concentrated on depression and autism. However, there are many other major mental conditions and illnesses which the people should be aware of and the chatbots need to put light on. The presented work aims at dealing with 8 such categories and present an approach so that many more can be added.

Haoet. al. [4] in their work concluded that self-help chatbots helped university students in dealing with depression in a com- paratively better way than bibliotherapy which uses literature to cure the suffering. They further state that the process of conversation matters more than the content and have used statistical methods to illustrate their point. Their chatbot turned out to be much natural one as it involved emotion recognition and Natural Language Understanding(NLU) for interpreting user inputs and then used Natural Language Generation(NLG) with a response database to reply to that input. However, their chatbot was still based on the conventional dialogue management system that involves the user to choose from given options to give his inputs. A major aim of this workis removing this step of dialogue management and generate responses only on the basis of the user inputs, so as to give emphasis to every single input message.

Falguni et.al. [5] in their paper, have presented a chatbot that identifies the user's emotions based on text inputs and classifies each of them as one of the 8 chosen classes, namely joy, happy, shame, disgust, sadness, anger, fear and guilt. Further based on the negative emotions, the user is classified as normal, stressed or depressed. This classification and response system is a result of a pipelined process which involves ISEAR dataset for training and detecting emotion. Next in the pipeline is the classification step which uses CNN, RNN and HAN for categorizing the text into emotion labels and providing corresponding responses. This work takes up a similar approach but instead of categorizing text into emotion labels, classifies the user into one of the 8 mental health conditions based on his initial input.

In the review paper by Nick Boettcher [6], 54 studies and 425 abstracts were screened which dealt with Reddit data collection, focus on mental health conditions, analytics and practical implications. Approximately 63% of the studies based on practice implications suggested the use of Reddit data for professional practice related to human mental health. Some studies even suggested future applications of Machine Learning classification algorithms to help Reddit users access their mental health. As Reddit data appears to be a consid- erably good source of developing models and applications in the field of mental health [7], the Reddit community posts and their corresponding comments were scraped and manipulated to create a dataset for response generation.

Kim et.al. [8] in their paper, have presented a deep learning model to use social media user content and detect mental illness. They have used Reddit community data associated with each of the 6 mental illness classes, namely depression, anxi- ety, bipolar, bipolar disorder, autism and schizophrenia. They have used both XGBoost algorithm and CNN to accomplish the task of binary classification for each class and check if the illness exists or not. For depression they obtained upto 75% accuracy, 78% for anxiety, 90% for bipolar and BPD, 94% for schizophrenia and 96% for autism with their CNN model. The presented work too works on extracted Reddit dataset for the chosen conditions but has taken a step further by categorizing input into 8 categories and instead of binary classification that just checks the presence and absence of an illness, has used a category detection approach.

Anca et.al. [9], in their work have used the SMHD dataset[10] for mental health conditions and employed three deep learning models namely, BERT, RoBERTa and XLNET for disease classification. Similar to the previous paper, they have incorporated binary classification to detect the presence of 9 different conditions, namely depression, schizophrenia, OCD, eating disorder, PTSD, anxiety, BPD, ADHD and autism. Using this approach, they obtained accuracies ranging between 70-80%, each category holding its best accuracy in this range. The proposed approach has used BERT base (uncased) pre- trained model for categorical classification and has got muchbetter overall accuracy.

Taking insights from the cited literature, a novel approach is presented for creating a mental health chatbot involving multiple steps like condition classification, semantic similarity matching and sentiment analysis [11] along with database manipulation and querying. The proposed work aims at creating more personalized chatbot responses and make them motivational at the same time to reduce psychological illness at the grass-roots level itself.

III. Proposed Work

The presented work is divided into two sections - mental health condition categorization and sentiment-based response generation. Both the sections involve data extracted from Reddit communities, each dedicated to one of the 8 selected conditions namely Attention-deficit/hyperactivity disorder (ADHD), Anxiety, Asperger's Syndrome, Bipolar Disorder, Depression, Obsessive-compulsive disorder (OCD), Post-traumatic stress disorder (PTSD) and Schizophrenia.

A. Mental Health Condition Classifier

This stage of the presented work deals with classifying the user into one of the eight chosen categories of mental health conditions. For this purpose, a dataset of 7995 Reddit posts is used, which is a combination of around 1000 posts extracted using PRAW (Python Reddit API Wrapper) from each category's Reddit community. This dataset is cleaned during the preprocessing step and all the unavailable posts records are removed. These Reddit posts, at the time of extraction, are the top 1000 posts of their respective subreddits which makes them reliable enough to provide relevance to the training data as well as for responses generated using their comments.

Along with the posts data, corresponding comments are also extracted with their number of upvotes, post-link ID and their text body. In the later stages of the work, these comments are queried from the comments data table using post-link ID as the foreign key, hence mapping each comment to its subreddit post.

In the next step of this stage, the Bidirectional Encoder Representations from Transformers(BERT) base uncased model[12] is used which is a pretrained model trained on a large dataset of English language book corpus. This transformers- based model [13] takes in input ids, token type ids and attention mask [13] which are derived by applying the tokenizer method of this model on the posts body column in the cleaned Reddit posts dataset. The output labels are created as integer values ranging from 0 to 7, each representing a mental health condition. The model is trained on 90% of the dataset, the 10% being the test data, using Adam optimizer, categorical cross entropy loss function and categorical accuracy as the evaluation metrics. Finally, the output of the model is an integer, corresponding to a condition and is fed into the next stage, which is generating responses with respect to the data of this particular condition.

Unlike other works, the proposed approach does not use binary classification as first of all, it achieves an overall accuracy of 93% for category classification and detecting the disease itself is a better approach in case of mental health instead of detecting the presence of disease. This is because, if an input has the textual characteristics of multiple diseases, it is hard to identify the actual dominant illness.

B. Sentiment-based Response Generation

This stage deals with generating a response based on four conditions - class, sentiment, sentiment score and relevance. First of all, the class is the mental health condition taken from the output of the previous stage. So, if the associated class is Depression, the Reddit dataset comprising of two data tables - posts and comments, is looked upon and queried. In order to do so, a semantic search based sentence transformers model all-MiniLM-L6-v2 is used. Once the user has briefed about his condition in a few words, it is taken as an initial input to the chatbot. After condition categorization, this input is fed into the semantic similarity model which matches the input to all the posts of the condition's posts dataset. The best match is chosen and the post id is mapped to the comments table's link ids as the dataset is filtered to obtain all the comments associated with the matched post.

In the next step, DistilBERT base uncased finetuned SST- 2 model is used for the sentiment analysis [14] of all the comments in the filtered dataset. This helps to obtain the comments sentiment and a corresponding sentiment score. Since the approach is to provide consoling and motivating responses, all the negative sentiment comments are removed in order to obtain only the positive sentiment comments. Further, in the following step, the filtered comments dataset is sorted based on the positive sentiment score and the number of upvotes each comment has got from the Redditusers. This helps in getting the most relevant response and that too of a positive sentiment. It is important to note that responding with just the most liked comment can go against the primary aim of consolation as its sentiment can be negative and instead of motivating, can even demoralize the patient.

In this way, results for all the other mental health categories can be obtained and human-like responses can be given to every message as these are the replies given by actual humans, the Reddit users. [15] Furthermore, since these responses comprise of enough information required to respond to a particular message from the user, they can be used in the chatbot in stages while rest of the conversations can be handled using conventional conversational flows for chatbots. For example, if the detected mental illness turns out to be OCD for a patient, he can be redirected to a chat flow asking questions and giving responses based on OCD only. These conversations can then be used for extracting data from user responses and on aggregation, can be fed into the response generation module which provides a structural flow to the chatbot as well as informative responses only at the required stages and not making the conversation boring and question- answer based.

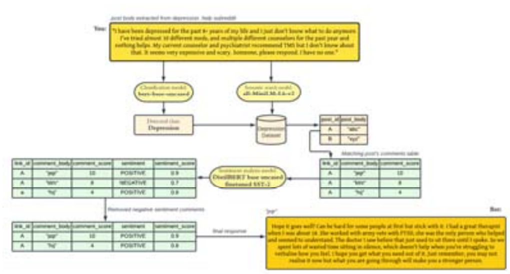

Fig. 2. Complete flow of work presented: a dialogue exchange

TABLE IA COMPARISON TABLE OF PREVIOUS WORKS AND PRESENTED WORK

S.No.	Publication	Mental health conditions	Classification accuracy
1	Falguni	8(emotion labels)	CNN: 75%, RNN and HAN:

	et.al. [5]		75%
2	Kim et.al. [8]	6	75-97% (binary accuracy for each category)
3	Anca et.al. [9]	9	70-81% (binary accuracy for each category)
4	Presented work	8	93% (categorical accuracy)

IV. Evaluation and Results

Upon evaluation of the classification model, the test data is put into play which constitutes the 10% of the Reddit posts dataset. Using categorical accuracy metrics, an accuracy of upto 93% is obtained for categorizing the patient into one of the 8 classes based on his brief about his condition. These results give the required reliability to the response system as the patient is only responded based on his condition. Other than this, this work stands out from other mental health Classification models since it covers more classes than the works done previously and the chosen classes are quite different from one another, which means that the patient does not get same responses in different classes of mental health. A comparative study of the previous works and the proposed work is depicted in the Table I. It can be clearly inferred that this work has more number of categories of mental health and has a sufficiently good enough accuracy in categorizing the patient to one of the eight of these. As illustrated in Figure 2, the initial input gets a relevant response in which the bot is telling its own story to which the user can relate and at the same time get motivated by the phrases used. Hence, the presented approach is able to generatea response to the user input maintaining reliability, relevance and sentiment, all at the same time.

V. Conclusion and Future Work

With the presented work, a chat response system is designed which first asks for an initial brief about the patient's condition and associates his to the corresponding class with an accuracy of upto 93%. On the basis of this assigned condition, a response to the input is generated after querying of Reddit posts and comments dataset based on similarity matching and sentiment analysis.

The work done so far incorporates multiple models for diminishing the limitations of previous chatbots and create a new design for a mental health chatbot. However, as the fields of psychology and mental health are quite vast, such works need regular updates and improvements. For a text-based chatbot, intent based tagging approach can be introduced for a much better interaction. Other than this, although there is a scarcity of mental health dialogue dataset, there is a future scope of creating such corpuses to train conversational models and based the entire chatbot on the basis of psychotherapeutic consultation.

Acknowledgment

We wish to acknowledge Reddit for making its data public for research purposes. We assure the organization, its members and users that we have scraped only its posts and comments text body and have taken no interest in the authors associated with them, hence maintaining the necessary confidentiality and anonymity.

***Abstract*— Learning is a process, in this course of long run it is necessary to measure it's performance on the major people discharging it. Because there is so much data available, using Deep Learning to anticipate what will happen in the future is becoming more and more common. The ability of deep learning to forecast students' academic performance is suggested by this study. At the end of the school day, students either pass or fail. When that happens, it's too late to save the students. To keep kids from failing, it is necessary to predict SAP in advance. When that happens, it's too late to save the students. To stop pupils from failing, it is necessary to anticipate their academic performance in advance. The study of data mining, machine learning, and statistics as they relate to information produced in educational contexts is known as education data mining (EDM). It is all about enhancing learning outcomes by examining data gathered while we lecture. The main goal of this paper is to give an appropriate method of measuring student performance using FNN, DBN, ICGAN-DSVM, LSTM, and BLSTM. This process involves collection of datasets, that is gathered from students' academic dataset which can be further enhanced by ICGAN that increases the data volume. It is discussed how the data were gathered, prepared, and developed. The models are built, trained and applied on the dataset. These results are compared to each other and are classified situationally to the requirement.**

Keywords*— Education Data Mining, FNN, DBN, ICGAN-DSVM, LSTM, BLSTM

I. Introduction

There lies a huge difference between learning, testing and deploying it in a real world. Performance of a student is based on these factors. These factors can be measured with various technologies such as machine learning, deep learning, etc. In the age of the information revolution, mathematics is one of the fundamental cornerstones for numerous subjects, as well as the backbone of scientific endeavor. A difficult activity that might assist students and teachers in monitoring student performance development is measuring student performance. Several strategies have been researched and compared to produce the optimum prediction model in an effort to improve the results of prediction. Learning is affected by various factors such as quantity of information, emotions, mistakes, novelty of the brain, learning styles, social learning, and teaching. Cognitive overload is the term used by brain scientists to describe the state in which a person's brain is overloaded with new information. Cognitive overload is caused by having too much new information, which eventually hinders learning. How might cognitive overload be lessened? There are primarily two methods. The first is the quantitative approach, in which you merely present less novel information. Before introducing new knowledge, you give students time to comprehend the majority of what they have learned. The other approach is qualitative, where you modify how you offer material to make it less intimidating. Research has shown that our emotions have an impact on every aspect of our lives, including how we remember information and how we interpret it. Kids, who are less mature, are especially at risk for this.

Students study a lot throughout the year and are tensed of proving it in an examination. Performance is measured based on testing, but this cannot prove an individual's content learned and applied. Considering various intrinsic values apart from the above ones, such as data being gathered on knowledge gained, skill growth, values clarification, and performance level. For all educational institutions, raising educational standards and student performance is of vital importance. There has been an increase in interest from higher education providers and institutions to adopt machine learning techniques to understand students' behaviors, learning patterns, and drop-out trends in education. However, educational analytics in learning has never been explored as is the case in the health sciences and chemistry.

Deep learning is chosen as a key for the following grounds. For more focused performance that is required to be similar to human activities, deep structures learning, also known as hierarchical learning, or Deep Learning (DL), first appeared in 2006. The capabilities of DL are strong in the areas of prediction, classification, identification, and detection. DL is more popular than other machine learning algorithms due to its ability to process both structured and unstructured data as well as manage large amounts of data. When it comes to prediction, DL has been used to a variety of issues, including the Intelligent Transport System and several economic and educational areas. Learning and higher education challenges have been addressed with DL in a number of studies in the realm of education. DL is effective for classifying, detecting, and identifying a lot of data in addition to prediction. Classifying, identifying, or detecting are examples of four DL tasks that can be combined and used interchangeably in a single study.

DOI: rp-9788770040723.009

Numerous problems need to be solved in education, particularly higher education. Starting with the most basic model, the Feedforward Neural Network, ICGAN-DSVM is best supported for small datasets, five classes of machine learning algorithms, and the Deep Belief Network (DBN) framework for deep learning were executed and compared.

II. RELATED WORK

Aya Nabil et al. [1] says that one of the significant research questions in the discipline of educational data mining is how to forecast the academic performance of students at a preliminary phase of a **course** (EDM). Subjects like "Data Structures" and "Programming" in undergraduate programs have significant failure and dropout rates because students struggle with a variety of issues. As a consequence, EDM is utilized to evaluate student data collected from different school environments in order to forecast the academic performance of students, which enables them to perform well in next courses. The primary objective of this study is to investigate the effectiveness of deep learning in the area of EDM, particularly in forecasting the academic performance of students and identifying students who are at danger of failing. Using the grades obtained in the courses written in the previous academic year, the K-nearest neighbor, decision tree, deep neural network (DNN), support vector classifier, logistic regression, gradient boosting and random forest were utilized in this paper to create models that would predict academic performance of students in future courses. Additionally, they compared ADASYN, SMOTE, SMOTE-ENN and ROS among other resampling techniques to address the issue of an unbalanced dataset. According to the experimental findings, the presented DNN model outperforms support vector classifiers, K-nearest neighbors, logistic regression and decision trees in predicting performance of students in the course of data structure and identifying students at threat of failing early in a semester. The result is obtained with an accuracy of 89%.

Mohammad Hafiz MohdYusof, et al. [2] proposed that the ideas of precision medicine have been adopted by precision education. It uses machine learning, algorithms, and techniques of data manipulation to make predictions, and will eventually be used to create customized school intervention plans. Numerous applications and themes in precision education research have been studied in this work. After that, a model was created using one of its techniques, deep learning in Malaysia. The purpose of the research is to forecast the performance of students in English. When the proposed deep learning model is tested for folder classification using three test datasets, it performs with 93% accuracy.

PhaukSokkhey, Takeo Okazaki [4] proposed that evaluating performance of students is a difficult undertaking that can assist both students and teachers in monitoring student performance development. One of the fundamental foundations of many topics, mathematics serves as the foundation for every scientific endeavor in the period of the tech revolution. Several strategies have been researched and compared to produce the optimum prediction system in an effort to enhance the results of prediction. In this article, they offered a comparative examination of machine learning (ML) algorithms, statistical analytic methods and a deep learning architecture for forecasting mathematics performance of students. The Deep Belief Network (DBN), a deep learning architecture, five classes of machine learning algorithms, and the statistical approach structural equation modelling (SEM) were used. The same properties from two datasets of varying sizes were employed. Random Forest (RF) was discovered to perform better than other models in predicting the performance of students across the three different datasets.

Kwok Tai Chui et al. [5] say that it's been established that supported learning has been extremely important in raising the quality of education. Tutoring in the classroom and at home offers pupils individualized support and constructive criticism of their learning. Predicting the performance of students, which shows their knowledge of the subjects, is of great interest. To provide a solid basis for upcoming courses and a profession, it is especially important for students to manage their core knowledge. This study proposes an enhanced conditional generative adversarial network-based deep support vector machine (ICGAN-DSVM) technique to forecast the performance of students in learning environments including classroom and home tutoring. Due to the nature of the student academic record, sample sizes are often small. Due to the academic dataset's limited sample size, ICGAN-DSVM offers two advantages: ICGAN increases the volume of data, while DSVM improves the accuracy of prediction through deep learning. The suggested ICGAN-DSVM produces specificity, sensitivity, and area under the receiver operating characteristic curve (AUC) of 0.968, 0.971, and 0.954, respectively, according to results from cross-validation of 10-folds. Additionally, the results indicate that including both home and school tutoring in the model may enhance performance over using just home tutoring or just school tutoring alone. A comparison between ICGAN & DSVM and the conventional conditional generative adversarial network has been done to demonstrate the need for ICGAN and DSVM. Additionally, the suggested kernel design using heuristic-based multiple kernel learning (MKL) is contrasted with conventional kernels including radial basis function (RBF), linear, sigmoid and polynomial. Following the presentation of the forecast of performance of students with and without GAN, a comparison with DSVM and regular SVM is made. In terms of the performance metrics specificity, sensitivity, and AUC, the suggested ICGAN-DSVM performs 8 to 29% better than comparable studies.

Yueh-huiVanesa Chiang, et al. [6] proposed that to forecast student performance in introductory computer programming classes, this paper utilized deep learning algorithms with Moodle logs. Particularly, this study would like to use prediction results to identify potential low-performing students who may need assistance from teachers. The results suggested that deep learning models are promising to predict student performance and identify low-performing students in the researched context. What the prediction results provided by the models can inform teachers in learning settings was also further discussed in this paper.

DOI: rp-9788770040723.009

DiaaUliyan [7] says that predictive analytics' ability to assist institutions judge performance of students is becoming more widely known. Big data analytics may offer information that supports academic performance and completion rates, like student demographic facts. For instance, analytics of learning is a crucial part of big data at universities and may give strategic decision-makers the chance to analyze learning activities across time. This study involved a two-year retrospective review of student learning data from the University of Ha'il. Bidirectional long short-term model (BLSTM), a deep learning approach, was used to analyze students for whom retention would have been at risk. The algorithm offers a variety of variables that may be used to gauge a new student's performance, which helps with dropout and early retention prediction. Furthermore, every student's label was predicted separately using the conditional random Field (CRF) approach for sequence labelling. The predictive model's experimental findings suggest that utilizing BLSTM and CRF approaches, student retention may be predicted with a high degree of accuracy.

III. Methodology

In this paper, we are discussing the different possible ways in the prediction of performance of students using deep learning technologies. The deep learning technologies that are discussed here are Feed Forward Neural network, Deep Belief Network (DBN), Improved Conditional Generative Adversarial Network based Deep Support Vector Machine (ICGAN-DSVM), Long Short-Term Memory (LSTM), Bidirectional Long Short-term model (BLSTM)and Conditional Random Fields (CRF). But before we apply the model, we need to do some steps which support the prediction. They are Collecting the data, Pre-processing the data, Method to validate the model and finding out the evaluation measures. Let us see each of these steps in detail.

A. *Collecting the Data*

In this step we need to collect the student data. To determine the performance of students with higher accuracy, we might require three types of data. They are Demographic data (Age, Gender, Area of location, Financial Status), Academic data (GPA and CGPA of students, Academic tests, Earlier test scores), and Behavioural data(Activity submission log, Library history).

B. *Pre-Processing the Data*

This process converts the data which is collected in raw format into the required format which is useful in acquiring the required result of predicting the performance.

a. Cleaning the data: In this step, the values which are missing are removed.

b. Data Discretization: In this step, attribute values of continuous data are converted into finite set of intervals. For example, let the student's data has different categories based on marks like Excellent, Very Good, Good, Poor, Fail. We can convert it into two categories called Pass and Fail in this step.

c. Encoding the feature: As the algorithm doesn't understand categorical data, we convert all the categorical data into numerical data. We can use label encoding for this.

d. Handling Imbalanced Dataset Problem: Suppose we have two class labels. They are Pass and Fail. Pass have higher number of occurrence than Fail. So Pass becomes the majority class and Fail becomes the minority class which affects the performance of the algorithm. So we need to use a resampling method to solve this problem. The resampling methods are Over sampling (It increases the count of minority classes. This method is used for small sized datasets), Under sampling (It reduces the count of majority classes. This method is used for large sized datasets), Hybrid (It is a combination of both Over sampling and Under sampling).

e. Feature Scaling: To improve the learning process of the method, the dataset's features need to be scaled so that it has a small range. The most common scaling technique that is used is standard scaler. We need to find out the standard deviation and mean for every feature to standardize the feature.

$$X_{Scaled} = \frac{x-\mu}{\sigma} X_{Scaled} = \frac{x-\mu}{\sigma} \tag{1}$$

C. *Validating the Model*

a. Method of Random Hold-out: We divide the dataset into 80% and 20%. 80% is used in training and the remaining 20% is used in testing.

b. K-fold Cross-Validation: For the dataset with a small size, we can use K-Fold Cross-Validation. This method divides the dataset into equal sizes containing K subsets. All the subsets except one will be used for training the model. One subset will be used for testing.

D. *Deep Learning Models*

a. Feed Forward Neural Network: The simple one among other types is Feed-Forward Neural Network. Here all the neurons are fully connected and does not form a cycle. The neurons are in inputs, output, and hidden layers. Multiple hidden nodes are traversed by the data since it always travels forward but not backward. The Feed Forward Neural network would be executed using the train and test data. TensorFlow may be used as the backend, and Keras as the frontend. Between the hidden layers, the ReLU activation function is utilized, while at the output layer, the softmax activation function is utilized. [2][3]

b. Deep Belief Network (DBN): A subset of deep learning is deep belief networks. It's a multi-layer belief network made up of Restricted Boltzmann Machines (RBMs) that are built on top of one another to create a DBN. A greedy layer-wise learning process is followed by a three-layer DBN that includes the pre-training. Particularly, while one layer is added to the network at a time using the contrastive divergence (CD) method, only the top layer of the network is trained as an RBM. Once each RBM has been trained, the weights were clamped along with the introduction of a new layer to repeat the procedure. In a DBN, there are two phases. Unsupervised pre-training, which is the first stage, teaches features using only input values with no labels. The

DOI: rp-9788770040723.009

second level of tuning involves employing a label using supervised fine-tuning and an error back propagation method. In order to maximise the benefits of the DBN model, we must build numerous models with varied hidden layer counts, hidden layer node counts, and hyper parameters.[4]

c. Improved Conditional Generative Adversarial Network based Deep Support Vector Machine (ICGAN-DSVM): Since educational datasets often contain modest amounts of data, the majority of machine learning algorithms exhibit a shallow learning approach. ICGAN mimics fresh training datasets to solve the issue of low data volume, whereas DSVM extend the SVM algorithm from shallow learning approach to deep learning approach. As a fundamental distinction from conventional deep neural networks, DSVM excels with limited datasets. In comparison to earlier efforts, the ICGAN-DSVM method increases specificity, sensitivity, and AUC by around 8 to 29%. More performance of student data for training are produced using ICGAN. The prediction model for performance of students is handled by DSVM. To expand the dataset's data amount, GAN is selected. In the training stage, the generator and discriminator strive to reach the Nash equilibrium. In reality, educational dataset which are of small size is usual. In general, it is challenging to collect continuous data at the beginning, while learners are still young. The random noise vector (the generator's input) is unhindered in the original GAN, which might result in disastrous theory corruption. Conditional variables are added to the generator and discriminator to overcome this restriction. The current architectures of CGAN, InfoGAN, and ACGAN are combined to create improved CGAN (ICGAN). ICGAN generates data with less bias. The concepts of (i) adding a conditional variable to the discriminator, (ii) including another network with the discriminator, and (iii) giving a label to each produced sample are all incorporated within ICGAN. The problems of Classification are typically solved by the Support Vector Machine algorithm. We can divide the n-dimensional space into classes using the best line we can draw using SVM, making it simple to classify fresh data points. The best line is called the best decision boundary or hyperplane. Utilizing DSVM architecture, the prediction model to predict the performance of students is put into practice. In general, it has an output layer of SVM and a number of hidden SVM layers. In comparison to many other deep learning architectures like deep neural networks, DSVM has a number of advantages, including the ability to handle the issue of very large input vectors and small training datasets, more flexibility in the design of kernel functions, and strong regularisation power in the output layer SVM to prevent over-fitting. [5].

d. Long Short-Term Memory (LSTM): Long Short-Term Memory (LSTM) is a form of artificial neural network used in deep learning and artificial intelligence. Unlike conventional feedforward neural networks, LSTM has feedback connections. In addition to single data points, a recurrent neural network (RNN) of this type may analyze entire data sequences. Both "long-term memory" and "short-term memory" are compared to a standard RNN. The name of LSTM is obtained due to this reason. This network model can be made using four layers. They are Masking, LSTM, Dropout and Dense layers. Cross-entropy method is used when training the model. Nadam is set as an optimizer. Masking layer was aimed at filtering the missing values caused by data from different semesters and courses with incompletely identical learning activities. The filtered data served as input to the LSTM layer. In each cell, its cell state, hidden state, and input data from 10 time points was processed consecutively one by one through the input gate, forget gate and output gate. The output of the last time point was the LSTM layer output and was sent to the Dropout layer for preventing overfitting. Last, the output was sent to the Dense layer, using softmax as activation function to calculate the possibilities of three classes (i.e., low-performing, average-performing, and high-performing). The highest possibility was the result of categorizing. [6].

e. Bidirectional Long Short-term model (BLSTM) and Conditional Random Fields (CRF): BLSTM includes a variety of elements that may be used to judge the performance of a new student, which helps with early dropout and retention prediction. Furthermore, the condition Random Field (CRF) approach to sequence labelling was used to forecast each student's label separately. One of the most effective artificial recurrent neural networks (RNNs) for time series data categorization and prediction is BLSTM. Using the sequence labelling approach, it may be utilized to process whole data sequences and keep them in compressed form. Additionally, BLSTM excels in a variety of sequence labelling tasks, including handwriting and speech recognition, and with long-term data dependencies. This benefit led us to develop the prediction problem from a sequence perspective. The BLSTM method must be trained over the student features in both directions, specifically forward and backward with hidden states, before concatenating the output from both directions. This follows the stage in which we attempt to describe students using their features. BLSTM has shown its effectiveness in a number of related tasks. Each unit in the BLSTM structure is made up of an LSTM unit. The primary responsibility of BLSTM is to extract and encode specific student attributes. To forecast each label of a student on their own, CRF is utilized for sequence labelling. It may then study the relationships between sets of features and labels using a state score and model the interactions between neighbouring labels using a transition score [7].

E. Evaluation Measures

Some of the evaluation measures are Precision, F1-score, Accuracy, Classification error, Recall, Sensitivity, and Specificity. The most common evaluation measure is accuracy. When the dataset contains the same number of instances for each class, accuracy can be employed. Here, TP - True Positive, TN - True Negative, FP - False Positive, FN - False Negative, N_n – Number of negative samples, N_p – Number of positive samples.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (2)$$

$$\text{Recall} = \frac{TP}{TP+FN}\text{Recall} = \frac{TP}{TP+FN} \quad (3)$$

DOI: rp-9788770040723.009

$$\text{Precision} = \frac{TP}{TP+FP}\text{Precision} = \frac{TP}{TP+FP} \quad (4)$$

$$F1 - \text{Score} = 2 * \left(\frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}}\right) \quad (5)$$

$$\text{Classification Error} = \frac{FP+FN}{TP+TN+FP+FN} \quad (6)$$

$$\text{Specificity} = \frac{TN}{N_n}\text{Specificity} = \frac{TN}{N_n} \quad (7)$$

$$\text{Sensitivity} = \frac{TP}{N_p}\text{Sensitivity} = \frac{TP}{N_p} \quad (8)$$

IV. RESULTS

a. *Feed-Forward Neural Network*

This model gives accuracy of 93% in 3 testing folds, 88% in 5 testing folds, and 77% accuracy in 10 testing folds [2]. This model gives an accuracy of around 35% when it is tested for accuracy [3]. This model sometimes predicts the Pass students as Fail and Fail students as Pass. So, this model is far from perfect.

b. *Deep Belief Network (DBN)*

This model generates an accuracy of 75% and 88% [4]. So this model also doesn't meet up the required prediction accuracy.

c. *Improved Conditional Generative Adversarial Network based Deep Support Vector Machine (ICGAN-DSVM)*

The suggested ICGAN-DSVM produces specificity, sensitivity, and AUC of 0.968, 0.971, and 0.954, respectively, according to results from 10-fold cross-validation.

d. *Long Short-Term Memory (LSTM)*

The accuracy was around 60% for the given LSTM model.

e. *Bidirectional Long Short-Term Model (BLSTM) and Conditional Random Fields (CRF)*

For the given method the precision was found to be 89.1%, and recall is 88.5%. Accuracy is found around 90%.

From these results, we can understand that the two methods work well in predicting student performance. They are

Deep Support Vector Machine with improved Conditional Generative Adversarial Network (ICGAN-DSVM)

Bidirectional Long Short-term model (BLSTM) and Conditional Random Fields (CRF)

We can also note that **BLSTM and CRF** give the highest accuracy of around 90%. This is due its long-term memory and its ability to train the student in both directions.

V. CONCLUSION

In this paper, we provided with a detailed method to conduct Student Performance analysis. Here we concentrated on Deep Learning technologies. The initial stages of the analysis include Data Collection, Pre-Processing the data, and Validating the Model. During the Pre-Processing stage, we are performing data cleaning, data discretization, encoding the feature, handling imbalanced dataset problems and feature scaling. The validation of the model is done using the method of Random Hold-out and K-fold Cross-Validation. This paper aims to produce multiple classifiers to investigate the model that can best describe a student's performance. The deep learning models considered here are Feed Forward Neural Network, Deep Belief Network (DBN), Improved Conditional Generative Adversarial Network based Deep Support Vector Machine (ICGAN-DSVM), Long Short-Term Memory (LSTM), Bidirectional Long Short-Term model (BLSTM) and Conditional Random Fields (CRF). By using different evaluation measures, we came to the conclusion that Improved Conditional Generative Adversarial Network based Deep Support Vector Machine (ICGAN-DSVM) and Bidirectional Long Short-Term model (BLSTM) and Conditional Random Fields (CRF) provide us with the best result. This may use to enhance the student's performance by analyzing their results in an earlier stage and to reduce the dropout rate which is at the primary level (Classes 1 to 5) increased to 1.5 percent in the academic year 2021–2022 from 0.8 percent in the previous year, according to the data. Dropout rates have increased at the upper primary level (Classes 6-8), rising to 3% in 2021–22 from 1.9% in 2020–21.

***Abstract* — Automatic language translation between two languages has encountered a quantum leap in perspective as of late in the field of machine learning. The term "neural machine translation" was developed in response to statistical machine translation, which relies on various count-based models and long dominated MT research. In contrast to conventional statistical machine translation, neural machine translation aims to build a single neural network that may be mutually changed to maximize translation efficiency. The current NMT models may be traced to previous versions of the encoder-decoder network family as well as to word and sentence embedding in this study. We will conclude with a succinct outline of recent developments in fields like NMT's bidirectional training (BiT).**

Keywords—Statistical Machine learning, Machine translation, word embeddings, Bi directional Training(BiT)

I. Introduction

One of the first objectives of text between languages was the automatic translation. The dawn of NMT positively checks one of the significant achievements throughout the entire existence of MT, and has prompted an extremist and unexpected departure of mainstream research from numerous past research lines. Given the fluidity of human language, machine or programmed translation may be among the most difficult AI undertakings. Earlier, rule-based frameworks were used for this task, but statistical techniques took their place in the 1990s. The field of neural machine translation, appropriately named, has more recently seen cutting-edge results from deep neural network models. The target language's feedforward neural language models were used to rank translation lattices in earlier attempts[1][2][3]. The principal neural models that also took into account the source language were established by using a similar model with bilingual tuples in place of specific linguistic words [4], directly scoring phrase pairs with a feedforward net [5,] or including a source defined range in the neural language model [6]. In this paper, we will discuss the origin of the NMT and try to give a basic overview of the concepts of NMT, Bi directionally training(BiT) it, and other current research in the field.

II. Word Embeddings

One of NLP's models most essential elements is the representation of words or phrases as continuous vectors. A d-dimensional real number vector should be used torepresent the word x. In general, a size d for the embeddinglayer that is noticeably smaller is chosen than the size of the vocabulary (d |Σ|). The following can be used to illustrate how a word is translated into its dispersed representation: a matrix of embedding called $E \in R\ d\times|\Sigma|$ [8]. The word x's d- dimensional representation is contained in the xth column of E,which is designated as E:

x. Embedded matrices are frequently learned along the network as a whole in NMT utilizing back - propagation algorithm [9] and a gradient-based optimizer. Many NLP subfields now make extensive use of pre- trained word embeddings made from unlabeled text[10]. The context in which a word commonly appears is usually taken into consideration by techniques for training word embeddings on raw text. [11][12], or enhance embeddings with cross-linguistic data[13][14]. Contextualized depictions make an effort to use the entire input sentence rather than just one word. In a number of NLP benchmarks, contextualized word embeddings have improved current technology. [15][16][17].

III. EmbeddingsWithin Phrases and Sentences

It is recommended to use phrases or sentences rather than single words when carrying out diverse NLP tasks. By utilising a scattered portrayal of the source sentence, for example, the distribution of the target sentences might be constrained. Reiterated autoencoders were a pioneering method for phrase embedding[18][19]. A phrase is designated as a d-dimensional vector by using [20] A word embedding matrix was initially trained by Socher et al. (2011). They then constructed an auto encoder network that uses the input as the fusion of two child representations to iteratively search for d-dimensional portrayals for 2D inputs. The word embedding chosen by the same auto encoder from two different guardians are the kid representations. A binary tree that can be created greedily controls the order in which representations merge. [20] or created with the aid of an Inversion Transduction Grammar[21][22]. However, in MT, the sentence representation must provide enough information to impose conditions on the objective sentence appropriation, and as a result, it must be higher dimensional than the word embeddings.

DOI: rp-9788770040723.010

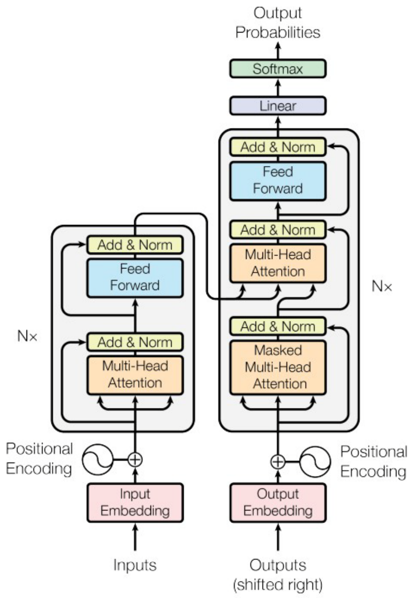
In order to get around the dimensionality issue with recurrent autoencoders, Kalchbrenner and Blunsom (2013)[23] found vector representations of words or sentences using convolution. Recent research finds sentence representations using self-attention much convenient rather than convolution. [24][25][26]. Yu et al. (2018) also looked at the possibility of using (recursive) connection networks. [28][29] which again totals the words in the sentence that are related to one another in pairs. Sentence representation frequently makes use of recurrent structures. It has been discovered that even untrained random RNNs can perform fairly well for a variety of NLP applications[30][31][32][33].

IV. Networks of Encoders and Decoders with Fixed Length Sentence Encodings

The primary authors who shaped the target sentence distribution using a distributed fixed-length representation of the source sentence were Kalchbrenner and Blunsom (2013)[23]. They modelled their recurrent continuous translation models (RCTM) I and II after the class of encoder-decoder systems [34], which is the most effective NMT design at the moment.

V. Architecture of an Attention Model

Sentences of various lengths pass varying amounts of information. Early NMT models had the drawback of commonly producing bad interpretations for lengthy words [35]. [36] Cho et al. (2014a) alluded that this error is due to the fixed-length source sentence encoding. A vector of constant length "does not have enough capacity to encode a long sentence with complicated structure and meaning"[36]



$\frac{1}{\sqrt{d_k}}$ e Transformer – Model Architecture

A. *Stacks of Encoders and Decoders*

Encoder: The encoder is made up of N = 6 discrete layers placed on top of one another. Each layer is composed oftwo sublayers. The first is a multiple-head self-attention mechanism, whereas the other is a standard feed-forward network thatis entirely related with positions. We employ a residual connection and then layer standardization to encircle each of the two sub-layers. For each sublayer, the outcome is Layer Norm(x + Sublayer(x)), where Sublayer(x) denotes the task performed by sublayer itself. Aspect model = 512 produces results for all model sub-layers and the embedding layers that can be used with the remaining associations[37].

Decoder: Similarly, the decoder is built from a stack of N= 6 similar layers. We employ lingering associations surrounding each sub-layer, similar to the encoder, followed by layer normalization. The self-consideration sub-layer in the decoder stack is also modified in orderto prevent positions from caring for resulting positions. The position's expectations due to this veiling and the fact that the result embedding are balanced by one position[37].

B. *Attention*

A set of vectors like key-value pairs, a planned inquiry, and a result can all be used to define an attention function. The weights assigned to each value are based on how well the question fits with its associated key, and the answer is generatedas a weighted sum of the values.

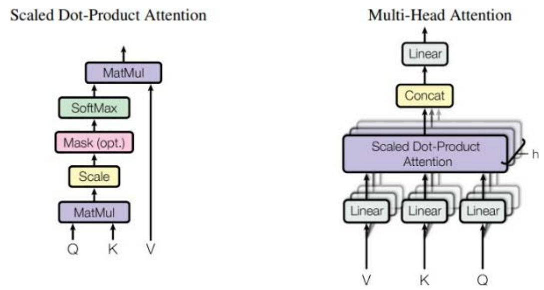


Figure 2: (left) Scaled Dot-Product Attention. (right) Multi- Head Attention consists of several attention layers running in parallel.[37]

C. *Scaled Dot-Product Attention*

As shown in figure 2, the input for "Scaled Dot-Product Attention" consists of queries, keys of dimension dk, and values of dimension dv. The weights for the values are obtained by dividing each key by dk, the softmax function, and the query's product with each key.

We simultaneously register the attention function on many queries that are integrated into a Q matrix. Additionally, the keys as well as values are merged into the matrices K and V. The output matrix is processed as follows:

$$\mathrm{Attention}(Q,K,V) = \mathrm{softmax}(\frac{QK^T}{\sqrt{d_k}})V$$

Additive attention and dot-product (multiplicative) attention are the two commonly utilized attention functions. For greater values of dk, the dot product grows enormous in magnitude, driving the softmax function into areas where it has small gradients. To balance this impact,we scale the dot products by[37].

DOI: rp-9788770040723.010

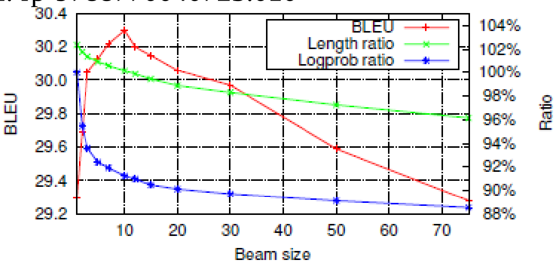

Figure 3: Transform model execution with varied beam widths on the English-German (WMT15) channel. At beam size 10, the BLEU score achieves its maximum, although the length proportion (Length of Hypothesis/Length of Reference) is less than 1. The proportion of the log-probabilities for greedy decoding is shown.

D. *Multi-Head Attention*

Instead of employing a single attention function with model-dimensional keys, values, and queries, we discovered that it is more effective to repeatedly direct project the keys, values, and queries to the dk and dv dimensions. The attention function is then applied simultaneously on every extended queries, keys, and values, producing dv-dimensional output values. Multi- head attention allows the model to process data from many portrayal subspaces simultaneously at various locations[37].

VI. Neural Machine Translation Decoding

Up to this point, we have seen how NMT defines thetranslation probability P(y|x).They do not explicitly explainhow to create a target sentence (y) from a given source sentence (x), despite this being the goal of machine translation. For two reasons, NMT decoding essentially expands significantly with sequence length, the search space first appears to be very large.

A. *Greedy And Beam Search*

To create the sequence outputs of tokens from a neural network model, greedy search and beam search are used. Both methods concentrate on models that go from sequence to sequence. Both algorithms operate simultaneously. A limited subset of the fractional hypotheses that have lengths (up to) j are chosen for extension in the following time step after being matched with one another in each iteration j. After a very large number of cycles have been completed, the algorithms stop, or all or the best of the selected hypotheses contain the finish-of-sentence symbol.

Beam search appears to be more exact, but there is no assurance that it will always lead to an interpretation with a higher or comparable score than greedy decoding. [38] According to Stahlberg and Byrne (2019), beam search has a huge number of searching errors.

VII. NMT Model Errors

In comparison to multi-level SMT systems like Hiero [39], which look at very broad search spaces, NMT beam search seems unnecessarily basic. This hypothesis claims that when the decoder fails to find the translation with the highest score, translation failures in NMT are more likely to be the consequence of search errors than model defects. It's interesting to note that this isn't always the case. Stahlberg et al. (2018), [38]Stahlberg and Byrne, [40]Niehues et al. (2017), [41][42]Stahlberg et al. (2018), and (2019). In particular, [38]Stahlberg and Byrne (2019) showed that the NMT decoding had a substantial number of search mistakes. Although, despite its theoretical advantage, NMT also experiences a variety of model mistakes in practice, as we will demonstrate in this section.

A. *Sentence Length*

Because the translated texts are becoming overly brief as a result of extensive beams, translation execution consistently declines (green curve). The log-probabilities of the found interpretations, as shown by the blue curve, are, nevertheless, declining as the beam size is increased. Anyhow, a big shaft for a bar search keeps the green path, thus it's seen as the more. This is encouraging right off the bat: outstanding translations may now be found with a rapid beam search and a small beam size. However, it indicates that providing search mistakes will fix the model fault of short translations with a thin beam is equivalent to retaliation. This means that any new NMT training approach will need to make adjustments to the beam size, which is another vital boundary.

VIII. Using Monolingual Training Data

The availability of data for concurrent MT training is often limited and costly, in contrast to the abundance of untranslated monolingual data. For instance, the translation grammar in Hiero [39] covers a large range of possible translations but fails miserably to assign points to them. Most of the time, it is the LM's responsibility to select a cohesive and fluid translation from that space. The NMT decoder should be integrated with an independently created RNNLM, according to Gulcehre et al. (2015, 2017). In a similar manner to traditional SMT, they also began combining the outcomes of RNN-LM and NMT using a log-linear model (a procedure known as "shallow fusion"). They demonstrated considerably better performance using "deep fusion," which makes use of a regulator network that gradually modifies the weights between RNN-LM and NMT. There have been a few increases in WMT assessment frameworks as a result of thorough integration and counting-based language models for n-best re-ranking [46][47]. The translation model is trained using the "simple fusion" method [48] to predictthe leftover probability of the training dataset mixed with the presumption of a fixed, pre-built LM.

Leftover probability of the training dataset mixed with the presumption of a fixed, pre-built LM. In the second research line, monolingual text is used to enrich data. By including monolingual data in the intended language, the natural concurrent training corpus will be enlarged. There are other ways to complete the source side of these sentences, including using a single false token[49] or replicating the intended sentence to the source side[50]. Reverse translation is the best method, and it makes use of a separate translation system to produce source sentences for sentences in a monolingual target language in the reverse direction. The performance of the final translation can, however, be significantly improved by improving the reverse system's quality if there are enough computational resources available. [52].

DOI: rp-9788770040723.010

The amount of interleaving that must be stabilized with the amount of simulated data greatly restricts back-translation. [49][53][54]. So, the back-translation technique can utilize part of the readily available unilingual data. Over- sampling, which involves multiplying real training samples by the size of the synthetic data, can partially correct an imbalance between real and synthetic data. Anyhow, in practice, really high over-sampling rates generally don't perform well. In order The manufactured sentence pairs are used to produce a richer training signal, [55]Edunov et al. (2018a) has recommended adding noise in the sentences that were reverse-translated. Additionally, [56]Wang et al. have confirmed the efficacy of enhancing data in NMT with noise (2018b). These techniques broaden the training data set, which complicates model fitting and ultimately generates additional training signals. By selecting different sentences from the reverse translation model, one can also enhance the number of synthetic sentences in back-translation [57].

To accommodate for monolingual data, the third group of techniques alters the NMT training loss function. As an illustration, According to Escolano et al. (2018), the training goal should include auto encoder words that characterize how well a phrase can be translated into its original form and then reconstructed ([58]Cheng et al. (2016b), [59] Tu et al. (2017), and [60]). Additionally, (unsupervised) parallel learning techniques depend on the utilization of the reconstruction error ([61]He et al., 2016a; [62]Hassan et al., 2018;[63] Wang et al., 2018c). However, it is often expensive to compute and requires approximations to train for the new loss. Alternative methods for combining source-side [64] and target-sidemonolingual data include execute multi-task learning. Starting Seq2Seq training using already-trained encoder and decoder networks is another method for leveraging monolingual data in both the source and the destination languages ([66] Ramachandran et al., 2017; Skorokhodov et al., [67] (2018)). Unsupervised NMT is an extravagant sort of lever-aging monolingual training data since it eliminates the necessity for parallel training data [68][69].

IX NMT TRAINING

Cross-entropy loss and backpropagation [70] are two typesof methods of optimizing like Ad delta 1 [71] are typically used to train NMT models. Recent NMT architectures such as fading gradients are one of the common training difficulties that are addressed by The Transformer, ConvS2S, or recurrent networks combining LSTM or GRU cells [72].

Research on training is still quite active. Now, early shallow models have been replaced with profound encoders and decoders with several layers. Deep architectures, particularly recurrent ones, are vulnerable to disappearing gradients[73], making training them more challenging because additional layers are required to transmit the gradients backwards. In the layer stack, residual connections [74] are quick associations that avoid more complicated sub-networks. Another method to prevent vanishing gradients is batch normalization [75], which uniformly sets each layer's hidden activations in tiny batches to have a mean of 0 and a variance of 1. Recurrent networks benefit most from layer normalization [76], a batch size-independent improvement to batch normalization.

A. *Regularization*

To aid in training, current NMT architectures are severely over-parameterized [77]. The model may be prone to over- fitting due to the huge number of features: The model perfectly matches the training data. Regularizers are techniques designed to stop neural networks that over fit and have too many parameters. The two manageable regularization techniques, according to one argument, are L1 and L2. It is meant to penalize the size of the weights in the network by include words in the loss function. Of course, these fines reduce a lot of variables to zero and make them irrelevant. Accordingly, the potential of the model is essentially constrained by L1 and L2. Label smoothing, early halting and dropout are the three regularization methods used most frequently for NMT. Dropout randomly resets the training exercises for both visible and concealed units to zero. It may be considered an effective regularizer in this way. Label smoothing significantly modifies the training objective, resulting in smoother distributions from the model.

B. *NMT by Bidirectional Training*

Bidirectional training is a quick and efficient pre-training method. The model will be bi-directionally updated at the earlier stage, and then tweaked as usual. The training samples can be reconstructed from "srctgt" to "src+tgttgt+src" to update bi-directionally without requiring any complex model adjustments. The suggested approach can be used in conjunction with current data manipulation techniques including back translation, data distillation, and data diversification. Large-scale investigations reveal that the methodology works as an innovative bilingual code-switcher, obtaining a better bilingual arrangement. Fortunately, with the help of BiT, our system [80] took first place in the low-resource track of IWSLT20218 for BLEU scores. Integrating BiT into our current systems [81][82] and confirming its efficacy in industrial level competitions will be intriguing.

C. *Results*

Outcomes on Multiple Data Scales: Various data sizes were(BiT) collected for 10 language directions, including IWSLT14 EnDe, WMT16 EnRo, IWSLT21 EnSw, WMT14 EnDe,and WMT19 EnDe, in order to test the method's utility. The largest direction has 38M sentence pairs, whereas the lowest direction only has 160K sentences. Table 1 displays the outcomes. The efficacy and thoroughness of the BiT are demonstrated by the fact that it significantly beats the solid standard Transformer in 7 of the 10 dimensions (importance test, p 0.01) and in remaining 3 directions (importance test, p 0.05) of the suggested bidirectional pre-training methodology. One advantage of BiT is that it reduces training time for the reverse direction by one- third. This benefit demonstrates that BiT may be a successful training method for multilingualism, such as multilingual pre training [83].

Table 1: Comparison with previous AT work on several widely-used benchmarks, including IWSLT14 WMT16 En↔Ro, IWSLT21 En↔Sw, WMT14 En↔De and WMT19 En↔De. "‡/†" indicates signific ence ($p < 0.01/0.05$) from corresponding baselines, and this leaves as default symbol in Table 2-6.

DOI: rp-9788770040723.010

Data Source	IWSLT14		WMT16		IWSLT21		WMT14		WMT19	
Size	160K		0.6M		2.4M		4.5M		38M	
Direction	En-De	De-En	En-Ro	Ro-En	En-Sw	Sw-En	En-De	De-En	En-De	De-E
Transformer	29.2	35.1	33.9	34.1	28.8	48.5	28.6	32.1	39.9	40.1

Statistics for Distant Language Pairs: Inspired by [84], we present the BiT findings for the distant language pairs Zh'en and Ja'en, which are members of various language families. This clears up any confusion regarding the use of BiT and languages that belong to the same linguistic family, such as English and German.

Table 2: Performance on distant language pairs, including WMT17 Zh↔En and WAT17 Ja→En. To perform BiT on languages in different alphabets, we share the sub-words dictionaries between languages.

Data Source	WMT17		WAT17
Size	20M		2M
Direction	Zh-En	En-Zh	Ja-En
Transformer	23.7	33.2	28.1
+BiT	24.9‡	33.9†	28.8†

Table 2 shows the outcomes as they were observed, compared to baselines, and developed through time as a result oftechnique in all cases. BiT improves on average by+0.9 BLEU over the baselines.

X.Conclusion

The most popular and effective type of machine translation has been neural machine translation (NMT) over the years. In this study, word, phrase, and neural language models were used to reconstruct the history of NMT. We examined the repeat, convolution, and attention building blocks of NMT architectures. We then briefly discussed cutting-edge NMT research areas such NMT By Bidirectional Training

***Abstract*—The senior population is disproportionately affected by Alzheimer's disease (AD), making it the most common form of neurodegenerative disorders. It has an impact on patients' life, causing cognitive capacities such as consciousness, speech, actions, and problem-solving to deteriorate with time.Unfortunately, there is currently no cure for AD, and progress has been slow on finding a cure.However, the focus was on use of current medical information to diagnose the cognitive status of a patient, which in fact shows that a computer can replicate the clinical decision-making process of a physician. These rapid improvements have made it possible to collect enormous amounts of multifunctional neuroimaging data, which has led to the recent deployment of deep learning to the prompt identification and classification of Alzheimer's disease. Computational intelligence study into Alzheimer's disease continues to be in its infancy, but it is expanding rapidly as even more hybrid information sources are being incorporated, and as transparency is increased through the use of explicit strategies that integrate knowledge of specific behaviours and paths associated with the disease. This finding can be further understood by comparing multiple data-driven methodologies based on large-scale organization healthcare information from AD risk stratification, which may one day lead to improved selection of people at risk for AD in clinical laboratories or early identification of AD in clinical studies.**

***Keywords*—Alzheimer's illness, Disease progression, Deep learning, Cognitive deficiency.**

I. INTRODUCTION

Alzheimer's syndrome is the neurodevelopmental disorder characterized by brain atrophy (shrinkage) and cell death. It is a common type of dementia, and it is marked by a gradual loss of capacity of the individual to operateindependently. Dementia is by far the most common kind. Early indicators of the condition include losing details about recent events or talks. With the progression of the disease, people living with Alzheimer's will develop serious memory impairments and become incapable of performing daily duties.Medicines may improve symptoms temporarily or slowly. These treatments can sometimes contribute to maximizing functioning and maintaining independence in people with Alzheimer's illness [2].

Alzheimer's disease patients and carers can benefit from a variety of programmes and services. Alzheimer's ailment, a degenerative brain disorder, currently has no effective treatments or cures. Infections resulting from significant brain losses — such as dehydration, starvation, or infection — result in death as the disease progresses. Alzheimer's disease is caused by an unknown factor. The functioning of brain proteins, on the other hand, triggers a cascade of damaging events in brain cells, disrupting the brain's workings (neurons). Damaged neurons lose their connections and finally die [7].

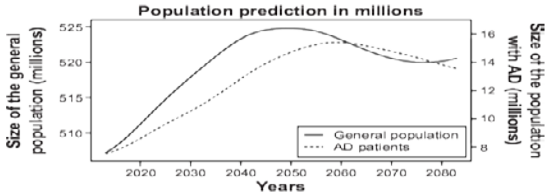

Fig. 1. Prediction of Population Vs AD patients

II.EASE OF USE

Genetic alterations cause Alzheimer's disease in less than 1% of cases, essentially guaranteeing that a person would get the condition. These unusual occurrences frequently result in mediaeval diseases.The damage usually begins in the memory-controlling area of the brain, although the initial symptoms do not occur for years. Neuron loss spreads to other parts of the brain in a predictable fashion. The brain had shrunk greatly during the late stages of the disease. Preclinical testing of Alzheimer's disease patients can lead to earlier detection of the disease and improved treatment options to delay its onset.The current AD biomarkers necessitate the acquisition of specimens or imaging data. E-health data, such as clinical records or organizational health data, on the other hand, do not require any additional time or effort to obtain. Furthermore, with the advent of digitization, the amount of such data has exploded [10].

Primary healthcare characteristics (maturity level, sexual orientation, profession), culture (physical exercise), midlife health- related risk factors (modest hypertension, body mass index, and total cholesterol), and cognitive assessments are often utilized to determine Alzheimer's illnesses. In clinical settings, evaluating whether these basic models, which are based on a small number of variables, can adequately account for the numerous etiologies of multifactor AD is a major challenge.In actuality, multi-factor modelling predicts the best disease risk, according to a meta- analysis research, however single-factor modelling does not reveal that successful AD risk prediction demands a wide range of factors.Here the magnitude is tested to which a data driven deep learning framework collects significant data from huge healthcare data that contain thousands of health records and predict the risk of AD individually [14].

To address these issues, the field of large-scale and high- dimensional analytical pictures is receiving a lot of

DOI: rp-9788770040723.011

interest in the developing field of deep learning, which customs underdone neuroscience facts to build functionality over "on-the-fly" training. We have reviewed publications systemically, using deep learning methods and neuroimaging information to detect AD early and predict AD progression [15]. ith this detailed overview, the intention of this learning is to provide readers with deep learning customized for AD and to help researchers to facilitate medical imaging. This work makes the main contribution

1. Introduced by an AI groundwork, AD is affected.
2. A clear road map for the need for deep learning and an analysis of general deep learning models for AD prediction has been provided in AD prediction.
3. Described the related research directions for medical researchers to make deep learning powered AD prediction.

This survey varies clearly from other recent surveys in the above points. It gives as much info as before. Section II discusses the theoretical source of AD to deep learning in AD. Thepaper has the following structure. Section III deals with a general data-driven deep learning model in AD prediction. Section IV lists and describes briefly the related directions of the research in Section V.

III. Theoretical Background

3.1 Artificial Neural Networks, Transfer & Multi-kernel Learning

ANN is used extensively for modeling highly nonlinear data patterns in machine learning models. Conventional learning models use only one domain sample that greatly influences their performance when there are very few samples accessible. Transfer learning is a technique that employs samples not just from the target field, but also from other (related) subdomains. A multimodal multiple regularized transfer learning to help learn the target domain by transferring knowledge from a secondary area. Information from a nearby hospital is transmitted into samples using the TrAda Boost approach. Even when unconnected domains are disregarded, transferring knowledge from all source domains diminishes the model's performance. It's also possible that the sample labels supplied to them are inaccurate [1].

A robust approach has transformed original markings into multi-bit vectors and at the same time has gained common characteristics to identify unconnected domains. To tackle these challenges, The acquisition of data from specimens to local specimens through the subspace method is designed to solve these problems. EEG signals for different artificial neural network variants were used. Numerous variants of the artificial neural network, like the radial basis neural function network and the probabilistic neural network, have been studied and proven to be the best solution for neural vector quantization. The classification approach is developed among several various algorithms including Radial Based Neural Function Network, Best-First Decision Tree, Decision Tree, Labeling, and the Perceptron Multi layer.

A real-life event can't possibly contain all of the data needed to train a model. In these cases, the training system is insufficient. For resource classification, a self-adaptive network assignment classifier is employed. Primary component analysis is used for feature extraction and classification in order to deal with complex data [8]. Longitudinal information from MRI images is combined with a multi-layer perceptron and a two-directional gated recurrent unit. Information from synchronous auditory input is used by the long-term memory network for Alzheimer's disease categorization. With diffusion tensor pictures, a fluffy technique with the Artificial Neural Network is utilised to differentiate ADissues. Data from many modalities adds to the amount of information available to learning algorithms in machines [16].

For that purpose, a multi-kernel learning environment integrated into a common feature space by region of interest and tensor. In order to support classification, a new Laplacian multimodal, regularized smaller squares model is used to support unlisted samples. The selection features separately from each model ignore the strong intermodal correlation between individual subjects that lead to under-optimal performance. A new multi-task learning selection model was developed to resolve this difficulty, which combined sparse features from all modalities were selected. Until now, the various kernel learning methods listed linearly mix many kernels from diverse modalities and are particularly sensitive to each modality's weights. The non-linear combination of data from many modalities is used to solve these difficulties. Using a privileged evidence method, the training is utilised during the training phase. To make use of privileged information, a new restricted Boltzmann machine was proposed. For categorization, an ensemble method was used [5].

3.2 Pathophysiology of Alzheimer's Disease

Aside from the prefrontal, posterior, and parietal lobes, other brain regions contribute to our cognitive abilities, including the serotonin ventral nerve, neurotransmission cytosol, and choline cytosol. The hippocampal, amygdala, neocortex, and cerebral interconnections can all show signs of basal nuclei, neuronal atrophy, and/or illness. The pathogenesis of Alzheimer's illness is depicted in Figure 2.

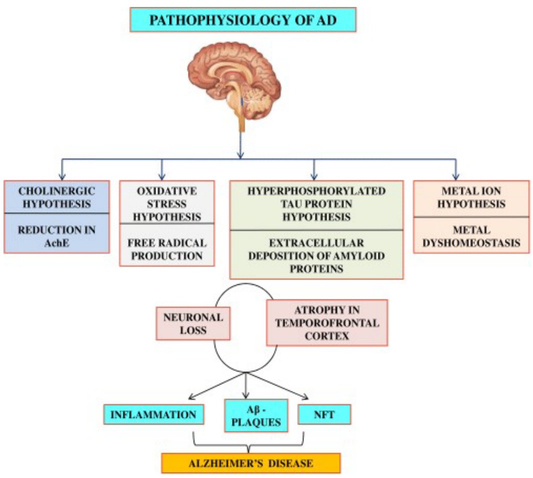

Fig. 2. Pathophysiology of Alzheimer's Disease

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.011

The hippocampal, the cerebral associating regions, the transentorhinal lobe, and the mesencephalon, all of which are influenced by the frontal, parietal, and occipital lobes, tend to develop tangles in a predictable order. The size and location of tangle formation is significantly more strongly associated with the ruthlessness of dementia than the magnitude of the development of senile plaques. Tau protein buildup has been associated to cognitive deterioration and cerebral shrinkage, particularly degeneration of the hippocampus.In Alzheimer's disease neuropathology, the temporofrontal cortex has neurons and atrophy loss, causing tenderness and depositing of amyloid plaques and an irregular cluster of portions of proteins, as well as a bundle of tangled fibres, resulting in an upsurge in the amount of cerebral cortex monocytes and macrophages, as well as stimulating the parenchymatous microglial cells in the parenchyma, resulting in an increase in the number of cerebral cortex monocytes [4].

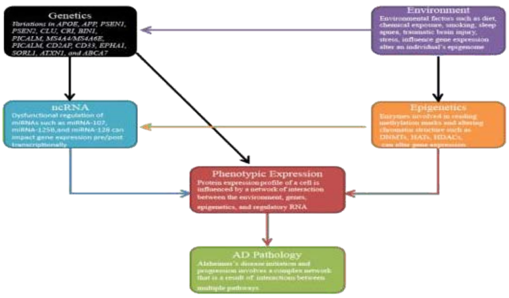

Fig. 3.Genetics, epigenetics and environmental influence - Alzheimer's disease pathology.

Ecological factors include peroxidation, inflammatory, and chemical contaminants. An individual's way of life can be affected by a variety of circumstances, including but not limited to their dietary habits and nutrition, brain trauma, inability to exercising, and smoke. AD pathology can be affected by genetic malfunction, non- coding of RNA and modifications in an individual's epigenome.[17].

IV. MachineLearning and Deep Learning Models for AD Prediction

Furthermore, inter-correlation-aware machine learning (ML) strategies have emerged as a pivotal component of computer-assisted statistical models, and are widely used in the computerized diagnostics and study of neurodevelopmental disorders. Although many differentmachine-learning approaches have been utilized for automated neurophysiological prediction and diagnosis, vector machine (SVM) and deep learning (DL)-based diagnostics approaches are two important avenues for further study. Numerous papers have been written about the application of machine learning techniques to diagnostic imaging. To highlight brain region correlations, functional connectivity (FC) patterns are widely used in contemporary SVM-based diagnostic models. Personalized FC arrangements are developed for paired regions of the brain that have been segregated using standard anatomical characteristics. In addition to its underperformance on original information, SVM has been criticised for the difficulty of obtaining significant features referring to [21].

As opposed to traditional models, DL platforms allow a computer to autonomously evaluate effective feature qualities in a training database using only the raw information supplied as input. The foundation of DL is an end-to-end modeled learning approach. End-to-end knowledge provides the advantage of simultaneously optimising all components of the optimization strategy, potentially resulting in maximum performance.In the realm of Alzheimer's disease prediction; Figure 4 depicts a general end-to-end hierarchy system model. There are four levels in the hierarchy, ranging from one (none) to four (everything) (full).The vast majority of current research uses Level 1 or Level 2 methods to achieve their objectives, which rely significantly on sophisticated software and, in some cases, precise parameter tweaks and manual noise removal. Because of these inter dependencies, those educations only used a part of the raw datasets for performance evaluation, leaving out obvious outliers and making it difficult to make a true enactment comparison. Additional benefit of end-to-end learning is that it allows you to observe how CNN arrived at their classification decision.The explanation aids in the clinician's understanding of CNN activity and the discovery of novel biomarkers. Level 2 explanations are restricted to the segmented area, which may obstruct understanding[22].

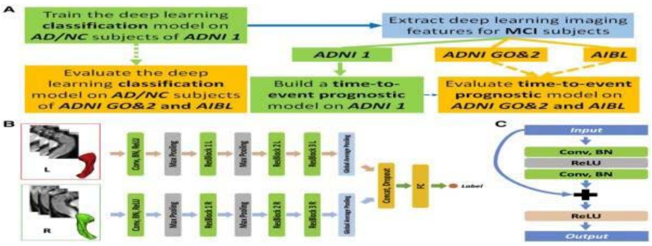

Fig. 4. Illustration of a generic, hierarchical system applicable to the field of Alzheimer's clinical diagnosis

Rather than building separate supervised models to forecast each attribute, a single model that predicts the evolution of numerous qualities can be built. One path to developing tools that can accurately simulate patient progression is to use statistical models based on artificial neural networks. Clinical data poses a number of challenges that are difficult to overcome with current machine learning algorithms. Many clinical datasets, for example, have a variety of data types (i.e., they are "multimodal"), few testing, and a high number of missed discoveries.When dealing with these issues, rigorous preprocessing or the deletion of variables that are too difficult to represent are frequently required. For example, one recent study focused solely on four characteristics that were frequently examined across 100,000 patients in a critical care unit data set on electronic health [13].

Three-dimensional (3D) or four-dimensional (4D) volume data, for example, is reformatted into 1D vector form and fed into DL networks such the limited Bolzmann machine (RBM) and deep belief network (DBN). Data complexity and time complexity, both of which are prominent components of medical data, can be blamed for the reliance on hand-crafted features. The ADNI dataset, for example, has only a few hundred images, yet each one has

DOI: rp-9788770040723.011

over 10 million dimensions. It's important to remember that past methods misunderstood neighbourhood relationships (spatial proximity) in central nervous system information throughout the feature extraction phase. If spatial connections are not preserved, it is impossible to grasp a reliable description of how the network makes a categorization choice [20][9].

The convolutional neural network (CNN) has been proved to be a powerful DL model for grid-like data such as RGB and MR images. The use of CNNs has spread quickly across a wide range of disciplines, starting with AlexNet's amazing success on the natural picture categorization problem. Early advances in medical image processing were made with 2D pictures like retinal and chest X-rays, which were eventually expanded to 3D images like MRI. The majority of current CNN-based MRI methods are classified as Level 2. After segmenting the grey matter area for the period of pre-processing, several research employment it as a CNN input.Dropout , batch normalization, and residual module are three regularization strategies used in 3D-CNN-based approaches. While the use of effective regularization methods yielded promising results, no unsupervised learning was required. When faced with data shortages and increased dimensionality, unsupervised learning is considered important in the field of deep learning [19].

This represents the first efficient implementation of a volumetric CNN-based framework on MRI data employing 3D-stacked Convolutional Autoencoders for Alzheimer's disease classifications, but the prototype could only be emulated with an exactness of 80%. The models have been created using testing is to ensure data to anticipate temporal information and fine-tuning methodologies. Furthermore, there was little effort taken to justify the classifying choice. The use of Multiple Discourse Modalities in a Learning Environment techniques have tried to incorporate a variety of inputs and DL prototypes in order to address the optimization difficulty of AD.Grad-CAM uses different visual description approaches to demonstrate patchwise prediction inconsistencies in 3D-CNNs. Despite being capable to demonstrate how CNNs attained at their classification result, no endeavour has been through to address the progressive vs. stable MCI classification issue [3].Shifting from variance. Given the complexity and multivariate nature of Alzheimer's disease, it's critical to simulate the evolution of whole patient profiles, including the progression of each sub-component of the ADAS-Cognitive and MMSE ratings, laboratory tests, and their correlations with baseline diagnostic criteria [9].

The development of strategies to overcome these restrictions is a critical step toward more widespread machine learning applications in precision medicine. Precision medicine is especially important for people with complex disorders who experience different disease progression and therapy responses. Alzheimer's illness and moderate cognitive injury (MCI) are both neurodegenerative diseases that cause a variety of cognitive and behavioral issues. To measure the severity of these symptoms, tests like the AD Valuation Gauge are frequently used. The heterogeneity of Alzheimer's illness and related dementia's makes them challenging to diagnose, control, and treat, triggering calls for improved strategies for predicting and tracking disease development, as well as better clinical trial design for AD. Differential diagnosis is also interesting due to the difficulty of distinguishing between similar diseases.

V. Comparison Analysis of Related Research Directions

Clinical evidence and imaging studies have been used to construct a number of disease progression models for MCI and AD. While previous methods for forecasting disease development were effective, they only predicted a specific outcome, such as the ADAS Cognitive score

Title	Classifier	Dataset	ADAccuracy	MCIAccuracy
[11]	RNN	PET	91.2	78.9
[12]	3DCNN	MRI	91.09	76.9
Lu etal.[2018]	DNN	MRI,PET	84.6	82.93
[6]	CNN	ADNI	95.73	82.31
[5]	Lenet-5,AlexNet,ZFNet, and R-CNN	MRI	75-25 crossvalidation and90-10 crossvalidation are97.68% and98.75%	76.54
[18]	DNN	Kaggle	95.32	83.9

Patients with the same condition may experience various symptoms, progress at different rates, and respond to treatment in different ways. The basic goal of precision medicine is to figure out how to predict and treat differences between patients. Computational models of illness development based on machine learning and deep learning are an appealing way for dealing with patient heterogeneity. These computational models may one day be used to guide medical decisions; however, present implementations are limited by both the availability of data and the algorithms' capacity to extract insights from it.

VI. Conclusion

Supervised learning, a state-of-the-art machine learning approach, has surpassed classical machine learning in the area of computer vision by revealing deeper layers in complex, resistant to high. Applying Machine Learning to Predictive Health Care and automatic categorization of Alzheimer's disease (AD) has recently garnered a lot of interest, thanks to considerable advancements in neuroimaging that have yielded large-scale multimodal neuroimaging data. Multifunctional neuroimaging datasets used in conjunction with deep learning techniques for Alzheimer's disease diagnostics categorisation shows steady gains in terms of accuracy. Early-stage deep learning investigation in Alzheimer's disease aims to increase efficiency by using more hybrid types of information, such as -omics info, and boost openness by developing methods that are easy to explain and take into account domain experts' knowledge of the disease's unique features and paradigms. In this study, we analyse and compare different machine learning and deep learning data-driven designs based on massive organisational health information for AD risk stratification with the intention of better selecting

DOI: rp-9788770040723.011

people at risk for AD in clinical studies or order to diagnose clinical issues at an earlier stage.

Abstract–*Deep learning current advancements help to identify and classify pulmonary disease in medical images. Therefore, various studies can be discovered in the literature to identify lung illness via deep learning. The present study offers an investigation of deep learning in medical images for pulmonary disease diagnosis. Only two study papers on deep learning focused on the way to the identification of lung illnesses were published in the recent five years. Yet the taxonomy and analysis of the current work trend are not presented in their study. As a starting point, this study intends to present taxonomy of current systems for the diagnosis of deep lung disease, as well as a view of current domain work as well as probable future directions in this subject. It's possible that other scholars will make use of the taxonomy provided to organize their own work. With the given probable future route, deep learning applications that aid in the detection of lung ailments may become even more efficient and numerous.*

Keywords– Deep learning, Pulmonary disease, Taxonomy, diagnosis, lung ailments, Medical Images.

I. Introduction

Disorders of the cardiovascular system, such as those affecting the lungs, can damage the airways and other parts of the lungs. The Lung disorders are such as bronchitis, tuberculosis, and coronavirus illness (COVID-19). The Federation of International Respiratory Associations [1] reports that there are more than 334 million individuals with asthma worldwide, that 1.4 million people are dying annually from bronchitis, and that 1.6 million people die annually from lung cancer. Because of the widespread spread of the COVID-19 pandemic [2], millions of people became ill and healthcare costs skyrocketed [3]. Undoubtedly, lung illness is one of the leading global killers and disablers. Enhancing long-term recovery and survivability prospects requires early identification [4, 5]. Traditional methods for diagnosing lung disease have included skin testing, complete blood count, sputum sample tests, chest X-rays, and computerized tomography (CT) scanning [6, 7]. Furthermore, supervised learning has shwed a significant amount of promise in diagnostic imaging disease detection, notably for respiratory problems.

Most instances of TB are due to a bacteria known as Mycobacterium tuberculosis. Inhalation of germs through the lungs is the supreme communal route of entry [8]. Inflammation of the lungs is a life-threatening illness [9]. Furthermore, early identification and treatment might result in complete recovery. Pneumonia, according to Er et al. [8], is an infection or inflammation of the lungs, most frequently brought on by a bacterium or a viral infection. In addition, ingesting vomit or other foreign things might induce Pneumonia. Asthma is a chronic illness that causes episodes of shortness of breath and wheezing, according to Er et al. [8]. Asthma attacks cause swelling of the bronchial tube lining, which narrows the airways and reduces the amount of air that can flow into and out of the lungs at the same time. COPD is a condition that may be prevented and treated, but the airway restriction is permanent [8]. Tobacco smoking's impact on lung capacity is also cumulative, and it's linked to the tissues' abnormal inflammatory response to inhaled toxins.

Sputum examination, computed tomography (CT), magnetic resonance imaging (MRI), and chest radiography are all frequent diagnostic tools for emphysema. Moreover, the abovementioned operations take a significant amount of time, are sometimes located some distance from the patient, and are typically thought to be expensive. In furthermore, the aforesaid methods are able to detect tumors at a preliminary phase, which is the stage at which a patient's probabilities of survival are quite low. For the most part, researchers are working hard to spot the early signs of pulmonic cancers. The processing of pictures and the use of Artificial Neural Networks improve medical diagnostics research [10]. Medical diagnostics have benefited greatly from the use of image processing and soft computing tools during the last few years.

Build a graphical representation of the current state of deep learning systems for lungdiagnosing; catalogue the recent advances made in this field; list the obstacles still to be overcome; describe potential future strategies for overcoming these issues. The documentation is organized in the following manner. The survey's limitations are discussed in detail in Section 2, which offers related works on employing DL methods to diagnose lung disease. In Section 3, we look at how deep learning can be used to spot lung disease in medical imaging. Detailed explanations of each specific topic are provided in Section 4, which presents the taxonomy. Knowledge about the datasets can be found in Section 5. The development of supervised learning in the detection of lung diseases and the research gaps that exist

DOI: rp-9788770040723.012

are discussed in Section 6 and 7 of this work. The paper comes to a close in Section 8.

II. Literature Review

To handle small databases and the idiosyncrasies of CT TB images with only anomalies in a few particular places, a 3D block-based residual deep learning structure with depth information injection at every layer (depth-ResNet) was chosen. Methods that utilize deep learning have quickly become a powerful tool for both early detection and accurate diagnosis of ailments. Data-driven feature representations can lead to significant medical advancements in this procedure. In medical imaging, deep learning has been utilized extensively to improve picture analysis. This research takes a deep dive into the field of machine learning, and it summarizes some of the most important contributions and cutting- edge results from this field thus far.

For the diagnosis of many malignancies in chest X-ray images, ShuaijingXu and coworkers [12] present an attention-driven ensemble learningand association context model. The CNN- ATTENTION-LSTM (CAL) network at first integrates a CNN model with a long short-term memory mechanism to identify items in both texts and images [13, 14]. In addition, a mining approach of implicit association intensity guides CAL network training to generate a chest lesion association structure (CLA).

There must be an effective cancer prediction system that utilizes a computer assisted automated detection (CAD) method at the clinical center. Enhanced lung image processing algorithms [15] are being utilized to probe the body's internal workings, recover features, retrieve vital info, and create an informed method for identifying lung disease. Some of the many processing methods utilized for lungs include: preprocessing, injured portion separation, extraction of features, and lung cancer diagnosis. Segmentation is one step in the process since it analyses each pixel in the lung imagery to determine which cells are linked to cancer and which are not, allowing for a more accurate classification of the both.

To enhance tumor categorization, Sarfaraz Hussein et al. [13] recommended different machine learning techniques. The first method relies on supervised learning; deep learning approaches such a 3D Convolutional Neural Network (CNN) and Transfer Learning have demonstrated significant improvements. Then, it is shown how to integrate task-dependent feature representations into CNN architecture via a graph-regularized sparse Multi-Task Learning (MTL) technique informed by radiologists' interpretations of the scans. When labeled training data is scarce, unsupervised learning methods can be utilized to improve medical imaging applications. Multiple instances learning (MIL) is an example of a minimally supervised classification that may prove useful here. One such approach to addressing problems is active in the learning process. Medical imaging problems can only beaddressed with the development of unsupervised learning systems.

Approaches for identifying COPD were proposed by Ran Du et al. [14], who suggested employing deep convolutional neural systems to assess 3D lung bronchial tree branches from the viewpoint of machine vision. CT images are used to extract airway trees, which are then 3D visualized in ventral, dorsal, and isometric views. A Bayesian optimization approach is used to build a single deep CNN model that can identify COPD.

In order to evaluate the effectiveness of medication adherence over time, Xiaohong W. Gao and colleagues [11] looked at how CT respiratory imaging may be used to detect and categorize tuberculosis across five severities.

III. Common Detection System for Pulmonary Disease

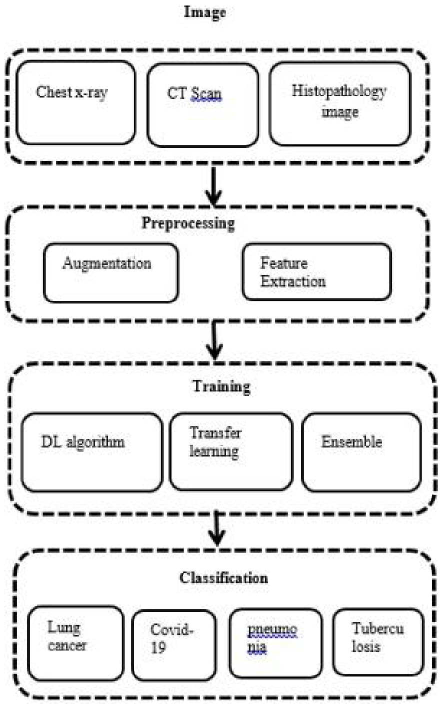

Fig. 1. Common Prediction Framework

1. *Image Acquisition*

The utilization of deep learning to analyze clinical images as a diagnostic tool for respiratory problems has been explained in depth. Two out of the three main processes are learning and classification. It is usual practice in the diagnosis of respiratory illness to characterize images as normal lungs and contaminated lung imagery. Training is necessary for the development of the lung disease classifier, or model. A neural network can be taught to recognize a certain sort of image when it is trained. Classifying images into their respective categories is a task well- suited for deep learning. The first step in applying deep learning to pulmonary disease diagnosis is the collection of imaging modalities of affected lung. Diseases can be identified once the neural network is trained.

Images are the first step. For a computer to create a classification model, it has to learn from its experiences. It takes a lot of photos for the computer to recognize an object. Deep learning models can be trained using a variety of data formats, including time series and speech recordings. Lung disease can be detected using photographs, which are essential data in this paper's context. Some types of images that might be utilized are those obtained via radiograph, CT scan, mucus smears microscope, and histopathological screening. This step generates photos that will be fed into the model's learning process.

2. Pre-Processing

The sharpness of a visual can be improved by enhancement or modification. CLAHE is a contrast enhancement algorithm. The region of interest for lung disease diagnosis can be found by image processing techniques including lung segmentation and bone eradication. Data can also be represented in a different way, and edge detection can help with that. The images might be enhanced to provide more information. Adeep learning model can recognize a specific entity in a variety of ways, including by retrieving relevant attributes from the data set. This stage has resulted in the improvement of these images or the removal of unwanted elements from them.

3. Training

In training, there are three ways to look at it. When deciding on a deep neural network algorithm, it's important to take into account a variety of factors, such as the application of learning algorithms and ensembles. Algorithms learn in a variety of ways. Specific algorithms are better suited to certain sorts of data. CNN excels in using images to convey information. In this case, a deep learning method should be used. In this method of learning, information is passed from one model to the next in a logical chain of reasoning. The phrase "ensemble" refers to the classification of data using multiple models. Learning time is reduced; classification performance is enhanced, and over fitting is avoided by utilizing learning algorithm and evolutionary algorithms.

4. Classification

When an image is presented in a certain way, the trained model will be able to estimate which class it belongs to. According to the model, the likelihood score for the image will be determined. Using the probability score, you may determine how likely it is that an image belongs to a given category. When we nearing the edge of this phase, the image will be categorized according to the probability score that the machine learning strategy assigned to it.

IV. Taxonomy of Lung Disease Detection

Among the many things this study adds to the conversation is a classification of existing deeplearning projects for diagnosing lung diseases. The purpose of the taxonomies is to identify and categorize the most pertinent questions and areas of emphasis in the current scientific literature. The taxonomy's seven characteristics were determined. These traits were selected because they are ubiquitous and can be observed in every object of investigation. The seven aspects of the taxonomies include image classes, attributes, up-sampling, deep learning method types, learning techniques, the ensemble of classifiers, and lung cancer diagnoses. Figure 3 depicts the current lung disease detection taxonomy based on deep learning.

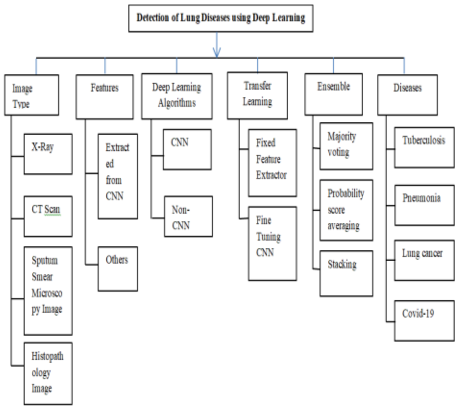

Fig. 2. Distinct Features of Deep Learning for Respiratory Disorders

4.1 Kinds of Images

TABLE 1. Types of Various Lung Images

S. No	Image Type	Description	Sample Image
1	Chest X-Rays [26]	1. Anatomical details such as images of blood arteries and lungs can be gleaned throughthisprocedure.	
		2. In order to examine X-ray images, they must first be processed onphotographic film.	
2	CTScan [25 23]	1. For radiographic imaging that uses computer processing. 2. From photographs taken from a variety of angles around the patient's body, create sectional views of varying depths. 3. It provides more information than X- rays, which are lessprecise.	
3	Sputu m Smea r Micro scopyImages [27]	1. Lungs and airways breathing tubes produce thick fluid. 2. For sputum examination, the illustration is placed on a glass slide witha very thin layer.	
4	Histopatho logy Images [2833,2934]	1. Glass slides are used for microscopic assessment of a biopsy or surgical specimen to study the signs of a disease. 2. One or more stains are used to highlight the tissue's variouscomponents.	

4.2 Methods and Importance of Features

In machine vision, characteristics are numerical measurements extracted from images that canbe employed to address certain challenges. Structures such as points, edges, colors, shapes, or objects can be used to depict features in the image. [16] The categories of images have a logical effect on the quality of attributes. It is possible to generate new features from existing ones by using feature transformations. However, in a different context, they may have a greater ability to discriminate than the original traits did. When transforming features, the purpose is to give a machine learning system for object identification a more usable feature.

4.3 Augmentation

When the number of observations in each category is equal or balanced, deep learning algorithms function best. In order to increase the size of the training dataset, it is not necessary to constantly add new images. Through the process of image augmentation, the source images undergo alterations. The effect is accomplished by employing the use of distortion, revolutions, flipping, translations, and digital zoom. Figure 8 displays a variety of enhanced photos.

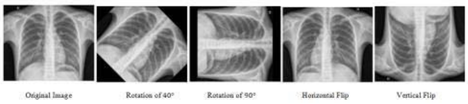

Fig. 3. Augmentation of Lung Images

4.4 Deep Learning Methods

"Deep learning" refers to a subfield of learning algorithms inspired by the structure of the human brain. The strong performance of this method is useful in many different areas, including medical imaging processing. Deep learning methods are used to sift through medical databases for relevant information. The application of deep learning techniques has improved the categorization, delineation, and identification of lesions in medical information. Diagnostic imaging information from MRIs, CT scans, and X-rays was analyzed using deeplearning methods. These discoveries have made it easier to detect and diagnose diseases like diabetes, brain tumors, melanoma, and breast cancer.

4.5 Lung Disease Detection

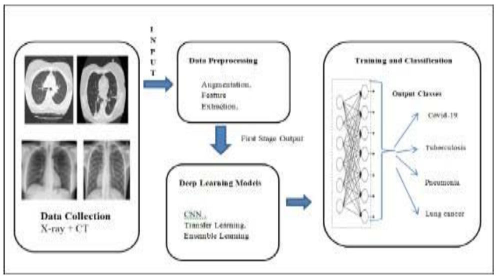

Fig. 4.Common Methodology of Lung Disease Detection using Deep Learning

Deep neural networks (DNNs) can be utilized to address picture recognition difficulties using convolutional neural networks [17]. When it comes to CNN's operation, computers must be able to recognize and interpret images presented as input. In order to make use of the photos, they must first be transformed to a matrix format. On the basis of disparities in picture and matrix, the system identifies what image is associated with what label. These variations in labelling are learned during training, and then applied to new images in order to create predictions.

Convolutional, pooling, and fully connected layers are all part of CNN's three-layer structure. The feature extraction approach includes both convolutional and pooling layers. However, categorization is done in the fully linked layer.

4.6 Transfer Learning

Due of its ability to create accurate models, transfer learning has become an increasingly used technique in computer vision [18]. Withtransfer learning, a model learnt in one field can be applied to another. A pre-trained model or not, transfer learning can be accomplished. Pre- trained models are those that were built to solve a comparable problem. It is preferable to Pre- trained models are those that were built to solve a comparable problem. Starting over with a difficult aspect in consideration is better to starting over with a particular challenge. In most instances, it was found that using a system that had been pre-trained on a different task than the current task improved performance.

Through some kind of series including forward and backward repetitions, the objective of the process of developing a deep learning algorithm is to locate the appropriate weights to apply to the nodes of the network. They are a valuable source of current situation information thanks to these pre-trained models Transfer learning may be applied in two ways as a feature extractor using CNN, which I fine-tune. [19] Some of the weighting in the early levels come straight from the pre-trained CNN model, whereas higher levels require optimizing weights. Typically algorithms can only be trained up at the base level, meaning just the weights at the top of the model are changed. It is possible to use first-layer data for a wide variety of purposes since it contains generic qualities. To acquire more advanced features unique to the specific dataset, it is necessary to educate the model's upper layers. However, CNN employs a feature extractor. The fully- connected levels can be removed, and the network can be used as a fixed feature representation for the new set of information.

4.7 Classifier Ensemble

Ensemble categorization is the outcome of using the outputs of multiple classifiers together. The forecasts of ensembles are much more reliable than those of a unified framework. A sampling of ensemble voting techniques comprises qualified majority, probabilistic score averaging, and stacking. In amajority vote, each system assigns a class label to a test case and then forecasts the class label that gets the most votes [20]. There are some models that have their votes counted more heavily than others when it comes to the majority vote. Probabilistic score aggregating is a statistical method for combining and dividing the predictions from many systems. In its place, weighted aggregating can be used to calculate an average by multiplying the prediction score of each modeling by its weight. [21] An approach called stacking ensembles takes the results of multiple less accurate models and tries to combine them in the best way possible so that the final forecast is more accurate.

4.8 Types of Diseases

This study details the use of deep learning techniques for the identification of TB, bronchitis, emphysema, and COVID-19. People with lung disease are more likely to die from COVID-19 than any of the other three diseases on this list because it's a pandemic that is still going on.

4.8.1 Tuberculosis

The World Health Organization [22] reports that TB is a major killer worldwide. In 2017, 1.6 million individuals all over the world passed away due to tuberculosis. The likelihood of a successful recovery from tuberculosis is greatly increased when the disease is discovered early on. In the literature, CNN has been used to classify TB. Improve the CNN's accuracy by factoring in user-provided age, sexual identity, and bodyweight information. Computer-aided diagnosis (CAD) was used with clinical data to score the chest X-rays. This combination enhanced precision and specificity when compared to using either type of information alone.

4.8.2 Pneumonia

As the most prevalent kind of pneumonia, bacterial pneumonia has more significant indications and requires medical attention.Although bacterial pneumonia can present itself gradually or quickly, the symptoms are often similar. There may be excessive sweating and rapid breathing and heart rate as well as a dangerously high fever of 105 degrees F. Lips and nail beds may turn blue if oxygen levels in the blood drop too low. A patient's psychological condition may be unclear or delusional. Pneumonia is difficult to diagnose because its signs are nonspecific and may be mistaken for those of a common cold or influenza.

4.8.3 Lung Cancer

The most frequent forms of lung cancer are small cell pulmonary cancer and non-small cell lung cancer [23]. Signs of lung cancer have included a persistent cough that produces blood, chest pain, fatigue, appetite loss and breathing difficulties or weakness [24]. The survivability rate increases from 15% to 50% with early identification [25]. Yet, this rate of survival must be raised above its present level. X-rays, CT scans, MRIs, and other noninvasive imaging methods aid in the early diagnosis of lung cancer. CT scanning is the gold standard for creating 3D lung pictures [25]. It is possible to lower mortality rates with early diagnosis and treatment. The method of early identification of cancer is crucial in stopping the progress of the disease cells. The accuracy of current lung cancer detection methods is inadequate. Therefore, it is crucial to find novel means of detecting lung cancer at its earliest stages.

4.8.4 Covid 19

COVID-19 is an infectious disease brought on by the SARS-CoV-2 virus. The majority of persons who contract this virus will have mild to moderate respiratory symptoms and will improve without any particular therapy. Some, though, will become gravely ill and necessitate professional medical care. People over the age of 65 and those who already have illnesses like high blood pressure, hypertension, asthma, ormalignancy are at a higher risk of becoming seriously ill. At any age, someone who has COVID-19 infection has the potential to become gravely ill or perhaps die.

V. Knowledge of Dataset

The LIDC-IDRI image review synthesizes thoracic CT images with annotated lesions for diagnostic and screening purposes. It is a worldwide internet-based resource for the creation, training, and evaluation of computer- aided diagnostic methods for the recognition and diagnosis of lung diseases. Nodular, non- nominal or nodule > 3 millimeters in diameter are all three categories that radiologists assign to CT scans in this initial step (NMD). The datasets utilized to detect lung disease are summarized in Table 2. Only public datasets are included.

TABLE 2. Summary of Dataset for Lung Disease Detection

Name of the Dataset	Image Category	Total Images	Reference
JSRT dataset	X-ray and CT	154 nodule & 93 non-nodule	[11]
LIDC-IDRI	CT	1018	[12, 15]
NIH-14 dataset	X-ray	112,120	[13]

VI. Challenges and Future Scope

Despite the accomplishments of deep learning technology from a medical and therapeutic perspective, numerous limits and problemsremain. Deep learning usually necessitates the use of a huge volume of labeled data. Medical image annotation faces a significant problem in meeting this need. Radiologists, for example, have extensive domain expertise that is required for labeling medical pictures. An adequate medical picture annotation is therefore labor- and time-intensive [26]. Regardless of the challenges of annotating medical information, a large number of clinical images are stored in PACS for an extended period of time. This results in a large number of images that do not have any labels attached to them. Deep learning algorithms might make use of the unlabeled pictures, saving a lot of time and effort in the annotation process. More training data sets will be used in the future, and the model's parameters will be tweaked to improve speed in the model. Some of the measures' settings will be put to the test as well. To enhance the accuracy, we can run experiments on a pre- trained classic. The representation of deep learning is another problem that needs to be addressed. The application of deep learning in the analysis of medical images is becoming increasingly popular, and additional research is being conducted to get it ready for clinical deployment [27]. Legal openness and interpretability would be required if deep learning applications were widely used in the medical industry.

VII. Conclusion

A current issue of discussion in the fields of medicine and information technology is the application of deep learning to the evaluation of medical images. Consequences of study in these areas are described extensively in this article: Initially, the neural network framework for deep learning was introduced, which was actively investigated. Classical models utilized in medical imaging were also included as part of the network's deep structure. In the beginning, neural networks were used in the treating a wide variety of respiratory illnesses. Analysis and categorization as well as a deep assessment of the framework advancement aregiven in this report to lay a substantial basis for future researchers in deep neural networks for various disease-related jobs. Also included in this work are some commonly used datasets on a variety of disorders, so that others might conduct similar investigations.

Abstract— Twitch is a platform that provides live streaming services for videogames; it has created a great environment for people that enjoys both watching and playing games, but with the increase in the number of streamers and games, streamers must find ways to get better recognition and find all points of leverage for better interaction on their streams and content. This paper analyzes the relationship between a Twitch streamer's success with their presence on Twitter

Keywords — social media, social media integration, prediction, random forest; decision tree, Twitch, Twitter, data science, machine learning

I. Introduction

Twitter provides free microblogging and social networking service. Twitter is one of the top 5 social media applications that is used worldwide. Twitter users can broadcast short posts which are known as "tweets", The tweets can be in the form of text, videos, photos, and links. People can get the latest updates and promotions from brands. More than 100 million users post 340 million tweets daily.Since the start of Twitter, academics and businesses have tried to find ways to gain intel and insights from it.

Twitch is a platform that provides live streaming services for video game streaming and other interactions. This paper deals with showing the relation between twitch streamers' presence on Twitter and the success of twitch streamers.

II. Data

A. *Dataset*

The data used in this analysis was taken from Kaggle, "Top 8800 Twitch Streamers" [1]: - The dataset contains information about the top 8800 twitch streamers that are currently streaming on the platform.

This dataset covers some essential criteria that are used to gauge the performance of a streamer.

B. *Exploring the Dataset*

The dataset about the streamers contains the following features as given in Figure 1.

attribute	description
top count	the ranking of the streamer based on watch time (disscussed later)
screen name	name of the streamer
watch time	total number of minutes people have consumed his content
stream time	number of hours he has streamed
peak viewers	number of peak viewers
average viewers	number of viewers the streamer receives on average
followers	number of followers the streamer currently has following his content
followers gained	number of followers gained in the last month
views gained	number of new viewers gained in the last month
partnered	whether or not the streamer is partnered with twitch
mature	whether or not the streamer's content is mature in nature

Fig. 1. All Features and their description

Since the dataset contains a few extra features which are not needed in this project a few features were taken and a few removed as given in Figure 2.

DOI: rp-9788770040723.013

attribute		reason
top count	removed	since it is not relevant to the analysis
screen name	kept	for sentiment analysis on twitter
watch time	kept	it is a very important feature
stream time	kept	since it is only variable the streamer has a control over
peak viewers	removed	since it is a one-time number and does not affect follower and viewers
average viewers	kept	the most important feature,as it leads to monetization and income for the streamer
followers	kept	to see its impact on average views
followers gained	removed	since it is not relevant to the analysis
views gained	removed	since it is not relevant to the analysis
partnered	removed	since it is not relevant to the analysis
mature	removed	since it is not relevant to the analysis

Fig. 2. All Features and reasons for keeping them

The attribute that decides which streamer is at the highest ranking is the watch time as it generates the mostrevenue and is given more attention by the algorithm,governing a streamer's appearance on a viewer's watch feed.

A variety of aspects affect a streamer's watch time, but there is one which is considered crucial among social media personalities and that is their social media presence, particularly Twitter. This is considered important as it effects how many people they are able to attract to their stream to view their content.

This presence is not direct, that is someone with a positive presence is not necessarily going to have the highest watch time and similarly people with the most negative presence may not have the lowest watch time.

So, in this paper we analyzed this aspect by using data from Twitter using Tweepy [11], the Twitter API. It filters Tweets made about a specific streamer in the past seven days and segregates them into positive, negative or neutral in nature.

III. Related Work

Many researchers have tried to find relations between the entertainment industry and social media, and how their presence on social media affects either their job or their popularity.

In [2] Dr.Rose Catherine aims to accurately predict the box office success of upcoming movies using tweets.

In [3] J. Huang, W. F. Boh, and K. H. Goh investigate the relationships between comments generated from social media and sales using a natural language processor, similarly in [4] and [8] by using meta-data mined from social media such as number of likes on a Facebook page for the movie, follower count of actorson Twitter and the number of likes on the trailer of themovie on YouTube.

In [9] Vasu Jain's analysis tweets about movies to predict several aspects of the movie popularity and covers how movies have a higher rate of success based on the visibility of the movie on social media help in the sales of the movie.

When twitch, a primarily game streaming platform is being considered it is understandable to consider games and their trends. The present technological boom has to lead to a major increase in people that enjoy both playing and watching video games.

In [5] Boris Bankov has written about the impact of social media on video game communities and the gaming industry. It describes the evolution of the gaming industry and the impact of integrating social media subsystems on gaming communities. The study includes a relationship between social media platforms and the gamingindustry.

[12] is a very highly recommended article about the author, Henry Jenkins teaching a course on Transmedia Entertainment and Storytelling, similarly [13] is also an article by the same author discussing the impact social media has on businesses.

[6] talks about trying to make predictions from socialmedia, and points out the many pitfalls, also the past methods used to do so.

In [10] ThienHai Nguyen and KiyoakiShirai build a model to predict stock price movement using sentiments on social media and subsequently describethe relation between the two. Both [14] and[15] analyze Twitter for predicting results of major events with a large crowds, that being Elections and the results of a football match in a league respectively.

IV. Approach

In a broad sense, the approach is to perform sentiment analysis on Twitter data corresponding to the respective twitch streamer and analyze how it impacts the streamers' watch time since it is deemed the most important figure to gauge a streamer's success. The first step is to clean the data. The dataset contains a lot of streamer names in other languages and not in English, hence it is not easy to process. Those names need to be replaced with their respective Twitterhandles.

By performing the sentiment analysis we get the following new columns as given in Figure 3.

attribute	description
positive	number of positive comment about the streamer
negative	number of negative comment about the streamer
neutral	number of neutral comment about the streamer

Fig 3:.New columns to the data

DOI: rp-9788770040723.013

Before segregating the results of the sentiment analysis to the respective column the columns look as follows:

s no	screen name	stream time	followers	watch time	positive	negative	neutral	average viewers
0	xQcOW	215670	3691010	7333609065	0	0	0	32913
1	Gaules	515595	1966465	6314532585	0	0	0	12254
2	summit1g	216000	5374710	6235007490	0	0	0	25931
3	ESL_CSGO	517965	4195657	4764929775	0	0	0	9249
4	NICKMERCS	131880	4415637	3853252845	0	0	0	29183

Fig 4: Data Frame before sentiment analysis is performed

The data in the new column will be zero as given in Figure 4, sentiment analysis has not been performed, hence these columns are left empty. Sentiment analysis is performed on all the streamer tags and increments the respective sentiment category. In [7] and [8] the type of sentiment analysis techniques is covered.

s no	stream time	followers	watch time	positive	negative	neutral	average viewers
0	215670	3691010	7333609065	8	2	20	32913
1	515595	1966465	6314532585	8	12	80	12254
2	216000	5374710	6235007490	10	22	66	25931
3	517965	4195657	4764929775	26	4	11	9249
4	131880	4415637	3853252845	51	9	40	29183

Fig 5: Data Frame after sentiment analysis is performed

Once sentiment analysis is done there is no need for the streamer tags, hence they can be removed.

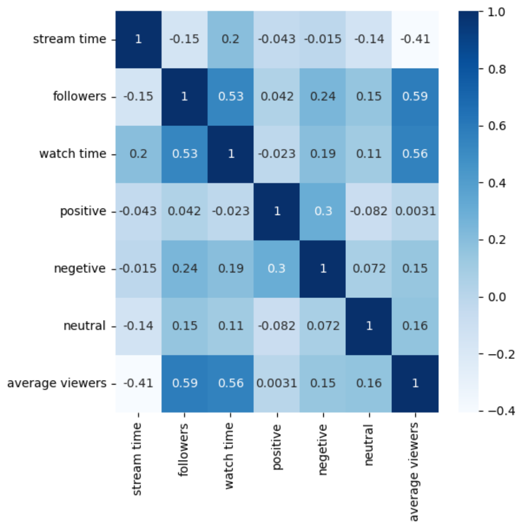

Fig 6: correlation matrix

Since watch time is the most important feature to focus on as it is the feature that determines the success of the streamer, we train a random forest regressor on it, since Random Forest Regression is a powerful and accurate machine learning algorithm that is used for both regressionand classification type problems.

From figure 6 we can understand that followers and Averageviewers are more related to Watch Time out of the three important features (‘stream time’, ‘followers’, and ‘average viewers’). Hence, we train the model on the data described in fig 5 leaving out the stream time feature and leaving out the:

i)positive and neutral features ii)negative and neutral features iii)positive and negative features

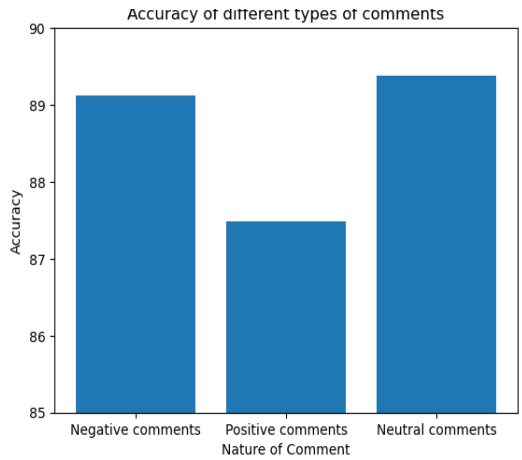

Fig. 7. Accuracy of different types of comments models

Figure 7 gives the accuracy of the random forest regression model trained on the previously mentioned criteria. The model’s accuracy is at a minimum, over 87% for positive type comments, and a maximum, over 89% for negative andneutral type.

IV. Conclusion

In this work, we presented an analysis of the relationship between the presence of a Twitch streamer on Twitter and the streamer’s success, based on how the streamer is perceived on Twitter. We know that a streamer is considered successful based on the streamer’s watch time. We found that the Watch Time is most related to Followers and Average Viewers.We also foundbased on the performance of our model that negative and neutral comments have more impact on the Watch Time.

***Abstract*—Agriculture is a major economic driver in India but productivity related issues pinpoints to the significance of choosing the right crop under given conditions. Agriculture is in turn intrinsically dependent on the fertilizer industry - one of the eight core industrial sectors in India. However, tackling issues overuse and runoff leakages has been a persistent problem because of a "one-size-fits-all" approach and can be corrected through the principles of Precision Farming. One of the ways of addressing geographical variances in agricultural needs could be by informing cultivators of site-specific required NPK (Nitrogen - Phosphorus - Potassium) ratio for various crops. Underlying this idea, this work pitches a two - dimensional recommendatory ML-enabled tool that assesses soil quality parameters to provide features of (i) Crop Recommendation using ensemble technique built by six classification base learners for greater accuracy encompassing greater number of crops, (ii) Intelligent and balanced fertilization by predicting weather-affected nutrient (specific to macro-nutrients NPK ratio) requirements of a region by calling live weather API.**

Keywords— precision farming, nutrient management, intelligent fertilization, Ensemble Learning, NPK ratio

I. Introduction

The Green Revolution was the harbinger of mass incorporation of fertilizers in Indian agriculture and made the country self-sufficient but also brought forth newer complexes. The sole focus on increasing productivity through High Yielding Varieties (HYV) of crops has still kept optimal and sustainable farming a farsighted goal because of unawareness related to agricultural sciences, fragmented land holdings, dependence on weather etc. Also, the concentration of its success in Punjab, Haryana and the subsequent rice-wheat boom highlights that the framework did not entirely address geographical or climatic variations across the nation. Precision farming introduces smart practices that address these differences.

Precision Farming is a concept that uses tech to ensure crops and soil receive what they need for optimal growth and productivity. It involves site-specific agricultural practices. Experts at the International Society of Precision Agriculture (ISPA) have highlighted the [1] 5Rs that can help attain the goals of Precision Farming are - right place, right time for the right input, in the right quantity in the right manner.

The Indian Council on Agricultural Research (ICAR) and the National Commission of Farmers 2006 concurred that the nation-wide [2] standard ratio of 4:2:1 for primary fertilizers NPK doesn't hold for all the regions of the country. Several studies show that farmers plant an inappropriate crop based on conventional or non-scientific approaches and try to ensure high yield through mindless use of fertilizers.

The aim of this project is to advocate the principles of smart farming by providing accurate crop recommendations and integrating nutrient management (of macronutrients - N, P, K) at a regional scale using weather conditions instead of standardizing it. The presented work is intended to present a prototype for introducing precision nutrient management in a more dynamic and dependable form.

The objectives of the project are : (i) To customize crop-fertilizer management (ii) To advocate for integrated nutrient management in farming (iii) To build a competent advisory service to eliminate unawareness and negligence in agricultural practices regarding fertilizer use inline with recommendations of ICAR and National Commission of Farmers (2006) (iv) Use of machine learning techniques to enhance accuracy and legitimacy.

II. Literature Survey

[3] This work seconds the need for agricultural practices integrated with nutrient management. The optimal nutrient input ratio has been greatly impacted by the large interstate and interregional variability in fertilizer use.

[4] A precision agriculture project in Karnataka used GIS mapping to accommodate spatial variations of soil properties to ascertain yield variability of three crops most commonly grown in three north-eastern regions. This pinpoints the fact that deployment of information technology at micro-level can much better cater to agricultural goals. Climatic conditions however were not considered.

[5] Precision farming practices address geographic and temporal variations in nutrient availability that facilitates better decision making based on the vital gap between plant demand and soil supply. Under this premise, the use of sensors for capturing soil properties, aerial crop images and site maps is not established for nutrient management. Their

DOI: rp-9788770040723.014

potential remains to be validated under various agro-climatic conditions.

[6] Focus should be on solving productivity related issues by thoughtful crop selection instead of trying to increase the yield of a lesser apt crop for the region. Eradication of problem at the source through better crop and fertilizer management would lead to diversification of crops and reduced fertilizer consumption. fter comparing with other technological frameworks, this work suggests ensembling technique to be best suited for crop recommendation. Three independent base learners have been used to build the recommendatory model, where the advantage in using independent frameworks lies in time efficiency in comparison to dependent frameworks.

[7] SVM, Random Forest have been used for soil classification and crop yield prediction whereas [8] Decision tree, K- nearest neighbor, Linear Regression, Naive Bayes also showed impressive results. The choice of base learners for our adopted ensemble learning framework was guided by the conclusions of these works.

[9] Taking NPK ratio for a single crop (i.e. rice) helps make the following conclusions: climatic factors such as temperature variations and total rainfall, change nutrient concentrations - rainfall in the right quantity can augment nutrient sufficiency but extreme rainfall would lead to runoffs.

[10] The prediction of crops as a function of rainfall in four states of India is determined using a comprehensive evaluation of all regression techniques. This is done predicting crop yield for a given amount of rainfall.

While random forest has been widely used independently for crop recommendation or crop yield prediction, [11] shows the abilities of conditional random forest models to evaluate data to create useful information in fertilization studies and that such techniques can be used in other long-term techniques.

III. PROPOSED SYSTEM

The proposed system emphasizes on the primary fact that climatic conditions and soil properties affect crop production and agricultural practices like fertilization should be attuned to these variations. Two operational modules are taken into consideration

A predictive model based on Random Forest Regression with K-fold cross-validation technique is used for determining nutrient requirement for a crop. The user is required to enter input features of crop (to be harvested) and location. The state and city entries direct the model to the live weather API which accumulates values such as regional rainfall, humidity and temperature to finally predict values of N, P , K requirements.

The second module employs the ensemble technique for crop recommendation across multiple Indian states for 26 crops through independent base classification learners. The N, P, K ratio for a particular location is used to classify crops. The choice of classification techniques is being guided by similar works done on crop recommendation. Entering soil inputs to get best suited crops and finding optimal soil requirements for maximum, sustainable output - the module can work both ways. The system is presented under the assumption that farmers or cultivators have access to nutritional information of the soil like nutrient presence and pH values through their respective soil health cards provided by the government. The use of sensors otherwise for quantifying nutritional values of soil in an IoT based environment, has seen limited on-site implementation and hence lab-based tests become a more dependable source of input data.

IV. METHODOLOGY

1. *Data Preprocessing of raw input*

The most crucial step for an accurate model requires pre-processing that can convert raw, unorganized data into a form that can be understood by computers and used for machine learning models. Mathematical concepts of mean, mode, median are employed along with scaling values to a particular range, data cleaning, data encoding and determining correlations among variables.

2. *Deploying exploratory data analysis*

Exploratory Data Analysis is an essential step of doing initial assessment on data in order to uncover patterns, identify irregularities, test hypotheses, and validate assumptions using summary statistics and graphs. This can take the form of univariate, bivariate or multivariate analyses. PDF, CDF are some instances of univariate analysis and box plot and heat map are forms of multivariate analysis.

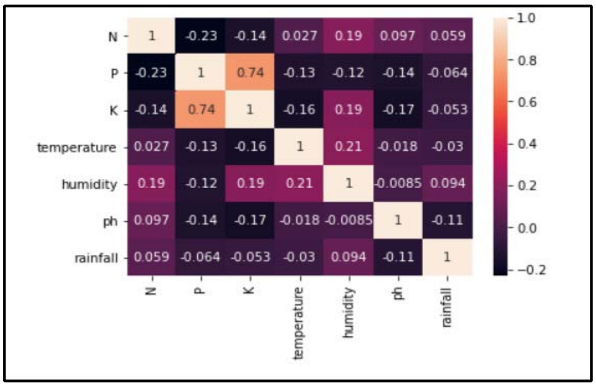

Fig.1. Heatmap-correlation metrics of the dataset for crop recommendation

3. *Data Splitting*

Training and testing datasets are formed on a 80:20 ratio. The 20% data is used to test the model on the unknown data and perform cross-validation to determine the hyperparameter - [13] these are parameters that govern the learning process acquired by a learning algorithm. These are 'top-level' parameters that drive the learning process and other model parameters that come from it.

4. *Training multiple models on the same dataset*

The preprocessed training set is fed onto multiple independent learning models whose results will be accumulated for ensemble technique that will finally give a class label from every classifier. Our choice of classifiers was followed by as assessment of related works, post which the most frequently used classifiers were chosen

a) Decision Tree - as a supervised learning tool based on a tree-like structure, it can be used for both regression

DOI: rp-9788770040723.014

and classification. [14] A decision tree has a structure similar to a flowchart, with a tree representing attributes and class labels.

b) Naive Bayesian Classifier - the advantage being that it is simple and straightforward and works under the premise that all features are independent of each other.

c) Logistic Regression - classification of a datapoint in an n-dimensional space. It is based on statistical recognition whereas SVM is based on geometrical properties.

d) Support Vector Machine (SVM) - where the main task involves determining the best hyperplane. Each data having n features is plotted onto a n-dimensional space and the hyperplane must segregate any two given classes (in a linear kernel) with the highest margin. [15] SVMs require lesser variables for a similar or higher MCR value

e) XGBoost - in comparison to decision trees, it is a more advanced tree-based approach sed for gradient boosting implementations

f) Random Forest - a miniature of ensembling technique in which multiple decision trees are assessed for maximum depth until nodes split with minimum variability and bias

5. Testing data

A query point is presented to each classifier. A class label is the output of every classification model.

V. Implementation

The dataset has been taken from kaggle and referred from an earlier work [12] because of the presumed ease with data preprocessing. The sample size for this work comprises 2200 crop samples of 22 unique crops. This collection of data had the scope of encompassing multiple features. For the fertilization module, feature selection was used as a dimensionality reduction technique to simplify the model.

Various public datasets about India are augmented and combined in this project, such as weather, soil, and so on. Contrary to complicated features affecting yield of crops, this data is relatively simple and has only a few but useful features. It includes nitrogen, phosphorus, potassium, and pH values. In addition, it contains the humidity, temperature, and rainfall needed for each crop.We have used Pandas library through which we preprocessed our data efficiently. We converted the raw data to mergeable data so that it can be appropriately passed through our model. Libraries used in python are - pandas, numpy, matplotlib, pyplot, seaborn, sklearn etc. The corresponding features are nitrogen, potassium, phosphorus, temperature, humidity using which 22 unique features are predicted.

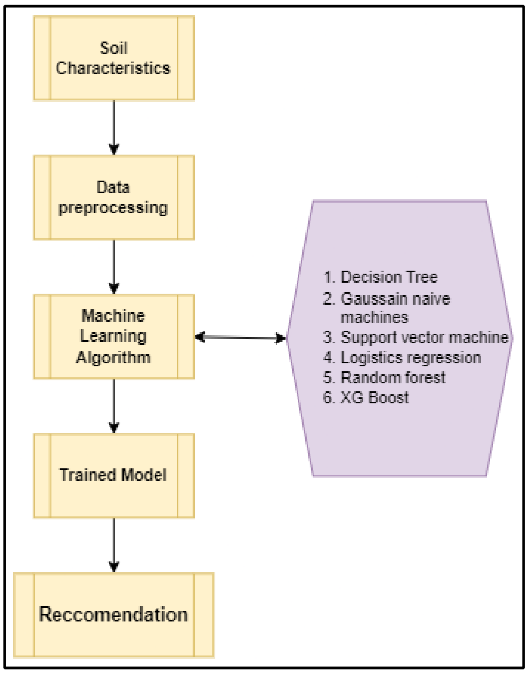

Fig. 2. Flow Chart of steps for Crop Recommendation using Ensembling Technique

The distinct class labels obtained from each classifier are applied to the majority voting technique to produce an ensembled class label as the final prediction.

Ensembling Technique for Crop Recommendation

Ensemble methods is a machine learning technique that integrates numerous base models to create a single best predictive model.The ensemble framework should be used primarily because it offers a classifier that performs better than each of the classifiers learning independently.

[16] Ensembling technique is of two forms - dependent and independent. In the former technique, the result of one classifier is further used serially in the learning process of the consecutive classifier. In an independent model, a class label is generated by each classifier without any input from preceding learners. Here, all classifiers work in parallel. Parallel execution makes it a more time - efficient alternative taking lesser execution time. It consists of the following components: training data (S) , base inducers (learners denoted by I), diversity generator and a combiner. Where the model M, can be represented as: M = I(S).

Random Forest Algorithm for Fertilizer Recommendation

Random Forest algorithm is also a classification algorithm that uses ensembling technique that combines the results of similar models to create a strong model built by multiple decision trees. The training is done via what is called as bagging (form of ensemble method) where the combination of multiple tree-like classifiers, trained on varying subsets of data, increases the overall accuracy. Three different random forests each having 50 decision trees (n estimators = 50), are created for each of the nutrients - N, P, K. The end result is the output of the mean of classes.

DOI: rp-9788770040723.014

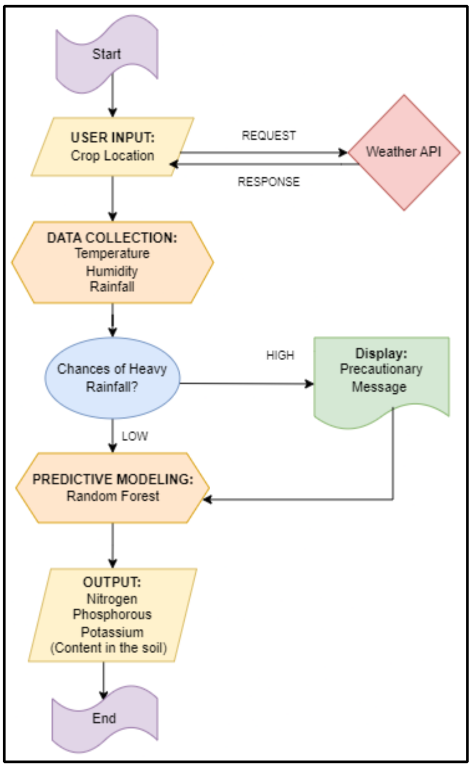

Fig. 3. Flow Chart of decision flow for Fertilizer Recommendation using Random Forest

We see here that the random forest model uses live weather API information to attain humidity levels or probabilistic values of precipitation using which required NPK values are displayed for a particular crop.

Majority Voting Technique

Majority voting is a concept using which the final result is obtained in independent ensemble learning. The labeling of an unknown data is done based on the highest number of votes obtained by a classifier - known as plurality votes. Majority voting is the most commonly used combiner in ensembling technique

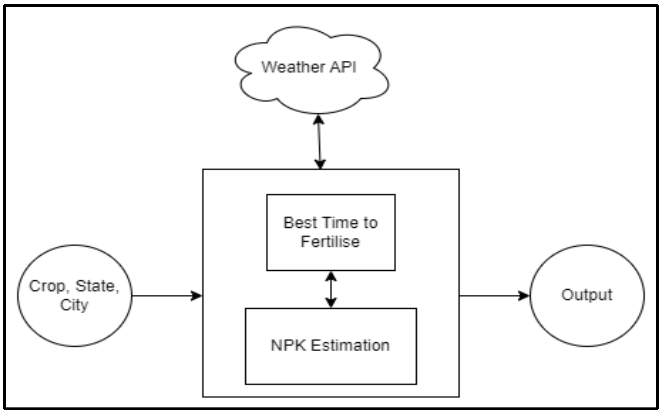

Fig 4. Block Diagram of Proposed NPK Fertilization

VI. Results and Discussion

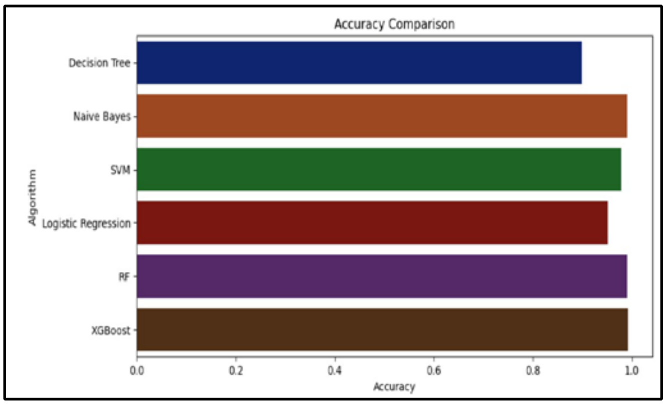

Fig 5. Accuracy comparison of different classifiers used in ensemble learning

Using Majority Voting Technique (MVT) different classifiers have been compared and the one with the highest votes is used to label the unknown data. The accuracy for crop recommendation has been shown to be 99% while required N, P,K ratio is being generated with an accuracy of about 87%

Hence, this project demonstrates how nutrient management can be implemented, through machine learning tools of ensemble learning and random forest with k-cross validation for better decision making in line with recommendation of commissions, that focused on a localized model for agricultural practices rather than a standardized one. A regional model will more comprehensively address the needs

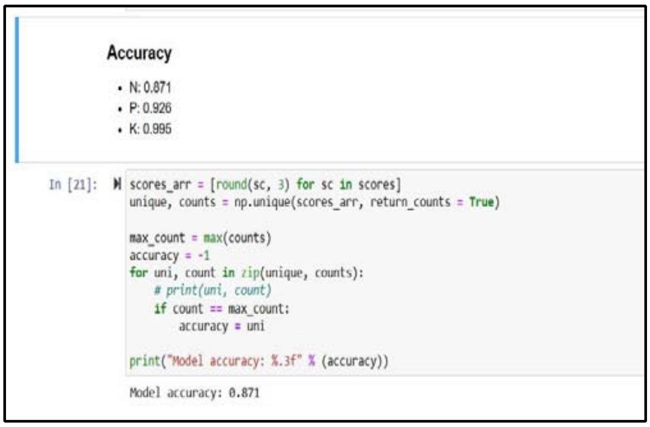

Fig 6: Model Accuracy of Proposed NPK Fertilization

VII. Conclusion and Future Works

A prototype Smart Farming tool has been presented with noteworthy accuracy to aid crop-fertilizer management by considering site-specific conditions of soil properties and rainfall. Fertilizer usage has been optimized through intelligent decision making.

Using crop sensors for soil assessment does allow nondestructive analysis of samples, however their validity has not yet been determined for precision nutrient management. This increases the scope of such a tool that can be deployed with more local information at micro-level for actual implementation as can be said from similar precision agriculture projects in states like Karnataka and

DOI: rp-9788770040723.014

Kerala, where good reviews were obtained. The main concern however with introduction of technology in conventional agricultural practices remains awareness and capacity-building through training etc.

***Abstract*—The environment is covered with many water resources. The living organism on earth relay more on water. Due to the growth of innovation and Technologies there is a need for protecting our environment. There are many plastics-based materials used in our day today life for packing, storing etc. These plastics pollute our environment and also reduces the quality of water. These pollutant affects the human life and also the aquatic organisms. The biggest challenge is to identify the object in the turbulence of water. In order to remove these various methods are used to detect the pollutants through object detection algorithms. This paper deals with overcoming the challenges of realizing the accurate pollutant detection techniques and provides a best method for real time garbage detection methods and its performance.**

Keywords—Deep learning, Floating Object, Intelligent Robot, Object detection, Water surface Cleaner.

I. INTRODUCTION

Water resources are potentially useful in multipurpose for human beings and other organisms. Water covers 71 percent of the earth's surface, but just 3 percent of that water is fresh. The water is contaminated by many unwanted substances which harms the organisms that relay on water. People relay on water for the purpose of drinking, cleaning, swimming and other essential activities. Although the crucial role automation plays in all industrial applications, properly disposing of sewage from industries and cleaning sewage remains a difficult task. The polluted water may affect the health of the organisms too. The major pollutants of water are industrial waste, oil spills, chemical fertilizers, wastewater and sewage. Humans pollute water in such a way that they throw plastics and other floating waste in water. Over decades, there has been an increase in the amount of water contamination brought on by human error. [1].

For every pollution there will always be several factor affecting it, likewise in case of water pollution the major factors affecting pollution are bacteria, viruses, parasites, weeds, chemicals from industries, food products and containers, and huge amount of plastics. Notably, plastics are the major cause of pollution which affects the lives of aquaticorganisms living in under water. major plastics do not degradeeven for years which affects all the living organisms in wateralso cause major health issues in humans. So this need for plastic removal is mandatory to lead a healthy life nowadays. Removing plastics from water bodies is not an easy task because of several factors affecting it such as some light weight plastics move along with the direction of airflow which is difficult to detect and collect the garbage from water [2]. Some heavyweight plastics which are submerged under water can cause toxicity for the animals and plants living in the water. Also, air flow plays the major role in plastic removalbecause the light weight plastics are carried out by the flow of air which cause hardship for the device to detect and collect the garbage as it should not leave any garbage whether it is static or moving in the water bodies.

The slippery and round shaped plastic bottles is a challenge to collect as the drag force usually makes the plastics flow away from the robot. Second, the robot is tele operated in a pond where Practical tests are used to gauge garbage collection capacity. Thirdly, the impact of matching the robot driving speed to the conveyor belt speed is investigated. To resist the disturbances that involves how to realize the real- time and accurate garbage detection while conduction of vision-based steering and despite the choppy water's surface, to grip the floating trash.

Detection: The moving robot makes a challenge to detect the plastics that flow away in the water surface. The object detection algorithm must be accurate and real time.

Navigation: The unpredictable dynamic factors such as wind and waves in the aquatic environment, that makes it necessary.

Collection: The objects will move on the surface of water due to the dynamic conditions and the robot itself. The plastics will move awayin according to the wind flow.

II. NEED FOR OBJECT DETECTION

DOI: rp-9788770040723.015

The various pollutants relay on water bodies which destroy the water and other organisms which depends on that water. So, the unwanted waste that float on water should be removed. In water it is difficult to remove waste as easy as possible due to the shaky movement of water. By human intervention activity it is not so easy to remove all those waste in case of large water bodies. Floating object Machine cannot work without any algorithms. We need to feed all the information in that machine in order to make it effective. The Fig 1. Shows the need for object detection. The first step tocollect waste is to detect waste. Therefore, there is a need forobject detection. There are many algorithms which give solution to this object detection with different accuracies. The primary goal of object detection is to identify occurrences ofa preset set of items and to use a bounding box to represent the locations of each object in the image.

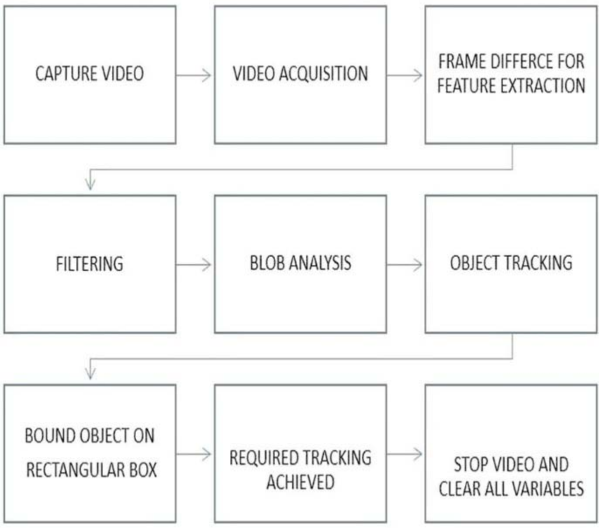

Fig. 1. Flowchart for need of Object Detection

IV. Object Detection

Detecting things in photos, movies, and other media is made possible by computer vision and image processing technology. The figure 2 shows the real time captured frame of image with floating garbage. AI is the fundamental concept behind object detection in this. Data is gathered by computer vision software and input into machine learning or deep. The camera gathers data from photos taken at various angles and transmits it to the image processing unit [4]. The findings are then presented based on the model's training data.

- Unfortunately, due to the saturation of hand-crafted features, object detection has reached a high after 2010. In 2012 the rebirth of convolutional neural and deep convolutional networks where successful at learning robust and representation of the image. The Convolutional Neural Network (CNN) has proposed and broken the deadlocks of object detection in 2014. Object detection has 2 genres: two stage detection and onstage detection.
- A set of object proposal starts with the extraction. The fixed sized image is fed into a pre trained CNN model

may not be in same position for a while, so by using waste boxes or with the hands of human is impossible [3]. So, to overcome these, a machine is to be invented. In case of plastic waste, the water may deposit inside the plastic bags which increases the weight of the waste so the machine needs to be designed which handle the weight of the waste.

to extract features. SVM classifiers are employed to identify object categories and forecast the existence of an item inside that region.

- R-CNN, SPP Net the image is processed at conv space layers for one time while the image is processed with R-CNN for as many times. However, it includes drawbacks like multistage and SPP Net ignores all preceding layers and solely fine-tunes its completely linked layers.
- In R-CNN, it is mostly unable to capture objects which are small. Pyramids can be used to solve this simple image to scale into different sizes. All the predictions can be combined when the detections are detected on each scale.

Fig. 2. Object Detection

IV. Proposed Methodologies

There are many methodologies that defines object detection in in a finer manner with different types of algorithms that detects objects and images. There exist many algorithms for object detection. some are very successful and some resulted in failures and some are still under testing state. Every algorithm has its own pros and cons. In spite of all drawbackssome notable object detection algorithms are also used widely which uses object detection and collection. some of the notable object detection algorithms are listed below:

A. *CNN*

CNN is a deep learning technique that stands for Convolutional Neural Network. Which is widely used in the few past years. It has high accuracy which is because used for image classification and recognition [5]. The computer scientist YannLecun proposed CNN algorithm in late 90's.he also shared that he was inspired from human visual perception of recognizing things. The convolutional neural network also known as artificial neural network; it is specially designed to process data in pixel. It has built in layers through which the high dimensionality of images is

DOI: rp-9788770040723.015

reduced without losing the information. In simple CNN is a supervised deep learning method and widely used in image recognition and detection [6]. It has 4 layers of network (1) convolutional layer, (2) pooling layer, (3) ReLU correction layer (4) fully connected layer.

Steps Involved:

- The foremost step is to **choose a dataset** which is choosing the image for classification is the initial step.
- Next is to **prepare dataset for training** which mostly deals within creating paths, and categories or labelling and also in resizing the image.
- Third is to **create training** data which contains pixel values from the image list.
- Next is to **shuffle the dataset** and the fifth step is toassign labels and features.
- The following step is to normalize and transform labels to categorical data.
- The CNN model is then defined, compiled, and trained.

The main advantage of CNN is its automatic detection of important features which can be possible without any human supervision is shown in Fig.3. It is also appreciated by learning about the key features by itself. But the encoding the position and orientation of the object is not possible in CNN [7]. It requires lots and lots of training which can take more timeto complete. It lacks in the ability of shifting the input signalto equally shifted output signal.

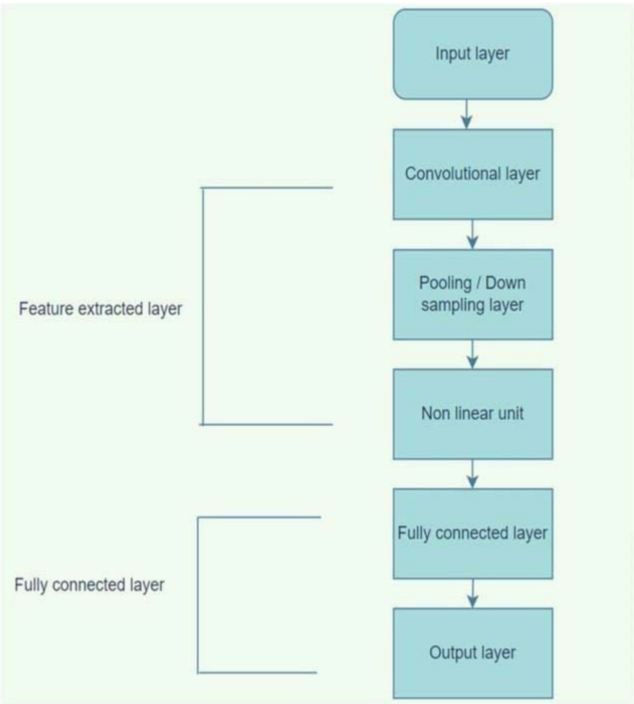

Fig. 3: Flowchart for CNN

B. Histogram of Oriented gradients (HOG)

The Fig 4. Shows the histogram frame works of image. Histogram of Oriented recognition gradients deals with face recognition that uses principal component analysis (PCA) to solve problems based on low accuracy. It is mostly used when the accuracy of the problem is low and it is used under nonrestrictive conditions. Most importantly the gradient orientation deals with the direction of greatest intensity change in the neighborhood of pixel. HOG uses features combined with linear classifier named SVM which is classification algorithm developed by V. Vapnik [8] along with his team. It is based on ideas of optimization and statistical learning. Both linear and nonlinear SVM training models are utilized for face recognition, and it is the primary approach for tackling pattern recognition problems.

Working steps in HOG

- Preprocessing: if a large image of size 720X475 is selected for a patch of size 100X200. The patch is cropped out of an image and resized to 64X128.
- Calculate gradient images: Sober operator is used to calculate the horizontal and vertical gradients
- Compute gradient histogram in 8X8 cells: the picture is divided into 8X8 cells, and the gradient is calculated for each 8X8 cell.
- 16X16 block normalization: A 16X16 matrix has four histograms that are combined to generate a 36X1 element vector.
- Calculate the histogram of oriented gradients feature vector: the concatenated vector is converted into one giant vector for calculation.

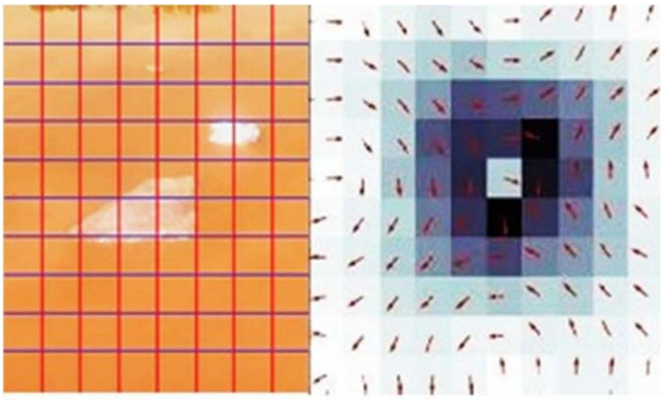

Fig. 4. Histogram Oriented Gradient

C. SSD

SSD stand for Single Shot Multi-Box Detector Single stage object detection method. Most of the object detection method detects the object by dividing it onto sliding windows, but SSD algorithm divides the object into grid cells which is responsible for detecting the object in that region of image. Detection of particular object is done by predicting thelocation of an object within that region. On different tiers of the output region, it employs default boxes of varied sizes, shapes, and aspect ratios. For better coverage of location, it uses 8732 boxes, scale and aspect ratios [9].

The majority of the predictions will be devoid of any item. It discards forecasts with a confidence value of less than 0.01. The main components of SSD are backbone model and SSD head it is shown Fig.5. The backbone model is a pretrained classification of image [10]. It is also like YOLO algorithm but it took only one shot to detect more

DOI: rp-9788770040723.015

than one object present in an image using multi-Box. To make this algorithm effective, training is mandatory. So, the input to SSD is givenas an input image with ground truth bounding boxes. During training, the default boxes are matched to the ground truth boxes in terms of aspect ratio, position, and scale. The intersection between predicted boxes and ground truth should be bigger than 0.5. Finally, we select the projected box with the greatest overlap with the ground truth. Thus, the object is detected using SSD algorithm.

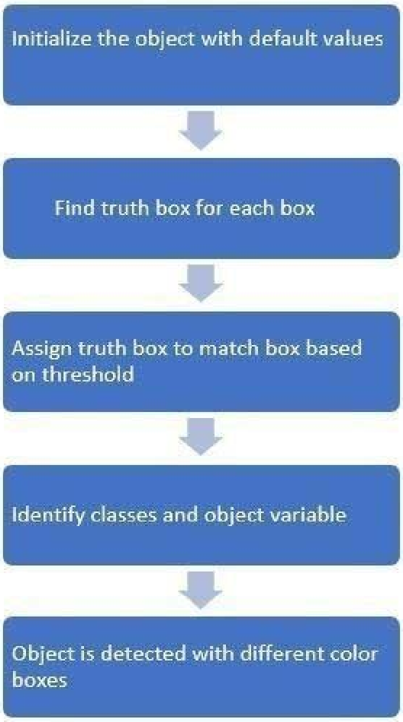

Fig. 5. Flowchart for SSD

D. YOLO (You Only Look Once)

YOLO is the most popular algorithms for the detection of objects and images the processing speed of YOLO is very fast that it is an algorithm to detect real time objects very fast. It produces high accuracy and overall processing speed which makes it popular [11],[12]. YOLO algorithm predicts the object and the location as bounding box of the input image. Using the four numbers it recognizes each bounding box; center, width and height of the bounding box.

Working of YOLO

At first the algorithm divides image into grids like 3x3 or 4x4, with the help of the grid it detects by objects per grid than objects per image, it encodes a vector for each grid to describe that cell. If a grid does not have any object, it is encoded as,

V1,1= (Pc, Bx, By, Bw, Bh, V1, V2) = (0, _, _, _, _, _) (1)

There is a possible that one issue might happen, if the algorithms predicts large number of bounding boxes for one class, to resolve this there is non-max suppression algorithmthat at first the box with maximum probabilityis considered[13] and it is compared with all the other boxes in that class with the use of Intersection Over Union (IoU), shown in equation 2.

$$\text{IOU} = \frac{\text{Area of intention between B1 and B2}}{\text{Area of union between B1 and B2}} \quad (2)$$

If the resultant IoU is exceeds the threshold, the box that has small probability is ignored. This process is continued and repeated until all the boxes are either predicted or excluded. The Fig. 6 shows the grid and cell vectors.

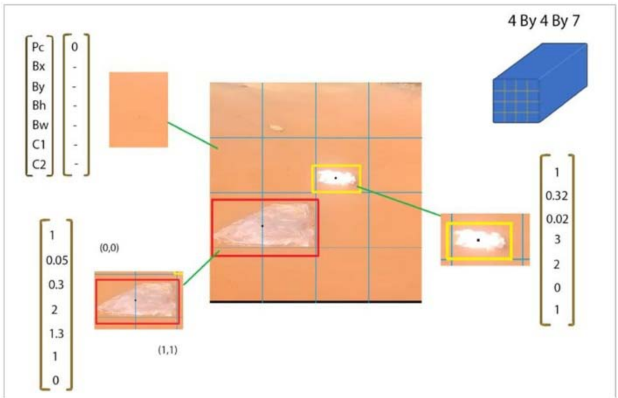

Fig. 6 Object detection using YOLO

V. Comparitive Analysis

Comparative analysis is the basic factor which defines the best among all. It is necessary to conduct comparative analysis to get a clear understanding of the problem or resultant relevant queries [14]. Notably when it comes to object detection, the chosen algorithm must be very effective to detect all the floating garbage's in spite of turbulence like airflow, heavy wind etc., because the algorithm should be trained to detect static as well as moving garbage's in water. In this paper, comparative analysis deals with finding the best object detection algorithm among the selected algorithms like CNN, SSD, YOLO, HOG [15]-[17]. Here the comparison is done based on the performance i.e., speed of the detecting algorithm, accuracy rate which defines how much accurate the algorithm works, and also with the speed of detecting the objects in the water surface. In addition to this analysis, the time taken for training is also a factor which makes this comparison effective.

TABLE 1: Cooperation of Object Detection Algorithms

ALGORITHMS	SPEED	ACCURACY RATE	TIME FOR TRAINING (hrs)	PERFOMANCE (Mb)
CNN	Slow	93.8	18	115
HOG	Medium	90.18	16	200
SSD	Medium	86.60	14	225
YOLO	High	95.02	10	25

Table 1 shows the comparative analysis of the above-mentioned algorithms

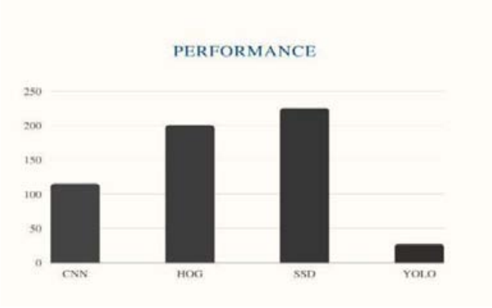

Fig. 7 Performance of Algorithms

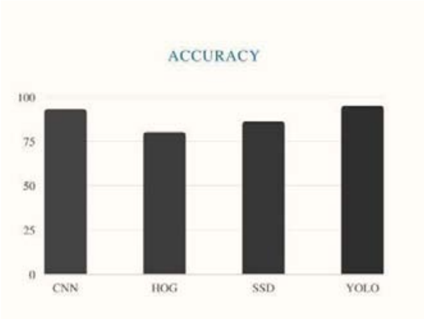

Fig. 8 Accuracy of Algorithms

Fig. 8 Time taken for training

From Figure 7, Figure 8, Figure 9 it is inferred that YOLO and SSD are efficient in comparison with CNN, HOG.

VI. Conclusion

This paper deals with introduction to the algorithms used for detecting objects and clarifies the need for object detection and a comparative analysis is done by comparing different parameters which results in the removal of floating garbage in surface of water. With these measured factors, the final result shows that YOLO algorithm is very effective than the other algorithms mentioned above. Yolo is also widely used nowadays for object detection with updated version releases.

***Abstract* —Ourobjective is to find an efficient method to classify the subject's mental cognitive workload as good or bad by obtaining features that can describe the continuous and underlying temporal dynamics of electroencephalography (EEG) data during the performance of mental tasks. To develop a BCI model that can forecast mental states like good and bad, we explore the ensemble learning technique using classifiers like the random forest classifier. From the alpha, beta, and gamma bands of EEG, the features like mean, root mean square, skewness, mode, data range, interquartile range (IQR), and three Hjorth parameters are extracted to differentiate a signal before-during mental arithmetic task. Our suggested model's analysis and results demonstrate that, when applying these techniques, accuracy is 96%. This model is further utilized for the application of automation in the Internet of Things (IoT).**

Keywords—Attention*, *Random Forest Classifier, Support Vector Machine, statistical analysis, Feature Extraction, Feature Selection, Electroencephalography, Brain Computer interface

I. INTRODUCTION

Neuroscientists have recently shown an interest in the creation of Brain-Computer Interface (BCI) [1] devices. The Common technique used for analyzing neural activity is electroencephalography (EEG). Additionally, it might be suggested for the treatment of anomalies, behavioral issues (such as Autism), attention disorders, learning difficulties, language delays, etc. [2]. Depending on the type of activity the EEG wave can be separated into beta, alpha, theta, delta, and gamma waves [3]. These frequency ranges are followed by them.

TABLE 1. THE FREQUENCY RANGES OF EEG WAVES

Waveform	Frequency Range	Activity
Beta	13 - 30Hz	Extremely active interactions and brainactivity
Alpha	8 – 13Hz	extremely calm widening the meditation
Theta	4 – 8Hz	drowsy, falling asleep, and dreaming
Delta	0.1 – 4Hz	A sound slumber without dreams
Gamma	30 – 100Hz	excessive brain activity

A typical BCI paradigm starts with the signal acquisition phase, in which analog brain impulses are gathered and transformed into digital values. Signal capture, data pre-processing, feature extraction, and classification are all processes in any standard BCI model [4]. Noise and artifacts are removed after pre- processing the acquired signals. The process of selecting and extracting certain characteristics from the data for categorization is known as feature extraction. These collected traits are sent into a classifier, which then determines which class they belong to.

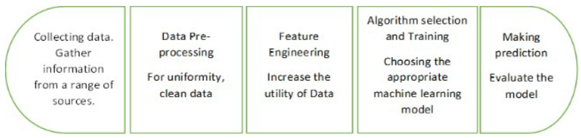

Fig 1. Steps to solve machine learning problems

Classification algorithms can be either supervised or unsupervised, depending on the application. Ensemble learning, as compared to traditionalmachine learning algorithms, is an approach that makes use of several learning algorithms to improve expected outcomes. A group of classifiers is used for learning in ensemble learning, which is a subset of supervised learning. Typically, these ensemble classifiers perform predictions using several straightforward classifiers, such as SVM, naive Bayes, and decision trees and then cast a vote to determine the final class [5]. The classifier used in random forests is made up of several unique classification trees, each of which functions as a separate classifier and is assigned a specific weight in the classification results. By selecting the mode (the output with the most votes) of all the classification outputs from the trees, the overall classification output is calculated [6] The rest of the paper's covers as, in Section II: Related works, in section III: Proposed methodology, which covers details on data collection, features that were extracted, and the techniques that were used to classify. In Section IV, the results and discussion are covered, and the work is wrapped up in Section V.

II. RELATED WORKS

The literature review relates various approaches for EEG signal analysis.From EEG data, Binish Fatimah recovered parameters such as mean, kurtosis, energy entropy, and L2 norms using the rhythms filter [7]. In this

DOI: rp-9788770040723.016

work, the feature extraction and classification methods were performed using SVM, decision trees, quadratic discriminant analysis, and entropy.

Binish Fatimah [8] described a method for identifying mental arithmetic tasks that require solving math problems (serialized subtraction of two numbers). To understand the brain response from a single lead EEG data, the Fourier transform is used. Men and women between the ages of 17 and 26 took part. Participants' ages ranged from 16 to 21 for women. The decomposed signals were filtered for variance characteristics before being classified using the SVM.

Qiang Wang [9] classified real-time EEG waves using multifractal analysis to identify mathematical workloads. In this study, features including power spectrum density and an autoregressive model were employed. The fractal dimension was determined and the attributes were classified using the Support Vector Machine (SVM).

BiswarupGanguly [10] created a categorization of mental arithmetic problems based on EEG to study brain-computer interaction (BCI). EEG data from 36 subjects were recorded, and eight characteristics were extracted from each electrode. These elements were input into the stacked long-short-term memory (LSTM) architecture to create and enhance the brain- computer interface model. FatemaNasrin [11] provides a method for figuring out the functional connectivity between the frontal lobe and pre-frontal lobe areas when young individuals (aged 16 to 20) perform mental arithmetic using single-channel EEG data (subtraction). He concluded that the precision of the Bidirectional Long Short-Term Memory (BLSTM) architecture was considered based on the results of his analysis. With a mean accuracy of 75.88% over 23 channels, this was able to recognize the proper condition of mental arithmetic in 5 seconds. With a significance threshold of less than0.05 in the states of mental calculation and face repose, HodaEdrisAbadi's [12] novel approach involved the extraction of numerous geometric features from Poincare design analysis. This analysis used the crucial comparison t-test to identify variations in brain activity. An artificial neural network has also been used in the two methods to perform autonomous learning and diagnosis (ANN). Electroencephalogram (EEG) data and Bayesian optimized K-Nearest Neighbor were used by LakhanDev Sharma [13] to characterize the mental load and identify the brain's response to stress stimuli (BO- KNN). Entropy-based feature extraction was followed by F-score-based feature selection to increase classification accuracy.

III. Proposed Methodology

3.1 Overview

Data preparation, feature extraction, and classification are the three key components of our suggested methodology. After the data has been gathered, the first stage is data preparation, which is carried out by the EEG device used for data gathering and involves noise reduction and filters. The next stage is feature extraction, where we take the preprocessed data and extract statistical characteristics like mean, root means square, skewness, mode, data range, interquartile range (IQR), and three Hjorth parameters. The final step involves classifying the obtained attributes using a classifier suitable for the collected real-time data. We propose utilizing a random forest classifier in themodel below, which uses an ensemble learning technique, to categorize the supplied data.

3.2 Data Collection

The 36 subjects in the dataset [7] whose signals were captured make up the dataset. 180 seconds before the mental arithmetic task and 60 seconds during the mental arithmetic task were recorded. According to Fig 2 and 3, there are 21 channels in each recording.

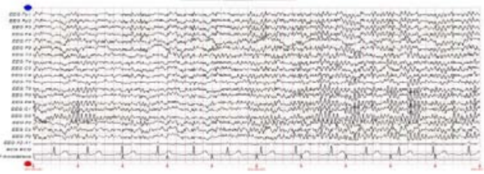

Fig. 2 EEG signals for a 10-second frame of before mental arithmetic calculation

Fig: 3 EEG signals for a 10-second frame duringmental arithmetic calculation

The electrodes are positioned to gather the most signals possible. The job of n-subtraction is given to each participant. Each subject initially receives two variables, x, and y. As many times as feasible, the subject must subtract y from x and recall the outcome. The individual constantly performs this task for one minute. Finally, by computing the remainder, it is determined if the subtraction was performed successfully or not. The sampling frequency was chosen to be 500 Hz

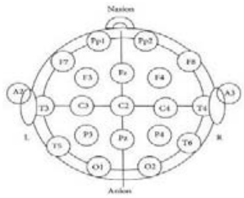

Fig 4. 10/20 International System of electrode placement

3.3 Feature Extraction

A 50 Hz notch filter is used in the pre-processing stage to eliminate the reference DC component. The extraction of characteristics from the alpha, beta, and gamma frequency bands is a step further in the study. Chebyshevbandpass filters with predetermined frequency ranges are used for this. From these filtered data, we have retrieved the features listed below.

1. Mean: The average of all the samples is provided by the signal's mean values.

$$x_{mean} = \frac{1}{N}\sum_{i=1}^{N} x(i) \qquad (1)$$

where N is the signal's overall sample count.

DOI: rp-9788770040723.016

2. Root Mean Square (RMS): The RMS value of XRMS is calculated as follows for a signal x(t)

$$x_{RMS} = \sqrt{\frac{1}{T}\int_{t-T}^{T} x(t)^2} \quad (2)$$

3. Skewness: The asymmetry of the data distribution relative to the central mean is measured. More data is to the left of the mean if the skewness number is negative, and to the right, if it is positive. It is said that the skewness parameter is

$$S = \frac{E(x-\mu)^3}{\sigma^3} \quad (3)$$

Where the sample's mean and standard deviation are$\mu$and σ, respectively (t). 'E' stands for 'expectation'.

4. Mode: The value that appears the most frequently in a dataset is called its mode, or x(t).
5. Data Range: It gives back the difference between the sample dataset's maximum and minimum values x(t).

$$Datarange = xmax - xmin \quad (4)$$

6. Interquartile Range: The interquartile range of the data samples in a time series object is returned by IQR. IQR refers to the difference between an array of random values' upper and lower quartiles (Q3 and Q1, respectively). The quartile measures the median by considering an even dataset of 2n values or an odd dataset of 2n+1 values. The median of the first quartile's values is in Q1, while the median of the third quartile's values is in Q3.

$$IQR = Q_3 - Q_1 \quad (5)$$

7. Kurtosis: Kurtosis is a term used to describe a measure of a random variable's probability distribution.

$$k = \frac{E(x-\mu)^4}{\sigma^4} \quad (6)$$

8. Hjorth Parameters: A time-domain signal's statistical characteristics are shown by Hjorth parameters. Activity, Mobility, and Complexity are the three different parameters [8]. These variables are quite useful when analyzing EEG signals.

a) Hjorth Activity: It shows the variance of any signal x(t)

$$Activity = v(x(t)) \quad (7)$$

b) Hjorth Mobility: Mobility is equal to the square root of the ratio of the variance of the signals and the first derivative's x(t) signals. This variable is proportional to the spectrum's standard deviation.

$$Mobility = \frac{\sqrt{\mathrm{var}\left(\frac{dx(t)}{dt}\right)}}{\mathrm{var}(x(t))} \quad (8)$$

c) Hjroth Complexity: The degree to which the signal shape resembles a pure sinusoid wave is determined by this parameter. If the signal is more like the sine signal, the complexity converges to unity.

$$complexity = \frac{mobility\left(\frac{dx(t)}{dt}\right)}{mobility(x(t))} \quad (9)$$

3.4 Classification

The classification of brainwaves using traditional classifiers has produced positive results in recent years for all forms of BCI data. Some of these include SVM, naive Bayes, k-NN, LDA, and others. Moreover, working with ensemble learning gives us a new way to learn from real-time data. Our method employs binary categorization, allowing us to determine if a person's count quality is good or bad. Our model includes a random forest classifier for classification that employs an ensemble learning strategy for prediction.

3.4.1 Random Forest

The Random Forest Classifier [9] employs a classification technique known as ensemble learning that employs numerous decision trees during the training phase and produces average predictions ofand 90% of the data for the model's training. The two subsections below provide information on the outcomes and performance of our approach.

Many decision tree algorithms are rule-based and depend exclusively on a collection of rules for making predictions about a set of data. In comparison, random forest classifiers find the root node and split the features randomly, as opposed to using the Gini index or information gain to calculate the root node.

1. Precision: It measures the proportion of real positives to all positives.

$$\frac{TP}{TP+FP}$$

2. Recall: The ratio of true positives to all positively classified samples is how it is described.

$$\frac{TP}{TP+FN}$$

3.4.2 Proposed Approach

When compared to decision tree classifiers, random forestclassifiersoperatesimilarly,butwiththe additionofensemblelearning.Thefirstphaseis building many randomly selected decision trees, each of which predicts a certain class based on the information provided. A voting process is used to determine the final class based on the results of the majority after each tree forecasts a class.

IV. Experimental Results and Discussion

We used 10% of the total data for the model's testing, and 90% of the data for the model's training. The

DOI: rp-9788770040723.016

twosubsectionsbelowprovideinformationontheoutcomesandp erformance ofour approach.

4.1. Confusion Matrix

A confusion matrix [16] in the form of a table for a collection of real data and predicted data is used to show a classification model's performance. The classification model's resultant confusion matrix

TABLE 2.CONFUSION MATRIX FOR RANDOM FOREST MODEL IN TEST DATA

Class	Good	Bad
Good	17	2
Bad	2	59

Table: 2 tells that the confusion matrix for random forest in taken for test data, where 17 samples accurately categorized the quality of the count as good, compared to 59 samples that were correctly labeled as bad. 2 samples were incorrectly labeled the count quality as good, compared to 2 samples that were incorrectly classified as bad. Hence, we observe that around 96% of the whole data set is projected into the appropriate classes.

4.2 Performance Evaluation

Precision, recall, accuracy, and other performance metrics are used to evaluate classification performance. Table 3 below is a list of a few of these measurements.

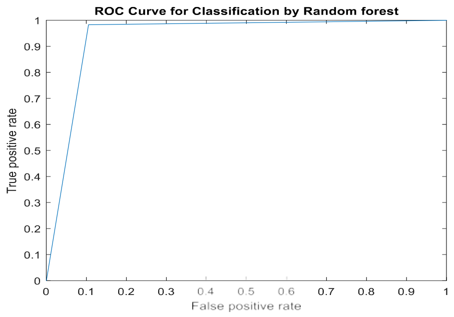

TABLE 3.PERFORMANCE MEASURES

Evaluation Metrics	Values
Correctly Classified Instance	96.20 %
Incorrectly Classified Instances	3.80%
Kappa Statistic	0.8941
Mean absoluteError	0.0380
Accuracy	0.9620
Precision	0.9558
Recall	0.9390
F1- Score	0. 9471
AUC	0.9390

The term "true positives" (TP) refers to samples that were correctly located and anticipated to have high-count quality. The term "true negatives" (TN) refers to samples that were correctly classified as negative and were expected to have poor count quality. False positive samples are those that are mistakenly classified as being good, and false negative samples are those that are classified wrongly as being bad.

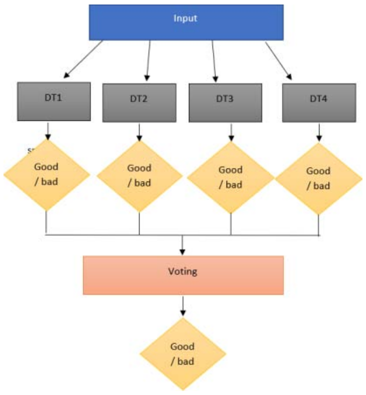

Fig: 5 Structure of Random Forest

The random forest classifier uses an ensemble learning strategy that has a 96% accuracy rate for class prediction.

V. CONCLUSION

In this study, a method for classifying mental states into good and poor categories is suggested. The methodology uses a random forest classifier and statistical feature extraction approach. After attempting to gather EEG data from 36 people, a machine-learning model was created, and the accuracy of this real-time data was 96%. This binary categorization might be used for a variety of things, such in the Internet of Things to turn on and off devices and manage other comparable household equipment by just changing your mindset. The predictive model we developed may be improved and used to control IoT devices more precisely since it gradually learns the users' mental states.

Abstract—Wireless sensor networks has expanded its view of applications from personal domains to as wide as asset monitoring domain. Homogeneous sensor nodes are deployed to gather information and inform the base station. However, attackers are on a continuous look out to backtrack and gain the source node location. Location privacy preservation of the assets against passive attackers is crucial. In this paper, we develop a source location preservation scheme based on the combination of backward and forward random walk, to provide security irrespective of the source location in the network. The performance of the scheme is measured in terms of safety period, randomness of the routing length and capture rate of adversaries. Simulation results prove that the proposed scheme provides significant improvement in privacy strength and other metrics as compared to existing approaches.

Keywords—source location privacy, security, adversaries, backward routing, random walk, forward random walk.

I. Introduction

In the fast changing, network oriented digital world wireless sensor networks (WSN) [1,2] play a key role in information processing. WSN is formed by a collection of sensor nodes deployed within an area to sense, process and transmit information by communicating among each other. The information transmitted in packets through multiple hops is directed towards the base station or sink. Sink can be termed as the final destination for all the packets sent by the sensor nodes, Due to the good feasibility and self-organizing structure of sensor nodes, WSN is used for monitoring applications like animal conservation, military, smart buildings and offices etc. [3-5]. In applications where the assets being monitored holds a very high value in terms of their importance to nation or nature, it is essential to preserve their location information from falling in wrong hands.

Location privacy preservation [6,7] is essential requirement in WSN. It is divided into sink location privacy preservation [8] and source location privacy (SLP) preservation [9,10]. As sink is the final destination of all the packet transmission taking place in the network, a successful attack on the sink would render the security measures useless. But it must also be noted that attack on sink is an extremely difficult task as sink is heavily protected to be resistant against all possible attacks. Whereas source location privacy preservation is aimed at securing the location of the sensor nodes that is transmitting information about the presence of the assets. Attackers in order to remain hidden might not interfere with the communication process but carry out passive attacks like eavesdropping, backtracking, network flow analysis, etc. to finally infer the source node location. This revelation can lead to capture of the assets or even loss of their life. Hence, SLP mechanisms must be devised to assure good levels of privacy against passive attacks by adversaries.

In this paper, we propose a routing mechanism named as Backward and Forward Random Walk (BaFRW) that is divided in 2 phases: first phase is where the event packet is randomly sent away from the source node towards the network boundary and second phase is where the packet is delivered to the base station using a previously developed mechanism termed as forward random walk. We discuss the mechanism in detail in Section 4. Major contributions of this work are:

- We develop a robust and randomized SLP mechanism BaFRW that guarantees a higher level of privacy strength against passive attacks.
- We perform an experimental analysis and simulation results depicted in Section 5 prove its efficiency.

The rest of the paper is structured as follows: Section 2 deals with the existing literature study and Section 3 gives an insight on the system models. The proposed scheme is explained in Section 4 while the experimental results are presented in Section 5. We conclude the paper and provide with possible future research studies in Section 6.

II. Related work

Ozturk et al. [11] in their work described about SLP problem through a Panda-hunter model. In this model, sensors are deployed in the network who pick up the presence of panda as soon as it appears within their transmitting radius. Then information regarding the location of panda is sent to the sink through multiple sensors in the path between the source node to sink. The authors suggested use of phantom flooding mechanism for SLP preservation. The packet containing information about the asset's location is sent from source node to a phantom node for a specific Time to Live (TTL) counter after which it is flooded towards the sink. This mechanism used up a lot of energy while flooding thus degrading the network lifetime. Then came a mechanism termed as Phantom routing by Kamat et al. [12]. They suggested a change in the Phantom flooding method by replacing the probabilistic flooding with a single route to sink. This change of flooding phase by a single route contributed to saving on the energy loss and increasing network lifetime.

Chen et al. [13] proposed Forward random walk (FRW) in an attempt to provide SLP preservation. Forward random walk suggests using the close and equal neighbor nodes to transmit information. This mechanism chooses one node randomly from the list containing close and equal hop count neighbor nodes. This process is repeated till the packet reaches the sink.

Manjula et al. [14] proposed a SLP routing based on randomized routes (SLP-R) that consists of 3 phases. In the first phase, the event packet is routed to the outermost ring through shortest path followed by an equidistant routing where packets are routed in the same ring for a specific number of hops. Finally using the shortest path approach the packet is delivered to sink. This mechanism improved privacy levels by increasing the randomness measure of the transmission routes.

Many routing schemes have been proposed that includes circular routing, fake sources injection, phantom routes, geographic routing etc. for SLP preservation. Circular routing by Han et al. [15] proposed selection of number of interference rings to transmit the packet in a circular manner through cluster heads. Then a starting node selected through token system from amongst the cluster heads in the outermost ring carries a dummy packet to the sink through greedy path and as it comes through the event ring, the dummy contents get replaced with the real content. This dynamic routing scheme ensured higher security but led to greater energy loss as well. However, it must be noted that there is always a tradeoff between performance measuring parameters due to which there is always one or the other degradation that increased privacy brings along with it. We aim to develop a mechanism that balances all the parameters along with good privacy strength.

III. System Model

A. Network model

The network model that we consider in this paper is Panda-hunter model. As per the model illustrated in Fig.1, sensors nodes are deployed in the network region to monitor the movement of panda and these sensor nodes keep transmitting information regarding the location of panda to sink. There is an adversary who monitors the wireless transmission between sensor nodes and backtracks in an attempt to get the source location. The packets must follow transmission paths that is difficult for the adversary to backtrack within a specified time interval. We assume the network model to consist of the following characteristics:

- The deployment of sensor nodes in the network region is done with a specific density ‘ρ’. The sensors once set in a place are not allowed to change its location.
- There is only one sink located at the center of the network.
- The network is divided into rings and grids. Each grid consists of a cluster head chosen among the sensor nodes placed in the grid. The grid to grid transmission of packets take place through cluster head.

B. Adversary model

Adversary intend to monitor the transmission to infer the location of source node. He is assumed to have the following characteristics:

- There is a single adversary who monitors the network communication.
- He carries out passive attacks such as eavesdropping, backtracking, traffic analysis, time correlation etc.
- He has access to advanced equipments to monitor the transmission and memory and energy constraints are not a limiting factor for him.
- We consider the adversary to be a local adversary with restricted range of hearing. Global adversaries [16] are far more powerful and tend to have a view of the entire network region. However, our work involves securing the source location against local adversary having the above mentioned features.

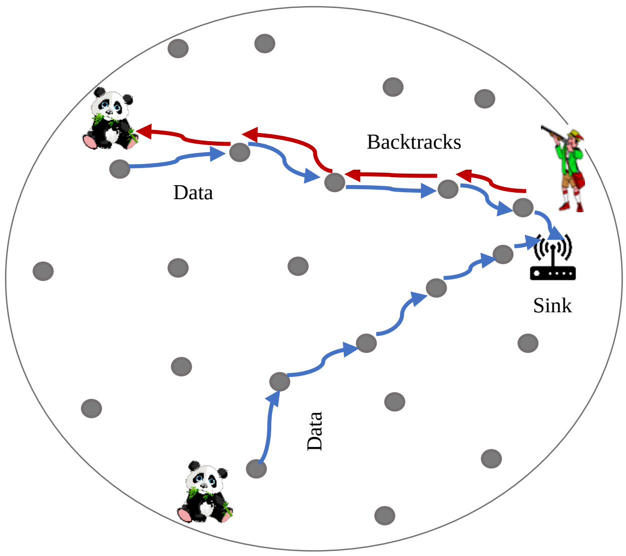

Fig. 1. Panda-hunter model

C. Energy Consumption model

The loss of energy for sensor nodes while packet transmission is computed by the following equations 1 and 2 [17] where equation 1 is for loss while transmitting the packet and equation 2 is the loss while receiving a packet.

$$E_t = l * E_{elec} + l * \varepsilon_{fs} * d^2, \quad d \le d_0 \qquad 1(a)$$

$$E_t = l * E_{elec} + l * \varepsilon_{amp} * d^4, \quad d > d_0 \qquad 1(b)$$

$$E_r = l * E_{elec} \qquad 2$$

The description of the parameters is provided in Table 1.

TABLE 1. System Parameters

Parameters	Values
Distance threshold ($\mathbf{d_0}$)	87m
Distance between source and sink	d

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.017

$\mathbf{E_{elec}}$	50nJ/bit
$\boldsymbol{\varepsilon_{fs}}$	10pJ/bit/ m^2
$\boldsymbol{\varepsilon_{amp}}$	0.0013pJ/bit/ m^4
Packet length (l)	1028 s

IV. Description of BAFRW Mechanism

Before the transmission begins, the sink floods the network with an initial message which is meant for initialization and neighbor nodes discovery. The message contains information about the network range, system parameters, location of the sink and a counter to measure the hop count. The node that receives this message fills its routing table with the information, increments the counter variable and attaches its own id and location before passing it to adjacent neighbors. The neighbor node then updates its routing table with the information received from the packet and is able to identify its neighbors and their location. Then every node partitions its neighbors in 3 groups: close neighbors, far neighbors and equal hop neighbors relative to their distance from the sink with respect to itself. After this operation is performed by every node, the routing transmission begins. BaFRW consists of 2 phases that are described below.

D. *Backward Random walk*

This phase is dependent on the presence of neighbor with the same or more hop count. The source node carries out two functions before transmitting the event packet:

- Selects a random number from the range whose minimum value is the number of hops required to reach the outermost ring and maximum value is double the hop count for outermost ring. This value is attached to the packet.

$$h_{brw} = \mathrm{rand}(R/_{2r} - h_{srcnode} \text{ to } R/_{r})$$

- The source node forms a backward list consisting of nodes from equal and far neighbors group.

The source node selects a node randomly from the backward list and decrements the h_{brw} counter by one before sending the packet to the randomly chosen node. The node that receives the packet again chooses a node randomly from its backward list, decrements the counter and transmits the packet. This process is repeated till the packet reaches the outermost ring or h_{brw} becomes zero. The node at which this phase ends is termed as terminal node.

E. *Forward random walk*

The terminal node forms a forward list consisting of nodes from equal and close neighbor group and then randomly selects a node from it and transmits the packet. Every node that receives the packet follows the same till the packet is delivered to the sink. This phase is aimed at randomizing the route while the packet is delivered to the sink.

Fig.2 depicts the architecture and routing protocol of the BaFRW mechanism.

V. Experimental Analysis

A. *Settings*

We have simulated the algorithm in MATLAB 2018b to determine and compare the efficiency of our proposed scheme BaFRW with FRW and SLP-R. The network region is a circular region with sensors deployed randomly in each grid. The size of each grid is same as the communication radius. The parameters are specified in Table 2. The results are computed to be an average of 50 simulations.

TABLE 2. Network Parameters

Parameters	Values
Network length	800 m
Communication radius (r)	40 m
Initial energy	0.5 J
Network density	0.0015
Number of packets per simulation	100
Number of simulations	50

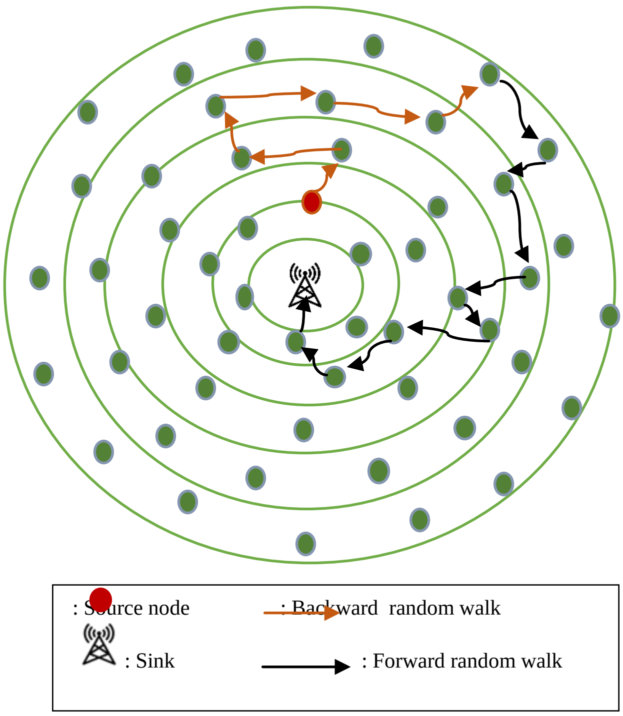

Fig. 2. Illustration of BaFRW scheme

B. *Results*

In this section, we discuss the experimental results of the three mchanisms i.e. SLP-R, FRW and BaFRW in terms of metrics like safety period, transmission delay, energy consumption, capture rate and entropy. Safety period is defined as the average number of packets that the sink receives before the adversary is able to locate the source node. Transmission delay is defined as the average number of hops taken by the event packet while being transmitted towards sink. Average energy consumption measures the loss accrued in the network while transmitting a single packet in each simulation. Total energy consumption is the amount of energy lost in the entire simulation and the loss is measured

DOI: rp-9788770040723.017

only while the sensor node transmits, receives and processes the packets. Energy loss is measured in terms of Joule. Capture rate depicts the adversarial success in locating the source node with respect to the total number of simulations. It is represented in terms of percentage. Entropy is a measure that depicts the randomness of the routes taken to deliver the packets to the sink.

a) Safety period: The measurement of privacy is done in terms of safety period that is computed on the basis of differing distances of source node from sink. The plot depicting the values for safety period is shown in Fig.3. FRW provides the lowest level of privacy to source node and the reason is the comparably shorter and frequently selected candidate nodes in the route. SLP-R performs better than FRW due to the packets being constantly sent to the outer most ring where further transmission takes place. This routes the packet away from source node and improves the randomness. The proposed scheme BaFRW provides higher safety period than the other mechanisms especially when the source node is located closer to the sink. This can be attributed to the fact that packets follow a more random route while routing the event packets away from source. However, we also observe that as the source node starts moving away from the sink and is located in the outer regions, SLP-R and BaFRW provides nearly the same safety period.

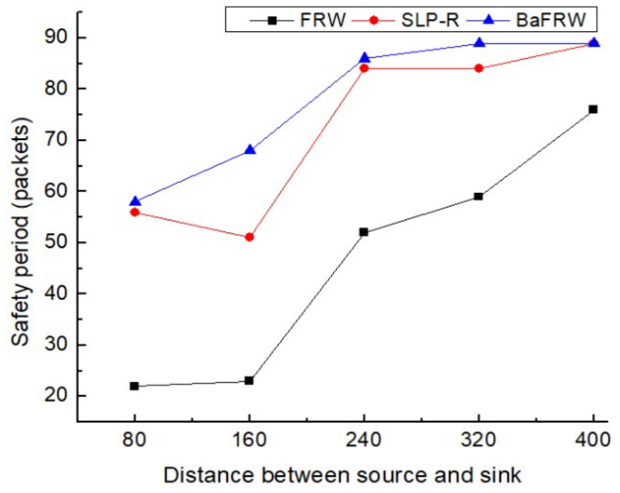

Fig 3. Safety period versus source location

b) Transmission delay: Fig. 4 shows the transmission delay for different location of source nodes in the network. It is the least for FRW as the packets are simply directed towards the base station by selecting the candidates with the same or lesser hop count, leading to a shorter route. We observe that the delay is the highest for our algorithm BaFRW as compared to other schemes. This happens because the hop counter attached with the event packet chooses a random number whose range is set high and moreover, it also combines forward random walk mechanism while routing the packet to sink in second phase. Both of these values yield a higher transmission delay for BaFRW while the source is located closer to sink.

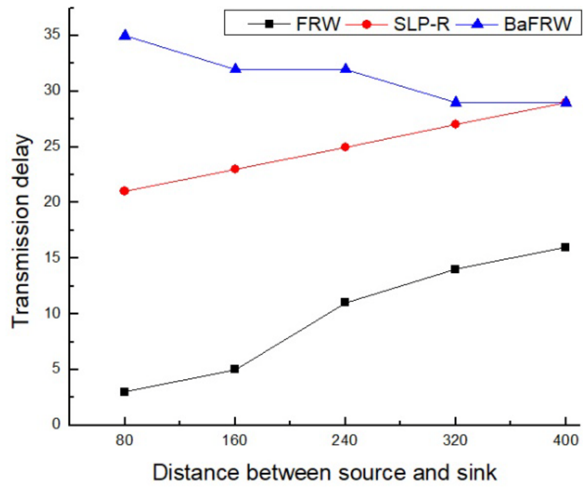

Fig 4. Transmission delay versus source location

c) Adversarial backtracks:The average number of hops backtracked by the adversary while attempting to locate the source node is expressed as adversarial backtracks. Gretaer the number of backtracking hops, higher is the security. Fig. 5 represents the adversarial hops for the three SLP mechanisms where it is clearly visible that BaFRW has the highest backtracks among the existing protocols. This shows that the adversary hasto travel a longer route and longer routes assist in improved security for the source node.

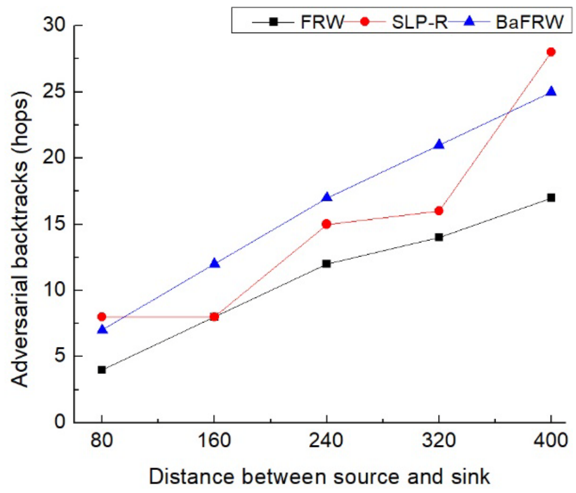

Fig. 5. Adversarial backtracks versus source location

d) Total energy consumption: The plot for representing the amount of energy loss in the simulation is provided in Fig. 6 and Fig.7. Fig 6 represents the average loss of energy per packet per simulation run whereas fig. 7 illustrates the total energy consumption occurred per simulation. We observe that the energy consumption is highest for BaFRW. It is due to the reason that safety period is high denoting a greater number of packets being forwarded and even the higher transmission delay that leads to a longer route. FRW consumes the least amount of energy in the entire simulation.

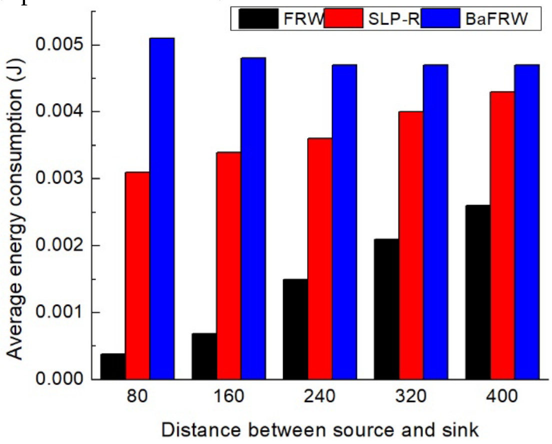

Fig 6. Average energy consumption for different source location

e) Capture rate: Capture rate denotes how well the algorithm secures the location by reducing the adversary's successful attempts at disclosing the source's location. A low capture rate means higher security. Fig.8 represents the capture rate with respect to source's location. The adversarial success rate is maximum for FRW. We observe that for source node locations closer to sink the capture rate is low for BaFRW as compared to SLP-R but for source located near the network boundary, the capture rate is similar.

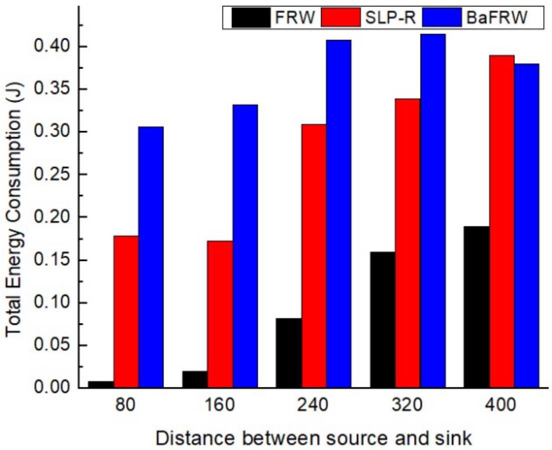

Fig. 7. Total energy consumption against varying source location

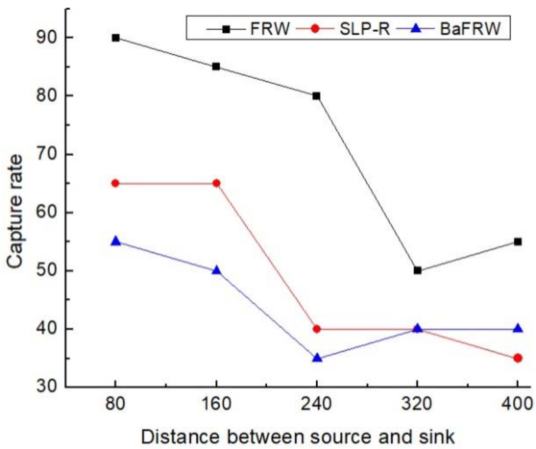

Fig. 8. Capture rate for varying source location

f) Entropy: The relationship between entropy and varying source location is shown in Fig. 9. The randomness measure is lowest for FRW and it represents that the transmission route usually follows through the same nodes to reach to sink. SLP-R has more random routes as compared to FRW. Gigher entropy level assures greater privacy. The entropy level is highest for BaFRW that denotes its efficiency in increasing the privacy.

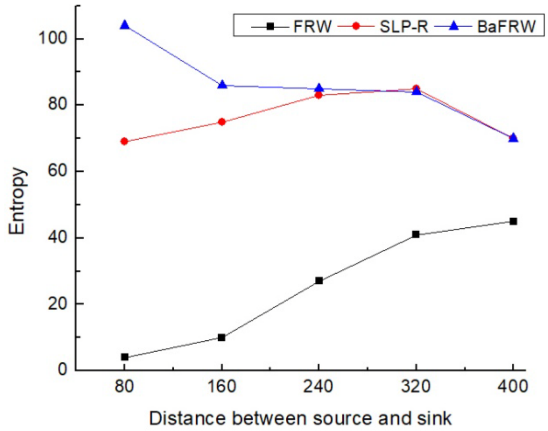

Fig 9. Entropy versus source location

VI. Conclusion

With the intent to secure the location information of source nodes in wireless sensor networks against passive attacks of adversaries, we developed a novel SLP mechanism named as BaFRW. In this, the transmission operation is divided in 2 phases: first phase is where each node forms a backward list and packet is randomly sent to one of nodes from backward list for a specific hop count towards the network boundary and after this phase ends, packet follows a forward random walk approach to route the packet to sink. Through simulated results, we observe that the proposed scheme improves the privacy, capture percentage and entropy for source located near the base station and almost same as SLP-R when the source node is located near the boundary of network. The major contribution is that the proposed protocol enhances the location privacy for assets moving near the sink that is considered a difficult task to achieve. Though the energy consumption is on higher range as compared to other SLP mechanism, it is also to be noted that BaFRW yields better security, lower capture rate and higher entropy. For future research directions, considering the improving strength of adversaries we plan on devising stronger routing mechanisms against global adversaries for securing the location of multiple assets on more practical approaches.

***Abstract*— This paper emphasizes about the importance of Network tools and their field of application. Understanding the importance of network tools and its applications is very important as far a researcher in network field is concerned. In this research paper an elaborate study of the different network tools that can be used for various purposes in computer networks like network management, monitoring, analyzing, simulating and emulating is done.**

Keywords*— *Network tools, Simulating, Cisco Packet Tracer, Wireshark, Monitoring, Analyzing, Computer Networks.

I. INTRODUCTION

In the world that we are living in today it is impossible to think of a system without computer networks as they play a significant role in our day to day life from education to each and every day to day activities. Due to immense use of computer networks there is a significant rise in network traffic. Computer networks is the base of communication. The nodes or devices connected together in the computer network share resources using some protocols for the network. The nodes or devices are interconnected using some network topologies.

Some of the challenges faced in computer networks are monitoring, maintenance, identification of host, conflicts during configuration, concerns related to capacity, security, more time taken for connectivity and degradation in performance. Network simulation is a tool used in computer network research to simulate the behaviour of a network by computing the interactions between its many components, such as its routers, switches, nodes, access points, and connections as given in Figure 1.

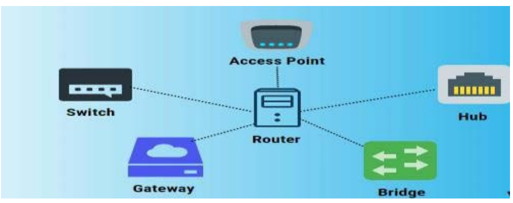

Fig 1. Different types of network devices

II. LITERATURE REVIEW

A review of computer network tools used for various purposes like monitoring, management, simulation, emulation, analysis is done in this section.

A virtual laboratory of computer networks was evaluated in progress by P. Gil et al. [1] using free simulation tools like GNS3 and associated libraries. The students were able to design and simulate topologies and implement as in real time. They were also able to evaluate the performance and study the behaviour of their network devices all for free. Based on the assessment the students were able to understand the subject's fundamental concepts easily. It posed certain limitations to emulate various protocols like Token Ring or WiFi. But, the findings of this study showed that virtualized computer network labs using GNS3 are effective in helping students learn, especially those who are unfamiliar with TCP/IP architecture and computer networks in general.

R. Emiliano et al. [2] demonstrated the reliability of networking lab environments using GNS3, providing a learning environment for both beginning and more experienced students and practitioners to more effectively learn networking topics in the classroom and through independent study. Figure 2 shows the diagrammatic representation of GNS3 simulation platform.

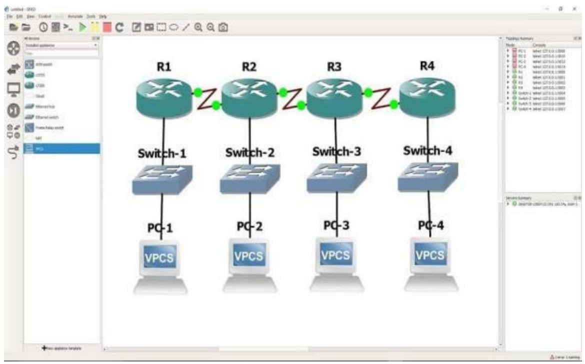

Fig. 2. GNS3 Simulation Platform

A network management simulation was run as a proof-of-concept to demonstrate how Peru could be reconnectedto the region's sophisticated networks via CLARA. In order to obtain a sort of baseline for operating the suggested network, a test comparing SNMP and Syslog was carried out as part of the request. Jose –I et al. [3] developed a GNS3 cloud environment by running emulation in two physical computers connected in a peer to peer fashion to alleviate the problem caused by financial constraints, when employing limited computers.

A really well secure communication protocol is SSH. However, the SSH protocol does not provide mobility management. I.-H. Huang [4] suggested a mobile SSH

DOI: rp-9788770040723.018

protocol that uses an application-layer handover mechanism to make SSH work in wireless networks. The suggested protocol has been added to Open SSH and Putty as shown in Figure 3. Their experimental findings indicate that the recovery latency is extremely short.

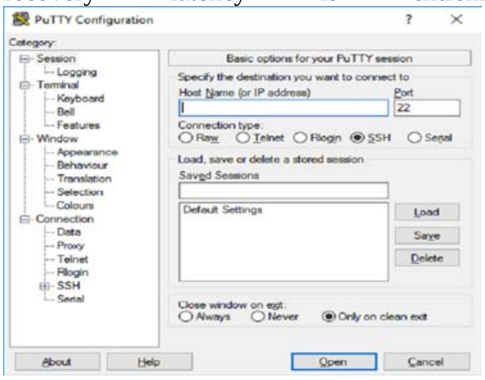

Fig. 3. Putty simulation Platform

The study suggested by Sinha D et al.[5] used several agents to find secure routes with the least amount of network strain. Having used several agents, the source node distributes the secure key to all likely paths. By lowering control packet overheads, these agents ease network congestion. The finalized path is chosen based on the route with the highest weighted trust value. The three phased strategy improved network performance totally and reduced network congestion using an agent based approach. The simulation platform of Secure CRT is as shown in Figure 4.

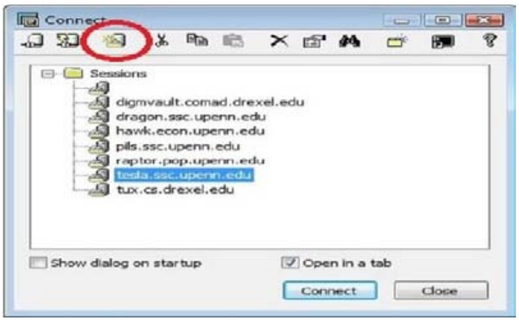

Fig. 4. Secure CRT simulation Platform

The theoretical line loss model was developed by Qiuxia et al.[6] where VBA tool was used and Microsoft Visio 2003 whose simulation platform is given in Figure 5 was the primary development platform . Visio 2003 based line loss computation software for high voltage networks was created which demonstrated that the Visio secondary development process provided a fresh and efficient way to create software for high voltage networks and other power applications that graphically calculates line losses.

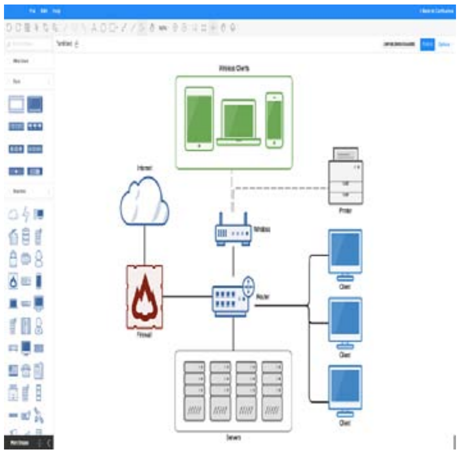

Fig. 5. Microsoft Visio simulation platform

The indemnity of service level agreement (SLA) violations affects the service provider in a cloud domain. W. Hussain et al. [7] proposed SLA violation risk reduction methodology for complex QoS prediction. A minimax disparity strategy is used to weigh the OWA operator in order to manage the risk of SLA breach. By taking into account every potential attitude of the service provider, this approach forecasted deviation in custom prioritisedQoS parameter intelligently and recommended necessity of mitigating action. This study made use of linguistic terms, fuzzy numbers, and interval figures to cope with ambiguous information. The analysed findings using PRTG network monitor whose simulation platform set up is as given in Figure 6 showed how the suggested strategy effectively addressed complicated risk reduction actions.

Fig. 6. PRTG Network Monitor simulation platform

As far as internet is concerned routing is very important. In [8] Ida Nurhaida et al. designed OSPF routing for IP internet networks using EVE and their performance was assessed. The experiment's findings suggested that VPLS over MPLS with VLAN Management can improve the performance of video conferences. According to the TIPHON standard, the measurement of QoS metrics such as packet loss, throughput, latency, and jitter was rated as "Good." A considerable impact was produced by the inclusion of VPN administration and the VPLS over MPLS scenario. Packet loss, delay, and jitter was decreased in video conference services by implementing VPN and VPLS over MPLS. VPLS over MPLS: 0.44% packet loss, 4.637 ms delay, and 4.636 ms jitter, respectively. A thorough evaluation of the VLAN management on OSPF, with throughput values up to 59.6%, packet losses up to 0.32%, jitter, and delays of 4.44 ms, was also provided by the study. The simulation platform for EVE is as given in Figure 7.

DOI: rp-9788770040723.018

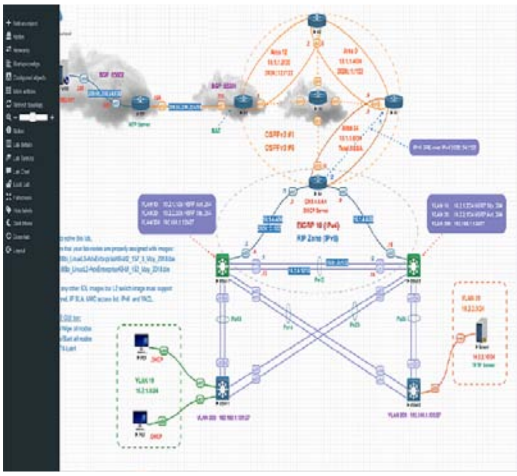

Fig. 7. EVE simulation platform

The 5G mobile communication was designed to meet the increasing user needs, which is summarized as having access to high quality services whenever and whenever they need them. Due to the distinct qualities of satellites, such as increased coverage, reliability, and availability, these demands can be met through the integration of satellites in 5G systems. It has become mandatory that before deploying the new technologies should be tested and improved so as to cut down on time, cost needed and limit blind exploitation of new systems. A great way to assess fresh concepts and put experimental systems to the test is by building a System Level Simulator (SLS). N. Badini et al. [9] described a Network Simulator 3 (NS3)-based open-source SLS (NS3). The simulation platform of NS3 is as given in Figure 8. This tool outperforms cutting-edge technologies and enables simulation of 5G Satellite-Terrestrial Integrated Networks (STIN).

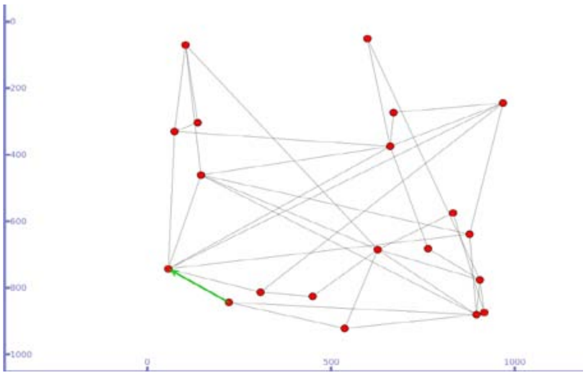

Fig. 8. NS3 simulation platform

According to the study made by Gandotra, R et al.[10], a framework that was created to enable non-intrusive real-time power consumption data gathering from the next generation of networking devices was presented in this paper. The experiment's findings using SNMP Agent simulator as given in Figure 9 suggested that, even in the absence of support for the necessary information models, power consumption data can be collected using non-standard tailored information models, standardised IETF information models, or by abstracting and exposing the data in a uniform format. The suggested methodology is functionally validated, and the findings from this study could be used to inform energy-efficient network management choices.

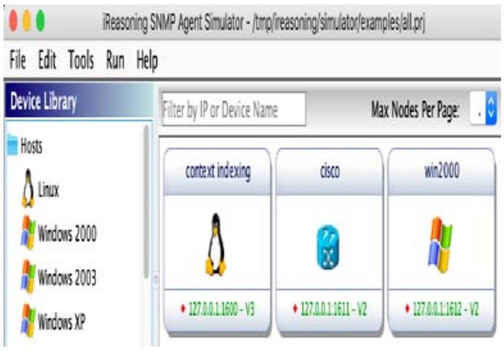

Fig. 9. SNMP Agent Simulator platform

The foundation of a smart city is made up of smart buildings. The IoT-based smart building for a scientific department was proposed in the work by O. K. T. AL sultan et al. [11] offered a variety of services like lighting, fire alarms and smart parks, all of which was remotely controlled via the Internet using either the IoT server webpage or the server static IP address through smartphones from outside or inside of the building, PC's or laptops. Java programming was used for setting up the sensors, gateway, and servers. By using IoT industry standard technologies and networking protocols, standardisations are taken intoaccount in the task. The paper discussed the idea to use the Ninevah University building as a prototype for our IoT smart building simulation utilising Cisco packet tracer v7.3, which offers many components and devices that imitate the real network. The Cisco Packet Tracer Simulation platform is as given in Figure 10.

Fig. 10. Cisco Packet Tracer Simulation Platform

IoT technologies employ sensors and controllers to network and organise devices as a single ecosystem, collect data, and control them. To create a system for a smart environment, IoT developers should experiment with a variety of devices and setups. A potent network simulation tool to test network behaviour is Cisco Packet Tracer. In addition, Packet Tracer can be a simulation environment for IoT development that offers an API for interacting with actual devices. In order to monitor and manage the actual IoT devices, the paper by Y. -C. Chen et al. [12] provided the Packet Tracer user interface.

In [13] A. Utsav et al. proposed a smart irrigation system for the climatic conditions of India utilising Cisco packet tracer software. To control and secure the farms, they

DOI: rp-9788770040723.018

deployed a variety of sensors, webcams, and other technological devices. In order to maintain efficient use of water and resources, various analyses for various crops (Kharif and Rabi) were described. The software performed accurate simulation for each situation. Security-based simulations were conducted and described in the subsequent section. They also claimed that our farmers can manage and keep an eye on the farms that are not connected to the Internet with its assistance.

In peer to peer networks a large number of risks is involved and it can be determined. The system itself is vulnerable to insider attacks, remotely and probably there can be heavy leakage of delicate and sensitive information when the data is sent over different data centres. In [14] A. Musa, et al. analysed the security of peer to peer networks using Wireshark. The simulation platform for Wireshark is as given in Figure 11. This paper had given a technique to improve the security of peer-to-peer networks using simulation based experimental study which was followed bya summary of prevailing techniques to mitigate possible threats on peer to peer networks.

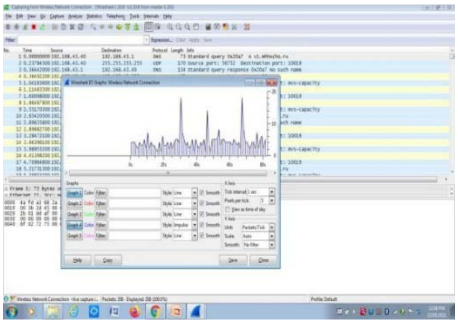

Fig. 11. Wireshark simulation platform

Every day, more people are turning to the internet for various purposes. The expanding and changing needs make it more challenging using the traditional network architecture. Traditional networks also have a complicated architecture and administration issues. To solve the aforementioned network issues, the idea of Software Defined Networks (SDN) has emerged. SDN is a revolutionary network technique that isolates the control and data plane from one another, as well as enabling network programming and responding swiftly to changing events by giving a global perspective of the network, in an effort to get around the limits of today's network infrastructure. The control plane is on top of the load balancer SDN application. Based on a number of factors, load balancers divide the workload between many servers. Using a variety of methodologies, load balancers divide the workload between various servers. unpredictable and some load balancing strategies include round robin. In [15], Ş. Aymaz et al. implemented these two POX controller-based techniques and wireshark analyzed them.

TCP/IP is the most important element of a study of networking aspects. Shaoqiang Wang et al. in [16] had given an understanding about how Wireshark may be used to teach students about TCP/IP protocolsThey showed that Wireshark might result in successful educational outcomes by highlighting how valuable it is for practical usage and widespread adoption.

III. Conclusion

For a beginner in computer network research this paper will be very useful. It gives a clear idea about the different network tools that can be used specifically for network management, monitoring, analysing, simulating, and emulating. It also shows the simulation platform setupfor the different network tools. It is very difficult to test any system physically. With the help of these network tools the tedious work of a network researcher is reduced to a greater extent. A Survey is conducted successfully in this paper which shows how the network tools can be a promising one in future for the next generation when it comes to simulation even from education field to deploying irrigation for our farmers.

IV. Applications and Future Enhancement

The network tools discussed in this paper can be used for taking good decisions related to capacity management which will in turn lead to a wide growth of the network. As future enhancement, deep learning predictive analysis techniques can be used to help telecom industry to predict the growth of the network. Quality of Experience and High Value Customers can help the network administrator get an insight about how to increase network capacity satisfying the customer needs.

***Abstract*— As the amount of web pages available on the visible net has increased to billions of pages with trillions of pages available from the invisible net, extracting data from the internet has become a highly essential procedure in the last few years. Several tools and protocols are made available which can extract this information, and these tools have come in great demand in recent times as researchers and surfers want to discover new knowledge at an ever-increasing rate. Investing in a company requires a lot of analysis to be done before plunging in. As part of this process, the analyst manually does a search of a company name in google, reads search results to determine if there are articles negatively impacting the company and based on this research recommends the company of investment. With enormous data available on the interest, this becomes a very tedious process. In this project, techniques like web scrapping and sentiment analysis are being applied. Libraries like beautifulsoup4, scrapy are being used for scraping the data. The web scraping process is automated using RPA (Robotic Process Automation) making the web scraping process easy as well as efficient. Another technique used is the sentiment approach that applies text analysis algorithms, natural language processing (NLP), and statistics to interpret customer sentiment classifying the customer opinions into positive, negative, or neutral categories. NLTK (Natural Language Toolkit) is applied to perform sentiment analysis.**

Keywords—Web scraping, RPA, Sentiment Analysis

I. Introduction

Finding answers to issues through the analysis and interpretation of data is known as data analytics. The procedure entails observing and identifying the issues, addressing the availability of pertinent data, determining the approach that will best assist in fixing the issues, and publishing the findings. The process of organizing, cleaning, reanalyzing, using models and algorithms, and eventually producing the end product is how the data is often divided. Data analytics eliminates hunches and manual effort. Companies can use the insights uncovered by data analytics to guide their decision-making and permits you to adjust client care in accordance with their needs. It also provides personalization and improves relationships with customers. Data analysis can reveal information about the preferences, problems, and more of the clientele. It gives you the opportunity to recommend improved products and services.

The objective of this paper is to extract information from different web pages resulting from a web search. The programming language which will be used here is Python. Python libraries are used to scrape the content from each of the links that result from the custom search. RPA bots will be automating the whole web scraping process. The contents arethen organized, analyzed, and cleaned and then on top of itNatural Language Toolkit is applied to perform sentiment analysis. The end result of the analysis would be stored in a csv file and the output is displayed to the user.

II. Related Works

As there is no specific work-related sentiment analysis for corporate permissibility for business activities utilizing NLP, this section covers information regarding web scraping automation using RPA and sentiment analysis. According to [1]'s authors, text in images can be automatically identified and updated in a target file using text recognition software. The suggested remedy employs a site URL as its information and a web data extraction method to obtain the image or text needed. From a location that the user specifies, the system extracts textual data. Additionally, the retrieved text is classified using Support Vector Machine (SVM) and Naive Bayes Classifier. The output can be saved as an Excel file, CSV file, PDF file, text file, or Google Sheet depending on the user's preferences. UiPath is a brand-new tool that was just recently released to the workplace and is a well-known[3] RPA. This tool functions as a bot that executes predetermined tasks that the user has defined for it by following the directions of a programmed flowchart. This article examines the use of RPA to create learning materials and documents that are used by lots of participants. An RPA was used in the study to test situations involving repeated tasks. It was suggested that automated work management and AI would produce a workflow that was more effective and efficient while lowering the error rate. Web scraping [4] is a technique used to collect data from a website and save the data in files or databases in an organized fashion. The tedious procedure of accessing lists of websites on a regular basis to seek for and store data is automated via web scraping. Manually copying and pasting data into files is a time-consuming and laborious task. An automated web scraping program completes the same task faster. Software for web scraping can be set up to work with any websites or it can be specifically built for a particular website. This study has established a straightforward methodology for analyzing job portals and web scraping information from job descriptions to analyze the needs of the Indian IT sector. [5] the concept of "web design scraping," that basically promotes the idea of extracting, understanding, and modelling website elements and features and so determining the significance of the web design. [6] The method suggested in this study gathers all recipe data using web scraping, after which Python and MongoDB are used to look for recipes that include the specified ingredient. The Python scrappy function is used in online scraping to take the content of a website. Web scraping methods are used to extract relevant information from websites by scanning hypertext elements and gathering the plain text that is encoded in them fromenormous volumes of web data.

Whether you work as a data analyst, developer, or in another profession that requires you to analyze huge datasets, having the ability to scrape data from websites is a vital talent to have. [7] Through cross- examination and information translation, information examination is a technique for locating solutions to problems. Web data scraping and freely supporting are outstanding techniques for regularly creating content on the web. The computer programs that write web scrubbers are set up to thoroughly mine each key piece of information from numerous internet retailers, compile it into the new website, and then publish it. [8] This study describes how web crawler and NLP can be utilized to deliver sophisticated solutions in computer science education. Using online job postings as a tool, they have examined a specific use of data extraction and Analytics to assess factors that may affect CS undergraduates' ability to find employment after graduation.

[10] The paper Web Scraping and application areas discuses about all the different types of web scraping techniques over the period of time. It also reveals various web scraping libraries which can be used in different areas of interest. It also specifies areas where web scraping is very minorly explored. It also gives an overview of different types of approaches, categories and tool used in this field. [11] aims to remove information from various sources with the aid of tool named as the web crawler Scrapy using the Python 3.6 programming language. A database is made that gathers all the unorganized data from different sources, analyses it according to its specifications by assembling, organizing, cleaning, re- analyzing, using models and algorithms, and then outputs the appropriate results. [16] In general, this paper refers to web scraping as the process of extracting data from a website. Web mining will make it easy to retrieve data from a website. By enabling data scraping from numerous sources, this tactic will reduce the amount of manual labour required, free up time, and increase the usefulness of the data relevant. The user will find it simpler to extract information from sites, store it for his needs, and use it however they see fit as a result of this. The information that has been scraped can be used to create databases, carry out analysis, and accomplish a variety of other tasks. [2] In this paper, They recommended a sentiment analysis technique based on deep learning for e-commerce goods review data. Using this strategy, comments are categorized as either positive or negative. The text is broken up into phrases, and the word length and word frequency are combined to train the neural network. In order to train an emotion classifier and mine the strong correlation between a feature set and an emotion tag, we employ a convolution neural network. According to the experimental findings, the model is a useful tool for online review analysis since it can accurately categorize sentiment and extract useful product attributes. [6] have put up an alternative concept known as aspect-based sentiment analysis, which more accurately recognizes characteristics and achieves the best classification accuracy. In actuality, the concept was created as a smartphone application to help travelers find the best hotel in the area. A number of real-world data sets were used to analyze the model architecture, and the findings showed that the proposed model was effective for both recognition and classification. [12] This paper's primary goal is to review existing sentiment analysis algorithms for Twitter data and present theoretical comparisons of the state-of-art approaches. A variety of approaches to Sentiment analysis at both the document and sentence level are also expressed.

Various approaches to sentiment analysis for Twitter are described, including supervised, unsupervised, lexical, and hybrid approaches. Finally, the latter's discussions and parallels are highlighted. [13] paper examines various well-known approaches or proposals for Sentiment Analysis. To add new components to the suggested plan, the pros and cons of the methodologies mentioned are examined. The new method employs a machine learning mechanism at the document level and combines verbs, adverbs, and adjectives. Along with adverbs, adjectives, and verbs, other combinations that are taken into account for analysis include adjectives-verbs, verb endings, adverbs-adjectives- verbs, and adjectives-verbs. Standard classifiers like Naive Bayes (NB), Linear Model, and Decision Trees are used to infer and interpret the findings. [14] This paper's major goal is to help scholars find the high sentiment analysis-based research publications. In this study, reference phrases are used to analyze sentiment on scientific papers using a previously created annotated corpus. To clean the data corpus, noise was eliminated from the data using several data normalization algorithms. They developed a system that uses six distinct data mining algorithms, such as Nave-Bayes. Lemmatization, n-grams, tokenization, and stop word removal are a few other feature selection approaches that are utilized to improve the system's accuracy. Their method increased outcomes up to 9% above the baseline system. On this data set, classification was performed using the Neural Network, SVM, LR, DT, KNN, and RF. The system's accuracy is then assessed using several assessment metrics such as F-score and Accuracy score. [15] Attempts have been made in this study to anticipate the direction of the stock market, determine prospective pricing for a company's stock, and make other financial judgements service this demand, streaming data appears to be a permanent supply of real-time data analysis. Spark streaming was used for data processing, while data input methods such as Twitter APIand Apache Flume were later used for analysis. The general model for sentiment analysis is done using the Stanford Core NLP tool, which aids in correctly identifying the sentiment of each tweet into three distinct classes: positive, negative, and neutral. [17] This study describes the creation and incorporation of a text analysis workflow into the open public cross-media analysis system. They also compared two major kinds of sentiment analysis methodologies prior to integration, namely lexicon-based and machine-learning approaches. They used the Stanford core NLP library, the Recursive Neural Tensor Network (RNTN) model, the Tomcat architecture, and its lexicon-based sentiment prediction method. Overall, RNTN outperforms the linguistic approach in terms of accuracy for favorable, unfavorable, and neutrality comments of varying length by 9.88%. However, when it comes to classifying compliments, the lexicon-based method works better. We also discovered that F1-score values are 0.16 higher than the

DOI: rp-9788770040723.019

RNTN.[18] In this research, In order to evaluate phrase sentiment analysis for sadness assessment utilizing SVM, NB, and ME classifiers, the author used a vote method and feature selection technique. Two datasets, the Twitter dataset and the20 newsgroups dataset, were used to test the proposed approaches. It shows that SVM outperforms Nave Bayes and Maximum Entropy classifiers in terms of performance. SVM accuracy is 91%, Nave base accuracy is 83%, and Maximum Entropy accuracy is 80%. [19] The objective of this paper is to detect hate remarks on Twitter by categorizingthem as racist, sexist, or neither. They experiment with a verity of classifiers in this research, including Logistic Regression, Random Forest, SVMs, Gradient Boosted decision Trees (GBDTs), and Deep Neural Networks (DNNs). These classifiers feature spaces are defined in turn by task-specific embeddings trained using three deep learning architectures: Fast Text, Convolutional Neural Networks (CNNs), and Long Short-Term Memory Networks (LSTMs). Combinations of CNN, LSTM, and Fast Text embeddings as GBDT features did not produce superior results. Finally, it was discovered that this strategy greatly outperforms the existing methods. The best accuracy values were found if deep neural network model were combined with gradient enhanced decision trees. [20] In order to find the most pertinent and top-notch YouTube videos, this paper proposes a sentiment analysis methodology based on NLP that is applied to user comments. The suggested process involves four steps. In order to set up the subsequent procedure, the comment collection and preparation module first does some linguistic preprocessing on the data (comments) from a specific YouTube movie. Second, NLP-based algorithms are applied to the text after it has been processed in order to create data sets. The positivity and negativity ratings are then computed for the data sets using the sentiment classifier (Sentistrength). The rating was then calculated using the Standard Deviation.

III. Proposed Framework

In this paper, we will suggest an application that will produce the necessary firm facts for the user. Rather than searching for details of a firm website by website, this saves time and yields more efficient results. To carry out the process, we employ tools such as web scraping and sentiment analysis. Web scraping is a software technology that extracts data from web pages. Such software applications typically replicate human internet browsing activities by implementing a low-level Hypertext Transfer Protocol (HTTP) or embedding a full- fledged web browser, such as Internet Explorer or Google Chrome. Web scraping is closely related to web indexing, a practice that most search engines use to index content on the web utilizing web crawlers. Contrarily, web mining focuses primarily on organizing unorganized online data, frequently in Html template, so that it can be saved for subsequent study in a local database or any other type of file structure.

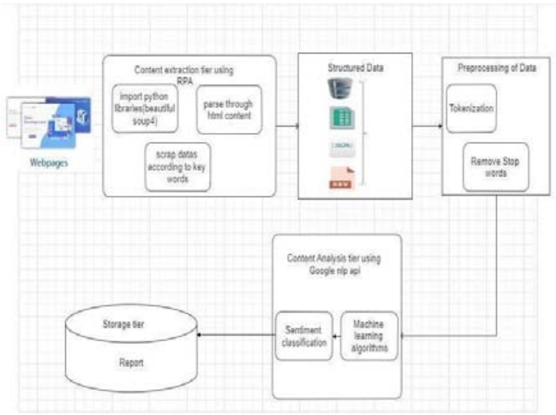

Fig. 1. Architecture Diagram

Robotic process automation (RPA) bots that carry out repetitive operations have automated the entire process. You no longer need to write code each time you gather fresh data from fresh sources. Web scraping is typically made easier andfaster by the RPA systems' built-in features, which also save time. Customer sentiment is interpreted using sentiment analysis, a machine learning technique that combines text analysis algorithms, natural language processing (NLP), and statistics to categorize customer attitudes into positive, negative, and neutral categories. After the content has been organized, analyzed, and cleaned, sentiment analysis will be done using the Natural Language Toolkit (NLTK) to get the sentiment score.

Fig. 1. depicts the architecture of the System. First, the contents from the web pages are scraped in the content extraction tier and the data is stored in the csv file and pre-processing and sentiment analysis are taken place. Then it is displayed in user interface.

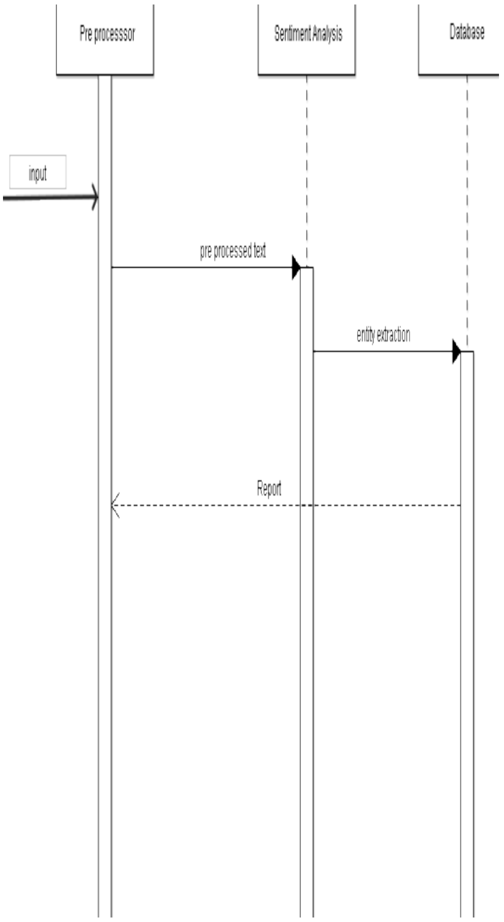

Fig. 3. Sequence diagram for Sentiment analysis

Fig. 3. depicts the sequence diagram of sentiment analysis where the input is given to the preprocessor and the preprocessor cleans and analyses the data and sends it to sentiment analysis tier and result is return to the user. The interaction between client and different tiers are shown in this diagram.

IV. METHODOLOGY

In this work, we'll provide a program that will provide the user with the necessary information about a corporation. Instead of scanning through every website in a company's website directory, this primarily saves time and produces more effective results. To complete the process, we employ methods like sentiment analysis and web scraping. Web scraping is firmly related to web indexing, which is the practice of utilizing a web crawler to index material on the web and is a method that is widely used bymost search engines. Web scraping, on the other hand, focuses primarily on the conversion of unstructured online data—typically in HTML format— into structured data that may be kept for further study in a local database or any other file structure. This whole process is automated using RPA, with RPA there is no need to write code every time you collect new data from new sources. The RPA platforms usually provide built-in tools for web scraping, which saves time and is much easier to use. Sentiment analysis is used to interpret customer sentiment by classifying the customer opinions into positive, negative, or neutral categories. The contents are then organized, analyzed, cleaned and then on top of it

DOI: rp-9788770040723.019

sentiment is performed. The end result of the analysis would be displayed in the UI. As for this project, it will be focused on the web content scraping and sentiment analysis using python as a programming language and automate the process using RPA.

A. Web Scraping using RPA

A Python package called BeautifulSoup can parse XML and HTML pages. For processed pages, it generates a parse tree that can be used to extract HTML data for web scraping. It provides Pythonic paradigms for iterating, searching, and altering the parse tree on top of an HTML or XML parser. We must supply a document to the BeautifulSoup function Object() in order to parse it. HTML entities are translated to Unicode characters before the page is converted to Unicode. The page is then parsed by Beautiful Soup using the built-in HTML parser, unless you specifically tell it to use an XML parser. The HTML content is transformed into a complex tree of Python objects by Beautiful Soup. Four different types of objects are often used: Comment, Tag, NavigableString, and BeautifulSoup. With a different section for each tag and each string, the prettify() method will convert a Beautiful Soup parse tree into a neatly formatted Unicode string. The goal of prettify() is to help understand the structure of the documents you work with. The whole web scrapping process is automated using RPA (Robotic Process Automation) and Orchestrator is used to schedule the process for specified time. The RPA process is carried out in UiPath.

B. *Sentiment Analysis*

The Natural Language Toolkit, or NLTK for short, is a comprehensive open-source framework for developing applications to handle human language data. It includes with powerful text processing modules for standard Natural Language Processing (NLP) operations including cleaning, parsing, stemming, tagging, tokenization, classification, semantic reasoning, etc. The user-friendly interfaces in NLTK are available for Word2Vec, WordNet, VADER Sentiment Lexicon, as well as other popular corpora and lexical resources. Here, sentiment analysis is performed using NLTK. We used NLTK's SentimentIntensityAnalyzer class and the VADER vocabulary to give each comment in the dataset a sentiment score. The Valence Aware Dictionary and Sentiment Reasoner (VADER), a vocabulary and rule-based sentiment analysis toolkit, focuses on the sentiments present in typical text applications such as online comments, social media postings, and survey replies. NLTKanalyses the text and generates the sentiment score for each review. Here, Sentiment analysis is being performed on all the reviews gives by customers for different companies. As an output, we get the sentiment and score value. In order to express the strength of how negative or good the sentiment is, VADER additionally produces a number score that ranges from negative one (-1) to positive one (+1). This is implemented via the SentimentIntensityAnalyzer class's polarity score method, which is known as the polarity score. A negative sentiment is often indicated by a polarity score between -1 and -0.5. In general, neutral sentiment is indicated by a polarity score of more than -0.5 and less than+0.5. Positive emotion is often indicated by a polarity score in the +0.5 to 1 range.

V. RESULT

Web scraping is performed and after which sentiment analysis is carried out and the company details are displayed to the user as output. As a result, the user enters the company name and fetches the score value which is performed with the help of a natural language processor. Web scrapping can be done with the help of many python libraries like beautifulsoup4, scrappy, selenium etc. These libraries can be imported into Pycharm and scrap data by typing lines of code into it. This method is not very efficient since the program has to be run every time in order to be scrapped. More efficient method is to use UiPath's RPA studio which does not require even a single line of code and can be automated by scheduling the time it needs to be scrapped. There are various approaches to perform sentiment analysis. One such way is by importing the csv file into pycharm and perform the analysis by typing several lines of code. It takes quite a long of time to process the code and the chances of producing error are significantly high. Another method is using UIPath studio which also can perform sentiment analysis but it's a tedious process and takes a longer period to produce the output. We found the Sentiment Analysis using NLTK is hassle free and quick, and also gives an accurate score values.

VI. CONCLUSION AND DISCUSSIONS

Web scraping and sentiment analysis are quite prominent in the technology industry in the recent years. When we combine the idea of automating a search with the help of APIs, extracting the content and then performing some analysis on it, the idea becomes vast with the number of applications being limitless. It reduces the manual work of people browsing through websites page by page. This process when automated can reduce the manual overhead thus saving time and energy. Now that title idea is established for automating the search and performing an analysis on that. It can be extended by introducing a few enhancements such as looking for a specific set of keywords or phrases (KWIC, KWAC, KWOC) that the user is expecting to make a decision based on that. The data which is now stored in a database can be presented to the user as a report or dashboard to show the number of web searches done, their corresponding scores and the types of entities it contained. It can contain a word cloud or a color-coded datatext for better visualization. The search can also be parallelized and done in an asynchronous mode to enable faster processing and results for the user.

***Abstract*—In the last few years, peoples were interested in breeding the pets. Fish farming is one among them. The peoples have to spend lot of time in on feeding, changing the water, monitor the oxygen level, managing the lights and temperature in the tank. Hence it is important to automate the above said process by using various recent technologies. In this paper, the smart fish tank system is used to monitor the fish and to control the process inside the tank. It uses artificial intelligence - based internet of things (IOT) technology that is combined along withthe sensors to get real-time operation for controlling the fish tank. This system performs detecting the pH level in water, monitoring the temperature, aeration of the system, as well as water renewal efforts. It improves survival rates of fishes in the tanks. The users able to monitor and control the process with the help of the mobile application. This system also helps the farmers in reducing their manual work which is required for maintaining the fish tanks.**

Keywords: Smart Fish Tank, IoT, Internet of Things, Automatic Fish Feeder, Smart Aquarium

I. INTRODUCTION

The Smart Fish Tank System using Artificial Intelligence is an innovative way to make the lives of fish owners more convenient. It uses AI technology to monitor the water quality and provide automated maintenance for the tank. The system can detect temperature, pH levels, and other environmental factors in order to provide the best possible environment for the fish. It can also maintain a consistent level of food and oxygen in the water, as well as alert the owner when something is off or if the fish needs to be fed. This system will make the lives of fish owners easier and more enjoyable, as they can trust that their fish are being taken care of without having to worry about it.

It is a revolutionary new technology that can revolutionize the way we keep and maintain our fish tanks. This system uses advanced artificial intelligence algorithms to analyze the water temperature, pH levels, and other parameters to provide a healthier environment for the fish. It can also detect and prevent disease, allowing fish to live longer and healthier lives. The system can be set up to monitor the tank and provide notifications when something needs to be changed or adjusted. This system can also be used to provide automated feeding and cleaning schedules, so that the fish can get the best care possible. With this system, we can ensure that our fish are getting the best possible care and are living in the most comfortable environments.

This project aims to create a smart fish tank system that uses artificial intelligence (AI) to monitor and manage the temperature, water level, and other environmental conditions of the tank. The system will use sensors to detect changes in the environment, and use AI algorithms to analyze the data and make decisions to adjust the environment based on the data. The system will also provide feedback to the user, such as alerts if the water level is too low or the temperature is too high. Additionally, the system will be able to suggest food types and feeding schedules for the fish. To develop a smart fish tank system using artificial intelligence. The system will be equipped with sensors and cameras to monitor water quality and the surrounding environment, as well as to monitor the behavior of fish in the tank. The system will use AI algorithms to detect and analyze data from the sensors and cameras, and then use this data to make decisions about the environment and the health of the fish in the tank. The system will be able to adjust the water parameters, such as temperature and pH, to ensure the health of the fish, and will be able to provide timely alerts when the conditions are not suitable for the fish. The system will also be able to suggest changes in feeding and other activities to ensure the health of the fish.

This system will be able to detect and recognize fish, monitor their health, and provide appropriate environmental conditions for their well-being. The system will be able to monitor water parameters such as pH, temperature, salinity, and oxygen levels. It will also be able to detect and identify any disease or other health issues in the fish. The system will then be able to provide targeted treatments and advice on how to improve the fish's health. Finally, the system will be able to provide information on the fish's behavior, enabling the user to better understand and interact with the fish. This project will improve the fish-keeping experience and increase the overall happiness of fish owners.

II. LITERATURE SURVEY

Just lately improvements in IOT have aided in the digitization of fish tanks, where several smart systems are either commercially available or have been published in the literature, allowing for the control and monitoring of various

DOI: rp-9788770040723.020

parameters inside these systems. onetheless, clever fish feeding practices that efficiently and precisely determine feeding parameters (such as frequency and pellet release rate) have not received considerable research.An earlier study examined the use of fish feeding The use of computer vision in a sustainable aquaculture feeding system was examined [6]. This research looks at the appetites of fish in a fish tank using computer vision to eventually distribute pellets automatically or manually. Another study employed a PIC microcontroller to construct a pellet dispenser system for managing the release of pellets in smart fish tank environments [8].The focus of this study, however, was on the mechanical device of the feeder rather than effective feeding of fish based on fish tank conditions. Furthermore, a previous study proposed an IOT-based fish feeder system that feeds fish at regular intervals at specific times and measures user-specified time parameters using various sensors. [9]. Despite the fact that this food feeder system was discovered to boost feed efficiency and decrease time consumption. An earlier study examined the use of fish feeding The use of computer vision in a sustainable aquaculture feeding system was examined. Similarly, a Raspberry Pi-based fish feeder system was created, with users able to access feeding procedures via a web application [10]. This system's interface allows for manual fish feeding, setting and changing the feeding daily schedule, and a camera that monitors the fish tank and allows the user to verify tank status. In essence, recent time some smart fish feeding systems have been presented in the literature, but there has been a limited amount of work done in fish tanks to integrate the factors of accuracy or specific time to determine the amount of food feed for fish to be released by the fish feeding system. As a result, the gap addressed in this publication is significant to research..In[11] the author proposed a system for monitoring the fish tank environment. In this system, the data of the fish tank environment was monitored by using sensors. The sensors are placed indifferent locations within the fish tank. The sensors are used to sense the light, temperature, pH level, and oxygen level in the fish tank. Hence the data's of the fish tank environment is monitored by the sensors fit in fish tank that display in the webpage where data transmitted from the microcontroller. The microcontroller is used to process the data and sends it to the server. The data are stored in database using server. The data of the fish tank environment is monitored by the sensors and transmitted to the microcontroller. The micro controller is used to process the data and sends it to the server. The server data are reset in the database. The data stored in database can be accessed by the user using the web application. The data of the fish tank environment is monitored by the sensors and transmitted to the microcontroller. The microcontroller is used to process the data and sends it to the server. The user can view and accessed the data in the web application.

III. Methodology

In the proposed system, the water quality from the fish tank and the data from the fish tank is pushed to cloud and the data can be viewed in the web application and android application and other modules work accordingly.

Live Data Accessibility

The sensor collects the data from the water present in the fish tank using the sensors such as DS18B20 to measure water temperature sensor, Analogue pH sensor with Amplifier Circuit to measure the pH quality of the water in fish tank, HC-SR04 Ultrasonic sensor to measure the water level in the fish tank, Turbidity sensor with module to measure the turbidity of the fish tank. The raw data from the sensors is received by the Arduino and process the data and transfer the processed data to the Raspberry Pi through serial port and it publishes the data from the Arduino using MQTT protocol on specific topics. The published data is received by subscribing to the specific topics at the web application and android application. So that the user can view the live data of the fish tank. The figure 1 describes the process flow.

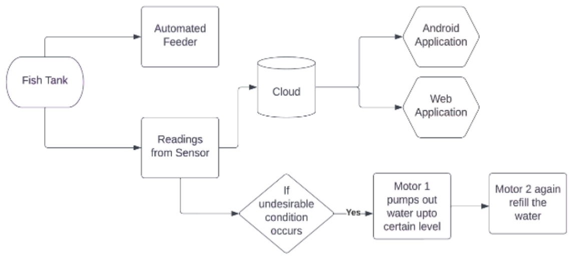

Fig. 1 Proposed System Block Diagram

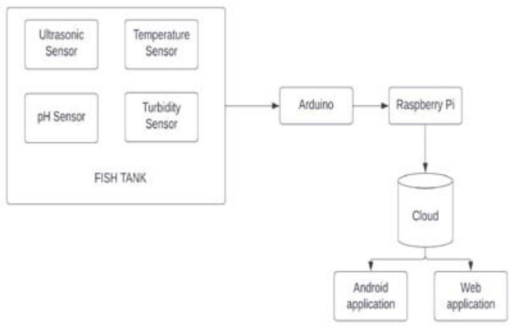

Fig. 2 Live Data View Process

Water Replacer

If the water inside gets contaminated that, if the quality of the water gets changed and it gets nearer to the non-suitable condition for fishes to survive in it. Then the water inside the fish tank is pumped out by the motor 1 to Auxiliary tank 2 the certain level (up to the minimum level in which fishes can survive). After pumping out the water from the fish tank, the fresh water in the auxiliary tank 1 which has suitable condition for the survival of fishes is pumped into the fish tank up to the certain level which is often monitored by the ultrasonic sensor. When the particular level gets reached the pumping process gets stopped. The Figure 3 describes the process of water replacer process. Here we use the 12 volts water submersible motor for the pumping processes in both fish tank and auxiliary tank.

DOI: rp-9788770040723.020

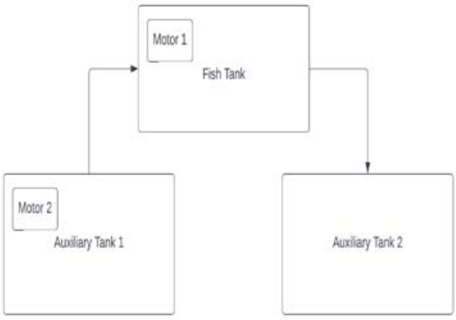

Fig. 3 Water Replacer Process

Automatic Fish Feeder using Artificial Intelligence

The smart fish feeders for IOT driven algorithms are limited. So in that case it is necessary to create the other. The smart fish feed is the essential one to comprehend such as feeding the fish within the fish tank. Various studies were conducted to comprehend the factors, and the key ones are summarized in table 1.

TABLE 1 FACTORS AFFECTING FISH INTAKE

Factors	Effects
Water Temperature	The water temperature increase can induce the increase in food intake like tracking the temperature of the water is critical in determining the amount of feed discharged in fish tank
Oxygen	The aquatic environment need oxygen to survive. If the water oxygen level drops, fish will consume less food and will require more frequent feeding. Monitoring the optimum oxygen level is also important.
pH	Various types of fishes requires different water pH levels but some of the aquatic animals tolerate higher pH level compared to other fishes. If the pH level falls outside of the range, the fish will get stressed, which may lower hatching and survival rates.
Stress	Stress causes discomfort and it results in physiological responses. It has a negative impact on growth, digestion and a change in eating behavior is a symptom of a behavioral response to fish stress. When fish are subjected to stressful situations, their food intake decreases and they grow slowly.
Light	Light influences the intake of fish food to an extent. It is a crucial aspect since an increase in light intensity promotes feeding and a drop in light level discourages feeding.
Ammonia	Ammonia is a harmful chemical that threatens aquatic ecosystems, and its prevalence is caused by overstocking and overfeeding. When the ammonia level in water rises, people consume less food.

The above factors are calculated from the fish tank using sensors though some of them cannot be calculated they can be left for the calculation. Although we can use the manual feeding method in which the feeding parameters such as amount of pellets to be feed, feeding time and feeding frequency. These can be automatically decided using the artificial intelligence based smart fish feeding algorithm. The outlook of the algorithm is

- Derive the values of the Factors
- Get number of fishes
- Adjust the amount of the feed(pellets)
- Adjust the frequency of the feed
- Adjust the time to feed

IV RESULTS

The Figure 4.1(a) shows the Web application's UI. On the left side of the UI we can see the parameters of the water and on the right side of the UI, we can see the value of that parameter which is generated from the sensor present in the Fish Tank. The value is transmitted through the MQTT protocol and the web UI is connected and subscribed to the MQTT by using JavaScript. The Figure 4.1(b) shows the Android application's UI. In the android application the live data is shown in the format of the graph (line chart). The android application also connected to the MQTT protocol and the live data is pushed to firebase so that old values can also be viewed and the graph shows the values of the last ten data inside the graph. Both the web application and the android application also haves the authentication pages and user registration pages for login.

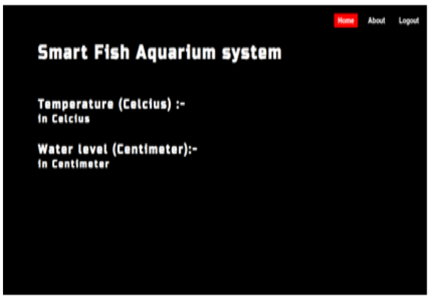

Figure 4.1(a)

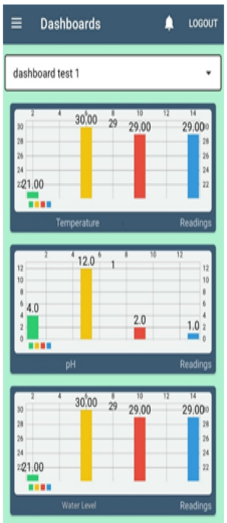

Figure 4.1(b)

V CONCLUSION

The smart fish tank system using artificial intelligence-based internet of things is to develop a system which can monitor the fish tank and provide information to the user about the fish tank. The system is designed using various sensors and controllers. The sensors are used to monitor the water level, temperature, pH level and the concentration of dissolved oxygen in the water. The controllers are used to control the water pump, aerator and the light. The system is also equipped with a camera which is used to take pictures of the fish tank. The system is connected to the internet and the user can access the information about the fish tank from any location.

***Abstract*— Because it meets a vital requirement for every living thing on this planet, agriculture serves as the backbone of human society. In terms of humanity, Paddy farming is significant, especially on the Asian continent. Since we humans are among the most intellectual animals, it is crucial that we preserve the value and productivity of agriculture. The productivity of agriculture has increased to some extent with the arrival of the IT sector. It has made significant contributions to agricultural healthcare. The term "deep learning" is popular in the IT industry. This trendy term has significantly increased agricultural output. The overuse of pesticides and chemicals created by humans has recently resulted in a rise in plant diseases. These plant diseases must be treated since they can develop into serious conditions. Additionally owing to a lack of technical understanding, it can occasionally be challenging to identify certain disorders. So, a model for identifying the disease that is with in paddy crop is presented in this study. The model employs transfer learning, a paradigm for effectively addressing deep learning issues.**

Keywords*— *Paddy crop disease, Deep learning, Transfer Learning, Convolutional Neural Network

I. Introduction

Agriculture development is seen as one of the most effective methods for reducing severe poverty and fostering shared prosperity. Agricultural production aims to support9.7 billion people globally by 2050. The global agriculture industry has a huge impact on earnings of all social strata [1]. However, there are significant hazards related to agricultural expansion, poverty alleviation, and food security. The production of the crops may be severely reduced due to continuous climatic fluctuations and other weather-related issues. In addition to slowing agricultural expansion, climate change also eliminates many farmer job options. A further significant factor in the decline of agriculture is human error, such as the overuse of insecticides and other herbicides. In addition to killing crops, these pesticides jeopardise biodiversity. Disease is one more aspect that has a highly negative impact on agriculture. A plant with a disease is justas serious as a person who has one. If not treated in a timely manner, the plant can eventually perish.

In Asia, the paddy crop has a significant impact on the number of farmers that are employed. In addition to creating jobs, it also contributes to the partial eradication of poverty. The Asian continent eats a lot of rice. In more than a hundred nations throughout the world, it is also regarded as a staple dish [2]. It is typically served with more than one meal each day in most families. It is extremely affordable and offers itself to everyone. It is starchy and heavy in calories. However, recent times have seen some difficulties with the paddy crop. Climate change, such as global warming, and illnesses including fungal, viral, and bacterial infections are making rice cultivation more difficult. The rice plant's potential health problem might lead to an early demise if it is not thoroughly investigated.

The suggested model determines what illness the plant has. There are three different types of ailments that the crop could contract: “Hispa”, “brown spot”, and “leaf blast”. The “Convolutional Neural Network” is used in the model to forecast and categorise the illnesses. “Convolutional Neural Network” was chosen because of how well it handles pictures. Four classifications make up the selected data collection, three of which are related to diseases and one to health. The suggested model enhances the image via image augmentation, then trains on it to get the desired outcome.

II. Related Work

Suraksha et al [3] .'s approach employs “data mining” and “image processing” in order to forecast the illness that the rice crop will contract. In the publication, they provide a model that makes use of “feature extraction” and “data mining” methodologies to identify illnesses that the rice plant is experiencing.

A model for identifying ailments that the paddy crop is afflicted with is provided by K.Jagan Mohan et al. [4]. The features are extracted using the “Scale Invariant Feature Transform”. The characteristics are then used, and the model uses “K Nearest Neighbours” and “Support VectorMachine” classifiers to use the characteristics to detect the illness.

Anuradha B. [5] has provided a paradigm for identifying the illness the plant is carrying. The author's clever edge detection approach was applied. In order to anticipate the illness that the plant has, the author tracked the edge and obtained the histogram value using the clever edge detection technique. The cultivated field is also periodically observed by the model. Early illness detection

DOI: rp-9788770040723.021

is achieved by the model. Then, training is carried out using machine learning. The model then makes the appropriate choice and foresees the sickness the plant will contract. A method for Rice disease area detection via image processing has been presented by LipsaBarik [6]. The model that the author has suggested also pinpoints the disease that the paddy crop is experiencing, in addition to the area that is impacted. The author employed "machine learning" and "image processing" methods including "Support Vector Machines" and "Nave Bayes" for categorization. After the prediction is complete, the disease's severity is established, and then classified it into several groups.

Using image processing techniques, Jayanthi, G. et al. [7] established a model for the investigation of automated rice blight categorization. Their research provided a thorough analysis of the various picture categorization techniques.

Big data is used in the model proposed by S. Nithya et al. [8]. They developed a paddy crop disease-based recommendation system based on symptoms. Information about illnesses is gathered from a variety of websites and blogs. Through the use of HiveQ, hive tools, and Hadoop the information has been examined.

A model that uses predictive modelling is proposed by Arumugam, A. [9]. This model uses "data mining techniques" to increase the productivity of the rice crop. Their research intends to offer a predictive modelling strategy that would assist farmers in producing rice crops with a high yield. They have employed machine learning methods like decision trees and clustering. They have used the weather data to apply them.

III. Background Study

Predicting the sort of sickness the rice plant is experiencing is the goal of this study. The illnesses that affect the paddy plant are outlined below.

A. Brown Spot

The rice plant's leaves develop black patches, which are indicative of this illness. The signs of this illness, such as the mortality of seedlings, the death of substantial portions of the leaf, and the presence of brown or black spots, can be used to identify it. It belongs to the class of fungi. It results in a loss of both quantity and quality. All throughout South and South East Asia, it results in a 5% yield decrease. By giving the crop the proper quantity of nutrients and preventing water stress, it can be made sure that paddy plant is not afflicted with this illness [10].

B. Leaf Blast

The most severe and devastating disease that affects rice plants is thought to be leaf blast. It may have an impact on the neck and leaves, among other leaf sections. In areas withsporadic rainfall, chilly temperatures, and little soil moisture, this illness is highly common. Leaf explosion can occur in a rice plant at any stage. It is distinguishable because the dots have dark green edges. They can be mistaken for brown patches with ease. It can completely destroy the leaf if it grows. They can be mistaken for brown patches with ease. If the field is flooded as frequently as feasible, it can be controlled. It can also be controlled by dividing the use of nitrogen fertiliser into two or more treatments [11].

C. Hispa

If the grub mining is evident on the leaves, this disease can be detected. The rice fields seem burned if the land is highly infected. The injured leaves of a badly afflicted rice plant wither away. Young plants are typically affected by this disease. A field should not be overfertilized in order to control this disease [12].

D. Sheath Blight

It is a sickness that is classified as a fungus. The main paddy farming regions in tropical and subtropical nations typically experience it. It is present in all regions of rice cultivation and is reducing rice yield, particularly in systems with intensive production. Studies reveal that it reduces tropical Asia's overall production by 6% [13].

E. Bacterial Leaf Blight

The rice plant's leaves can develop bacterial leaf blight, which is easily identified by looking at the yellow and white stripes on the paddy leaf. We can tell whether a plant has bacterial leaf blight by examining the newly grown leaves, which will have a faint yellow colour. By applying less nitrogen fertiliser and tilling straw and stubble into the soil after the crop has been harvested, this disease can be prevented [14].

F. Grassy Stunt

If the leaves are thin, pale green in colour, or yellow in colour, this disease is present. It is a kind of virus. It can also be identified if leaves develop sporadic dark brown patches. It can spread by leaf hoppers. In South, Taiwan, Southern Japan, Southern China and South East Asia, the illness is widespread [15].

These are the several diseases that the rice plant may contract. We have considered Hispa, Leaf Blast and Brown Spot illnesses out of all of these ailments. These disorders can be properly categorised by our approach. The rice plant would be categorised as healthy if it was free from any diseases.

IV. Methodology

A. Dataset

The dataset we used is custom dataset which consists of 9000 images collected from various Bing Search API and Kaggle Datasets. A Python script was used for Bing Search API to find pictures with multiple queries related to "brown spot", "leaf blast" and "hispa" which aids us in data collection. Hence our dataset consists of three classes with 3000 images per each class.

B. Proposed Method

Neural Networks are a collection of intricate algorithms that, by simulating how the human brain functions, identify the main relationship among a group of facts. Neural networks are frequently utilized in business trading, planning and business analysis, as well as for product and medical maintenance purposes. They have succeeded in achieving wide adoption in corporate applications and also

DOI: rp-9788770040723.021

has a significant part in identifying diseases like diabetes, breast cancer, and brain tumor [16].

Out of all the many variations of neural networks, CNNs are the optimal option for use with photographs. Convolutional neural networks come in a variety of designs, some of which include DenseNet, ResNet, Inception, VGG 16, LeNet-5 and Alexnet. These builds work as a powerful “feature extractor” that may be applied to a variety of sophisticated tasks, including object identification, picture segmentation, and image classification [17].

Because it is highly convenient to deal with a big number of photos, we have chosen the Transfer Learning methodology out of all of these designs. Transfer learning is a machine learning methodology that emphasizes on applying the model's previous experience with other issues to address a new difficulty. In other words, it is a well-known methodology that utilizes a model that has previously been trained on a comparable problem and that addresses issues in a variety of fields which include natural language processing, computer vision, and image processing. Transfer learning may be used in two ways: pre-trained model approach and developed model method [18]. The four crucial phases of the developed model approach are the selection of the source task, the development of the source model, the reuse of the model, and the tuning of the model.

C. *Architecture*

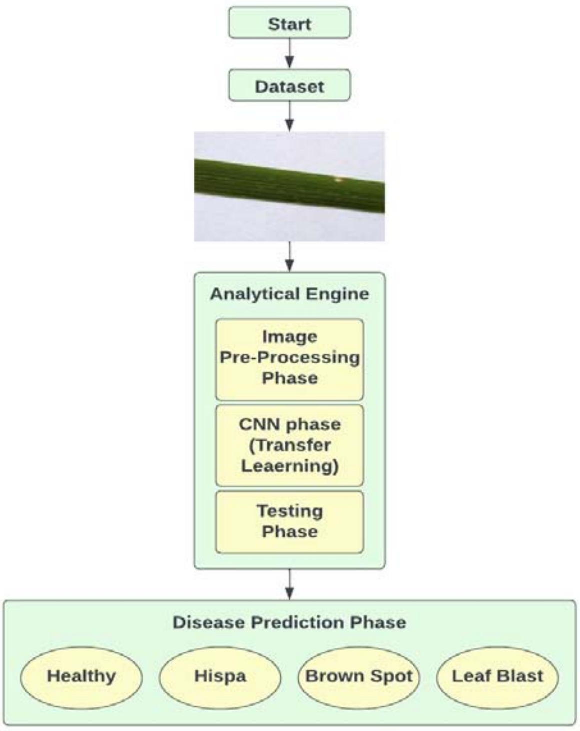

Fig. 1. Architecture of the proposed system

Firstly, we collect the dataset as shown in the architecture diagram in Fig. 1. The Analytical Engine phase of our architecture consists of three main sub phases. The first sub phase is the image pre-processing phase where several pre- processing methods like brightness corrections, segmentation and geometric transformations are applied. In the second sub phase, we train our CNN model coupled with transfer learning which results in faster train times and higher accuracy. In the testing sub phase, we test the performance of our model with other CNN models in order to obtain a comparison among various models. Finally, we employ the best performing model among all the compared models for our Disease Prediction Phase.

V. EXPERIMENTS

We employed the VGG16 architecture for our CNN model with transfer learning. Which means we have 16 layers that have weight. The average pooling technique was used in the pooling layers. We used ReLU and Softmax activation functions were used for the convolutional layers and the dense layer respectively as we have to perform predictions of 4 classes at the end.

A. *Results*

We put our model to the test using several Convolutional Neural Network topologies. We employed a single layer of CNN, two levels of CNN, and the 16-layer VGG-16. Our model has a 91.7% accuracy rating, which is its highest. Compared to the previous models we have employed, the one layer CNN and the two layer CNN—the loss in our model is likewise relatively low. Utilizing transfer learning, we were able to achieve 94.4% training accuracy and 91.7% testing accuracy.

TABLE I.COMPARISON AMONG DIFFERENT MODELS

Model Name	***CNN one layer***	***CNN two layers***	***Transfer Learning with VGG-16***
Test Accuracy	71.8%	76.1%	91.7%

B. *Performance Evaluation*

The model effectively identified the illnesses that the rice plant could have after being put to the test using the test data. We were able to get an accuracy of 91.7% employing the transfer learning methodology. It is a powerful technique for solving complex deep learning problems, especially those that use image-based data. This set of architectures may be quite helpful when we have a difficult problem to solve.

VI. CONCLUSION

In people's life, cultivation is essential. It also offers food for both humans and animals, as well as sources of work for people. Agriculture must be safeguarded and kept since it is necessary for both people and other creatures to exist. Lack of technical expertise and understanding in the agricultural sector may seriously affect the health of plants. The procedure of detecting and diagnosing different lethal illnesses has altered as a result of the substantial involvement of the IT industry in agriculture during the past several years.

Transfer learning, a technique for gracefully and successfully addressing difficult image processing problems, is used in this model. This model uses the transfer learning VGG-16 architecture to forecast illness in rice crops. It takesthe features out of the leaves and determines what kind of sickness the plant is experiencing. The classification and

DOI: rp-9788770040723.021

detection concept is closely adhered to in this model. This approach has many promising applications and a bright future. It may be implemented in a website and turned into an app. The website or developed app is used by the farmer or individual to submit a carefully taken picture of the plant leaf, and it promptly detects what sort of disease the plant is facing. It will let us know whether the plant is likely to have a disease.

***Abstract*—To maintain the quality of the River's water, environmental regulations demand that the River's environmental state be monitored. Conductivity, dissolved o2, and microorganisms are measured manually using manual sensors. Additionally, a Secchi disc is used to measure turbidity roughly. Workers would survey the rivers located once a week from May to October to conduct testing. It takes many hours to complete the journey and data collection. Upon finishing, the collected data is sent to a web server. To sample bacteria, water is collected, and it is delivered to a laboratory nearby. Between each of these weekly cycles, there appears to be a lag in time and a danger that data will be misrecorded or lost. Due to these possibilities, the River-Keeper cannot fully assess the current state of the river and has little time to look into and address sources of poor water quality. Therefore, it's crucial to monitor water quality. To solve this challenge, we suggest an embedded technology that continuously checks the water quality and publishes the output data to a web UI, so that the customer can know about the status of the water, whether it is consumable or not.**

Keywords—River Monitoring System, IoT, Water monitoring, internet of things, Message Queuing Telemetry Transport, cloudiot.

I. Introduction

Globally, the problem of water pollution is becoming more and more important, and it is having a serious effect on both the environment and human health. Due to the time and resource requirements of traditional techniques of water quality monitoring, it is difficult to quickly and effectively identify and address water pollution. By providing real-time monitoring of water quality parameters, sensors, and remote sensing technologies offer a possible answer to this issue. Thistechnology can deliver data on water quality that is more precise and effective, enabling the early identification and reduction of pollution.A more thorough understanding of the factors affecting water quality can be achieved by combining remote sensing with ecological water quality modeling, which are both useful techniques. The main causes of water pollution can be found and addressed, as opposed to only addressing the symptoms, by looking at the transfer function between sources of pollution and water quality. The construction of an automated water monitoring system with various pH, conductivity, turbidity, and dissolved oxygen sensors can significantly increase the precision and timeliness of data on water quality. IoT technology can be used in this system to create a widespread early warning system for portable water quality, enabling quick detection and action in the event of water pollution. The protection of both human health and the environment depends on solving the problem of water pollution. It is possible to create more effective and efficient water quality monitoring systems by utilizing advancements in sensor and remote sensing technology and ecological water quality modeling. With the use of these technologies, water pollution's negative effects can be lessened and water resources can be safeguarded for future generations. Water pollution is a serious environmental issue that requires monitoring of various parameters. Manual collection and analysis of water samples are resource-intensive and time-consuming, making sensors a more efficient solution. A multi- sensor real-time water monitoring system can be used to monitor water quality, which varies depending on intended human use and environmental factors. The IoT concept can be used to connect and communicate with other items in the environment to enhance water quality monitoring. Maintaining current quality requirements and protecting fisheries and recreational use are typical water quality regulations.

II. Literature Survey

A water level sensor is used in the proposed system, an Internet of Things-based river quality monitoring system, used for real- time water level detection. The information is kept on a cloud server, and a remote dashboard shows the water levels. This approach might be helpful in disaster-prone places where water levels are a crucial factor in flood forecasting[1]. The mechanism for detecting water quality described in this paper is an Arduino development board with sensors that measure conductivity and water for temperature, turbidity, and pH. Through Bluetooth, the system transmits data to a smartphone and sends alerts for unusual values. Results indicate that the system is reliable and precise, making it a good choice for many water quality monitoring scenarios[2]. In this study, a low-cost approach to determining water quality is presented. It makes use of the signal conditioning IC, three sensors, and the ARM CORTEX M4F Microcontroller-Unit for scaling and collection of data. A microcontroller and Wi-Fi module is utilized and the information is transmitted to a cloud server. The association between temperature and pH is investigated once the sensors are calibrated using a standard solution.For the upcoming water quality research, the measured data is kept in a cloud database[3]. By building a monitoring

DOI: rp-9788770040723.022

system for water management, an IoT system may be constructed to measure the quality of the water. Remote communication technology can aid in sending the data, and the Raspberry Pi can be utilized as an embedded system to help with the development of the detecting sensor device. The resulting real- time online water quality monitoring system powered by the Internet of Things (IoT) can function as an autonomous surface water monitoring system.[4]. The study suggests a cloud- and deep learning-based river monitoring system that predominantly checks the quality of water in water bodies to guarantee safe water delivery. To measure different water parameters, the system makes use of IoT devices like Node Micro-Controller-Unit and numerous sensors. Predictions about how usable water will be are made using deep learning algorithms. Fighting environmental problems and raising living standards are the goals of the system[5]. Based on the information provided, it appears that the existing system for monitoring water quality is primarily manual and relies on human intervention to take readings and collect samples for laboratory analysis. This approach can be time-consuming, inefficient, and may not provide real-time information on water quality. To address these limitations, an automated system could be implemented that uses sensors and other advanced technologies to continuously monitor water quality parameters and provide real-time data on water quality. This system could be integrated with a central control center, which could receive and analyze data from multiple sensors and devices, providing a comprehensive view of the water quality at various locations within the system. The system could also be designed to automatically detect and alert operators in case of any deviations from acceptable levels of water quality. Additionally, data from the automated system could be used tooptimize treatment processes and ensure that the water meets the required quality standards. Overall, an automated system for monitoring water quality could provide several advantages over the existing manual system, including increased efficiency, accuracy, and real-time monitoring capabilities.

III. Methodology

Our suggested system uses the appropriate sensors to analyze water parameters such as turbidity, pH, temperature, and ambient temperature & humidity. To produce the appropriate output, the above-mentioned sensors are connected to the digital and analog pins of the Arduino UNO. A serial interface, the Raspberry Pi 4 Model B, and Arduino UNO are now integrated. The Pi's serial port is used to access the output data. To read the data sent through the serial port, a straightforward Python script is utilized. The findings are then shown online when these data are sent to the cloud platform. Then we distribute the data to nodes or subscribers who have subscribed to the central node, using the Message Queuing Telemetry Transport server. The broker on the raspberry pi serves as a centralized node by disseminating data to all subscribing devices.

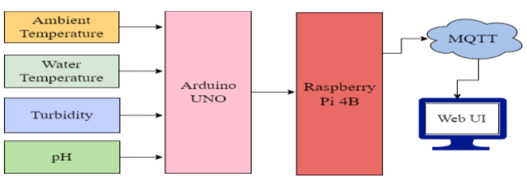

Fig. 1. Proposed system block diagram

Our system includes a Digital Temperature and Humidity11 sensor to gauge the temperature and humidity of the environment, as well as a DS18B20 sensor that analyzes water parameters and provides us with the temperature in degrees Celsius. We determine whether water is drinkable based on the pH sensor's ability to determine whether the water is acidic, neutral, or alkaline. The turbidity sensor measures the water's cleanliness. It reveals if anything is clear, cloudy, or unclean. The digital pins of the Arduino UNO are wired to the data pins of the Digital Temperature and Humidity11, turbidity, and water temperature sensors. Since the data pin of the pH sensor is attached to the analog pin of the Arduino, it is an analog sensor.

The proposed solution of using embedded technology to continuously monitor water quality and publish the output data to a web UI could be an effective way to improve the River- Keeper's ability to monitor the river's environmental state. This solution has several potential benefits, such as:

A. Real-time monitoring: The embedded technology can monitor water quality continuously, providing real-time data on the river's environmental state. This will enable the River-Keeper to detect any changes in the water quality immediately and take necessary action.

B. Improved accuracy: The manual sensors used currently have limitations that may lead to inaccuracies and inconsistencies in the data collected. The embedded technology can eliminate these limitations and provide accurate data.

C. Reduced workload: The proposed solution can reduce the workload of the River-Keeper as they will not have to manually collect data once a week. This will free up their time, enabling them to focus on identifying and addressing sources of poor water quality.

D.Improved accessibility: The web UI will enable easy access to water quality data, allowing interested parties to check the status of the river's environmental state at any time. This can increase transparency and accountability.

E.Cost-effective: The embedded technology can be cost- effective in the long run as it eliminates the need for manual sensors and reduces the frequency of lab testing.

The raspberry pi's Message Queuing Telemetry Transport (mosquitto) protocol is used to publish the output data from the Arduino to the Web UI. The data is uploaded to the Web using a straightforward Python program. Here, the publisher and subscriber concepts from MOSQUITTO were applied. Data is published by Mosquito utilizing topics. To get the data and transmit the data to the web UI, we must subscribe to the same topic on the subscriber end.

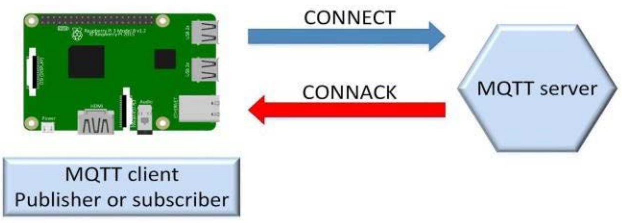

Fig. 2.Message Queuing Telemetry Transport

DOI: rp-9788770040723.022

An Message Queuing Telemetry Transport client must subscribe to an Message Queuing Telemetry Transport topic to receive messages. Publishing is the process of sending messages in Message Queuing Telemetry Transport. A client is free to publish on whichever subject they like. There aren't any reserved topics at the moment. Brokers may, however, limit access to some topics. If multiple clients subscribe to the similar topic, the published message will be sent to each client. Multiple topics can be allowed only if they are parsed as json payload or single string. The broker will send a message to all connected clients who have subscribed to a topic when a client publishes a message on that subject. The message is taken down from the broker once it has been delivered to thoseclients. The message is deleted from the broker if no customers have subscribed to the topic or if they are not currently connected. Typically, the broker doesn't keep messages on file.

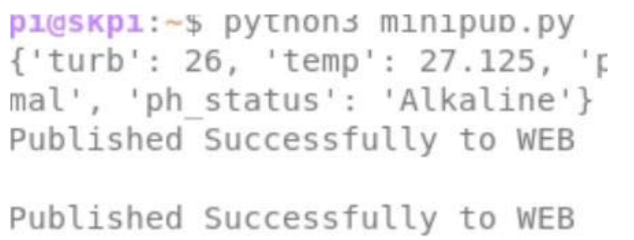

Fig. 3. Message Queuing Telemetry Transport publisher output

IV. System Software

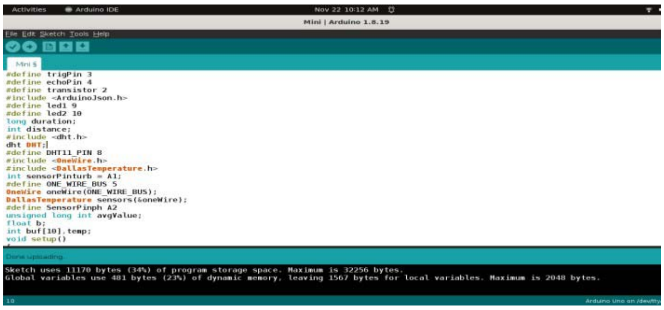

Fig. 4. Arduino IDE simulation window

To display readings from the sensors, we have created a web user interface. We used turbidity, pH, water temperature, and environmental temperature sensors in this instance. The user dashboard presents the data in a card view. PHP is used to retrieve the cards from the database. Here, the data from the sensor was published via Message Queuing Telemetry Transport. Javascript was used to create the publisher and subscriber objects, which send and receive data respectively over Message Queuing Telemetry Transport. Once theconnection has been made, the payload string will be returned when we subscribe to the topic that we published in Message

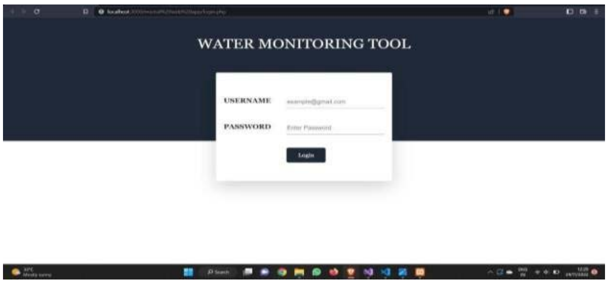

Fig. 5. Web UI login page

Queuing Telemetry Transport. Using card ID, the Message

Queuing Telemetry Transport returned value is shown on the web. The database was queried for the sensor list. The sensor id and its name will be generated at the same time as the dashboard exists. Replace the id with the appropriate sensor value using javascript.

V. Results And Discussion

Our proposed system has been successfully developed to continuously monitor water quality parameters, including conductivity, dissolved oxygen, microorganisms, turbidity, ambient temperature, and humidity. It's also great to hear that the system is capable of analyzing chemicals and impurities present in the water.The use of Message Queuing Telemetry Transport (MQTT) server to deliver data to the targeted system is an effective way to ensure that data is transferred securely and efficiently. The use of Message Queuing Telemetry Transport protocol also allows the system to handle a large number of sensors and data streams simultaneously, making it suitable for continuous monitoring.The web-based UI is a user-friendly interface that allows easy access to the output data generated by the system. This will make it easier for interested parties to check the status of the river's environmental state at any time.It's also great to hear that the suggested system operates continuously, allowing for daily water quality analyses. This will provide the River-Keeper with real-time data to detect any changes in water quality and take necessary action promptly.However, it's important to ensure that the system is regularly maintained and calibrated to ensure accurate and reliable data. Additionally, proper data management is crucial to ensure that the data is properly stored, analyzed, and accessed in a timely manner. Overall, the suggested system seems like an effective solution to improve water quality monitoring and provide accurate, real-time datato the River-Keeper. The system's continuous operation and web-based UI will allow for prompt action to address sources of poor water quality, leading to improved water quality and a healthier environment.

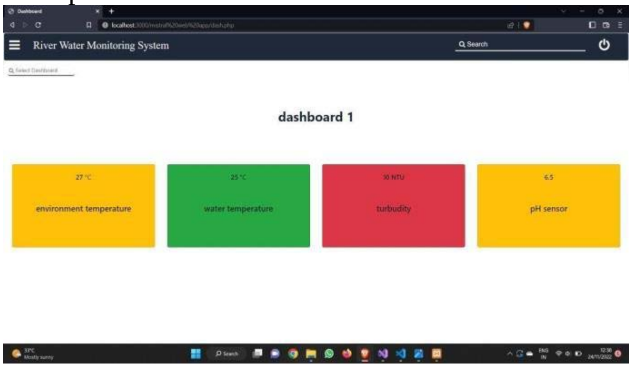

Fig. 6. Web UI output

TABLE 1. History of Sensor Values

Time	**11:00**	**11:10**	**11:20**	**11:30**
Environment Temperature (℃)	26	27	26	28
Water Temperature (℃)	25	27	25	26
Turbidity (NTU)	10	11	10	10
pH	6.5	7	7	8

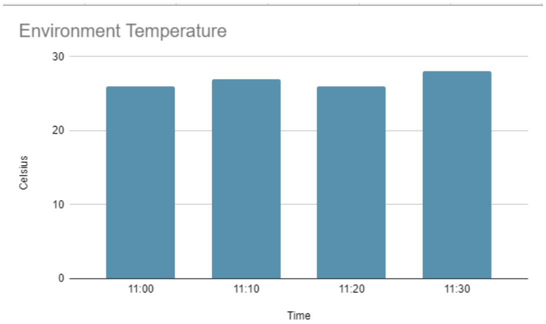

Fig. 7. Environment Temperature graph

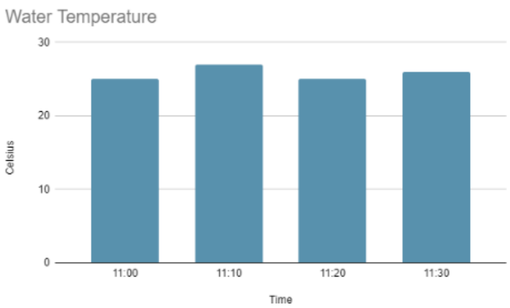

Fig. 8. Water temperature graph

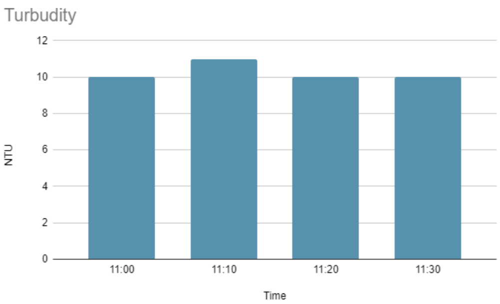

Fig. 9.Turbiditygraph

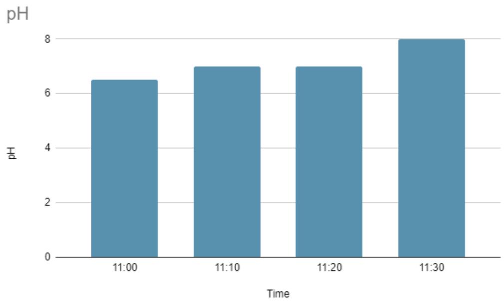

Fig. 10. pH graph

V.Conclusion

The major objective of our work is to constantly evaluate the water quality 24/7 and the data will be sent to the web-based UI. The data also gets stored in the database to review the history. Our suggested system tells whether the water is consumable or not. Our system is more feasible and efficient as it shows more accurate values. In the future, our system can be enhanced with more sensors and we are planning to add a mobile application also.

***Abstract*—This paper provides an overview of the current state of the art in text categorization and opinion mining on news headlines. The task of categorizing news headlines into different topics and determining the sentiment expressed in them is important for a variety of applications, including media monitoring, information retrieval, and content organization. However, the high volume and dynamic nature of news headlines present several challenges for NLP researchers. This paper discusses various NLP techniques and algorithms for accurately categorizing headlines and determining their sentiment, as well as the challenges and limitations of such a task. The paper also presents evaluation metrics for measuring the performance of different approaches and highlights areas for future research. This paper examines the application of text categorization and opinion mining in the field of Natural Language Processing (NLP) for news headlines. The task of categorizing news headlines into different topics and determining the sentiment expressed in them has significant practical applications in fields such as media monitoring, information retrieval, and business intelligence. The paper presents a review of current NLP techniques and algorithms for accurately categorizing headlines and determining their sentiment. The challenges and limitations of such a task are also discussed, as well as evaluation metrics for measuring the performance of different approaches. This paper highlights the potential for continued research and development in the application of text categorization and opinion mining on news headlines. The system utilizes advanced natural language processing (NLP) techniques and algorithms to categorize news articles into different topics and determine the sentiment expressed in them. The evaluation of the news tracker application shows high accuracy in categorizing news articles and determining the sentiment expressed, making it a valuable tool for media monitoring, market research, and business intelligence. This paper highlights the potential of the news tracker application and provides insights into future research directions. The application is user-friendly, easy to navigate, and can be customized to meet the specific needs of different users.**

Keywords—–Natural Language Processing (NLP), News Headlines

I. INTRODUCTION

The field of Natural Language Processing (NLP) has seen significant growth in recent years, with increasing applications in various domains such as sentiment analysis, text classification, and information retrieval. One particular area of interest is the categorization of news headlines and the analysis of the sentiment expressed in them. Text categorization involves assigning a label or category to a given text based on its content. In the context of news headlines, this could involve classifying headlines into topics such as politics, sports, technology, etc. This task is important for a variety of applications, including media monitoring, information retrieval, and content organization. Opinion mining, also known as sentiment analysis, is a subfield of NLP that focuses on identifying and extracting opinions, attitudes, and emotions expressed in text. In the context of news headlines, opinion mining can be used to determine the overall sentiment expressed in a headline, such as positive, negative, or neutral. The combination of text categorization and opinion mining on news headlines presents several challenges and opportunities for NLP researchers. On one hand, news headlines are usually short and lack context, making it difficult to accurately categorize and determine the sentiment expressed. On the other hand, the high volume and dynamic nature of news headlines provide a rich source of data for NLP research and development. In this paper, we aim to provide an overview of the current state of the art in text categorization and opinion mining on news headlines. We will discuss various NLP techniques and algorithms for accurately categorizing headlines and determining their sentiment, as well as the challenges and limitations of such a task. Additionally, we will present evaluation metrics for measuring the performance of different approaches and highlight areas for future research.

DOI: rp-9788770040723.023

However, the high volume and dynamic nature of news headlines present several challenges for NLP researchers. News headlines are usually short and lack context, making it difficult to accurately categorize and determine the sentiment expressed. Despite these challenges, there has been a growing interest in the application of text categorization and opinion mining on news headlines. Opinion mining, also known as sentiment analysis, is a subfield of NLP that focuses on identifying and extracting opinions, attitudes, and emotions expressed in text.In the context of news headlines, opinion mining can be used to determine the overall sentiment expressed in a headline, such as positive, negative, or neutral. This information can be used to gain insights into public sentiment towards a particular topic or event. News headlines are a rich source of information and are usually short, providing a quick and concise summary of the content of a news article. Text categorization on news headlines involves assigning a label or category to each headline based on its content, such as politics, sports, technology, etc. This helps in organizing and retrieving relevant news articles more efficiently.

II. RELATED WORK

Text categorization and opinion mining on news headlines has been a popular research topic in the field of Natural Language Processing (NLP) in recent years. There has been a growing interest in developing NLP-based approaches to accurately categorize news headlines into different topics and determine the sentiment expressed in them.

One of the early works in this field was conducted by (Cai and Liu, 2005) who proposed a text classification model based on Naive Bayes to categorize news articles into different topics. (Lee and Kim, 2006) presented a sentiment analysis approach based on machine learning algorithms for news articles, showing promising results in detecting the sentiment expressed in news headlines. More recent works have focused on the application of deep learning techniques for text categorization and sentiment analysis. (Liu, 2015) proposed a deep convolutional neural network (CNN) model for text classification, which achieved state-of-the-art results on benchmark datasets. (Kim, 2014) introduced a novel approach to sentiment analysis using a Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN) architecture, demonstrating its effectiveness in detecting the sentiment expressed in news headlines. The development of large pre-trained language models such as BERT (Devlin et al., 2019) and GPT (Brown et al., 2020) has also had a significant impact on the field of NLP, including text categorization and sentiment analysis. These models have achieved remarkable results in various NLP tasks, including sentiment analysis on news articles (Sun et al., 2019).

In conclusion, the literature survey shows a growing trend in the application of NLP techniques and algorithms for text categorization and sentiment analysis on news headlines. Recent works have shown promising results in achieving high accuracy in categorizing news headlines and determining the sentiment expressed, but there is still room for improvement, especially in handling real-world complexities such as language variability, sarcasm, and subjectivity.

III. EXISTING NEWS APPLICATION

The existing system for text categorization on news headlines deploying opinion mining in NLP application is primarily based on machine learning and deep learning algorithms. The following are some of the existing systems in this field:

Naive Bayes-based text classification: One of the earliest works in this field was a text classification model based on the Naive Bayes algorithm proposed by (Cai and Liu, 2005). The system was designed to categorize news articles into different topics, and the results showed that the Naive Bayes model was capable of achieving high accuracy in text categorization.

Machine learning-based sentiment analysis: Another early work in this field was a sentiment analysis approach based on machine learning algorithms proposed by (Lee and Kim, 2006). The system was designed to determine the sentiment expressed in news articles, and the results showed that the machine learning-based sentiment analysis approach was effective in detecting the sentiment in news headlines.

Deep Convolutional Neural Network (CNN) text classification: A more recent work in this field was a deep convolutional neural network (CNN) model for text classification proposed by (Liu, 2015). The system achieved state-of-the-art results on benchmark datasets and demonstrated the effectiveness of deep learning techniques in text categorization.

Combined CNN and RNN architecture for sentiment analysis: Another recent work was a novel approach to sentiment analysis using a combined CNN and RNN architecture proposed by (Kim, 2014). The system showed promising results in detecting the sentiment expressed in news headlines and demonstrated the effectiveness of combining deep learning techniques for sentiment analysis.

Pre-trained language models for text categorization and sentiment analysis: With the introduction of pre-trained language models, such as BERT and GPT, the field of NLP has seen a significant impact in recent years. (Devlin et al., 2019) proposed BERT as a pre-trained language model for various NLP tasks, including text categorization and sentiment analysis. (Brown et al., 2020) introduced GPT, a generative pre-trained language model that has achieved remarkable results in various NLP tasks, including sentiment analysis on news articles (Sun et al., 2019).

In conclusion, the existing systems for text categorization and opinion mining in NLP application have made significant progress in achieving high accuracy in categorizing news headlines and determining the sentiment expressed. The continued research and development in this field will play a crucial role in improving the performance of NLP applications in the real world.

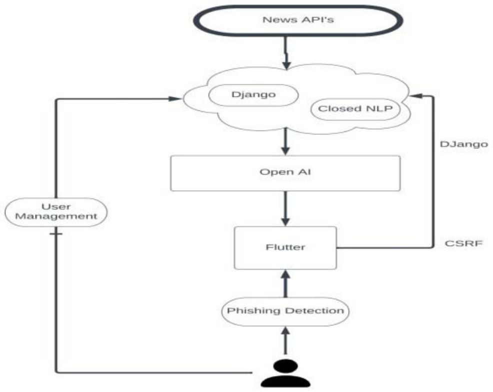

Fig 1. Process of news search system approach

1) Google News: Google News is a free news aggregator service developed by Google. It presents a continuously updated list of articles that are sorted by categories such as world, nation, business, technology, entertainment, and sports. The categorization is done based on the content of the news articles and the topics they cover.

2) Apple News: Apple News is a news aggregator application developed by Apple Inc. It presents articles from a wide range of sources and categorizes them based on topics such as business, politics, technology, sports, and entertainment. The application also includes a feature that allows users to customize the news sources and topics they want to follow.

3) News360: News360 is a news aggregator application that uses artificial intelligence and machine learning techniques to personalize news content for each user based on their interests. The application categorizes news articles into different topics and presents a summary of the article along with its sentiment analysis.

4) Feedly: Feedly is a news aggregator application that allows users to subscribe to news sources and blogs and categorize them based on topics such as business, technology, politics, and entertainment. The application presents a summarized view of the latest articles and also provides the option to read the full article.

These are some of the existing news search applications that use text categorization and opinion mining techniques to categorize and analyze news headlines. The specific details and features of these applications may vary, but they all provide a way for users to search for news articles based on their keywords and topics of interest and stay up-to-date with the latest news and developments

IV. Proposed Methodology

The NEWS Tracker system is going to be implemented for e-NEWS reading. With this app, the user can access interested news and get a quick peek. A news-sharing app helps users find relevant and important news easily every day. For zero-trust security, implementation of Django APIs with advanced flutter system has occurred.

The proposed system for text categorization and opinion mining on news headlines in the field of Natural Language Processing (NLP) would likely involve the following steps:

i) Data Collection: The first step would be to gather a large dataset of news headlines from a variety of sources, such as news websites, blogs, and social media platforms. This dataset should be diverse and include headlines from different categories, such as politics, business, technology, sports, and entertainment.

ii) Pre-processing: The next step would be to pre-process the data to clean and prepare it for analysis. This would include removing stop words, stemming and lemmatizing words, and transforming the data into a format that can be easily processed by NLP algorithms.

iii) Text Categorization: The main task of the proposed system would be to categorize the news headlines into different topics based on their content. This could be achieved using a variety of NLP techniques such as term frequency-inverse document frequency (TF-IDF), n-grams, and machine learning algorithms such as decision trees, support vector machines, and neural networks.

iv) Opinion Mining: The next step would be to determine the sentiment expressed in each headline. This could be done using a variety of techniques, such as sentiment analysis algorithms, lexicon-based approaches, and deep learning models. The system would analyze the words and phrases in each headline to determine its sentiment, whether it is positive, negative, or neutral.

v) Evaluation: The proposed system would be evaluated using a range of metrics, such as accuracy, precision, recall, and F1-score, to determine its performance. The evaluation would help to identify any limitations or challenges with the system and inform future improvements.

vi) Deployment: The final step would be to deploy the proposed system as a web application or mobile app that would allow users to easily access and analyze news headlines in real-time. The system would provide valuable insights into the content and sentiment of news headlines, which would be useful for media monitoring, information retrieval, and business intelligence applications.

vii) News Sorting: Sort the news headlines based on the user's preferences and display the sorted news to the user

viii) Continuous Monitoring: Continuously monitor new news headlines and update the sorted news accordingly.

ix) User Feedback: Allow users to provide feedback on the relevance of the sorted news and make improvements to the system based on the feedback

DOI: rp-9788770040723.023

Fig 2. Group idea

Each step could be represented by a different block in the diagram, with arrows showing the flow of the process from one step to another. You can add additional details and annotations to each block to provide a more comprehensive representation of the proposed system.

V.EXPERIMENTAL RESULTS

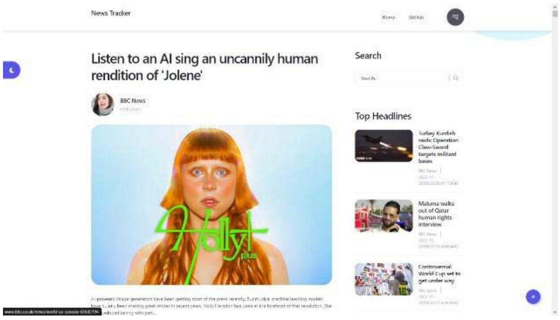

Fig 3.Output Image

VI. CONCLUSION

In conclusion, the combination of text categorization and opinion mining in NLP for news headlines provides a powerful tool for analyzing and understanding the content of news headlines. By categorizing headlines based on both the content of the headline and the sentiment expressed in it, this approach provides a more complete understanding of the news story, allowing for more effective filtering, prioritization, and analysis of the news. The field of text categorization and opinion mining in NLP is rapidly evolving, with ongoing research into developing more effective algorithms and models for this task. A news app that integrates text categorization and opinion mining in NLP can provide a personalized and dynamic experience for users. The app can categorize news headlines into different categories and also determine the sentiment expressed in each headline, allowing users to filter and prioritize news based on their interests and preferences. This can help users stay informed about the latest news and events, while also avoiding news that may be biased or misleading. With the increasing demand for personalized and trustworthy news, a news app that utilizes text categorization and opinion mining in NLP has the potential to be successful and widely adopted by users. The development of such an app requires careful consideration of user privacy, ethical issues, and the challenges of accurately categorizing and analyzing news content. Nevertheless, the potential benefits of a well-designed news app that incorporates text categorization and opinion mining in NLP make it an exciting and promising area of research and development. With the increasing importance of understanding news and public opinion, this field is likely to continue to grow and evolve in the coming years.

***Abstract*—As with any industrial enterprise, underground mining operations require an effective and robust safety system. Underground miners encounter numerous hazards, including working in low-light circumstances, exposure to air pollutants, and the risk of fire and explosion. This project provides a solution by establishing a smart and safe mining system that can monitor the worker's body temperature, heart rate, oxygen saturation level, temperature, and pressure, and release of poisonous gases. There are two nodes in the system. A node monitors the workers' health conditions, while another inspects the work site before workers enter the field. The sensor modules connected to the NodeMCU can detect abnormal conditions based on threshold values. As soon as NodeMCU detects a threshold value crossing, an alert message is sent to the mining control room. For inspection of the site before workers enter, rover equipped with environmental sensors and a camera is used. Using the raspberry pi, an operator in the control room can also view the transmitted live video and sensed information to ensure the safety of workers.**

I. Introduction

The world has an intensively varying natural resources and a huge mining industry. Underground mining by workers could be extremely hazardous, and the risks increase as the depth from the ground increases. Mining is already looking into the future of automation. Digitization might not be a new concept to this sector, but the industry is still trying to find out how to make it the greatest. In the mining industry, workers' safety, proper communication and supervision are very important. Mine fires, explosions, gas intoxications, electric burns are the major causes of disaster in Underground Mines. These regions consists of emissions of Particulate Matter(PM) and gas like Carbon Monoxide(CO), Methane (CH4), oxides of nitrogen and Sulphur which are harmful to health. Different types of mining activities generate PM in various ranges. Methane is highly inflammable which is present in air around 5% to 14%. White damp or CO which is 0.1% can cause demise within a few minutes. To protect the workers from such a risky environment, certain physiological parameters have to be examined. Coronary heart rate and Body temperature are the common health monitoring works. On the other hand, temperature, pressure and amount of gas are the different parameters to check the mining site. In this paper, we present a mobile environmental and physiological IoT system for workers which is applicable for industrial site. This system contains various sensors which are able to communicate with each other. Each worker is provided with a wearable system which can monitor the oxygen and pulse rate. This concept uses mobile hotspot for internet connection and User Datagram Protocol (UDP) for communication purposes. Prior to workersmoving to the site, a rover equipped with a USB camera embedded with gas, temperature and pressure sensors monitors the environment. Depending on the condition, the workers are allowed. The monitored data is compared with current vital sensory values respective to working environmental data. It can guide the workers if any health issue happens and also can avoid unwanted death. If there exists any abnormal condition, the system alerts the workers.

The Internet of Things (IoT) involves linking computer-based technologies with industrial equipment or household appliances over a network to enable teleoperation, workflow management, and data collection through the use of sensors [1]. Users can receive real-time data from the IoT through the browser or mobile applications wherever they are [2]. Wireless Sensor Network(WSN) is one of the foundational technologies for IoT that mainly uses interdependent smart sensors to sense and monitor physiological factors. Currently an emerging technology called Compressed Sensing(CS) is intensively applied for effective information analysis and imposed on applications where gathering data is exorbitant [3]. In addition to healthcare applications, WSNs can also be used to monitor environmental factors like temperature, humidity, and gas for safety purposes. WSNs provide exceptional benefits for a variety of different activities [4]. IoT systems merge and create robust networks that offer several solutions for developing sensible PPE products for underground mining applications due to

DOI: rp-9788770040723.024

technological immaturity, accidents, and closed systems. Smart sensors in combination with connectivity solutions and data storage are enabling Personal Protective Equipment (PPE) to provide health protection and enhance safety. By using this solution, manufacturers can take concepts from the primary plan to development of prototype Bluetooth Low Energy, also called Bluetooth Smart, which is an advanced wireless technology allowing fast wireless connections and featuring drastically reduced power consumption [5][6].In the automation world, ZigBee plays a significant role as a cost-effective, power-efficient, and low-complexity networking technology. Each ZigBee network has a network coordinator that starts the mesh network and controls the operation of devices to and from the network [7]. Due to the imminent technologies, IoT devices using Lora WAN which can run for several years without any substitution. It contains simple network architecture, strategic designing which is effective in outdoor IoT applications [8]. In wired communication, there exists higher price and higher risk in underground mines especially during gas inflammation or disaster. On the other hand, wireless communication has a low-cost RF transmitter and receiver and doesn’t have any risky consequences [9].

Implementation of robots have been successful in complex environments. The components inside a robot help to assist in control and its movement and a communication system that enables effective data transmission by the camera and the sensors [10]. Alert system is implemented for all workers from different locations within the mining area and sends the alert to the control room. Applicable actions would be taken whenever there exists a dangerous situation [11]

The major contribution of this paper is addressed below

1. To propose a Health Monitoring System which includes the detection of oxygen level and the heart rate.
2. To present the Work Guidance System which includes the recognition of temperature, pressure and type of gas using IoT.

The organization of the paper is as follows. Section II describes the proposed system including a block diagram and a flow chart. Section III elucidates hardware implementation and section IV summarizes results and discussions.

II. Proposed System Methodology

The block diagram shown in Fig. 1 elucidates the health monitoring of mining workers and their safety in the mining field. The proposed system includes two nodes: one is named as the health monitoring node and other node is named as safety node. In the health monitoring node, a wearable device embedded with the MAX30102 sensor monitors the oxygen level in the blood and heart rate of the workers. An alert message “Worker Unhealthy” will be sent if the health condition of the worker is worsened. The safety node has a four-wheel rover setup along with a USB camera integrated with Raspberry Pi to transmit the live video of the mining field to ensure the condition of the environment is fine. The sensors embedded in the rover are used to monitor the level of temperature, gas, and pressure in the work field. All the monitored data will be transmitted and displayed by a local server in the control room.

The flowchart shown in Fig.2 illustrates the mechanism for the health monitoring and work guidance system for mining workers.

III. Hardware Implementation

A. *Detailed description about the components used in this proposed system:*

1) *Raspberry Pi* 4

The Raspberry Pi 4 Model B is a microcontroller commonly used in health nodes, where it is connected to sensors, cameras, motor drivers, and a four-wheel robot setup. This model boasts faster processors and enhanced multimedia performance compared to its predecessors, as well as more memory and improved connectivity options. End users can expect desktop-like performance from this microcontroller, which is comparable to entry-level x86 PC systems. Its high-performance quad-core processor can support dual displays at up to 4K resolution via micro-HDMI, and it can decode hardware video up to 4Kp60. Additionally, it comes equipped with 8GB of RAM, dual-band 2.4GHz/5.0GHz wireless LAN, Gigabit Ethernet, and USB 3.0 ports. The Raspberry Pi 4 Model B is powered via a USB port that delivers 5V(2A).

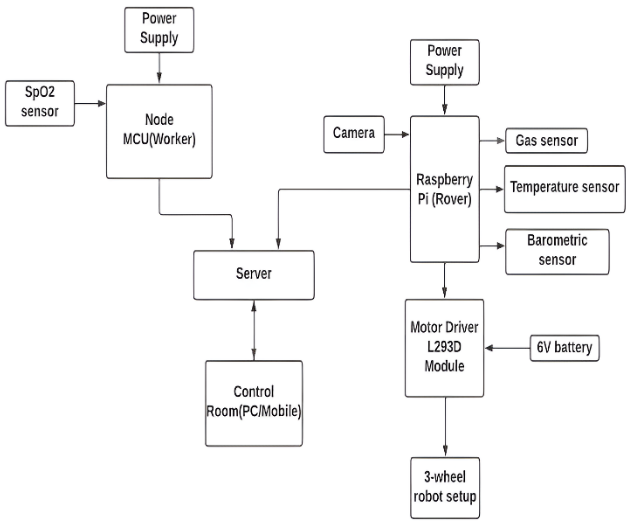

Fig. 1. Block Diagram of the proposed system

2) Power Supply: In order to operate Raspberry pi and Node MCU it is provided with 5v Dc power supply for Raspberry pi through USB port and 5v for Node MCU through USB type B.

3) USB camera: USB camera is used to monitor the work field from the mining control room. It has no built-in microprocessor and no non-volatile memory card, so it does not "remember" pictures because it is designed to capture images and send them right away to a computer. For this reason, webcams have USB cords that start at the back. By connecting the webcam to the computer, and then transferring the digital data taken by the webcam’s image

DOI: rp-9788770040723.024

sensor back to the computer, the data can be sent to the internet.

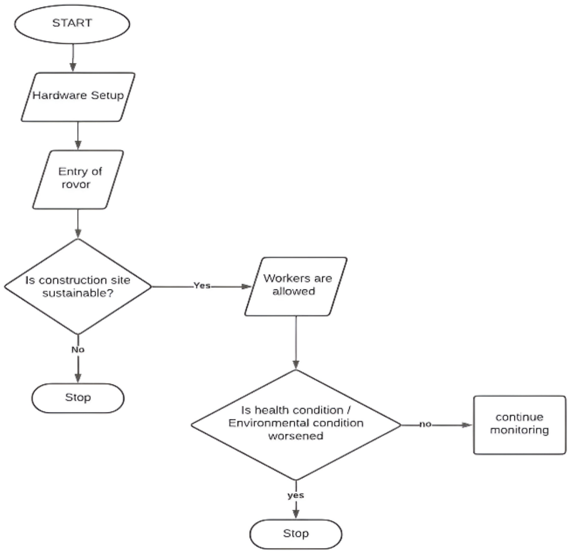

Fig. 2. Flow chart of the proposed system

4) MCP3008: The values sensed from MQ2 and MQ7 sensors are analog. To convert those values from analog to digital MCP 3008 is used. It is a 8-channel 10-bit ADC IC measures 8 different analog voltages with a 10-bit resolution for every channel. It measures analog voltages between 0 and 1023 and sends the measuring values to a microcontroller over SPI communication. Analog voltages are converted into digital values using the SAR method.

5) L293D motor driver: A Motor Driver regulates the speed and direction of the wheels connected with dc motors. Two motors at the same time. This motor driver is made with the L293D IC. It has 16 pins where 8 pins are dedicated for controlling the motor on all sides. There are two INPUT pins, two OUTPUT pins, and one ENABLE pin on each motor.

*6) Motor:*A device that transforms DC electrical energy into mechanical energy and enables the rover's wheels to move is known as a DC motor.

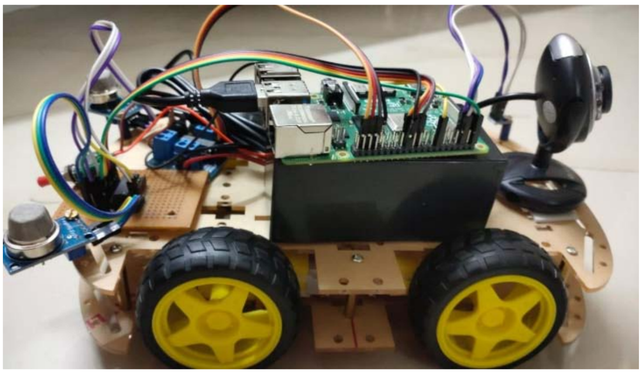

Fig. 3. Hardware setup for Safety Node

7) Battery: Battery is one of the best portable power supply. Since Lead -Acid battery is a rechargeable one and cheap. It is used as a backup power supply for the rover. Sealed lead acid battery provides better battery life.

8) MQ 2 Gas sensor: This gas sensor detects gases such as LPG, propane, methane, hydrogen, alcohol, smoke, and carbon monoxide in the air. It contains a substance which can alter the resistance as it comes in contact with the gases. This MQ2 sensor ranging from 300 - 10000 ppm. Sensors identify these gases by measuring voltage. Each gas has its unique voltages. By measuring the current discharge, it can measure the concentration of gas.

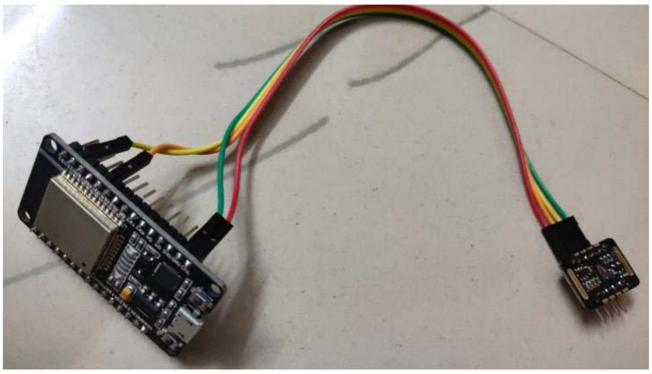

Fig. 4. Hardware setup for Health Monitoring Node

9) MQ 7 Gas Sensor: The sensor detects the carbon monoxide (CO) gas concentration in the air .The detecting range is from 10 to 500ppm.

10) BMP 180 Sensor: BMP180 is an atmospheric pressure sensor used to measure atmospheric pressure and temperature in the environment where it present and convert the findings into an electrical signal. This sensor works based on the weight of the air. The sensor measuring range is from 300 to1100 hpa.

11) Node MCU: Node MCU is used in the safety Node connected with MAX30102 sensor. It is an open-source plat- form that connects and transfers data to other connected devices. It is based on an ESP8266 microprocessor.

12) MAX30102 Sensor: This sensor measures pulse oxime- try and heart rate using analog signal processing and also includes a photodetector and two LED's .It is designed to ease the design-in process for mobile and wearable devices.

13) The complete Hardware Setup for Safety Node and Health Monitoring Node is shown in Figure. 3 and 4 respectively.

IV. Results and Discussion

A. Safety Node

A rover with USB Camera is made to invade the mining field, the movement of Rover could be controlled by using the keys present in the keyboard with the help of Motor Driver L293D Module. The forward and backward movement of the Rover is done by pressing up and down arrows respectively. By clicking the left and right arrow keys, the movement of Rover in left and right direction could be done as shown in Figure. 6. The movement is last for a particular period of time and the continuous pressing of

DOI: rp-9788770040723.024

keys could be implemented for its continuous movement. Then the rover starts sensing the level of temperature, pressure and presence of toxic gas in the environment and transmit the sensed value to the control room via mobile hotspot. Then the sensed values are displayed in the VNC viewer in the order of temperature, pressure, altitude, CO and CO_2.

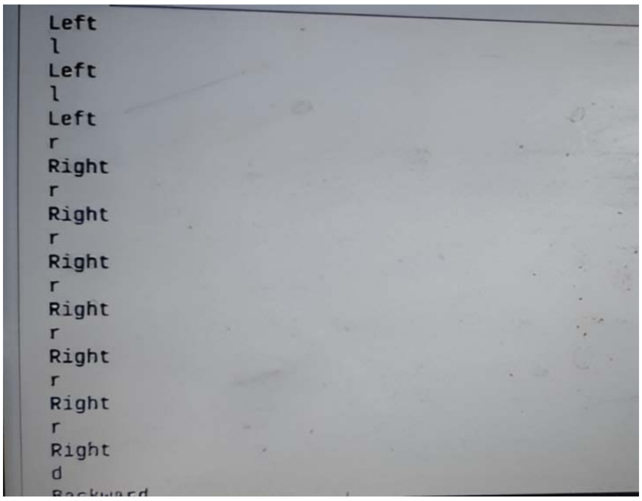

Fig. 6. Movement of Rover

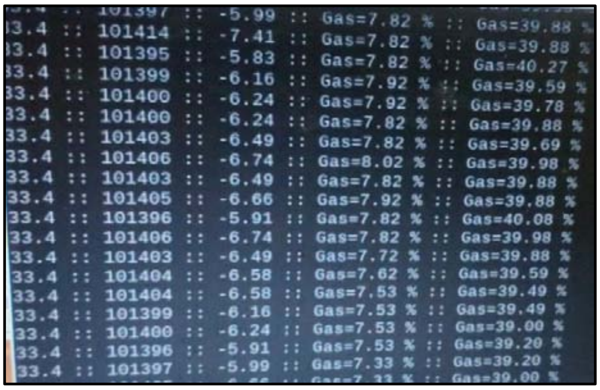

Fig. 7. Sensed data in normal condition

The normal threshold value of pressure is 101400 Pascals, for temperature it is 37°C inside the body and 28°C around the environment and 50% is the threshold amount for poisonous gases. If any of the received sensor value exceeds the threshold value then the alert message “High Pressure/High Temperature/High Toxic Gases” is displayed respectively next to the sensed values in VNC viewer as shown in Figure 8. The result is represented in the form of Temperature(in °C)::Pressure(in Pascals)::Altitude(in feet)::Amount of CO(in %)::Amount of CO2(in %).

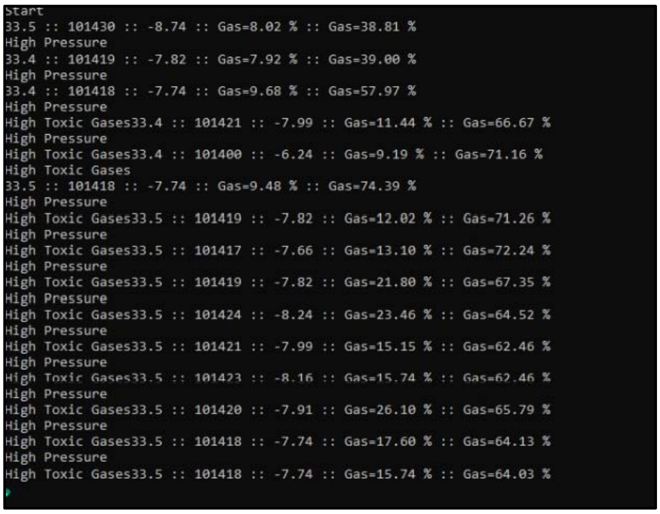

Fig. 8. Sensed data in abnormal condition

B. Health Monitoring Node

After verifying the data’s transmitted by the rover, the workers are allowed to the mining field equipped with a wearable device. The wearable device is embedded with MAX30102 sensor continuously monitors the Spo2 level and heart rate. The threshold value of heart beat rate ranges from 60 to 100 bpm whereas the Spo2 level should be higher than 90 percentage. When the sensor value exceeds the threshold value, an alert message “Worker Unhealthy” will be displayed in the screen. If the device is not properly worn by the worker, an alert message “NO Finger” will be displayed as shown in Figure 9.

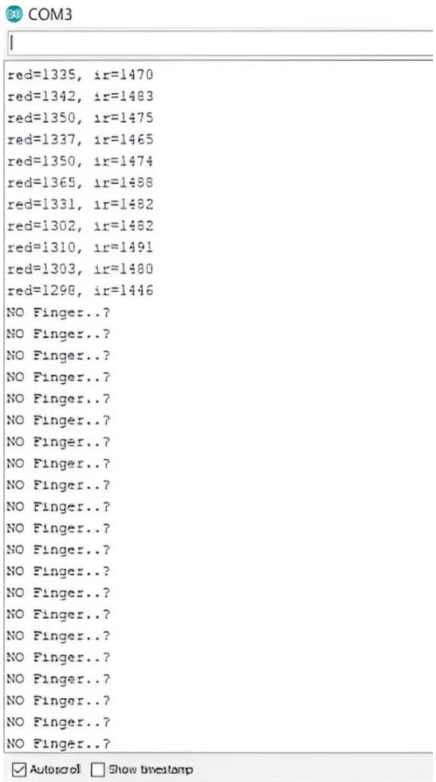

Fig. 9. Alert message for wearing the device imperfectly

V. Conclusion

This paper aims to design an IoT based health monitoring and work guidance system for mining workers' welfare in order to monitor their health and safety. The proposed system continuously monitors the health condition of the workers and governs the environmental condition by using rover. With the help of data received from the health node and safety node in the control room, the worker's will be rescued if any of the conditions are abnormal in the mining field. The first component of worker safety in underground coal mining was addressed in this research. This project is not only for coal miners, but also for workers who perform subterranean work. In the future, the system could be equipped with a range of environmental and physiological sensors to meet the specific requirements of various work settings.Overall, expanding the server infrastructure and allocating distinct IP addresses to each server can be a wise investment for the project, allowing for more effective management of vast mining regions, better performance, improved security, and easier troubleshooting.

Abstract **– The majority of non-communicable disease-related morbidity and death is caused by chronic kidneydisease (CKD), which affects 10% to 15% of the global population. The impact of patient health issues likehypertension, poor nutritional health, mineral bonedisorder, anaemia, acid base abnormalities, andneurological complications is thought to be significantlyreduced by early and accurate detection of CKD stagesand prompt intervention with appropriate medications. Incertain studies, machine learning approaches have beenutilised to detect CKD early. In this assessment, CKD isidentified using the logistic regression technique. To determine which algorithm offers the most accuracy, many proposed algorithms are compared. AI repository containing a great deal of missing traits.**

Keywords **– CKD, Machine learning, SVM, RF, ANN, K-NN, Logistic.**

I. Introduction

Their results in CKD diagnosis have been promising. The models indicated above are based on the disease criteria in the data and fill in missing values using the mean imputation technique. Due to the lack of knowledge regarding the diagnostic implications of a sample, their method cannot be applied in this situation. For a variety of reasons, patients may actually skip many assessments before diagnosis. Aside from that, average imputation statistics, which are employed to fill in gaps in categorical data, may drastically deviate from the actual values. Despite the fact that components with just two categories can have their categories set to 0 and 1, the average value of the variables may lieanywhere between 0 and 1. The models suggested, which are based on attribute selection technology, had their computational costs lowered through feature selection.

A. Chronic Kidney Diseases

A gradual deterioration in renal function over months or years is a defining feature of the kidney failure type known as chronic kidney disease (CKD). Initial symptoms are absent, however later warning signs include confusion and fatigue, nausea, and leg edema. Among the complications are heart failure, elevated blood pressure, bone damage, and anaemia. Polycystic kidney disease, glomerulonephritis, diabetes, and high blood pressure all contribute to chronic kidney disease. One of the risks is a history of chronic renal illness. The diagnosis is established through urine testing for albumin concentration and blood tests to measure glomerular filtration rate. The root of the issue could be identified via an ultrasound or a kidney sample. The utilisation of several severity- based staging schemes. At-risk people should be screened, according to the advice. As a first line of treatment, patients may use medications to decrease cholesterol, blood pressure and blood sugar. Angiotensin converting enzyme inhibitors (ACEIs) or angiotensin II receptor antagonists (ARBs) are frequently used as first-line blood pressure drugs since they lowered the risk of heart disease and delayed the course of renal impairment.

B. Machine Learning

The study of changing computer algorithms over time is known as machine learning (ML). It falls within the heading of artificial intelligence. Even when they are not explicitly trained to do so, machine learning algorithms create a model utilising test data, commonly referred to as "training data," to make judgements or predictions. When it would be difficult or impossible to create standard algorithms, machine learning approaches are typically applied. Examples include email classification and computer vision. But not every machine learning technique involves statistical learning. Machine learning does not always rely on statistical learning, though. Computational statistics, a subset of machine learning, is an area of AI technology that concentrates on computer-aided prediction. Mathematical optimization research advances machine learning by providing methodologies, application fields and ideas. Similar research is done in the discipline of data mining, which concentrates on unsupervised learning for exploratory data analysis. The practise of teaching computers to perform tasks without explicit programming is known as machine learning. In order to accomplish particular jobs, computers acquire knowledge from available data.

DOI: rp-9788770040723.025

II. LITERATURE REVIEW

A. ANN and SVM for the prediction of chronic kidney disease: A comparative study.

The authors of this study, Njoud Abdullah Almansour, HajraFahim Syed, and others, set out to use system learning methodologies to detect CKD at an early stage in order to help prevent it (CKD). Artificial Neural Networks and Support Vector Machines are employed as teaching tools in this test. In order to conduct experiments, every missing value from the dataset was changed by recommending the relevant attributes. The Artificial Neural Network and Support Vector Machine algorithms' ideal parameters have been established after significant parameter tuning and a great deal of testing. The two recommended tactics' final versions were built based on the attributes and qualities that were most well-liked.

B. Explainable Prediction of Chronic Renal Disease in the Colombian Population Using Neural Networks and Case-Based Reasoning

These studies by Sergio M. Martnez- Monterrubio, Gabriel R. Vasquez-Morales, et al.Following training, In the test statistics set, the model achieves a 95-accuracy rate, enabling its use in disease diagnosis. According to recent research on explainable AI, dual systems should be used, where any other white-field technique that produces results that are broadly consistent with the expected values is added to a black-field system-learning technique. Because to its ability to identify illustrative explanations, case-based reasoning (CBR) has shown to be a very effective supplemental method. It may augment a neural network's prediction with explanations provided by examples. This article puts the NN-CBR dual device that generates CKD prediction logic to the test and evaluates it. This study determined that 3,494,516 Colombians, or 7% of the population, were at risk for developing CKD.

C. A Machine Learning Methodology for Diagnosing Chronic Kidney Disease.

This image reflects the views of ErlendHodneland, EirikKeilegavlen, and others. Renal function gradually deteriorates over time, which is a sign of chronic kidney disease, a dangerous medical condition. In patients with chronic renal disease, the most recent research highlights the effectiveness of photo registration techniques for detecting pathological aberrations. Methods: Nine patients with suspected chronic real illness and ten healthy volunteers underwent dynamic T2 weighted imaging. Results: From biopsy evaluations, it is found that that deformation, normalized extent changes, and strain gradients were all substantially associated with arteriosclerosis. The findings also imply that the sensitivity required to accurately detect minute variations in tissue stiffness is lacking in the photo registration methods now in use. The use of image registration with dynamic time collecting as a tool for invasive measures of arteriosclerosis should be further investigated.

D. Amharic based Knowledge-Based System for Diagnosis and Treatment of Chronic Kidney Disease using Machine Learning.

In their research on developing a self- learning system and experience for identifying and treating the initial three stages of chronic kidney disease, Mohammed and Beshah used machine learning. This study used a tiny amount of data, and they developed a prototype that allows patients to query KBS to learn more about how advice was given. They used a decision tree to generate the rules. It has been stated that the prototype's overall performance is 91% accurate.

III. METHODOLOGY

We built a model to predict CKD sickness for the research subjects. Both the model's overall performance and the effectiveness of particular elements were evaluated. Machine learning classifiers like Logistic Regression, Artificial Neural Network SVM, K-Nearest Neighbor and Random Forest were used to train the model. Each classifier's performance and validation matrices were calculated independently. The following stages were included in this study's procedure: (I) preparing the dataset, (II) choosing the features, (III) applying the classifier, (IV) Using SMOTE, and (V) analysing the classifier performance. A deep neural network and machine learning models were used to compare the results of the two different types of neural networks. This was done using an artificial neural network classifier. Statistical testing, namely the McNemar's test, was utilised in this work to determine the significance of two models.

A. Logistic Regression

By employing supervised learning, the classification technique known as logistic regression forecasts the likelihood of a target variable. Due to the target or dependent variable's dichotomous character, there are only two viable classes.

B. SVM

Using a linear model called the Support Vector Machine, or SVM, classification and regression issues can be resolved. It has several advantageous uses and can solve both nonlinear and linear issues. The SVM method splits data into categories by creating a line or a hyperplane.

C. Random Forest

Both classification and regression can be performed using a powerful machine learning technique called Random Forest. Because ensemble learning is the approach employed, many tiny decision trees, known as estimators, which each generate a different set of predictions, make up a random forest model. To produce more accurate predictions, the random forest model combines estimates from the estimators.

D. K-Nearest Neighbor

Algorithm for Simple Machine Learning the Supervised Learning approach is used in K-Nearest Neighbour. This method assumes that occurrences and existing cases will be comparable, and it assigns new cases to the category that are most similar to previous ones.

E. Artificial Neural Network

Computers are taught to understand data similarly to the human brain using neural networks, which is an example of artificial intelligence. Deep learning employs network of

nodes or neurons to replicate the layered structure of the human brain.

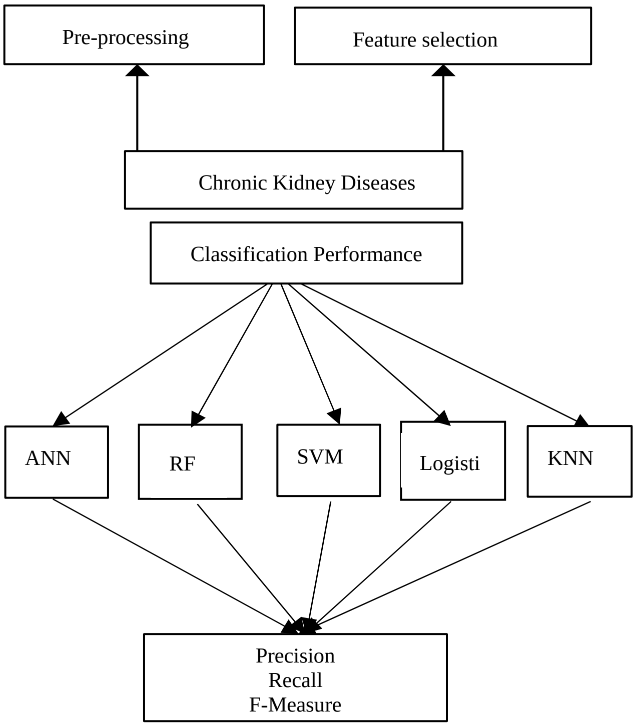

Fig. 1 – Flow Diagram for CKD prediction

IV. Data Description

The dataset from the UCI repository's public chronic kidney disease (CKD) repository was used in this investigation. This dataset includes 400 samples from two distinct classes. 11 of the 25 qualities are numerical, 13 are notional, while one is a category attribute. The dataset includes variables that can be used to anticipate the onset of CKD.

V. Result and Discussion

We feel that this methodology could beused in more complicated circumstances. When analysing more complex data, several algorithms are explored to generate models. Following misjudgement analysis, superior methods that result in diverse errors of judgement are retrieved as component models. Then, by creating an integrated model, the classifier's performance is enhanced.

Because the CKD data set comprises mixed variables, mixed data similarity analysis tools such as the general similarity coefficient could be used to determine sample similarity (numerical and categorical). We utilised EUCLIDEAN distance to determine sample similarity. Therefore, we did not use the techniques for figuring out sample similarity.

VI. Conclusion

The recommended CKD diagnostic methodology is workable with regard to data imputed and sample diagnosis. The model that is integrated was fairly accurate after unsupervised logistic imputation was used to impute empty values from the data set. In this evaluation, to identify CKD, we advocate utilising a Logistic Regression System. As a result, it will be useful to employ this technology in real-world settings to detect CKD. To develop a precise medical diagnosis, this technology might also be integrated with clinical information from other conditions. Unfortunately, the amount of data samples that can be utilised to build the model is rather little, at just 400, due to the restrictions of the parameters.

The generalizability of the model may be constrained as a result. The prototype is also unable to determine the severity of CKD because there are only two different types of data samples included in the data gathering (ckd and notckd). As more compr[illegible] quired to train the model, its [illegible] e will improve in the future. This will enable the model to determinedisease severity. We believe our model will become better as data size and quality grow.

***Abstract*—Automatic Number Plate Recognition (ANPR) is a technique that reads a vehicle's license plate using photographs given to the Deep Learning model as its input. Existing ways to find and identify license plates on cars are severely limited by the low resolution and significant loss of edge data in plate photos. The process of automatic identification of license plates necessitates a high level of accuracy when cars are moving rapidly, and number plate abstraction is a difficult task due to number arrangement and environmental factors. The primary objective of this work is to create an Automatic Number Plate Detector that aims to recognize the text present in the number plates of cars, vans, bikes, trucks, and other vehicles that are either stationary or in motion with good accuracy. The recognition model was created by training it on a large dataset. The deep learning models Faster-RCNN and Yolo were employed to fetch the Region of Interest, followed by OCR for character extraction.**

Keywords*— YOLOv5, RoI, Automatic Number Plate Recognition, Faster RCNN, OCR

I. Introduction

Automatic Number Plate Recognition (ANPR) uses Deep Learning models to read license plates automatically and precisely. For various number plate recognition applications, multiple levels of image analysis are needed, such as recognising the types of objects in the image, locating these objects, and determining the precise boundaries of each object. Number plate recognition systems are frequently used to manage traffic, identify stolen automobiles, regulate access to buildings and parking lots, collect tolls automatically, and determine which advertisements are most effective. This ANPR system is supported by an abundance of documentation and general public knowledge. Nevertheless, there are constraints to consider, such as specific detectors or viewing angles, adequate illumination requirements, recording in a specific zone, and specific vehicle types. In this scenario, Deep Learning (DL) techniques emerged as a useful parameter.

Faster RCNN is superior to both RCNN and fast RCNN. In this approach, a convolutional neural network receives an image as input and produces a convolutional feature map. Then, a different network is used to predictthe region proposals. Following that, the suggested regions are reshaped using a RoI pooling layer. This layer classifies the picture within the region and forecasts theoffset values for the bounding boxes. OCR stands for "Optical Character Recognition." It was first identified as a computer vision problem. A simple OCR engine functions by storingnumerous font and text image templates. The OCR then uses pattern-matching algorithms to compare text images to its internal database, character by character. The proposed work involved working with a manually picked dataset that contains both Indian number plates. The vehicles used here include cars, trucks, bikes, army vehicles, autos, and taxis. The environmental conditions of these photos are either blurred, dusty, clear, or in motion. In this study, the Automatic Number Plate Detection System is divided into 2 processes, namely

i) Number Plate Detection

This is the first phase in which the Region of interest is selected. A bounding box is created to determine the exact coordinates that surround the vehicles' license plates. The construction of this detector will be carried out using the YOLO [1] transfer learning model and Faster RCNN [2],[3]which will be trained on a dataset consisting of a diverse variety of vehicle images, like normal vehicles, taxis, army vehicles, bikes, etc.

ii) Digit Number Recognition

This is the second phase of the model. After the bounding boxes and the coordinates are saved, the digits and characters are extracted from them with the highest accuracy possible. The images will be cropped to the size of the coordinates received in the first phase. This new image is fed to an OCR for digit recognition.

II.Literature Survey

The main task of Automatic License plate Recognition (ALPR) is to localize and recognize license plates in vehicle images. The conventional ALPR has two components, i.e., License Plate Detection (LPD) and License Plate Recognition (LPR). To help readers comprehend the work done in ALPR systems, thefollowing section highlights the reviews of various techniques used for LP detection and LP Recognition in literature. LP detection can typically be divided into two groups: one-stage and two-stage LP detection. Fast R-CNN [4] and Faster RCNN [5], which produce substantial region recommendations in the first stage and enhance them in the second, are the basic works of the two-stage detection networks. A unified framework called TE2E (Towards End to End) in which the model used Region Proposal Network (RPN) for License Plate(LP) detection and Recurrent Neural Networks(RNN) for character recognition. Here, the TE2E framework adopts

DOI: rp-9788770040723.026

two-stage detection involves the RoI pooling layer and high-quality bounding box proposals method for LP detection and RNN for character recognition. However, their findings revealed that RNNs were ineffective for character recognition [6]. To increase effectiveness, Xu et al developed a CNN-based architecture called Roadside Parking Network (RPnet). However, as the character's finer characteristics are lost, small-size images have a negative impact on recognition performance [7]. Another approach involved image Processing Techniques for plate detection and the OCR algorithm for text extraction. They got a success rate of around 85% in the extraction of the number plates and 80% in OCR. In the next work, the authors utilized a Faster-RCNN model for number plate detection. In that, the contrast operation was performed using Top-hat and Black- hat morphological transformations. They also performed character segmentation and recognition and utilized different optimization algorithms for recognizing the number plate [8].

Next, A region proposal network (RPN) was developed by Ren et al. to provide almost cost-free region proposals by sharing full-image convolutional features with the detection network. Fully convolutional networks that predict object limits and object scores at every place are known as RPNs. The RPN is trained from start to finish to provide high quality region suggestions, which Fast R-CNN uses for detection. They also combined Fast R-CNN and RPN into a single network by sharing their convolutional features—using the pretty popular concept of neural networks with 'attention' methods, the RPN component instructs the unified network on where to look [5]. Another research involved YOLOv3 for plate detection and OCR for image enhancement and recognition. However, their method achieved an accuracy of nearly 90% for number plate detection and 91.5% for number plate recognition [9].

In the next research, the authors combined YOLOv4 and contour methods for detecting and recognizing the number plates. However, the results achieved by the contour model are comparatively low when compared to existing methods. In another research, the authors compared two methodologies - YOLO and Traditional Image Processing for finding a suitable method for number plate detection. The accuracy, recall, and precision for the traditional image processing technique were found to be 72%, 0.92, 0.92 whereas for YOLO it was 90%, 0.91, and 0.92 respectively [10]

Some of the limitations observed in these papers are:

- Most of the images are of cars and not any other vehicle.
- Only vehicles with non-transporting number plates are used.
- Models which were used are outdated.
- Characters are detected wrongly such as 's' as 8 and 'o' as 0. The rest of this paper is organized as follows: Section III describes the proposed architecture while Section IV elaborates on the models used and Section V includes the discussion of obtained results. Section VI concludes the paper with possible scope for further investigations.

III. SYSTEM ARCHITECTURE

The initial stage of the project involved image collection and dataset preparation using a customized dataset. The data collection includes 1160 images that were captured while a car was moving through metropolitan traffic. These images were extracted from 50 distinct videos, each with a frame rate of 40 frames per second (FPS) and a duration of one second (1S). Additionally, the UFPR-ALPR dataset [11] was utilized, which consists of 4,500 completely annotated pictures taken by 150 vehicles in real-world situations. The model was trained with a custom dataset that included 5660 images drawn from both the collected images and the UFPR-ALPR dataset. The annotations in the datasets were converted into different formats depending on the deep learning models used. This dataset is then used to train the model and detect the number plate, given an image of the vehicle at different angles. This research utilized Faster RCNN and You Only Look Once (YOLO) models for detecting the number plate. Although both algorithms are reasonably good, YOLO surpasses Faster R-CNN in terms of accuracy, speed, and efficiency. YOLO is an end-to-end object detection model which predicts the bounding box and probability of each class and classifies the entire image at once. Finally, the coordinates of the number plate will be predicted. Now, this number plate will be extracted from the given image with the help of the coordinates predicted and a new dataset will be created that contains only the digits of the number plate, which will then be fed to the OCR for reading its digits.

1. *Image acquisition and Dataset preparation*

This step involves preparing a dataset composed of 1160 images of different types of vehicles, like cars, bikes, taxis, and army vehicles, with Indian license plate numbers and foreign number plates. To train the dataset on the YOLOv5 and Faster RCNN models, annotations were required for each image. These annotations provided the coordinates of the bounding box that the model needed to detect from an image. The LabelImg tool was used for this purpose, which is a graphical image annotation tool developed using Python and utilizing Qt for its graphical interface (version 0.92). The proposed framework is shown in Figure 1.

In this research, a new dataset was developed that includespictures of cars, heavy vehicles, and buses. A novel framework was proposed that combined YOLOv5 with a modified OCR model which can be trained end-to-end for number plate detection and recognition. Additionally, a comparison was made between the proposed model and a state-of-the-art model in the literature for the detection and recognition of number plates.

2. *Number Plate Detection*

YOLO (You Only Look Once) is a single-shot detection method that detects objects in an image in one go, rather than having to scan the image multiple times or in a sliding window fashion [12]. This makes it much faster than other object detection algorithms, although it may not be as accurate.

DOI: rp-9788770040723.026

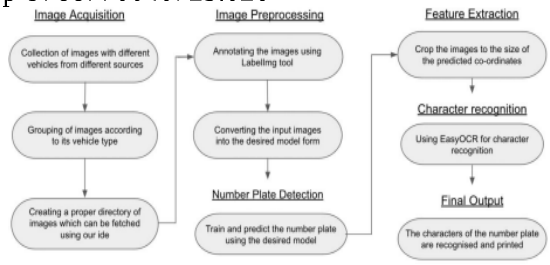

Fig1. System architecture

YOLO divides the input image into a grid of cells and predicts the presence of object-bounding boxes and class probabilities for each cell. If the center of an object falls into a cell, that cell is responsible for detecting that object. YOLO also uses anchor boxes, which are predefined bounding boxes of different aspect ratios, to improve detection accuracy. There have been several versions of YOLO released, with the latest being YOLOv5. YOLO has gained popularity due to its fast detection speed and good performance on a variety of object detection tasks.

3. Optical Character Recognition

OCR (Optical Character Recognition) is a technique that translates printed text into a digital version. The wide variety of typefaces and styles used to write a character in the printed image makes it difficult to recognize the letters. The image must be pre-processed before an OCR algorithm can be selected. The text is straightened, despeckled, and transformed from colour to binary image - an image with just two colours, black and white - in this stage. Following pre processing, the feature detection algorithm detects a character by studying the image's lines and strokes.

The recognition method then examines the character in its entirety and recognizes a textual line by searching for rows of white pixels separated by rows of black pixels. It can also determine where an individual character begins and finishes. It then transforms the character's picture into a binary matrix, where white pixels represent 0s and black pixels represent 1. It, using the distance formula, calculates the distance from the matrix's center to the farthest 1, and then draws a circle with that radius and divides it into moregranular pieces. Figure 2 shows the image character tobinary conversion.

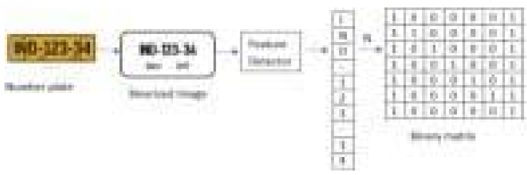

Fig 2. Image character to binary matrix conversion

At this stage, the OCR system will compare each subpart to a database that consists of matrices where each matrix represents a character in various typefaces to determine which character it has the most in common with statistically. Doing this for each line and character makes it simple to convert printed media to digital. Character recognition using feature extraction is shown in Figure 3.

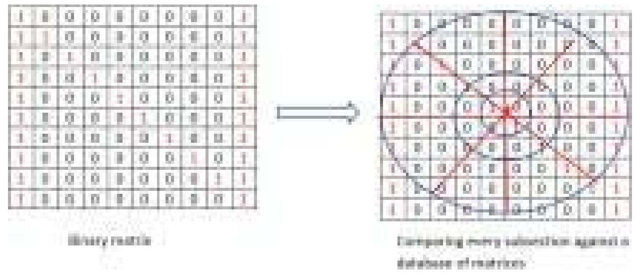

Fig 3. Character recognition using Feature extraction

IV. Models Used

A. Faster RCNN

Early in the 2010s, Ross Girshick and colleagues atMicrosoft Research created the object detection method known as R-CNN (Regions with Convolutional Neural Networks). R-CNN creates a set of features by taking an entire image as input and processing it through a CNN. The image is then categorised into one of several predetermined classes using these features. R-CNN uses a sliding window method, where it moves a window over the image and categorises each window, to find objects in the image. Given that running the CNN numerous times is required, this can be computationally expensive. [13].

R-CNN has been improved, and Fast R-CNN accelerates the object detection procedure. In order to create a set of features, a CNN is used to process a whole image as input. The image is then classified into one of a number of predetermined classes, and the bounding boxes for image objects are predicted using these attributes. Fast R-CNN avoids executing the CNN more than once by using a method known as region of interest (RoI) pooling, in contrast to R-CNN, which employs a sliding window approach. [4].

Faster R-CNN is a type of object detection algorithm and is an even faster version of Fast R-CNN. Feature Network, Region Proposal Network (RPN), and Detection Network are the three neural networks that make up Faster-RCNN. The Feature Network is an image categorization network that has already been trained, similar to VGG but lacking a few top/last layers. The form and structure of the original image are preserved in this network's output. RPNs are typically basic networks with three convolutional layers. Two layers—one is used for classification and the other one is used for bounding box regression—are fed from a common layer. As a result, a few bounding boxes known as ROIs are created. The RPN and Feature Network provide input to the Detection Network, which then uses that information to create a bounding box and the final class. It usually has four dense or completely linked layers. Two layers are stacked on top of one another that are common to both a classification layer and a bounding box regression layer. To make it easier to categorise only the contents of certain boundary boxes, the features are trimmed in line with those boxes. [5].

Faster R-CNN has a number of advantages over other object detection algorithms, but its speed in both training

DOI: rp-9788770040723.026

and inference is by far its biggest benefit. It is also accurate, making it a popular choice for object detection tasks. The prediction of the Number Plate by the Faster RCNN model is shown below in Figure 4.

Fig 4. Plate detection using Faster RCNN

B. YOLO (You Only Look Once)

YOLO primarily uses Computer Vision for object recognition and picture categorization and it divides animage into an NxN grid and extracts k bounding boxes from each grid. The network generates an offset value and class probability for each of the bounding boxes [12]. The bounding boxes are chosen and used to locate the object inside the image if their class probability is higher than a predetermined threshold value as shown in Figure 5. YOLO outperforms other object identification algorithms by orders of magnitude (45 frames per second). The YOLO algorithm's drawback is that it struggles to pick up minute details in the image. For instance, due to spatial restrictions, it might struggle to recognize a flock of birds.

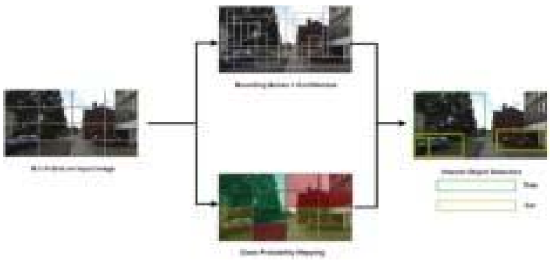

Fig 5. YOLO architecture

There are many versions of YOLO available, out of which YOLOv4 was considered the best real-time object detection algorithm on the standard MS COCO dataset as per the MAP benchmark. On the other hand, YOLOv5 which was introduced in 2020 has high speed, low volume, and high precision. In this research, YOLOv5 will be used to ensure high detection speed and accuracy. The backbone, detection head, and feature pyramid network are the three fundamental structures of the YOLOv5 network model. The feature pyramid network then gathers features from multiple scales and transfers them to the detection network after the backbone network extracts features from numerous images at various sizes. The object bounding box is the result of the detection network using the image features to forecast the item category in the image. [14]. Both YOLO and Faster RCNN require the annotations to be in a specific format so that they can be used as input. For YOLO, the bounding box coordinates of each image have to be in the format: class, x center, y center, width, and height. Each image has its corresponding annotations stored in a text file with the same name as the image file. For faster RCNN, the annotations for all images have to be stored in a text file, with each row containing: file path,x1,y1,x2,y2, and class name, which can be created by using the annotations obtained from LabelImg for YOLO. The prediction of the Number Plate by the YOLOv5 model is shown below in Figure 6.

Fig 6. Plate detection using Faster YOLOv5

C. OCR

OCR stands for Optical character recognition. It is a method that encodes the text that is present in visuals so that a machine can read it. For this purpose, Easy OCR was used. Easy OCR uses CRNN for character recognition. Feature extraction using Resnet, sequence labelling using LSTM, and decoding using CTC make up its three primary parts. The OCR analysis transforms the input, which is a digital image of printed or handwritten text, into a machine-readable digital text format. The digitised image is then broken up into smaller pieces by OCR, which performs analysis to look for text, words, or character blocks. After being further divided into components, these blocks of characters are then contrasted with a Character Dictionary. Figure 7 and 8 show the input image given and the output image detected by the YOLO model. Figure 9 shows the output extracted by the OCR model.

Fig 7. Input image given to Number Plate detector

Fig 8. Output from the Number Plate detector

Fig 9. The result given by OCR

V. Experimental Results

A comparison was made between the transfer learning methods used in this work and other deep learning methods such as Morphological methods [15], Projection Methods

DOI: rp-9788770040723.026

[16], and Feature salience methods [17]. As shown in Table 1, it can be concluded that not all the transfer learning methods are suitable for this type of problem, as only Yolo is performing well in terms of computing speed with a computing speed of 0.25s and an accuracy of 95%. On the other hand, Faster RCNN did not perform well in terms of accuracy but was still faster than the methods used in [15][16] and [17]. Table 1 shows the comparison of differentnumber plate detection algorithms with existing methods in the literature.

TABLE 1. COMPARISON OF DIFFERENT NUMBER PLATE DETECTION ALGORITHMS AND EXISTING METHODS IN THE LITERATURE

Algorithm	Accuracy	Computation time(in sec)
Morphological methods [15]	90%	0.60s
Projection methods[16]	89%	0.90s
Feature salience method [17]	93%	0.50s
Faster RCNN	86%	0.70s
YOLOv5	**95%**	**0.25s**

TABLE 2.COMPARISON OF DIFFERENT NUMBER PLATE RECOGNITION ALGORITHMS WITH EXISTING METHODS IN THE LITERATURE

Algorithm	Computation time(in sec)	Recognition rate(%)
i-novel [18]	471s	73.1%
Template matching [19]	1000s	93-94%
ANN using featureextraction [20]	75s	92.2%
YOLOv5+OCR	**75s**	**97%**

As shown in Table 2, the model, which is a combination of YOLO and Easy OCR, outperforms the other methods in terms of both computation time and recognition rate. Specifically, it has a computation time of 75s and a recognition rate of 97%, as compared to other methods such as those in references [18], [19], and [20]. Hence, from the above comparison of results, it can be concluded that the best accuracy for number plate detection was achieved using YOLOv5. By applying this model, the license plate of the vehicle can be localized to obtain its coordinates. Then, feature extraction is used to crop the image to the size of the coordinates of the number plate obtained from the earlier prediction so that it can be used as an input to the OCR. For number plate recognition EasyOCR is used which extracts the characters into a string format.

VI. CONCLUSION AND FUTURE WORK

The proposed research utilized YOLOv5 and OCR, to jointly train a network for number plate detection and recognition respectively. The proposed methodology outperformed a few other strategies that have already been published in the literature in terms of computation time and recognition rate. This framework can also be applied to smart traffic, which identifies license plates of vehicles that violate traffic laws, or to optimized parking, which keeps track of the vehicles parked. The advantage of the proposed approach is that it handles all types of license plates with different sizes and shapes. Although the proposed algorithm is efficient in detecting different types of Indian license plates, we also believe that the same model should be applied to other country vehicle databases to detect and extract the number plate effectively.

Abstract— As technology continues to evolve and become more accessible, the need for improved security of data is at an all time high. Biometrics as a form of authentication have been around for quite some time now, but while the technique itself is fairly sound, the way it is implemented can be modified to enhance the system's security. This is where blockchain comes in. By integrating both these technologies, we can minimize the probability of biometric data being leaked or misused while also ensuring that authentication process goes on without any hiccups. Furthermore, offering it as a service will encourage many other services to opt for biometric authentication without having to worry about the security and integrity of the data being stored. By utilizing the concept of smart contracts in our project, we ensure that the project can handle dynamic data and also make sure that the essential conditions are met before the user can utilize our project to enhance the security of their websites. This project will be of immense value to a diverse set of people who need means of providing biometric security to their data but neither have the tools nor the resources to carry it out.

Keywords—Biometrics, blockchain, smart contracts,biometric security.

I. Introduction

Each and every task done by a human today has been taken over largely by technology. Physical devices like calculators, alarm clocks, maps, compass, etc have been integrated into a single smartphone. This is in a way good as the need for having separate things. But the minority people who have visual impairments find it very difficult to adapt to this technological shift. Also we do not tend to make our advancements friendly to use with for visually challenged people.

Biometric technology has become increasingly prevalent in the past few years. From the fingerprint scanners in our smartphones to iris and voice-based authentication.The technologyhasbecome the defactomeansfor authentication.But the storage of the biometric data has been overlooked by many parties, resulting in sensitive data beingstored in less secure manner. Such data falling into the wrong hands can result in disastrous consequences. This is where integrating blockchain and biometrics becomes a viable solution. The security offered by blockchain technology combined with biometrics can ensure that authentication process goes smoothly while also ensuring that the data itself is a lot more secure.

Biometrics as a Service is already implemented by various companies on different scales. Services such as anonymous face recognition exist, but the data is being stored on third-party cloud services offering SaaS solutions. The challenges of setting up and deploying cloud services have been extensively discussed in the literature. In a cloud computing environment, for example, it may be exceedingly challenging to ensure data privacy while providing quick and secure access, especially in a federated or multi-cloud scenario. Blockchain as a storage is a concept that has been implemented a few times, most popular being InterPlanetary File System (IPFS). All computer devices are intended to share the same file system using a distributed file system called IPFS. The founding objectives of the Web are somewhat comparable, however IPFS is more like a single BitTorrent swarm sharing Git objects.

Our system aims at providing a BlockchainAs A Service for Biometric Authentication (BAAS). The issue with current systems is that they are too complex for certain entities to take advantage of, or they ensure the verification part is secure and smooth, but falters when it comes to secure storage of the biometric data in the system. By utilizing blockchain technologies, we ensure that the biometric data does not get stored with a central entity. It enables web developers to integrate biometric authentication since the decentralisation is applied on the biometrics. It empowers the end users to store the biometric in one entity and use it for authentication anywhere. The block chain provides decentralisation and security for data. Thus the biometric data uploaded by the user remains untampered and unmodified.

II. Related Work

[1] The cost and performance tradeoffs that arise when utilizing public blockchain to store biometrics are analyzed and various techniques of storing the biometrics in a secure and efficient manner are deconstructed in this paper. Some of the techniques

DOI: rp-9788770040723.027

involved include the utilization of smart contracts, data hashing, merkle trees, convolutional neural networks. Storage requirements become very high, thus driving costs up. This is made even more complex by the fact that the value of ether is in constant fluctuation.

[2] A new protocol is put into use that increases the degree of encryption and is "blind," meaning it only shows the identification of a person and no other details about them or their biometric. To achieve this, SVM and neural networks to assign classifier parameters to specific biometric, and authentication is done w.r.t. to that encryption. Multiple communications between client and authentication server, loss in accuracy of biometrics, need for homomorphic encryption scheme increases complexity.

[3] The focus of this paper is to overcome limitations of traditional ballot based voting by uploading user data to the blockchain via smart contract and verifying iris to authenticate into the system. The system complexities are high, given that loss in accuracy of iris data, resulting in users not being authenticated into the system, low success rate due to noise while procuring data from user, variations in data resulting in inconsistencies are present.

[4] Recognition of fingerprint is performed by utilizing Bitmap image and images are converted into templates and then processed. The primary objective is to figure out how biometrics are stored in android device. Trusted Third Party Environment(TTE) is a key component of fingerprint processing in Android devices. The biometrics are encrypted and stored in the isolated environment. But there are chances that if the encrytion key is cracked, then the biometrics can be compromised.

[5] The goal is to implement a facial recognition system that performs face detection and recognition. The color intensity of the image is used for face detection and recognition. The recognition process is performed by implementing geometric features and template matching approaches. Factors such as brightness and contrast affect results, variations based on sensor quality.

[6] A system that eliminates the requirement for a central hub by allowing clients to handle template portions independently and conduct authentication chores on their own. This decentralised strategy makes strong authentication feasible while lowering the likelihood of single-point failures. The first sensor gathers the required biometric information, and then a biometric template is produced. The authenticator assesses if the input and enrolled templates are equivalent, while the administrator manages the registered templates. Each template fragment will be saved randomly selected nodes,not in all nodes.

[7] Despite various security measures being implemented, most of the data are stored in a centralized manner, which can lead to potentially disastrous consequences in the event that security is breached. The cornerstone of this paper is to implement decentralized cloud storage using blockchain technology. This is done by making use of techniques such as IPFS and smart contracts. The sizeof the file and the availability of peers affect how long it takes to upload files.

[8] A novel hybrid model pattern is used to increase the randomness based on the RFID and FingerVein pattern. Thus, they are much more recognisable. They secure the Fingervein and RFID of the patient information using an algorithm and stored in blockchain.

[9] It makes use of a permissioned blockchain technology. Access is necessary in order to join a permissioned blockchain and utilise its functionalities.

[10] It increases the reliability of the data by ensuring that files added to the distributed file system can be tracked and audited. The efficiency, traceability, and security of the IPFS and Ethereum networks are merged in this approach.

[11] A method that provides the iris templates with privacy as well as trust in the calculated output by combining BC technology with encryption. Using Paillier HE in SviaB ensures the privacy of iris templates.

[12] Mitigatation of the security issues prevalent in cloud services by integrating blockchain with the existing service models is done.

[13] A smart contract-based system architecture that combines a multimodal biometric identification system with a permissioned blockchain offers a better form of authentication.

[14] In fingerprint based biometric authentication, the fingerprint data is converted and processed into templates which are split into chunks and stored in the database. During recognition phase the fingerprint template is reconstructed from the broken template and matched.

[15] The major security challenge of blockchain is 51% attacks, where the attackers can rool back the transactions in the side chain and an also hide the information and tractions happening in the main chain. Eclipse attack in the block chain isolates a user from the block chain network, where a attack is performed on user level. The major cause is because a decentralised network does not allow many computers to simultaneously connected all the nodes.

[16] Using a touch-less fingerprint processing chain that reduces the error rate to 1% EER, touchless fingerprints may be compared to those gathered by touch-based fingerprint scanners. FIngerprint scanners work better than mobile fingerprint sensors because of controlled recording condition.

[17] Blockchain can be integrated with the Electronic Healthcare Records (EHRs) to distribute data across healthcare providers thus ensuring the integrity of data. It ensures unique identification of a patient’s records. It ensures security and privacy of healthcare that are exchanged between hospitals and Insurance firms.

[18] Blockchain based storage of EMR(Electronic Medical Records) ensures that the patients records are untampered. Ethereum based smart contracts are used

DOI: rp-9788770040723.027

for data retrieval and viewing permission between patient and the providers.

[19] Blockchain technology can be used in cloud computing to distribute data blocks across clusters of systems. Cloud based mining reduces mining time and at lowcost. Block chain based cloud can be used for payments,data access,etc.

[20] Blockchain Hashing technology can be used for encryption of the files stored in the cloud. The cipher keys are stored and managed in logs similar to ledger in the block chain. It eliminates the presence of the provider in ciphering the files in the cloud.

III. IDEATE

Utilizing biometrics as a method of authentication comes with a few limitations that make the technology in it’s current form susceptible to a series of issues. The following are some of the aforementioned issues.

Security risks: Biometric data is sensitive information and can be subject to hackers and data leaks if improperly safeguarded.

Privacy concerns: Storing biometric data raises privacy concerns as well as questions regarding possible identity theft.

Convenience: Users who do not want to share their biometric data or do not have access to the required technologies may find it difficult to save biometric data on a server.

Such issues are mitigated by the utilization of blockchain. Blockchain has key features that are well suited to tackle the issues we observed. Some of these are:

Security: Data saved on networks using blockchain technology are protected using sophisticated cryptography, making it difficult for hackers to access or alter the data.

Decentralization: Data is held among several network nodes rather than in a single central location in decentralisedblockchain networks, which makes it more difficult for a single point of failure to arise.

Transparency: On a blockchain network, all users may see the transparent, unchangeable ledger in which transactions are recorded.

Traceability: Every transaction that takes place on a blockchain network is documented, giving users access to a history of their data that may be used for a variety of purposes, including supply chain management and financial auditing.

Cost-effective: Blockchain technology can reduce costs by doing away with the need for middlemen.

Interoperability: Blockchain networks are capable of exchanging information with other networks and systems, facilitating data sharing and transaction execution across several platforms.

Self-executing smart contracts can automate processes and do away with the need for middlemen, and blockchain networks can make this easier to implement.

Another key aspect of our project is the integration of blockchain and cloud computing. This allows us to provide the project as a service on a wider scale and also handle the large compute power required by blockchain for the mining process. It also enables us to run multiple blockchains in order to store each chunk independently, thereby enhancing data security and integrity.

The advantages of implementing multiple blockchains inside cloud also include:

Flexibility: Using several blockchains allows a more adaptable and flexible storage solution because individual blockchains may be customised for different data kinds and use cases.

Scalability: Due to each blockchain's ability to function independently, scalability may be enhanced, allowing for the processing of more transactions and the storage of more data.

Interoperability: By utilising several blockchains, it might be able to link different blockchain networks and transfer data between them.

Security: By distributing the data among several blockchains, it can be made more challenging for hackers to access or tamper with the information held on the network.

Privacy: Different blockchains can be used to store different kinds of sensitive data, and access to the data may only be granted to those who are authorised.

Another important aspect of our project is the utilization of smart contracts. A smart contract is a self-executing contract with the terms of the agreement recorded in code. The code and the agreements it includes are present on the blockchain network. Automation of processes is made possible by smart contracts, which are frequently used to hasten, guarantee, and enforce contract negotiation and performance. Advantages of smart contracts include:

Automation: Smart contracts streamline operations by automatically carrying out the conditions of the agreement. This decreases the need for middlemen and boosts productivity.

Transparency: Smart contracts are transparent since all parties can see the contents of the agreement and how the contract was carried out because they are both stored on the blockchain network.

Trust: Because smart contracts are executed automatically and the terms of the agreement are recorded on the blockchain network, there is a potential for increased trust between the parties.

Security: Hackers find it challenging to tamper with the agreement or the contract's execution since smart contractsare secured by the blockchain network and the programming that makes up the contract.

Cost-effectiveness: Smart contracts can lower expenses related to middlemen and manual procedures.

Immutable: Once they are recorded on the blockchain network, smart contracts cannot be changed. This

DOI: rp-9788770040723.027

guarantees the validity of the arrangement and the proper performance of the contract.

Efficiency: Since smart contracts self-execute and don't require middlemen, they can speed up the execution of contracts and transactions.

Proposed system over existing system

Currently, blockchain data is kept in databases that the business may own or buy from third parties. Although though using databases to store data is the simplest option, using databases can sometimes cause problems. Databases are often centrally located and maintained by a single entity. They may therefore be more vulnerable to issues like various forms of centralised control and security breaches. This problem is fixed by the widespread adoption of decentralization in blockchain technology.

The fact that they are managed by a network of participants rather than a single institution reduces the negative effects of centralization. This applies to both private and public blockchains. The private blockchains are also decentralized but the number of people who are able to access the blockchain is heavily restricted.

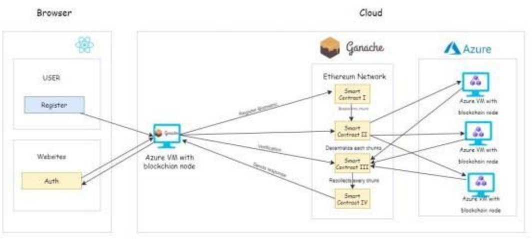
Data integrity issues have plagued databases for a long time. Integrity here refers to the accuracy and consistency of data over a period of time. If the data is not consistent, the system is not trustworthy and dependable. Data integrity in blockchain is ensured by the implementation of Merkle trees. It provides a way to both ensure integrity as well as verify the integrity of the data.

The client has access to the four operations, which are sometimes referred to as the CRUD operations (create, read, update, and delete) in conventional databases. A blockchain is not designed to function similarly to a database. The blockchain technology is related to read and write operations. As the complexity of the system increases, CRUD operations may introduce unnecessary complexity. Such issues are not prevelant in blockchain.

IV. System Design

The project aims at enhancing the security of biometric data by utilizing blockchain to store the data, thereby mitigating a majority of the safety and privacy concerns that exist across multiple alternative implementations of biometric authentication systems.

Architecture



This is the proposed architecture for the project. The system involves maintaining a private blockchain in cloud. Virtual Machines are used to decentralise and maintain the block chain. Biometrics are procured from the user and broken down into chunks. These chunks are decentralised using private block chain maintained across VMs. The developer will be able to integrate the system as service into their websites.

The processes can be divided into two modules. The first module consists of procurement of biometrics. The user registers with the service and enrolls their biometric for storage in the system. The fingerprint is sent to the virtual machine running in the cloud and pushed into the first smart contract, where the biometric is broken down into multiple chunks. These chunks are then pushed into separate blockchains that are isolated from one another and decentralized. This operation is carried out by the second smart contract.

The second module consists of verification and authentication of biometrics. When the fingerprint is required for verification, the client sends a request to the service for authenticating the fingerprint the third smart contract is invoked and fetches the chunks from the blockchain. The chunks are reconstructed into the whole fingerprint template in the fourth smart contract. This is then used to compare and authenticate the fingerprint received from the client for verification.

Smart Contract – 1

The Smart Contract – I takes a biometric template as input and returns encrypted and broken chunks of the biometric template. The broken chunks are given as input to the second smart contract

Smart Contract – 2

This smart contract distributes the data across the virtual machines in the Microsoft Azure cloud. A decentralised private network is maintained across the cloud VMs. Each VM maintains a copy of the blockchain. This smart contract takes each data chunks and stores it in the VM.

Smart Contract – 3

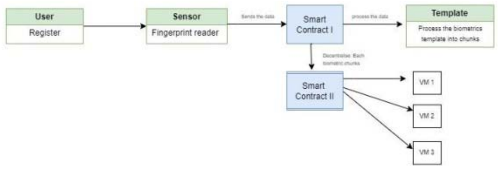
This smart contract fetches the biometric chunks from the VMs. The biometric template is reconstructed from the chunks. The chunks are retrieved based on its hash values. A DTH (Distributed Hash Table) maintains a mapping of the chunk's hash and its corresponding node's address that contains the data chunk. Once the chunks are retrieved the biometric template is reconstructed. The reconstruction is done based the order in which the chunks are stored in the DTH table.Thus the smart contract returns the stored biometric template.

Smart Contract – 4

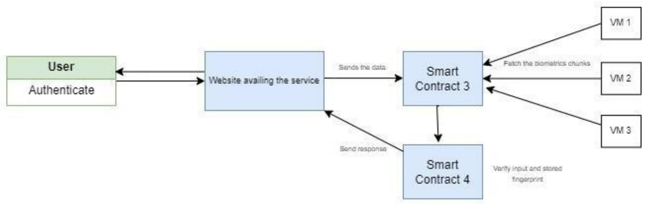
This smart contract accepts the user given biometric and the stored biometric template as input and verifies it. It compares the given biometric against the stored biometric. If the biometrics match then the user is authenticated and a success response is sent to the client. If the biometrics do not match, then the user is not authenticated and a failure reponse is sent back to the client.

DOI: rp-9788770040723.027

System Flow

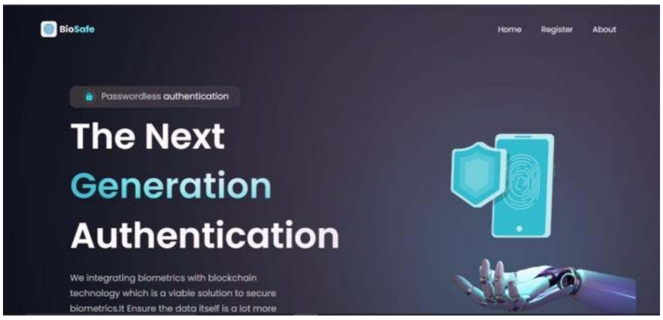


The above diagram showcases the flow of the first module. The user provides fingerprint for registration, and this is forwarded to the first smart contract where it is broken into chunks. Each chunk is then stored in a separate blockchain viathesecondsmartcontract.



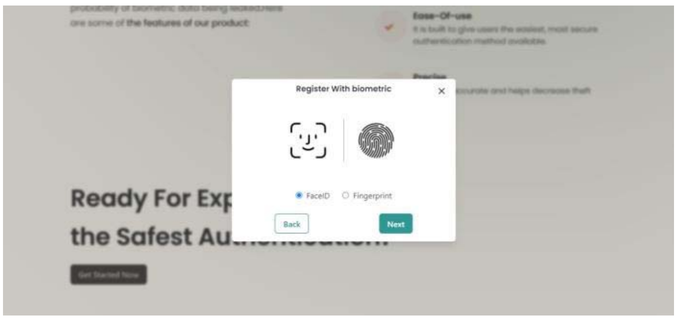
The above diagram showcases the flow of the second module. The client sends the fingerprint to be authenticated. The third smart contract fetches the chunks from the blockchains, and sends them to the fourth smart contract where the fingerprint is reconstructed and used for verification with the fingerprint that was received from the client.

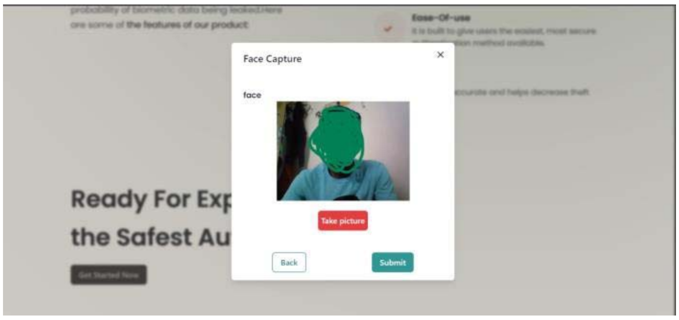
V. IMPLEMENTATION



The home page is where the user can sign up for availing the service by providing their biometric for storage.

After signing up, the user can upload their biometric to the system. The user has the choice between providing facial data or fingerprint data for storage in the blockchain.



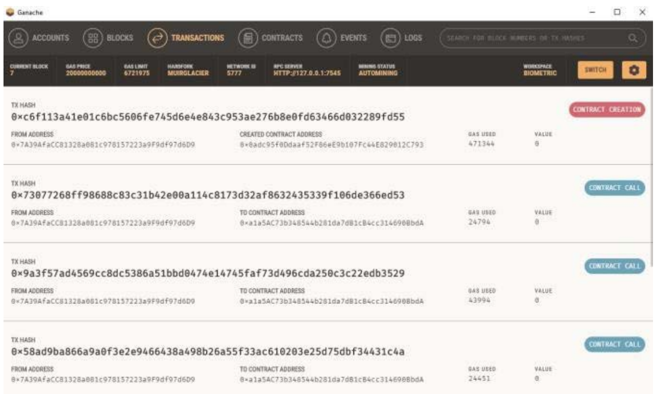


The data is initially supplied to the smart contract when a client delivers a request containing biometric information that has to be validated. A self-executing contract known as a "smart contract" is used to simplify, confirm, and enforce contract negotiations and execution.

As soon as the data enters the smart contract, it is divided into several pieces and stored on several blockchains. It is more challenging for hackers to access or tamper with the data stored on the network due to the decentralisation of data over numerous blockchains, which increases the security and resilience of the system.

Each time a new piece of data is sent, a new block is mined and the chunks are placed inside of it. We keep the data on the Ganacheblockchain, a local blockchain used for testing and development. Both the block's hash and the block that is currently forming are visible. This makes it possible for us to monitor and evaluate the veracity of the data stored on the blockchain.

By segmenting the data and storing it across several blockchains, we can improve the security and integrity of the data and make it more difficult for hackers to access or tamper with it. The Ganacheblockchain also allows us to monitor and verify the accuracy of data.



The biometric authentication system contains an authentication algorithm since it is crucial to the security and precision of the system. Our solution uses a Python-based authentication approach that is run on a Flask server and is created using cutting-edge machine learning algorithms.

DOI: rp-9788770040723.027

When a client wants to utilise the service to authenticate a biometric, they send us a request along with the necessary biometric information. These details are then sent to the server, where they are compared to the data stored on the blockchain. The information on the blockchain is called, put together again, and then compared to validate the user's identity.

A response is delivered to the customer following the conclusion of the verification procedure. The answer will be successful if the biometrics match; otherwise, it will be unsuccessful if the biometrics do not match. This procedure is essential for preserving the security and integrity of the system and for guaranteeing that only authorised users may access it.

VI. Conclusion and Future Work

This paper presented a new biometric authentication system providing a decentralized and distributed authentication based on blockchain. This improves the security and reliability of the existing biometric authentication systems by splitting a biometric template into fragments and managing them based on blockchain mechanism. By implementing both the storage and the authentication of the biometric under the same roof, we avoid the problem of having to send data via the Internet to third party services, which may result in data leakage, putting a huge number of people at jeopardy.

Combining numerous blockchains running on the cloud to construct a biometric authentication system can offer a flexible, scalable, and secure method for storing and managing biometric data. Different types of data can be stored on various blockchains that can be optimised for particular use cases thanks to the use of numerous blockchains. Data decentralisation across several blockchains can increase the system's security and resiliency by making it more challenging for hackers to access or alter the data stored on the network.

Future advancements could use the application of AI and machine learning techniques to enhance the accuracy of the authentication process and to spot and eradicate fraud. Additionally, biometric data can be stored more securelyand privatelyusing zero-knowledgeproofswhilemaintaining the data's opennessandtraceability. Additionally, smart contracts can be used to automatically grant access to the biometric data, ensuring that only those with the right authorization have access to the information. In the future, edge computing can also be integrated into the project. By processing data closer to its source and lowering latency, edge computing can be leveraged to enhance the system's performance and accessibility.

The utilisation of many blockchains operating in the cloud can provide a dependable and safe mechanism for managing biometric data, and this is a promising area for additional research and development.

***Abstract* —One of the deadliest malignancies in the world, brain tumors are caused by the brain's cells growing unnaturally. The stage at which the cancer is discovered affects the disease's survival rate. In order to increase the survival probability through effective treatment regimens, it is crucial to precisely identify the tumor area in the brain as well as the tumor type as initial as feasible. The use of magnetic resonance imaging of the patient as being among the primary methods for analysing the tumor is one of the most essential aspects of this process. The vast amount of data being created makes manual procedures ineffective and prone to classification errors. Performing a manual analysis of the magnetic resonance imaging (MRI) pictures might be difficult. As a result, there is a need for computerised methods to tumor diagnosis that are more accurate. Nevertheless, establishing their volume, form, boundaries, size, segmentation, and categorization continues to be a process that is fraught with difficulty. The study comprises two parts: first, an experimental exploration of brain MRI images that concentrates on specific features, and second, a comparative analysis of multiple transfer learning models based on convolutional neural networks (CNNs) for the purpose of classifying brain tumors. Using MRI images of the brain, it reveals how successful deep knowledge approaches may be in the detection of brain cancer. Performance is determined based on how accurately training and testing are carried out. In this instance, a numeric classifier is used, with the classifications no tumors and tumors. Using a range of methods integrating medicinal copy dispensation and artificial idea for improvement, division, and cataloging of brain finding, the goal of our research is to properly identify and categories brain tumors.**

Keywords—GBF, Otsu's Threshold method, GLCM, BWARD, CNN, VGG16, EfficientNetBO

I. Introduction

Brain tumors are regarded as a fatal condition that affects many people's lives worldwide. The World Health Organization (WHO) notes that in 2016, the tumors are classified as low-grade (LG) and high-grade (HG) glioblastomas and gliomatumors, respectively. A benign tumor, commonly referred to as a low-grade tumor, does not significantly harm surround healthy tissues. A malignant tumor, on the other hand, is the exact opposite of a benign tumor; in this case, the tumor cells directly cause the person's death and they are known as high-grade tumors. They are also quickly spread through the surrounding brain tissues. Thus, scanning techniques are castoff to detect tumor cells in the brain earlier in order to avert this fatal occurrence. Excellent resolution, complex soft tissue distinction, and improved contrast are only some of the MRI image processing technologies that may be used to cope with the features of the human brain. [4].

When it comes to monitoring oncologic treatment, one of the most important responsibilities is the accurate and morphological quantification of tumors Popular which the brain tumor is segmented after the MRI pictures have been analyzed. Several image segmentation techniques have been used to separate this malignancy.

Researchers have developed a variety of ways for identifying brain tumors, but because the brain is so complex, these methods still fall short in terms of accuracy. These essential factors served as our inspiration for doing this investigation[5]. The GBF filter is employed for pre-processing to improve the value of the brain image in instruction to get around these problems. These in-depth features can reveal information about the various tumor kinds and are very discriminative. The majority of cancers may now be found early on thanks to the development of scientific theories and imaging technology. This study investigates deep learning methods for MRI-based tumor applications[6].

The subsequent is a list among the most important contributions made by this suggested methodology:

- An upgraded guided bilateral filter (GBF) is used in the pre-processing period to reduce sound and blurring. A GLCM technique is also used to extract features.
- To choose the best features, the (BWARD) algorithm is presented.
- To effectively cluster data for the segmentation procedure, Otsu's Threshold approach is employed.
- In order to classify brain tumors as either normal, benign, or malignant with high accuracy, Convolutional Neural Network (CNN), VGG16, and EfficientNetB0 were utilized. The study is divided into five sections, beginning with a literature review in Section 2, followed by a description of the proposed method in Section 3. Section 4 presents the results and discusses their implications, while Section 5 provides a general conclusion.

II. Literature Review

In this literature, various number of sensor-based wearable health monitoring devices in machine learning with edge has been suggested. Several studies have been developed to use MRI scans to diagnose brain cancer. Many studies were studied, and the methodologies and datasets used were examined. Despite the fact that common datasets were used in numerous analyses, distinct results were

DOI: rp-9788770040723.028

obtained. The primary reason for this is because the parameters differ even when the same process is used. In one study, existing models were altered and theclassification technique was carried out. Greater accuracy rates were sought in this manner.

he creation of CAD tools for tumor grading using multiple medical imaging modalities is a burgeoning field of study.MRI is the research method of choice in this situation. The main stages involved in CAD tools are preprocessing, segmentation, feature extraction, and classification. Feature selection is a crucial aspect of these tools. AI techniques can be divided into two categories based on feature selection: Machine Learning (ML) and Deep Learning (DL). In classical ML models, features are manually defined and known as "handcrafted features". The characteristics are automatically extracted from the photos in the case of the DL approaches, however, during training. This is a summary of a few of the classic ML-based research for classifying brain tumors.

The image denoising becomes more costly and less reliable as the patient population and the quantity of data that has to be analysed each day continues to grow. A visual issue is presented to the spectator as a result of a number of different characteristics, including the form, dimensions, difference, and high changes with regard to the intensity of the tumor. This necessitates the development of a computer-aided diagnostic (CAD) system that may provide radiologists and medical professionals with further support [7].

It is possible for a computer assisted diagnosis (CAD) program to be an efficient tool that can readily categorise brain tumors, which may aid in successfully following a treatment protocol. The MRI pictures may be obtained from the MRI equipment by such a system as the initial stage in the process. In current history, a number of scientists have suggested and created a variety of automated classification techniques for brain tumors using MRI data. In 2013, Sach deva and colleagues created a computer-aided diagnosis (CAD) system that encompassed picture segmentation, the extraction of features, and the multiclass categorization of six different types of brain cancers. The total quality of classification was found to be 85% [8], which was determined by carrying out three separate tests deploying artificial neural networks.

Emre et al. classified benign and malignant tumors using a procedure called support vector machine (SVM), which is a machine learning approach. With an effectiveness of 91.49%, a sensitivity of 90.79%, and a specificity of 94.74%, this method was able to describe the brain tumors. [9].

The overlap index parameter and Jaccard coefficient are employed to compare the results with manually segmented ground truth ROI images derived from the original images. Praveen and Agrawal proposed a multistage method that involves image preparation processes, feature extraction using histogram and GLCM approaches, and classification using a random forest (RF) classifier. Prior to the categorization process, it is critical to extract relevant components from the available data. To isolate the tumor from segmented brain images, the authors utilized circularity and area characteristics. The authors achieved an average overlap of 72.9% when comparing their segmented images with ground truth images to verify their methodology. In contrast, deep learning, a type of machine learning that does not require the subjective extraction of features, was used to achieve an accuracy of 91.43% in this study.

The latest advancement in machine learning involves enabling computers to recognize the most significant characteristics that accurately capture the data. Deep neural networks, such as the Convolutional Neural Networks (CNN) and Fully Convolutional Networks (FCN), have emerged from thisconcept, which transforms feature-driven problems into data- driven ones. These deep neural networks have found applications in a wide range of areas.

They are specifically employed in medical image analysis as well as general image processing in today's society. Brain Tumor Imaging (BTI) has increased significantly during the past few decades. In particular, there has been a notable rise in the quantity of publications addressing the measurement of brain tumors using MRI scans. Differentiating between tumor-infected and healthy tissues is the goal of brain tumor segmentation (BTS).

The approach of pixel classification is utilized to address the segmentation problem in various brain tumor segmentation (BTS) applications, thereby converting the segmentation problem into a classification problem, ultimately leading to the successful segmentation of brain tumor images. The majority of the academics make use of the benchmark dataset known as Brats 2013. In subsequent years, a number of other categorization schemes for brain tumors based on CNN were presented. Meningiomas, Gliomas, and Pituitary Cancers Were Identified Using One Approach This specific system classified all three kinds of tumors, which resulted in a classification accuracy of 97.3% [12].

Following an assessment of existing systems, it was discovered that there are various research gaps that have yet to be filled. Because brain tumor categorization is one of the more challenging study topics, numerous successful strategies must be combined to generate superior prediction results. However, the time complexity is significantly increased, which decreases overall performance. One challenge is that complex models are computationally inefficient, and models require a substantial amount of input data to yield improved outcomes. To address all research gaps and achieve superior classification results, a new deep learning methodology is introduced in this study. By incorporating more distinct input features, the proposed approach achieves higher accuracy rates.

III. Methodology

The purpose of the future research is to improve the efficiency of the operation of traditional classifiers. These classification methods are useful for computer aided brain tumor identification and classification because they need minimum datasets for training as well as a reduced computational complexity of the algorithm. This makes it

DOI: rp-9788770040723.028

possible for the computer to identify and classify brain tumors.

When it comes to detection, we advise utilising a Convolutional Neural Network (CNN), namely VGG16 and EfficientNetB0. To differentiate between benign and malignant brain tumors, it is essential to determine the extent of the tumor-affected region. Otsu's threshold approach is initially applied during the segmentation process for MRI images. Gray-Level Co-Occurrence Matrix approaches (GLCM) are utilized for feature extraction, resulting in thirteen characteristics that can be utilized for classification (11). During the course of the present study project, we have investigated the studies of a number of different classifiers, such as CNN, VGG16, and EfficientNet Classifier. In general, it worked to improve performance by using traditional classifiers wherever possible. The functioning of the new implementation that has been suggested is shown in figure 1.

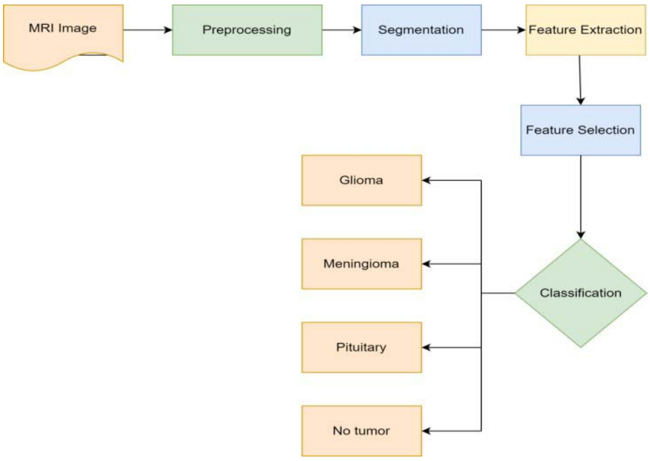

Fig. 1.Process Flow

3.1 *Pre-processing*

Several preprocessing techniques are used to decrease the impact of the noise and blurring. The multiple processes decide whether measurements are of greater quality. In the suggested approach, the GBF (Guided bilateral filter) is a technique used in image processing to enhance the visibility of certain features by removing noise and other unwanted frequencies in the image. It works by convolving the image with a Gaussian kernel, which acts as a filter to pass through only a certain range of frequencies, while attenuating others. This can be useful for tasks such as edge detection and feature extraction. The process of preprocessing an image using a GBF filter involves applying the filter to the image before performing any other image processing tasks.

3.2 *Segmentation*

Segmenting brain tumors using Otsu's thresholding method can be a useful technique. The following steps can be used:

1. Convert the MRI scan to a grayscale image.
2. Preprocess the image by removing noise and other unwanted artifacts using techniques such as Gaussian smoothing or median filtering.
3. Compute the histogram of the grayscale image and find the optimal threshold value using Otsu's method.
4. Apply the threshold value to the image by setting all pixels with an intensity value greater than or equal to the threshold to 255 (white) and all pixels with an intensity value less than the threshold to 0 (black). This creates a binary image with the tumor as white and the healthy brain tissue as black.

It is significant to note that Otsu's thresholding method may not be the best choice for all brain tumor images. It works best for images with bimodal histograms, where the brain tissue and tumor pixels have distinct intensity values. In cases where the histogram is not bimodal, other methods such as adaptive thresholding or region-based methods may be more suitable.

3.3 *Feature extraction using GLCM methods:*

The image processing technique known as GLCM (Gray- Level Co-occurrence Matrix) is used to extract texture information from a picture. The following steps can be used for feature extraction using GLCM methods in brain tumor images:

1. Convert the brain tumor MRI scan to a grayscale image.
2. The grayscale image can be partitioned into smaller regions of interest (ROIs), such as the tumor and the surrounding brain tissue.
3. For each ROI, compute the GLCM by counting the number of times different gray-level values appear in pairs in a specified spatial relationship (e.g., 0, 45, 90, or 135 degrees).
4. Extract texture features from the GLCM.
5. Compare the texture features of the tumor ROI to those of the surrounding brain tissue to identify any significant differences.
6. Utilize the extracted characteristics as input for a classifier, such as Support Vector Machine (SVM), to categorize the ROIs as either tumor or healthy brain tissue.

3.4 *Feature selection*

In the proposed framework, the fourth module involves feature selection, wherein significant characteristics are extracted while insignificant ones are discarded. The fundamental purpose of the feature selection process is to reduce the computational complexity overall by minimising the dimensionality problem. The suggested framework uses a hybrid optimization approach based on meta-heuristics to choose the best features. This paper suggests a new BWARD algorithm to choose the pertinent features and improve classification precision

3.5 *Classification*

3.5.1 *CNN-Based Architectures*

A CNN convolution layer is a kind of system that combines an image with several filters in order to generate feature maps. These feature plots are then sent on to the subsequent complication sheet in order to remove an additional high-level component from the input picture. Within the difficulty sheets, non-linearity equations, in

DOI: rp-9788770040723.028

conjunction with a down cast probability sampling, are used to accomplish the goals of adding non-linearity to the picture as well as reducing the image's complexity [13]

3.5.2 VGGNet

Some other CNN architecture that also was developed in 2014 was called VGGNet16. This design finished in second position in the competition on the basis of correctness, but it took the top spot in the ILSVRC. All completely linked layers use the ReLU activation function, while fully connected layers employ dropout regularisation.Compared to AlexNet and GoogleNet, the CNN model is computationally more expensive because of the high number of parameters.[13]

3.5.2 Efficient NetworkBO

A technique for scaling CNN's depth, width, and resolution is called an efficient network. From EfficientNet-B0 through EfficientNet-7, there are eight categories in the Efficient network. To enhance the overall performance model, Efficient Network scales using a defined and consistent set of coefficients. An example of compound scaling from the baselinenetwork is shown in Figure 3.[14]

IV. Dataset Collection and Description

The Kaggle database's brain tumor dataset includes 2659 T1- weighted, contrast-enhanced pictures. The dataset includes three different kinds of brain tumors: glioma (927), meningioma (373), pituitary (926), and no tumor (433).The files were all saved in.jpg format. Table 1 and image 3 provide MRI dataset samples of glioma, meningioma, and pituitary tumors.

TABLE 1:Representation of MRI Dataset

V. Results and Discussion

Edge Metrics and evaluation of performance a classifier's performance can be assessed using a variety of defined performance indicators. The quality index that is most frequently employed is classification accuracy. The proportion of samples that were correctly classified to all samples of data is known as accuracy in classification. The following classification accuracy results were attained in our tests. On the training set, CNN achieves an accuracy of 99.38%, while on the testing set, it only achieves an accuracy of 73.35%. With VGG16, the training set accuracy is 84.75 percent, however the testing set accuracy is just 53.30 percent. For EfficientNetB0, the accurateness on working out set is 99.46%, but the correctness on testing set is 74.37%.

The data shows that using CNN, VGG16, EfficientNetBO to categories the deep CNN features results in better performance. Nevertheless, the dataset that was utilized for the classification issue that was being discussed is not consistent. Because of this, the recommended system has to be evaluated in a more comprehensive manner, making use of additional performance metrics. We made use of confusion matrices in order to assess the efficacy of the system we developed for classifying tumors.

Evaluation Metrics

The efficiency of the suggested system for classifying and detecting brain tumors is assessed by calculating assessment metrics based on the four primary outcomes that are employed and to calculate a test's accuracy, Using the following equations, we determine the total number of instances that were examined and the number of cases that yielded true positive and true negative results:

$$\text{Accuracy} \quad \frac{TP+FN}{TP+TN+FP+FN} \tag{1}$$

Sensitivity is a measurement of a system's capacity to properly categorise brain tumors. It is derived from the percentage of cases in which the diagnosis was correct by using the following relation:

$$\text{Sensitivity} = \frac{TP}{TP+FN} \tag{2}$$

DOI: rp-9788770040723.028

The capacity of the modeling to correctly identify the real kind of brain tumor is referred to as particular, and itmay be calculated as follows

$$\text{Specificity} = \frac{TN}{TN + FP} \tag{3}$$

Precision is the true positive measure and is computed using relation:

$$\text{Precision} = \frac{TP}{TP + FP} \tag{4}$$

By contrasting the suggested CNN classifier model with earlier neural network techniques, he model's efficacy was assessed. Table 1 displays the performance comparison. With a training accuracy of 99.85% and a testing accuracy of 78.93%, the recommended method outperforms the earlier developed methods.

TABLE 5. REASONABLE INVESTIGATION OF CLASSIFICATION ACCURACIES

Model	Train	Test
CNN	99.38%	73.35%
VGG16	84.75%	53.30%
EfficientNetBO	99.46%	74.37%

VI. CONCLUSION

The proposed study aims to develop an effective deep learning- based brain tumor classification model that provides accurate tumor categorization. The model consists of five primary modules: pre-processing, segmentation, feature extraction, feature selection, and classification. Initially, the MRI images are pre-processed using the GBF filtering approach, and then the tumor regions are extracted using the Otsusthresholding technique. Key texture and edge features are retrieved from the images using the GLCM technique, and the extracted features are reduced using the BWARD algorithm to address dimensionality concerns during classification. Finally, the proposed CNN model categorizes the input features into four categories: glioma, meningioma, no-tumor, or pituitary tumor. Through simulations, the model achieves an overall accuracy of 99.46% on the brain tumor MRI dataset.

In the future, new types of MRI images, such as multi-modal imaging, will be explored to provide more informative classifications. Furthermore, new and hybrid deep learning models will be investigated to deliver more accurate categorization results. In addition to brain tumor classification, there are several other crucial diseases in need of a classification model, and it is expected that these disorders will be prioritized in the near future to reduce mortality rates and improve treatment techniques.

***Abstract* – The paper details various machine learning techniquesto identify the best technique to predict consumable water. Being the most essential natural element, identifying drinkable water amidst the deteriorating qualities of drinkable water is yet a worrisome issue. The versatility of employing techniques and algorithms of machine learning in solving real-world problems proves to bring efficient results. This paper details a comparative study using algorithms like – Logistic Regression, Decision Trees (DT), Random Forest (RF), XGBoost, Gradient Descent, Support Vector Machine (SVM), AdaBoost, and k-Nearest Neighbours. The used dataset is self-developed with reference to water potability parameters. Originally 5000 data entries were provided as input. XGBoost outperforms other models in terms of identifying consumable water. It is worthwhile to note that algorithm's performance is validated as best when it provides equal importance to both majority and minority classes. Thus, Synthetic Minority Oversampling technique (SMOTE) and Adaptive synthetic sampling approach (ADASYN) were employed to conclude and accurately identify for the best technique. XGBoost pertaining to SMOTE outperformed other techniques and was the best model to predict water potability.**

Keywords* – *Machine learning algorithms, ADASYN, SMOTE, XGBoost

I. INTRODUCTION

Water is indispensable for life to exist. One of the most jeopardizing issues that needs to address is identifying consumable water. According to UNICEF and WHO, 2.1 billion people worldwide lack access to safe drinking water. Adverse effects impacting every sector and aspect of life, including the vulnerability to water-borne diseases, are certain by consuming unclean or unsafe water.

Consumable water is expected to be free from pathogens that are harmful as well as from toxic chemicals. Contaminated water could be both natural and man-made. Naturally contaminated refers to those water bodies in which certain elements like fluoride, chloride, etc., have been found slightly more than the accepted level, whereas man-made contamination due primarily due to water pollution that is either by dumping waste into water bodies or by dumping chemicals from factories. Water quality is defined by various factors:

(1) Physical parameters: color, taste and odor, temperatures:
 1.1. Color of water results from form the dissolved organic substances
 1.2. Taste and odor are due to inorganic salts and dissolved organic components & gases
 1.3. Temperatures are usually typical for safe drinking water. Fluctuations in temperatures may be due to the presence of harmful chemicals and substances

(2) Turbidity:Suspended materials in water determine the turbidity levels of water. It is the amount of solid matter present in suspended form.

(3) Chemical parameters include BOD (biological oxygen demand), COD (chemical oxygen demand), etc. Amount of arsenic level (As), chloride (Cl^-), fluoride (F^-), zinc (Zn), iron (Fe), manganese (Mn), and other toxic substances also play a significant role in determining whether or not water is safe.

(4) Biological parameters like disease-causing organisms

(5) pH levels:The alkalinity of water is determined using pH levels. It is a logarithmic measure from 0 to 14 pH scale. The scale is divided into two sections – acidic and basic. Any value from 0 to 7 represents acidic nature, and any value above 7 represents basic nature. As per WHO standards, the permissible limit of pH for pure water is from 6.5 to 8.5. Any other value is considered impure in the case of water.

(6) Hardness:Calcium and magnesium salts cause water hardness.

(7) Total dissolved solids:Mineralized water consists of a high TDS value. However, the maximum limit for TDS ranges from 500 mg/l to 1000 mg/l for drinking purposes.

(8) Total Organic Carbon

(9) Conductivity:As per WHO standards, water conductivity must not exceed 400µS/cm.

(10) Other components like Trihalomethanes can be present only up to 80ppm.

The collected dataset considers pH, hardness, concentration of molecules, chloride level, sulphate levels, conductivity, TOC levels, amount of trihalomethanes, turbidity, and potability as its attributes. Machine learning serves to provide powerful tools and algorithms that can be used to bring efficient results to tackle real-world problems. For this problem statement, algorithms, namely - Logistic Regression, Decision Trees, Random Forest, XGBoost, Gradient Descent, Support Vector Machine

DOI: rp-9788770040723.029

(SVM), AdaBoost, and k- Nearest Neighbours, were used.I. LITERATURE SURVEY

In [1], the authors employed a SVM, Group Method of Data Handling (GMDH), and ANN in order to determine the quality of water of the river Tireh. It was found that the performance of GMDH was not satisfactory, and thus ANN and SVM were more suitable for predicting the quality. It was also noted that the Tansig transfer function and RBF kernel functions gave the best performance. Considering DDR index values, SVM was evaluated to have a lower value and, therefore, was found to be the most accurate of the three models [1]. Authors of [2] used ANN with a nonlinear autoregressive time series model to develop a complete framework for efficient prediction and analysis. Scaled conjugate gradient and log sigmoid was used for the training algorithm. Chlorophyll, specific conductance, dissolved oxygen, and turbidity were primarily considered as the determining factors by them. Results concluded that ANN- NAR proves to be a reliable method to identify the potability of water [2].

The primary aim was to employ Breiman's random forests and validate the results. It was also found that random forest techniques were also effective in solving this problem [3]. Random forest, deep neural network, gaussian naïve bayes, artificial neural network, and data distribution analysis were used to tackle the issue. The algorithms performed well wither maximum testing accuracy corresponding to ANN with 98.12%. The author of [4] was able to arrive at a conclusion that a total of 89.71% of water was found to be safe for drinking purposes [4]. In this paper [5], a decision tree and k- Nearest neighbour were used to estimate the water quality class. The models were optimized, and hyperparameter tuning was performed. The model's accuracy was once again validated. The k-nearest neighbour was identified to be better than the decision tree, with accuracy scores of 61.7% and 58.5%, respectively [5].

The author of paper [6], employed used (1) stratified sampling and wavelet de-noising ANFIS Model, (2) Fuzzy models and time series analysis, and (3) integrating ANFIS model with intelligence algorithms like – genetic algorithm and particle swarm algorithm. In the first algorithm, TDS, sulphate, chloride, and fluoride were the primary inputparameters since they have higher correlation values with electric conductivity. This algorithm was used to predict EC. WT-ANFIS model trained with a stratified sampling strategy was found to perform better than MLR, ANNs, ANFIS, and EANFIS. In the second algorithm - fuzzy and time series analysis also stratified sampling strategy was employed. With parameter EC in BB, FTS was able to predict well. For the third case, a comparison was made between ANFIS, ANFIS- GA, and ANFIS-PSO, that is, ANFIS integrated with intelligent algorithms. ANFIS-PSO was identified to outperform the other two cases [6].

Supervised machine learning approaches- support vector regression and extreme gradient boost (XGBoost). The algorithms were provided with big data. Both algorithms predicted well for temperature parameters. SVR was able to perform well even for dissolved oxygen. In the case of turbidity, the prediction by the two algorithms had more than 5% variation. However, cyanobacteria and fDOM had large variations. Other parameters didn't show much variation. Thus, considering these three factors to determine the better of the two, the authors identified SVR to be better than XGBoost for this model [7]. Authors of the paper [12] considered temperature, turbidity, pH, and TDS (total dissolved oxygen) as input, to apply to supervised ML approaches. It was found that gradient descent with a learning rate of 0.01 and polynomial regression with degree 2 performed better than other models [12]. Thus, it was also noted that PCA with SVR was performing better [15].

In this paper [8], the authors integrated IoT and performed real-time water quality checks using machine learning. The idea was to analyse the data using sensor inputs from lakes in rural locations and use k means for the process. Arduino UNO and Raspberry Pi embedded devices were used to validate the same. The sensor inputs were given to the pi4 edge-level processor, where k-means were used to predict the quality. The predicted values were then stored in a cloud server for future access. Thus, water could be monitored using IoT techniques without any human interference [8]. A similar approach was used by the authors of the paper [14], where Arduino was interfaced with the ZigBee handset, which detected low- quality water [14]. Synthetic minority oversampling technique and explainable AI were used in the paper [9] to predict the water potability prediction model. Oversampling was performed using Synthetic Minority Oversampling Technique (SMOTE). Therefore, replication of minority classes is performed in oversampling. As a result, the authors were able to replicate the data as 1998 for both not portable and portable after oversampling, from 1998 not portable and 1278 portable data, respectively. Later machine learning approach is applied to validate the results. Radom forest was found to outperform other models [9]. DT, RF, and MLP methods were employed for air quality with the same approach as that of the water quality case [13].

WQI was evaluated for Ebinur Lake Watershed using ML and remote spectral indices via fractional derivatives methods. The model pertaining to a spectral index of 1.60 was found to perform better than other models. The proposed models were GA-SVR and band difference algorithms [10]. In paper [11], the authors identified that the most commonly used machine learning approaches were ANN, RF, SVM, regression cubist, genetic programming, and DT. It was found that Chlorophyll- a, temperature, suspended solids, colored dissolved organic matter, salinity, and turbidity were the commonly used determining factors for the problem statement. 138 samples of water from Agastheeswaram, Tamil Nadu, were collected pre- and post-monsoon by the authors of the paper [17] to predict groundwater quality. Off DT, KNN, and SVM used, SVM was found to achieve better results [17]. Apart from these models, a fuzzy system was used to classify water into five different groups. Water from three lakes from Hosur, Tamil Nadu was collected, and the classification was computed [18].

III. PROPOSED SOLUTION WORKFLOW

DOI: rp-9788770040723.029

The primary objective was to perform a comparative study that validates the potability by analysing various algorithms.First, the dataset is thoroughly studied by performing data visualisation and exploratory data analysis (EDA). Then thefollowing three stages are computed to identify the best algorithm.

Stage 1: Analysing models without oversampling - At this stage, the original dataset is fed to the models, and the performance is analysed. Initially, a total of 5000 inputs were given to the model with the attribute values - pH, hardness, the concentration of molecules, chloride level, sulphate levels, conductivity, TOC levels, amount of trihalomethanes, turbidity, and potability. The values were randomly generated in Excel considering WHO standards. Logistic Regression, DT, RF, XGBoost, Gradient Descent, SVM, AdaBoost, and k- Nearest Neighbours were used, and the accurate algorithm was identified.

Further investigation was done by performing oversampling. Oversampling is done to reduce the possibility of ignoring minority classes by machine learning when unbalanced data is fed to the model requirement [9]. Thus, ML algorithms tend to be biased toward the majority class. Since potable data was found to be a minority class and is the criterion of interest. It was necessary to balance the data to get accurate and unbalanced results. Two techniques – the Synthetic Minority Oversampling technique (SMOTE) and the Adaptive synthetic sampling approach (ADASYN) were used with the same algorithms to conclude for the best technique.

Stage 2: ADASYN approach is used to balance datasets by adaptively generating minority data samples that are based on their distributions [16]. The advantage of using ADASYN is that it can shift the classifier's decision boundary to focus on- difficult to learn aspects, which allows the algorithm to improve its learning performance.

Stage 3: SMOTE works by analysing and identifying adjacent instances in feature space. A line is drawn to link them and to generate a new sample positioned at that line. By doing so, new data is replicated, and oversampling is successfully achieved.

Finally, a comparative study was computed to determine the best algorithm.

IV. Algorithms Used

A. *Logistic Regression*

Logistic Regression used in both classification and regression cases, is a statistical model that estimates the probability of the occurrence of an event. Logit transformation is applied on the odds whose function is given by:

$$log(\pi) = \frac{1}{1+e-\pi} \qquad (1)$$

It is a supervised learning technique for predicting categorically dependent variables using the provided set of independent variables.

B. *Decision Tree*

The decision tree - a supervised learning non-parametric algorithm used for both classification and regression problems is based on trees that consist of features like root node, leaf nodes, branches, and internal nodes. In order to identify optimal split points, decision tree employs a divide and conquers strategy by greedy search.

C. *Random Forest*

In this learning approach, ensemble learning is used that solves complicated problems by several classifiers. This technique is also employed for classification and regression purposes. Random forest is made up of many decision trees. The outcome is determined based on the prediction made by the decision trees. As the number of trees grows, the precision of the result also increases. It is primarily used to address the shortcomings of the decision tree method.

D. *XGBoost*

XGBoost is a machine-learning toolkit for distributed gradient boosting. It has been optimised for: (1) efficiency, (2) portability, and (3) flexibility. It is a parallel tree boosting algorithm that solves problems quickly and accurately. It is also a supervised learning technique to accurately predicttarget variables by combining weaker models. A depth of 8 was considered.

E. *K-Neighbors*

K-Neighbors or KNN is a supervised learning non-parametric algorithm that uses similarities between new and available cases and places a new case into a category that is closest to one of the available cases. KNN is also used to solve both classification and regression cases. It uses Euclidian distance (equation 2) as the determining distance metric criterion.

$$d(x, y) = \sqrt{\sum_{i=1}^{n} \ (yi - xi)^2} \qquad (2)$$

Nine nearest neighbors were considered, with leaf size as 20 for the comparative study.

F. *SVM*

SVM is a supervised learning algorithm that uses a decision plane and boundaries. A decision plane divides groups of data points into several classes. Therefore, in an n-dimensional space, the input data is viewed as two sets of vectors. SVM has several kernels like (1) Linear, (2) Polynomial, (3) Gaussian, (4) ANOVA, (5) RBF – Gaussian Radial Basis Function, and (6) Sigmoid. To compute the comparative study, RBF kernel was used since the results pertaining to RBF had better accuracy than other kernels.

G. *AdaBoost*

AdaBoost or adaptive boosting is a statistical meta-algorithm used for classification purposes. It is an ensemble technique used to solve complicated problems by combining weaker classifiers and building a stronger one. In AdaBoost, weaker ones are termed as decision stumps that denote decision trees with a single split. AdaBoost classifier with a learning rate of 0.002 was used.

H. *Gradient Descent*

Gradient boosting is an optimization technique. It is used to find the global minimum of a given function.

DOI: rp-9788770040723.029

However, it applies mainly in cases with few local minima. Gradient boosting with a learning rate of 0.05 and a maximum depth of 5 was used.

V. METHODOLOGY

Data visualization is presenting data in graphical or pictorial form. Heat maps are widely used in order to represent correlation matrix graphically. Correlation is a statistical metric to represent the relationship between two variables and ranges from -1 to +1. Figure 1 indicates a heat map of the given attributes. Considering values as $xi$and $yi$and mean values as X and Y, the correlation value is calculated as:

$$correlation = \frac{\sum(xi-X)(yi-Y)}{\sqrt{\sum(xi-X)2(yi-Y)2}} \qquad (3)$$

EDA is a sophisticated method for examining datasets to highlight key features often associated with visual methods. It provides valuable information that could be used in scientific research and visualizations. Box plots are plotted to identify outliers. Figure 2 represents a distplot that is used to plot univariate data distribution against density distribution.

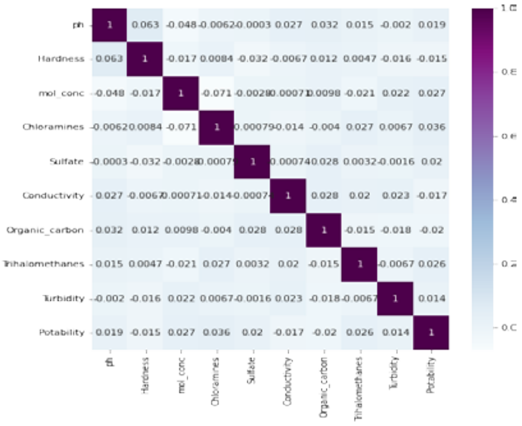

Fig.1. Heatmap representing correlation between attributes

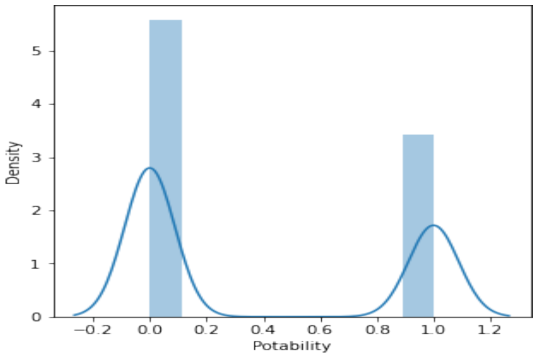

Fig.2. Distplot of potabilityvs density distribution

Observations from the dataset fed to the system is analysed as follows: in Figure 3, the blue box plot corresponds to non-potable. The minimum and maximum values found in the dataset were 1.2 and 14. However, the lower and upper fences were considered as 2.175578 and 13.10774. Thus, any value below and above the lower and upper ranges were treated as outliers. The median for the non-potable case was 7.848005, whereas q1 and q3 were 6.317914 and 9.093132, respectively. Similarly, the red box plot corresponds to potable. Here, the lower and upper ranges were 3.738116 and 12.10508. The median for the potable case was 8.004796, whereas q1 and q3 values were 6.677912 and 8.944125, respectively. Figure 4 is a box plot with respect to the hardness of water and potability. The blue plot box in figure 6 corresponds to the non-potable. The minimum and maximum entries received were 50.0006 and 354.2365, respectively. Any value other than this range was treated as an outlier. The lower and upper fence values were 168.9892 and 325.8871. The median for this case was 247.5177, whereas q1 and q3 values were 227.5106 and 267.0189. The red box plot corresponds to potable. Here, the values of the lower and upper fence are 161.4792 and 328.62, respectively. The median for the potable case was 247.3163, whereas q1 and q3 values were 224.6147 and 266.7835. It is worthwhile to note that as per WHO standards, the permissible pH value for pure water was between 6.5 and 9, while hardness limitations are in the range of 200-300mg/L.

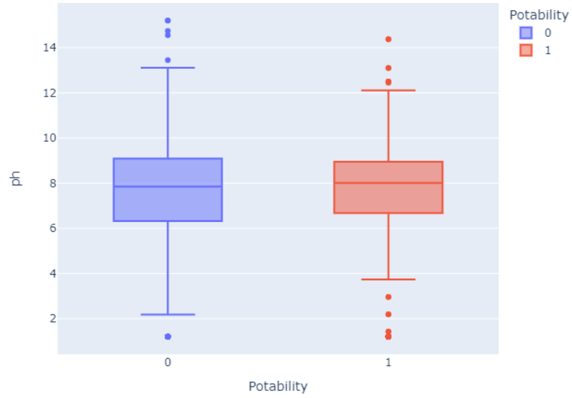

Fig. 3. pH box plot (Blue Box plot – non potable, Red Box plot – potable)

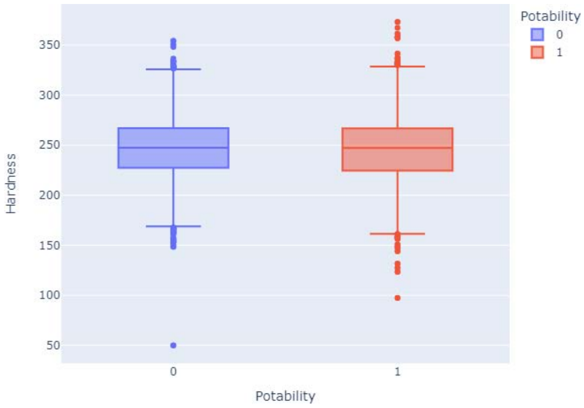

Fig.4. Hardness box plot (Blue Box plot – non potable, Red Box plot – potable)

DOI: rp-9788770040723.029

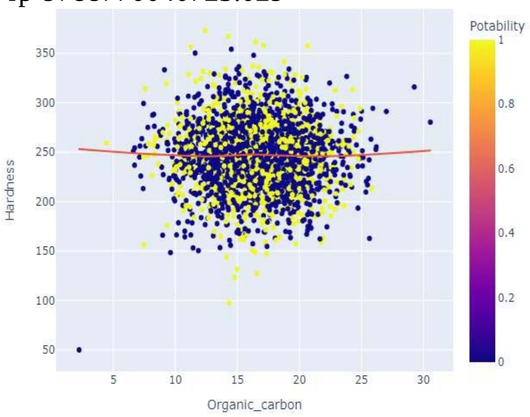

Fig.5. Hardness and Organic Carbon as determining factors to identify potability

Water contamination or determining factors could be due to two attributes, for such cases, a scatter plot corresponding to two determining factors (Figure 5) was implemented.

Considering input parameters such as pH, hardness, the concentration of molecules, chloride level, sulphate levels, conductivity, TOC levels, amount of trihalomethanes, and turbidity. Then, a feature scaling technique called Standard Scaler is applied to x. This standardizes data into a standard format that is that mean of the data to zero and standard deviation to one. Standard scaler performs an operation on the dataset as mentioned in equation 4 where xi represents values and X is mean. Later, a train test split is performed, and the models are trained and validated.

$$standardscaler = \frac{(xi - X)}{standarddeviation} \quad (4)$$

Potability represents whether or not water is drinkable. The value of potability is binary – 0 and 1. For the given conditions, if the value corresponds to 0, that indicates that water does not fall under the drinkable category. A value of 1 indicates that the water is consumable and safe. Initially, out of the 5000 entries, 62%-38% was the distribution of potability in the dataset. After ADASYN and SMOTE, a total of 6196 and 6206 entries, respectively, were used for model training. Table 1 summarises the distribution.

TABLE 1: SUMMARY OF DATA ENTRIES

Name	Total	X_train	X_test	Y_train	Y_test
Before Oversampling	5000	3350	1650	3350	1650
ADASYN	6196	4192	2004	4192	2004
SMOTE	6206	4156	2050	4156	2050

VI. RESULTS AND DISCUSSION

To validate accuracy precision, recall, and f1-scores are analysed. The accuracy of an algorithm is the score that corresponds to the number of correct predictions to all predictions. It is given by:

$$accuracyscore = \frac{TP+TN}{TP+TN+FP+FN} \quad (5)$$

The precision determines how many predictions (positive) are correctly made. This is a measure of true positive given by:

$$precision = \frac{TP}{TP+FP} \quad (6)$$

The recall is also referred to as sensitivity checks for correctly predicted cases over the entire positive cases in the data. It is given by:

$$\text{recall} = \frac{TP}{TP+FN} \quad (7)$$

F1-score is given by: $f1 - score = 2 * \frac{precision*recall}{precision+recall}$ (8)

TABLE 2: COMPARISON OF PRECISION RECALL F1-SCORE AND ACCURACY VALUES BEFORE OVERSAMPLING

AdaBoost	0.60	0.53	0.32	0.79	0.41	0.64	55.08%	0.58	0.53	0.31	0.77	0.40	0.63	54.09%
Gradient Descent	0.66	0.65	0.64	0.67	0.65	0.66	65.61%	0.66	0.66	0.65	0.67	0.66	0.66	65.90%

Table 2 details the performances of models without oversampling. It is noted that XGBoost is able to provide an accuracy of 77.51%. The idea behind oversampling is to avoid algorithms tending to be biased towards one category while predicting the output. It can also be noted that other models were able to perform well, giving approximately 70% results. Thus, it was not sufficient to conclude that XGBoost was the best method among all the other algorithms. To rectify this issue and to conclude on the best algorithm, ADASYN and SMOTE results are compared with the before oversampling case. Table 3 details the performance of models after oversampling. It is worthwhile

DOI: rp-9788770040723.029

to note that Logistic regression, decision tree, random forest, k-nearest neighbors, SVM, AdaBoost, and gradient descent have a significant decrease in the performance. This concludes that these models did not give equal importance to the minority class, which was to be required in this problem statement. However, XGBoost's performance is seen to improve from before sampling case of 77.51% to 77.29% in ADASYN (approximately same but better than other models) and to 80.34% in SMOTE with improvements in precision, recall and f1-scores, indicating that it is the best accurate model to determine consumable water. Confusion matrix are plotted to validate the results. Figures 6, 7, 8 correspond to XGBoost algorithm. Bar plot in figures 9, 10 and 11 represent accuracy scores. These are the accuracy plots for individual cases. It can be observed that accuracies of other models are gradually decreasing when unbiased data is fed. Finally, a combined performance analysis plot is plotted (Figure 12). Green line corresponds to SMOTE, blue for unbalanced dataset and yellow for ADASYN. Overall performance of XGBoost outperforms other models.

VII. Conclusion

Water is one of the most important and essential resources that determines life on Earth. The availability of safe consumable water is a jeopardizing situation that is being faced in many countries around the world. Apart from natural contaminants, water pollution has become a major concern for many environmentalists. Water potability is affected by a number of factors. In this paper, factors such as pH, hardness, the concentration of molecules, chloride level, sulphate levels, conductivity, TOC levels, amount of trihalomethanes, and turbidity were considered. The used dataset is self-developed. However, the models will work with the same efficiency as other river or lake datasets with the same attributes. Exploratory data analysis is widely used by researchers to study and investigate various data. The same concept is applied here to understand and analysis the distribution of data when considering different attributes. WHO standards were considered, and analysis was performed on the dataset.

Machine learning algorithms are powerful and sophisticated tools that can tackle problems such as water quality index determination or water potability. From the previous research, it was identified that various algorithms were used to analyse the same. But it was noted that the algorithms were performing differently depending on the dataset. On further investigation, it was found that the models tended to be biased toward the majority class.

Therefore, an imbalanced dataset was used to have a comparative analysis of various models. The imbalanced dataset consisted of more data entries with non-potable conditions. The goal was to predict potability, thus maintaining potable cases as a minority class. To balance the dataset, ADASYN and SMOTE were used. In both ADASYN and SMOTE cases, models like logistic regression, decision tree, Support vector machine, AdaBoost, and Gradient descent had the same performance/accuracy level with negligible percentage difference. However, it was also observed that these models had a drastic decrease in their performance from their original performance, as in the case of the unbalanced dataset.

XgBoost, on the other hand, performed well and had a slight improvement in its accuracy too. The precision, recall, and f1-scores of XgBoost were significantly higher with values - 0.80, 0.81, 0.80 for non-potable and 0.81, 0.80, 0.80 for potable cases. This model can effectively produce results when interfaced with IoT or TinyML real- time projects. Therefore, the comparative analysis concluded that XGBoost was the best technique since it outperformed other models in all three stages of the proposed workflow.

***Abstract*— This Cardiovascular disease is one of the serious issue that we are facing in current day it has become a massive challenge to try and analyse the cardiovascular disease survivors. Artificial intelligence is a component of machine learning, which is used to address several issues in data science. We can predict results based on past data which is a very frequently used application of machine learning for the machine to forecast predictions it has to identify patterns from the previous data and these patterns can be used on latest or new data to predict the outcome. The health business generates enormous amounts of raw data, which data mining transforms into meaningful information that might aid in making decisions. Decision Tree (DT), Adaptive boosting classifier (AdaBoost), Logistic Regression (LR), Random Forest (RF), Gradient Boosting classifier (GBM), and K-Nearest Neighbor (KNN) are the classification methods used in this study.**

Keywords*— *Cardiovascular disease, Machine learning, Random Forest, Decision Tree, Adaptive boosting classifier, Gradient Boosting classifier, KNN

I. Introduction

The biggest cause of death worldwide, as reported by the WHO, is heart disease. According to estimates, cardiac conditions account for 24% of deaths in India from non-communicable diseases. The cause of one-third of all fatalities worldwide is heart disease. Heart diseases are to blame for 50 percent of mortality in the United States and other industrialised nations. Every year, around 1crore 70 lakh people worldwide die from cardiovascular disease (CVD). It might be difficult to identify (CVD) due to several contributing variables, including high BP, high cholesterol, diabetes, irregular pulse rate, and several other illnesses. The symptoms of CVD might occasionally vary based on a person's gender. For instance, a female patient may also suffer nausea, severe tiredness, and shortness of breath in addition to chest pain, but male patients are most likely to have chest pain. Researchers have investigated a variety of ways to predict cardiac diseases, but predicting so at a beginning stage is not particularly successful for a variety of reasons, including complexity, execution time, and method accuracy. Consequently, efficacious diagnosis and treatment can save a lot of lives. Between healthcareservice guidelines, medications, and lost productiveness as a result of death, in 2014 and 2015 it cost roughly $219 billion annually. Heart failure, which can result in death, can also be avoided with early detection. Although angiography is thought to be the most exact and accurate procedure for predicting cardiac artery disease (CAD), it is quite expensive, making it less accessible to families with limited financial resources. Physical examination can cause few errors which might even lead to death of few patients as heart disease is a very complicated disease and we have to take at most care and here using machine learning based expert systems will help us to effectively diagnose Cardio Vascular Disease (CVD). Data Mining plays a major role in many fields like engineering, business, and education to extract data and find interesting patterns out of those. Examining data to find hidden information that will be useful to take important decisions in the future is a process called as "data mining". By decreasing the error in factual results and forecast, Understanding the complexity and non- linear interplay between several components, a wide range of machine learning techniques have been used. Medical experts must employ ML and AI algorithms to analyse data and draw exact and detailed diagnostic judgments because the amount of medical data is always growing. Different categorization algorithms are used in data mining of medical data to predict patients' CVD and deaths from heart attack.

II. Literature Survey

[1] Melillo et al. proposed a system that automatically distinguishes high-risk patients from low-risk individuals. Classification and regression tree (CART) (93.3% sensitivity, 63.5% specificity) performed better in their investigation. Only 12 little-risk and 34 huge-risk patients were examined. To determine whether their suggested method is beneficial, a larger dataset must be examined.

[2] Guidi et al examined the clinical support system (CDSS) for heart failure analysis. This model provided outputs such as HF(Heart Failure) sensitivity . They conducted study using various machine learning classifiers and compared the results. Random forest and CART performed best with 87.6% accuracy out of all classifiers.

DOI: rp-9788770040723.030

[3] Parthiban and Srivatsa have done a extensive study and have conducted research to find out heart disease in those patients who have diabetes.They used many predictive features like blood pressure, blood sugar, and age there is a imbalance in data set and the writers of have not employed any strategy to address this issue. they were able to achieve an accuracy of 94.60% by using support vector machine (SVM) classifier. Al Rahhal*et al* have used a novel approach using deep neural network (DNN) they used raw ECG data to predict using an unsupervised learning technique stacked denoisingautoencoders (SDAEs) to examine the highest level of features. They allowed expert engagement, which can induce biases, throughout each training cycle. It may bring about prejudice.

[4] Muthukaruppan and Er proposed a fuzzy expert system for the identification of CVD that is based on Particle Swarm Optimization (PSO). Fuzzy rules were created when rules from the decision tree were retrieved. Their accuracy using the fuzzy expert system was 93.27%. On the short dataset used in their investigation, a few rules were extracted. Alizadehsani and others

[6,7] Alizadehsani*et al.* utilised a group-based learning strategy. They utilised a dataset with 303 cases that they aquired from the "Rajaie Cardiovascular Medical and Research Centre" for their study. For CVD prediction, authors employed the introductory C45 ensemble learning approach. Left circumflex stenosis, left anterior descending stenosis, and right coronary artery (RCA) stenosis were accurately identified with 68.96%, 61.46%, and 79.54%, respectively (LAD). By using the SVM model, the results were improved and "80.50% accuracy for RCA, 86.14% accuracy for LAD, and 83.17% accuracy for LCX" were reached by a new team of researchers.

[8] Tama *et al.* presented the idea of a two-tier ensemble paradigm, where certain classifiers serve as the basis for another ensemble. Using class labels from Extreme Gradient Boosting (EGB), Random Forest (RF), and Gradient Boosting Machine (GBM), the suggested stacking architecture is constructed (XGBoost). Four different types of datasets are used to evaluate their suggested detection model. Moreover, they employed feature selection methods based on particle swarm optimization. With a k value of 10, their suggested model fared better in the k-fold cross- validation. Only the stacking of tree-based models was considered by the authors. Additional statistical and regression-based techniques might be used to improve model results.

[9] Abdar et al. established the N2Genetic optimizer, a novel optimization approach. The patients were then identified as having CHD or not using the nuSVM. On the Z- AlizadehSani dataset, the proposed detection approach had an accuracy of 93.08% when compared to earlier works. Raza proposed an ensemble architecture with majority vote. To forecast heart illness in a patient, it incorporated logistic regression, multilayer perceptron, and naive Bayes. A classification accuracy of 88.88% was attained, surpassing all base classifiers combined.

[10] Mohan et al developed a hybrid approach based on combining a linear model with a random forest to predict cardiac disease (HRFLM). On the Cleveland dataset, the suggested technique raised performance levels and had an accuracy rate of 88.7%.

[11] Soni and Vyas they used WARM, and their degree of confidence was 79.5%. dependent on age, smoking behaviours, BMI range and Hypertension their research assigned weights. Soni et al. on the other hand, gave each quality a weight depending on the advice they obtained from the medical experts. By attaining a maximum score of 80% confidence, Using a weighted associative classifier, they demonstrated a bright and effective cardiovascular attack prediction system.

[12] Ganna A, Magnusson P K and team. Effort on using machine learning algorithms to identify cardiovascular heart disease has had a substantial effect on this work. In this paper, a summary of the literature is presented. Using a variety of methods, an effective prediction of cardiovascular disease has been achieved. Logistic Regression, KNN, Random Forest Classifier, etc. are a few of them. The outcomes demonstrate the capability of each algorithm to register the given objectives. The findings indicate that every algorithm is capable of registering the given objectives, with KNN displaying the greatest performance (88.52%).

III. Proposed System

In this literature we have proposed multiple machine learning algorithms to detect if a person has Cardio vascular disease or not. Building, training, testing and validating the architecture for a specified challenge is a complex process. Decision Tree, Adaptive boosting classifier, Logistic Regression, Gradient Boosting classifier and K-Nearest Neighbor are the classification methods used in this study. Google colab was used to run the experiment. In this study the data is collected from 1025 patients which consists of both healthy and patients suffering from cardio vascular disease and we use attributes like age, sex, chol, cp(chest pain) etc to predict if a person is healthy or suffering from cardio vascular disease and this data set contains a total of 14 attributes the above mentioned algorithms are considered to be best for predicting the cardio vascular disease as they are all supervised learning algorithms.

A. Overview of architecture

Fig 1 consists of the overall architecture of the cardio vascular disease prediction using multiple ml models and the main parts of this architecture is data collection, data preprocessing and predicting the data using the given algorithms. Our technique uses the data of patient to predict the patient's heart condition weather the person has the heart disease or not. And these predictions are made by the best algorithm of all the ml algorithms used and the model is trained before hand with a genuine data set to make accurate predictions.

DOI: rp-9788770040723.030

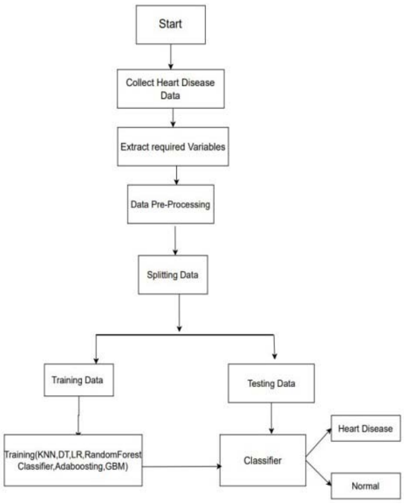

Fig..1. Flowchart for Heart disease prediction

B. *Related Work*

ApurvGarg et al have proposed a model that predicts the chances of getting heart disease using two machine learning algorithms that are KNN and Random forest they have compared these two models in order to get the best accuracy possible out of which KNN yielded a prediction accuracy of 86.88% where as the RF yielded an accuracy of 81.96% [15]

Archanasingh and Ramesh kumar have proposed a prediction based model with multiple machine learning algorithms like SVM, DT, LR, KNN out of which KNN yielded highest accuracy of 87% they have first collected data then selected the required attributes then the data is preprocessed and then balanced the data they have used UCI repository dataset [16]

In this study we have used similar approaches and we were able to get better accuracies for the models by using different dataset with more number of data points. We were able to achieve better accuracy for our proposed model KNN

C. *Data Collection*

We took our data from kaggle website for free and our data is called heart.csv this data set contains of 1025 patients records. Out of this 1025 people 499 people are normal and526 people have heart disease and this data set has 14 attributes and out of these people there are 713 male and 312 female. And out of people that have heart disease 300 are male and 226 female

D. *Data Pre processing*

In this step we use one-hot encoding technique to transform categorical values to numerical values then we drop of unnecessary variables then we separate features, now we normalize the data using min-max method now we split the data into two parts training and testing out of which the ratio of training is 80 and testing is 20 and now the data is ready and can be used in any model.

IV. Machine Leaning Algorithms

A. *Logistic Regression (LR)*

Logistic Regression is one of the best available tough classifier among the supervised ml algorithms. It is an elongation of general regression model it reflects the likelihood of the occurrence or nonoccurrence of a certain instance. Logistic regression is used to describe data and the connection between a dependent variable and one or more independent variables. Nominal, ordinal, or period types are all acceptable for the independent variables. The likelihood that a new observation will fall into a particular class is determined by LR, with the result falling between 0 and 1 because it is a probability

B. *Decision Tree (DT)*

Decision tree is one of the oldest ml algorithms. For issues related to classification and regression we have a best supervised algorithm that can deal with them and that algorithm is Decision tree and most of the times it is used for classification problems. It is basically a Tree shaped classifier root node is the top node while others are child nodes. Internal nodes represent the features of datasets while leaf node consist result Decision node and the leaf node are the nodes that make up decision tree. Decision node generally makes up decisions as it has many branches whereas leaf node can’t make any decisions.

C. *K-Nearest Neighbor (KNN)*

DOI: rp-9788770040723.030

KNN is among the very few oldest algorithms or statistical learning technique. In KNN K is basically to represent the total number of nearest neighbors used which is directly mentioned in the object builder. As a result, related situations are classified similarly, and a new instance is classified by comparing it to each of the existing examples. KNN method will search the pattern space for k training samples adjacent to the supplied unique sample when one is provided. Two distinct methods are offered to translate the distance into a weight so that predictions from many neighbors of the test instance may be calculated based on their distance.

D. Adaboost

An ensemble method in machine learning is called AdaBoost, also known as Adaptive Boosting. The most popular AdaBoost algorithm is a decision tree with one level, or a decision tree with only one split. A model is created via AdaBoost, and all the data points are given the same weight. After that, it gives points with incorrect classifications more weight. The following model now accords greater relevance to all of the points with higher weights. As long as no low errors are received, it will continue training models.

E. Random Forest

A ML technique that uses many numerous decision trees to make a decision is known as Random forest. It is a ensemble learning based technique. While it is in the training stage, itProduces many trees and a forest of decision trees. Each and every tree, a component of the forest, predicts a class label for each and every occurrence during the testing period. The model will take the class with the highest votes and makes it as prediction. The individual tree makes a class prediction from a very large independent tree models working together will give out the best result.

F. Gradient Boosting

Using boosting, weak learners may become strong learners. Each new tree created by boosting is fitted to a modified version of the initial data set. It is anticipated that when merged with older models, the new model will produce forecasts with lower error rates. The major goal is to set objectives for this next model to reduce mistakes. Gradient Boosting in a gradual, additive, and linear fashion trains many models. Because each case's goal results are decided by the gradient's deviation relative to the predictions, the phrase "gradient boosting" came into popularity. Every model picks up speed in the correct way by reducing the prediction errors.

E. Proposed Algorithm

In this study the best out of all the algorithms is KNN which has achieved an accuracy of 97% which is considered as one of the best algorithm in supervised classification algorithm and other than that it is simple KNN is non-parametric and lazy, which means it does not assume anything about the distribution of the underlying data anddoes not create a model from the training set. As an alternative, it memorises the full training dataset and utilises it to make predictions when presented with fresh test cases. For many applications, KNN is a straightforward and efficient method, although it can have large computing costs and be sensitive to the choice of K and the distance metric used to compare instances. KNN is a flexible technique that may be used to solve a variety of issues since it can be applied to both classification and regression jobs.

V. Evaluation

For the machine learning models, there are some approaches for performance evaluation. It is anticipated that the blending of several assessment tools will support the advancement of analytical research. Four fundamental measures (accuracy, precision, recall, and F-Score) will be looked at in this study to see how machine learning-based algorithms differ from one another.

Using the confusion matrix, we may assess the four measures. The Confusion Matrix's constituents are True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN).In the medical data the most important thing is to find out (FN). The performance metrics are provided below

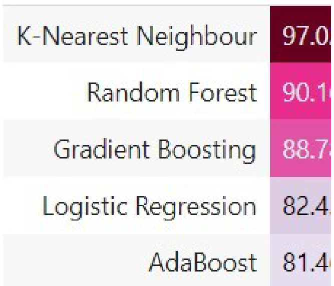
Accuracy = Number of correctly classified predictions / Total predictions (1)

Precision = TP / TP + FP (2)

Recall = TP / TP + FN (3)

F–Score = 2*precision*recall / precision + recall (4)

The total collection of features in the heart disease dataset have been exposed to comparison analysis of supervised machine learning classifiers. Some classifiers performed well on evaluation measures, whereas others did not. In order to predict heart failure survival, this work employed tree-based, statistical-based and regression-based models. The DT, RF ensemble models are tree-based. AdaBoost and GBM are two tree-based boosting methods. Statistically-based models whereas regression-based models include LR and KNN



K-Nearest Neighbour	97.0
Random Forest	90.1
Gradient Boosting	88.7
Logistic Regression	82.4
AdaBoost	81.4

Fig. 3. Different accuracy comparison

As per the table we have KNN with the best accuracy of 97.02%, Random forest with an accuracy of 90.16%, Gradint boosting with a accuracy of 88.7%, LR with a accuracy of 82.43%,Adaboost with a accuracy of 81.46%and with the least accuracy is the decision tree algorithm with an accuracy of 79%

DOI: rp-9788770040723.030

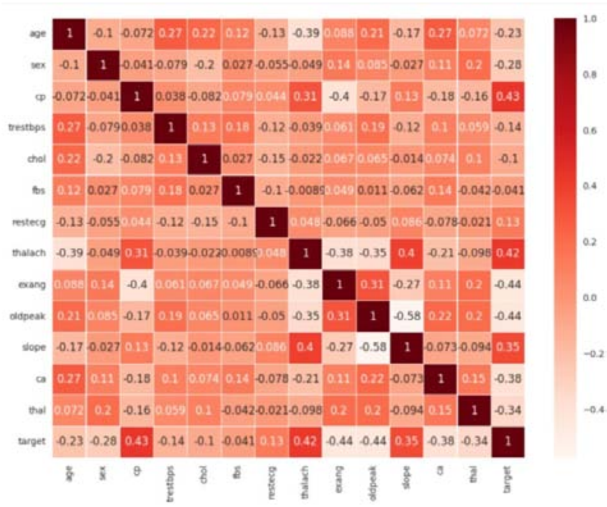


Fig. 4. Correlation matrix of variables

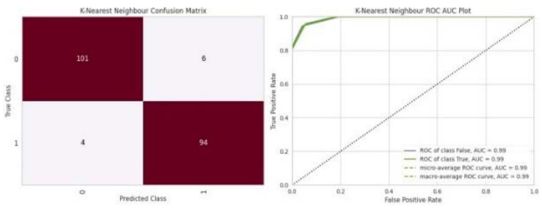

Fig. 5. Roc and confusion matrix of KNN the best algorithm

TABLE.1. PRECISION, RECALL AND F-MEASURES

Algorithm	Precision	Recall	F-1
K Nearest Neighbor	0.97	0.97	0.97
Random forest	0.91	0.90	0.90
Gradient Boosting	0.89	0.89	0.89
Logistic Regression	0.84	0.82	0.82
Ada boost	0.82	0.81	0.81
Decision Tree	0.80	0.79	0.79

TABLE.2. VALUE OF AREA UNDER ROC

Algorithm	AUROC
K Nearest Neighbor	0.99
Random forest	0.96
Gradient Boosting	0.95
Logistic Regression	0.91
Ada boost	0.87
Decision Tree	0.86

In conclusion, a dataset on heart illness was gathered, preprocessed as needed, and then analysis was done to better understand the dataset. Following the application of six machine learning algorithms Ada boost, LR, Gradient boost, KNN, DT, and RF we assessed the predictions using the F-1 Measure, ROC curve, recall, accuracy, and precision. We discovered that all of the used algorithms performed well, with KNN demonstrating the greatest performance with 97% accuracy, showing that these algorithms are the most effective at predicting cardiac disease.

VI. CONCLUSION

Heart patients' lives will be saved through the processing of raw health data of heart information using machine learning algorithms. By identifying risk factors for heart failure, preventive steps can be taken to lower mortality rates. In this study, a machine learning-based technique for predicting the survival of heart patients is suggested. The following machine learning methods are used: LR, AdaBoost, RF, GBM, DT and KNN. KNN with a accuracy of 97% the highest of all algorithms with precision score0.97 recall 0.97 F-1 0.97 and AUROC 0.99 the work done here has the potential to advance the medical field and help doctors forecast how long a patient with heart failure will live. Additionally, it will aid doctors in realizing that if a heart failure patient survives, they can concentrate on key risk factors. To gain from their combined advantages, the research can employ a range of machine learning model combinations in the future. To better the efficiency of ML models, better feature selection methods may be created. Due to the fact that these feature selection issues are NP-hard, meta-heuristics can be used.

***Abstract*—Students and faculty members of any college on a day-to-day basis use the buses provided by the college to commute. There is a lot of meticulous planning that goes into this. The data required for planning will surmount to decisions made such as how many buses should run today, the routes they need to take and have the buses reached the college premises. A kit has been developed in order to ease the work of the transportation department. Using this data collection will help in enhancing the experience of the passengers and also make the work of the transportation department easier. The two features that come in the transportation kit are: a license plate detection model to detect the number plate of buses and cars entering the college, which is developed using OCR and YOLOV7 model in machine learning and a bus tracking mobile application to track buses for students and faculty members, which is developed using Flutter and Firebase.**

Keywords— Students, Faculty, Transportation Kit, License Plate Detection, Bus-Tracking Application

I. Introduction

Rajalakshmi Engineering College has many great facilities especially like the transportation department. It provides transportation from home to college and vice versa every morning and evening. Two solutions were required namely number plate detection and real time tracking for students and user side (students and faculty). This is a tool kit consisting of two features developed and given as a package to the college. The first project consists of a license plate detection system where machine learning is used to develop a model and detect the license plate with accuracy and automate the system of registering buses which enter the premises of the college.

The second part of this project is the live tracking application. Students and faculties some days tend to miss their buses or in general want to plan when they can leave their houses depending on where the bus currently is. This is also useful for parents to track the buses to see if the student has reached college or vice versa. In conclusion, these two features together will definitely play a vital role in helping the transportation department and the many students and faculties who are using it.

II. Literature Survey

A. Object Detection Models

A paper was by Rantelobo, K., Indraswara, M. A., Sastra,N. P., Wiharta, D. M., Lami, H. F. J., &Kotta, H. Z. had the title “Monitoring Systems for Counting People using Raspberry Pi 3”. The objective of this study is to develop a monitoring system for population counting in a room using a visual sensor in a Wireless Sensor Network (WSN) environment. The system can determine the number ofpeople in the room from the image processing results and then send that information to the web [9].

A paper by T. A. A. H. Kusuma, K. Usman, and S. Saidah had the title “People counting for public transportations using you look once method”. This research is suggested so that the service operator can use image processing with the You Only Look Once (YOLO) method [15].

A paper by ZahraasalahDhaief Al-Mustansiriya had the title “People Counting Technology”. The proposed approach turns a color image into binary. The suggested method employs erosion and dilation methods to remove noise from the image, which may also contain noise. The technique relies on pre-existing packages to speed up development. Java is used to implement the suggested methodology [14].

A paper by Kasper-Eulaers, M., Hahn, N., Berger, S., Sebulonsen, T., Myrland, Ø.,&Kummervold, P. E. had the title “Detecting Heavy Goods Vehicles in Rest Areas in Winter Conditions Using YOLOv5”. You Only Look Once (YOLO)v5 can be used to detect heavy goods vehicles at rest areas during the winter. In order to determine whether the front cabin and the back are sufficient characteristics for heavy goods vehicle recognition, transfer learning was applied to YOLOv5 because these photos often contain a high number of overlaps and cut-offs of vehicles. The front cabin of heavy goods vehicles can be detected by the trained algorithm with a high degree of confidence [16].

A paper by Yonten, Jamtsho, PanomkhawnRiyamongkol, RattapoomWaranusast had the title “Real- time license plate detection for non-helmeted motorcyclists using YOLO”. The real-time LP detection for non-helmeted motorcyclists utilizing the real-time object detector YOLO (You Only Look Once) is presented in this work. A single convolutional neural network was used in the suggested method to automatically identify a non-helmeted motorcyclist's LP from the video stream. The false positive caused by the helmeted rider leaving the video frames was removed using the centroid tracking approach

DOI: rp-9788770040723.031

and a horizontal reference line. 98.52% of all LPs were detected overall [17].

B. Object Detection Model with License Plate Reading

A paper by R.A. Lotufo, A.D. Morgan, A.S. Johnson had the title “Automatic number-plate recognition”. The study's goal is to create a computer vision-based automatic vehicle identification system that uses optical character recognition (OCR) methods to identify vehicles. Investigations on real- time automatic number-plate recognition and its application to other aspects of monitoring and controlling road traffic are part of the effort [1].

A paper by Arth, C., Limberger, F., &Bischof, H. had the title “Real-Time License Plate Recognition on an Embedded DSP-Platform”. The proposed system operates in real-time while processing a video stream on an embedded DSP platform. A region-based method is used to partition detected license plates into separate characters. Support vector classification is used to classify characters. A Kalman tracker is incorporated into the system to quicken the embedded device's detection process. Additionally, the classification accuracy is increased by combining the findings of successive frames' classification [3].

A paper by Silva, S. M., & Jung, C. R. had the title “Real-Time Brazilian License Plate Detection and Recognition Using Deep Convolutional Neural Networks”. 2017 30th SIBGRAPI Conference on Graphics, Patterns and Images. Deep Learning (DL) techniques have lately been used in the context of ALPR, as they have in other computer vision tasks, with a focus on country-specific license plates. In this study, a state-of-the-art Convolutional Neural Network architecture-based end-to-end DLALPR system for Brazilian license plates was suggested [7].

A paper by Qadri, M. T., & Asif, M. had the title “Automatic Number Plate Recognition System for Vehicle Identification Using Optical Character Recognition”. The goal is to create a successful automatic approved vehicle identification system that makes use of the license plate. The created system first recognises the car before taking a picture of it. Using image segmentation in an image, the region containing the vehicle number plate is extracted. Character recognition is done using an optical character recognition technique. The obtained data is then used to compare with the records in a database [13].

A paper by Laroca, R., Severo, E., Zanlorensi, L. A., Oliveira, L. S., Goncalves, G. R., Schwartz, W. R., & Menotti, D had the title “A Robust Real-Time Automatic License Plate Recognition Based on the YOLO Detector”. A two-stage method specifically for character segmentation and recognition using low-tech data augmentation techniques like reversed license plates (LPs) and flipped characters was created. The resulting ALPR method produced remarkable outcomes in two datasets. The trial versions of commercial solutions had recognition rates under 70% for the suggested dataset [10].

1) Drawbacks:

From all the Literature Surveys the following problems/gaps have been identified: -

The models which were used where of lower versions better versions have come up for example the version used is YOLOv7.Inference speed for the version YOLOv7 is 114 FPS as opposed to the comparable YOLOv5's 99 FPS, and YOLOv7 also achieves greater accuracy (higher AP by 3.9%). The YOLOv7 gets a 21 FPS faster inference speed than the YOLOv5 when compared to models of a comparable size. Accuracy can be improved with the collection of dataset being manipulated to suit our needs.

C. Bus-Tracking Application

A paper by Rahman, Mir SazzadurHaque, SM. HasanHafizul had the title “Location Based Service for the Mobile users using the GPS Technology”. Some of their mobile application developers created some LBS services using the LBS API offered by the cell operator. However, this is notavailable at the moment due to the platform's development of security. Consequently, the GSM network can provide a mobile user's location information [2].

A paper by Battin, P., &Markande, S. D. had the title “Location Based Reminder system using Google Maps”. Here it added a few permissions to allow the Android SDK to retrieve the user's location. This software runs flawlessly on Android Oreo, but other comparable apps won't. Google Maps directions: Get driving instructions from the app to the task location. Address Search: Use the place picker to look up addresses to add location reminders. Setting location reminders is now simple. Reusable reminders allow you to easily reset them without having to add them again and saves great effort [4].

A paper by Muhammad NurZakiJuhari and HasmahMansor had the title “IIUM Bus on Campus Monitoring System”. The goal of this project is to provide a low-cost, real-time campus monitoring system for IIUM buses. Students at IIUM must wait for the bus without knowing when it will arrive, which is a huge waste of time [5].

A paper by WillianMuliaMirandaa, Ricardo Tavares RibeirodeMendonçaa, AllefAndersondaSilvaa, André Márciode Lima Curvellob, FlávioLuís dos SantosdeSouzaa and Henrique JosédaSilvaa had the title “BusMe: Automatic Bus Localization System and Route Registration”. The solution unifies GPS transmitted data from buses to Android applications using Amazon AWS as the cloud backend. The terminal is a Raspberry PiTM that transmits data using an HSDPA module and a GPS receiver. It is put in the bus. The received data is plotted in real time using Google MapsTM in the Android application, enabling the user to see where his preferred bus is and even where it is on its journey [6].

A paper by Jisha, RC., Mathews M. P, Kini, S.P., Kumar, V, Harisankar, U V., &Shilpa, M. had the title “An Android Application for School Bus Tracking and Student Monitoring System”. The suggested technique offers a technical solution for the above issue, which occurs occasionally and necessitates pupils waiting a significantly longer period of time for their school bus to arrive. The

DOI: rp-9788770040723.031

system comprises an Android application with Internet access that communicates with a server. The system also offers authentication, attendance monitoring, and vehicle tracking. Using this Android app, parents may monitor the bus's movements at all times [8].

A paper by S.Sabareesh, S.Sibicharavarthi, K.Vishnu, N. Mohammed Illiyas and K. Naveen Durai had the title “Location-Based Bus Tracking Application Using Android”. The main goal of this article is to gather GPS data and transfer it to a Firebase server, from which an Android application will retrieve it and display the bus' real-time location on a Google Map that is included into the Android application [11].

A paper by S., Islam, T., Olanrewaju, R. F., & Binyamin,A. A. had the title “A Cloud-Based Bus Tracking System Based on Internet-of-Things Technology”. In order to save time, energy, and human involvement, a cloud-based bus tracking system based on IoT is proposed in this study. The precise location and arrival time of the bus can be recorded dynamically using a mobile application. Additionally, by paying online, customers can purchase tickets without standing in line and reserve the available seats [12].

A paper by BadghainyaAnchal, MaripallyLokesh, MohdSaleem, UmamaMahreen, Ramesh Alladi, had the title “Smart Bus Tracking Application using IOT”. Building a mobile application for real-time bus tracking is the paper's main goal. The system offers the necessary data, including the driver's contact information, the route specifics, the average waiting time, and the anticipated arrival time. The flutter framework is used to create the mobile application, and a real-time firebase database integrated with a Node MCU is also used [18].

A paper by N AyushUbale and DrMohdTajammul had the title “efficient model for automated school bus safety and security using iot and cloud”. This study proposes an SMS- based method for parents to monitor their children's school bus location. An RFID and GSM-based system is used to authenticate the student's identity and count the number of students in the bus. Parents receive SMS notifications about their children's location, and a visual studio application installed in the AWS cloud controls the system. [19].

A paper by Sourav Kumar, ShreyashMoundekar, MansingRathod and RupeshParmar and the title “Location-Based Bus Tracking Application Using Android”. An application that overcomes the shortcomings of the public transportation system was proposed. It gathers the necessary information, and using it, the bus is traced. Passengers can access these details at any time in real time [20].

1) Drawbacks:

From all the Literature Surveys the following problems/gaps have been identified: -

This system developed using Flutter instead of native Java as Flutter supports Cross-platform development (Android and IOS), It has higher development speed it supports multiple platform which require only a single code base, the cost of development is reduced and the amount of resources and libraries are much higher compared to Java [21-23]. The database used for this system is google firebase. This database service is much preferred compared to other database providers because the learning curve for other database services such as AWS Amplify and Microsoft Azure SQL as a whole are actually steeper, since there are a number of things that are quite difficult to implement [24- 26]. Old version of Google Maps API causes the accuracy of location to be low and the app does not work when the phone enters sleep mode, the distance between two geo locations have been calculated manually, only one bus is able to be tracked and the cost of Amazon AWS and usage of IoT are expensive.

2) Common Deficiencies:

From all the Literature Surveys the following problems/gaps have been identified: -

A better model can be used for object detection. Accuracy can be improved with more dataset which is manipulated to our needs and for the bus-tracking application, mostly IOT is used along with old location frameworks. Hence they tend to not be user-friendly. IoT is comparatively expensive and data handling via IoT is difficult.

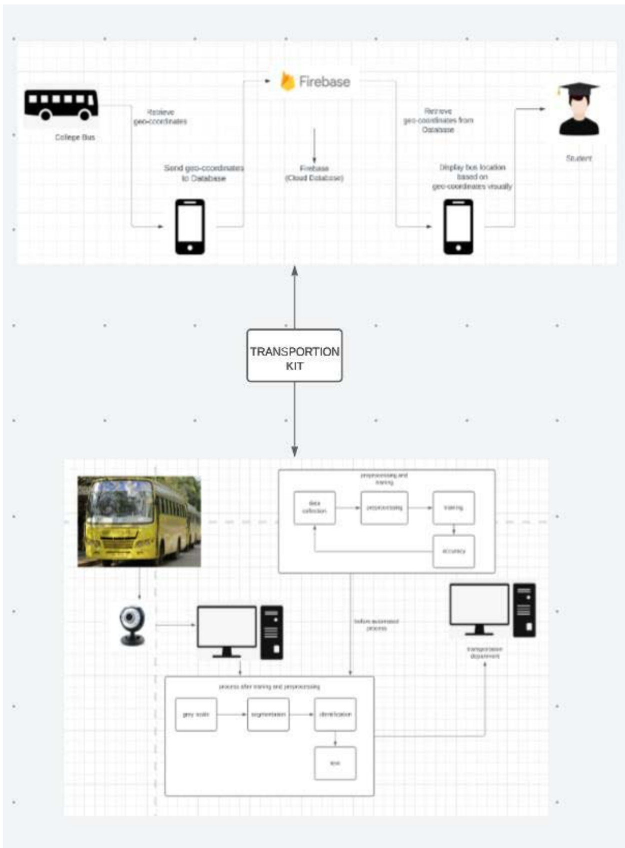

Fig. 1. Transportation Kit System Architecture

A. *License Plate Detection and Recognition*

The system that is proposed is to make the detection model using the yolo (you only look once algorithm). Many projects use the 5th version to make their projects but now there is version 7 which is superior to its predecessor, hence

DOI: rp-9788770040723.031

for the detection model the yolov6 or yolov7 algorithm will be used. For the Optical Character Recognition algorithm, a simple algorithm can be written which will pair properly with the object detection model being used. For better efficiency Theos AI tool is used to train test and split. Using the same tool, we can label our dataset. Once the dataset is labeled it is trained using YOLOv7 algorithm. It is then paired with OCR code to read the letters that is present inside the detected license plate.

III. Proposed Work

This section provides the proposed methods for the three projects in the kit respectively.

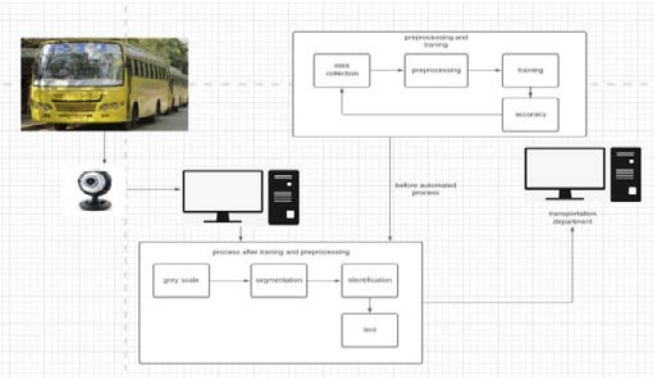

Fig. 2. License Plate Detection and Recognition System Architecture

The dataset will consist of multiple images and videos since it is only the license plate of the buses which needs to be extracted. The dataset can be manipulated to suit our needs and ultimately improve accuracy.

B. Bus Tracking Application

The proposed system for the bus-tracking system is a mobile application. With this application students and faculties will be able to find the location of their respective buses with ease in a short period of time. The only requirement needed to use the application is a mobile device with active internet connection and feature to access the location.

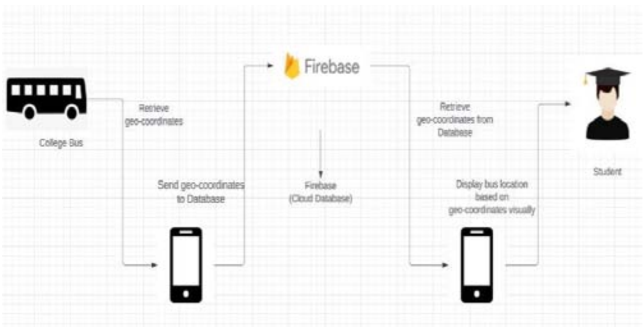

Fig. 3. System architecture for bus-tracking application

As mentioned above, the technologies used here are Flutter to build the mobile application and Google Firebase to play the role of the database. Two applications are developed using Flutter (Driver App and Student App). Once the driver logs into the application using the credentials provided by the Transportation Department, the bus number mapped to that particular account gets retrieved into the application. The driver will then be able to start streaming his location by clicking the 'Start' button. That location stream is sent to the Firebase database along with the bus number. In the student application, the student can log into the application using their college mail and start tracking their bus live by selecting the bus number.

Firebase makes this job easy as it is accurate with data and has an immutable class called 'GeoPoint' in-built which allows to easily work with location coordinates. On the other hand, Flutter provides smooth functioning of the mobile application with a clean user interface [27-30]. The proposed system helps combat the problems/gaps in the existing system using the following methods - New version of Google Maps along with geolocation package is used in Flutter which has a lot of in-built algorithms which enhances the time complexity and user efficiency, there is no limit to the number of buses to be tracked and only Firebase is used as the database and two apps (Driver App and End-User App) are being used, thus eliminating the need of IOT devices and thereby reducing costs.

IV. Results and Discussion

Based on the comparison and differentiation performed with the existing systems mentioned above, some of the advantages of the proposed system are:

a) *Recognition of model :*Our model is able to regognize the licence plate and is able to read the plate with a confidence of 60-70%.

Fig. 4. Object detection and recognition result

b) *Bus tracking driver app:* In this application the driver can start/stop streaming his live location.

DOI: rp-9788770040723.031

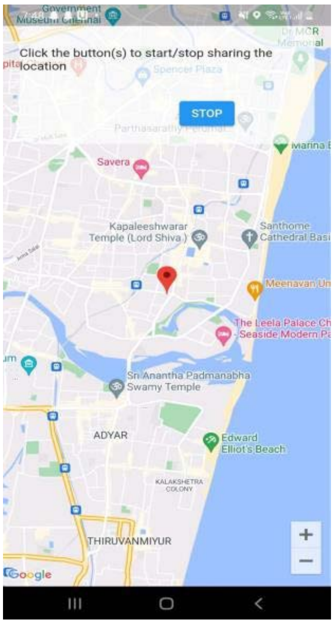

Fig. 5. Bus tracking driver app

c) Bus tracking student app: In this application the students can select their respective bus number and start tracking their bus live location.

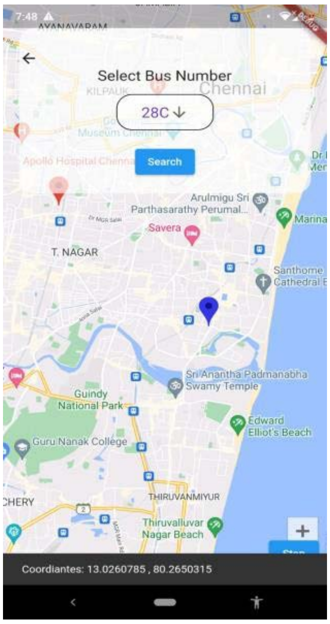

Fig. 6. Bus tracking student app

d) *Firebase database:* Due to its accuracy with data and built-in immutable class named "GeoPoint," Firebase makes this task simple by enabling simple working with geographic locations.

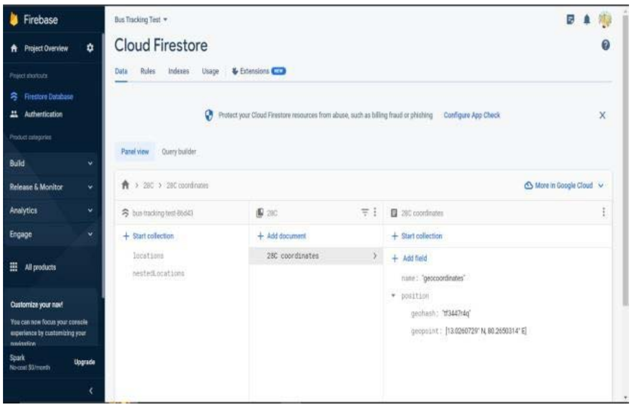

Fig. 7. Bus tracking firebase database

V. Future Endeavor, Scope And Conclusion

In this paper, the main objective is to ease the work of the transportation department by providing them with easy-to- access products which helps them in managing their resources efficiently. In conclusion, these three kits together will definitely play a vital role in helping the transportation department and the many students and faculties who are using it.

Future modification can only be made with feedback from the user side for example the plate detection system can only be tuned better after seeing the accuracy it has generated after detecting the bus's number plate. Similarly for other models future works and enhancements can be made purely based on user feedback.

***Abstract* — This paper presents the design of Talking Gloves which converts Sign Language to Speech. The project's main aim is to develop an affordable communication aid which can help the speech and hearing impaired people to express their thoughts and opinions without any difficulties, thus bridges the gap between two different groups. Specially challenged person can also uplift their career with the help of Talking Gloves. When speech and hearing impaired people wear that glove, they can communicate through sign language easily just by bending their fingers. The respective output is heard from the speakers using the DF mini player which reads the SD card and selects the sample voices stored in it and the corresponding text is also displayed using the LCD with I2C module.**

Keywords —Arduino UNO, LCD with I2C module, DF-mini player, speaker, Resistors.

I. Introduction

People with hearing and speech impairment had difficulties in communicating in the society till now while others do not understand this sign language as it involves the orientation and movement of hands, arms/body, combining of various hand shapes and various facial expressions to express the thoughts. A new communicational aid is developed which converts the hand gestures into speech output which enables deaf and dumb individuals to interact verbally with the other people and share their thoughts and opinions.

The device of communication is a "The Talking Glove". The glove is fitted with the flex sensor whichmeasures the change in resistance based on the degree of bend it is subjected to. The values of the flex sensors is compared with the data alreadystored and the respective speech is heard using Speakers as played by the DF mini Player.

II. Literature Survey

The work related to Sign language conversion using Arduino Mega, Bluetooth, flex sensor, ARM controller is described in this section.

SanishManandhara et al [1] The Hand Gesture Vocalization was proposed by him for Speech and Hearing impaired people. This system includes Arduino Mega, Accelerometer and Flex sensors, which is used to translate the given hand gesture into its proper form of text, audio, and graphical representation, which is easily understood by any other common person. In the current system, the training model predicts the accurate output with a percentile of 85 which makes of the Random forest algorithm.

Mangesh T Nikam et al [2] put forward a system consisting of 3 axes accelerometer sensor being mounted on hands. The system for Deaf and Dumb People is named as Talking Hands. The micro- controller senses the movements using the accelerometer with the help of ADC. Each movement is set with a specific word and this movement is read by the micro-controller and makes the Voice IC to play that particular pre-recorded message.

KshirasagarSnehal P et al [3] proposed gesture vocalizer for deaf and dumb. The proposed systemuses AVR microcontroller (ATmega16), flex sensor, accelerometer, speech synthesizer, speaker, and LCD.Flex sensor detects the degree of bend and its output along with the output of the accelerometer are converted to the digital values where they are compared with the prerecorded values and the corresponding audio is played via speaker and the text message is displayed using LCD.

SupriyaShevate et al [4] proposed a Vocalizer based on Gestures for Hearing and speech impaired people. This vocalizer detects all the hand movements and converts it into an audio and displayed on the LCD screen. For all speech synthesizer and sensors ARM 7 controller is used. Two types of accelerometer and flexible sensors as a titled sensor are present in data glove.

Mali PoojaDadaram et al [5] proposed a system using gloves with Flex Sensors and Arduino to convert Sign Language to Speech. This method uses a flex sensor and microcontroller such as Arduino UNO attached to glove, while the data is transferred, the LED will light up. With respect to each touch a change in resistance which is uniform is made by the rotation detector and the hand gestures are analysed. This process is completed in controller. The values are compared according to the touch in the website, and audio and text are generated as output.

Khan, Mubashir et al [6] proposed "SignTalk and animator for speech and hearing impaired." This system uses flex sensor, Arduino Nano, accelerometer, gyroscope and bluetooth where the hand gestures are converted to digital values using ADC.These values are sent to mobile phones through Bluetooth and the respective audio is played.

Boppana, Lakshmi et al [7] has put forward a system for Deaf and Dumb, an Assistive Sign Language Converter. This device enables a person to interact with other people where controller processes images, compared with samples using processing techniques and identifies signals with in-

DOI: rp-9788770040723.032

depth reading models. The text-to-speech module converts these features to real-time speech.

Rajaganapathy S, Aravind B, Keerthana B, Sivagami M [8] "Conversion of Sign Language to Speech with Human Gestures". This system uses Microsoft Kinect to track the human joints and gestures. The stream of input data is the live actions of human skeleton. The System keeps tracking with the user defined gestures if both the gestures are matched the corresponding word is played.

Aishwarya V, NarenRaju N, Singh S Johanan Joy, T NagarajanVijayalakshmi P [9] "Hidden MarkovModel-Based Sign Language to Speech Conversion System in Tamil." This work constitutes the use of accelerometer, gyroscope sensor-based hand gesture that recognises various signs and converts into corresponding Tamil phrases.

Harini R, Janani R, Keerthana S, MadhubalaS,Venkatasubramanian S [10] "Sign Language Translation". This system consists of image capturing cum processing, feature extraction and conversion by using OpenCV python library. The prediction can be done with atmost accuracy and it also uses convolution neural network.

ParamaSridevi, Tahmida Islam, UrmiDebnath, Noor A Nazia, RajatChakraborty, Celia Shahnaz. [11] "Sign Language Recognition for Speech and Hearing Impaired by Image Processing in MATLAB".The proposed system converts the sign language to speech using MATLAB where it extracts the features of the hand gestures and it is compared with the already stored features in the database and produces the output depending on the highest resemblance.

YashJhunjhunwala, Pooja Shah, PradnyaPatil [12] has put forward a direct algorithm which converts the basic Alphabets and numeric which will be further extended for recognition of words.The glove uses flex sensor which monitors the amount of bend which in turn relates the change in resistance.

III. Existing System

In the existing system, the glove translates the American Sign Language alphabets to speech using Arduino Nano. The glove uses flex sensors, accelerometer and HC-05 bluetooth module to connect the glove to the mobile phone. This system is not efficient enough to help the speech and hearing impaired people to communicate with others.

IV. Proposed System

The proposed method involves the use of flex sensor in the place of image processing technique. Initially, the hand gestures are converted to analog signal, then it is converted to digital signal with the help of ADC from the Microcontroller. The digital signal is processed in the Arduino and the corresponding is heard output.

The Figure 4.1 and 4.2 decribes the block diagram and work flow of the proposed system.

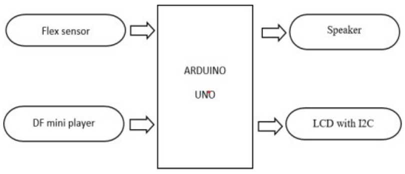

Fig. 4.1. Block diagram

Fig. 4.2. Work flow

V. Working Principle

Initially a power supply of +5V is given to the circuit as an input. Arduino Uno acts as a microcontroller and the code is executed using the software Arduino IDE. The Flex Sensors detects the change in the resistance based on the degree of bend it is subjected to. The output of these flex sensors are analog in nature which are sent to the Arduino where analog signals are converted to digital and this digital information is compared with the already stored data in Arduino. If the output from the flex sensors are matched with the stored data i.e., the string or alphabets, then the respective output is heard from the speakers using the DF mini player which reads the SD card and selects the sample voices stored in it.It also displays the output speech to text using the LCD16X2 with I2C module.

VI. Results and Discussions

The proposed scheme provides a interpersonal communication between the two groups easily by converting the hand gestures into speech. The additional feature of this system is to display the output speech into text using the LCD with I2C module. So, this project is quite feasible and easy to operate which breaks the gap

DOI: rp-9788770040723.032

between both the communities. For convenience few actions are translated and the output is shown.

The Figure 6.1. Signifies the hardware connection that is required for converting sign language to speech.

The Figure 6.8 and 6.9 depicts the graphical representation between the change in the resistance versus the degree of bend of the flex sensor and the time response of the flex sensor to change the sign language to speech with respect to voltage.

Fig.6.8. Relationship between the variation of resistance and degree of bend.

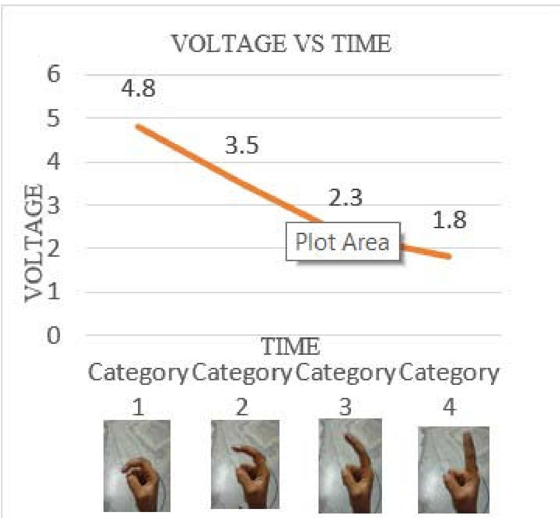

Fig.6.9. The time response of the flex sensor to change the sign language to speech.

VII CONCLUSION

In this project, we developed a system using a glove which provides an opportunity for the speech and hearing impaired people to communicate with others easily. The use of flex sensors, DF mini Player, Speaker, Resistors onto a glove helps to reduce the gap between the two different groups of people. This device will suit better for all the people with various oral disabilities. This project can be further enhanced by integrating with various services which helps to increase the employment for the deaf and dumb people .This can be paired up with fitness sensor to monitor health of the individual. Further, they can be geared up with the controller to provide home automation on finger tips.

Abstract*— The identification of individuals based on their distinguishing biological and behavioral attributes is the focus of the newly growing field of biometrics. Biometric algorithms play a significant role in the efficient operation of identification technologies, which are used for a variety of tasks such as identification, access control, and surveillance. The purpose of the study is to examine the various biometric approaches and performance levels employed in the development of biometric technology. The survey's results are listed below. The many phases involved in developing a biometric system, such as data collection, feature extraction, pairing, and choice, will be described in the next section. The study's primary focus will therefore be on evaluating biometric algorithms, coupled with performance metrics including accuracy, untrue admission rate, and non-match rate. To examine the efficiency of several biometric algorithms, benchmark datasets including the Biometric Vendor Test and the Fingerprint Identification Competitor will be used. Future breakthroughs in biometric algorithms are also covered, including the development of hybrid techniques that integrate several biometric modalities for improved performance and the use of deep learning techniques for feature extraction and matching. Identifying key properties inside a biometric, such as a face's specific form or the grooves of a biometric, is referred to as feature extraction. All of these traits are being used to create a unique foundation for each person. The pattern generated from the biometric data is compared to a dataset of previously stored data in the comparison process. Overall, the biometrics approach is a complex and advanced procedure that needs specialized expertise and tools to be successful. With the popularity of biometric systems growing, more scientific study will be needed to improve the accuracy and dependability of the systems. Suggestions to improve the accuracy of the system, the biometric would be best option.

***Keywords*— Security environment, biometric authentication, and biometric technology authentication, verification, performance metrics.**

I. INTRODUCTION

The word "bio" as life, "metria" as measuring are source of the word "biometry." The method of assessing specific body characteristics of individual using automated systems is our goal in the area of security sciences, and it is referred as biometric identification. To use a specific technique to identify or validate a person is one way to increase security for the purpose of person verifying and identifying attributes utilizingbiological and behavioral types, biometric systems are used. The two primary types of biometrics are: biological or behavioral traits. The most trustworthy and secure solutions to traditional means, such as knowledge-based and token-based systems, are faces, fingerprints, veins, and speech. Uni biometric systems have a number of issues, including inconsistent biometric data, a poor recognition rate, the ability to be easily fooled, and others. The multimodal biometric system's sensor measuring unit receives information from several attributes. A biometric pattern identification system compares biological or behavioral characteristics of a person's biometric attributes to determine their identity. A biometric system is an automated identification method that uses a person's distinctive traits to identify individuals.

Identification: By comparing the biometric test sample to the trained structure recorded in the database, the authentication of a person is carried out.

Verification: By comparing the test image to the alleged biometric characteristics in the database, the authentication of a person is carried out.

Verification and identification are the two crucial building blocks of human identification in the biometric system. As was said above, each block is used in a variety of applications and under various circumstances. The selection is made after comparing the image to the databases' recorded photos, which makes the identification procedure more difficult and expensive. In contrast, one-to- one matching is carried out in the verification system.

II. LITERATURE REVIEW

A. *Access control-based remote authentication method for multi-server environments.*

Min Zhang, Wen-Rong Tan proposed the importance of the user's access log on the website has significantly increased. Additionally, the site analytics service is extensively utilized and is now frequently effective. This study's goal is to provide behavioral biometrics that may be used to forecast a user's level of interest in a particular product by looking at website access data. We carried up an experiment in which the participants were instructed to purchase online. Comparative analysis is done between the amount of interest in a certain category of goods that is expressed in an interview and the website access logs recorded throughout the purchase process. The findings reveal that there were considerable differences between the web-searching activity patterns and several factors based on the access log.

The multi-server authentication technique provides a

DOI: rp-9788770040723.033

number of advantages over the single-server scheme, including a lot of benefits. Users don't have to remember several passwords or sign up for each application server for instance.

B. Fusion of Hand-Based Feature Levels for Biometric Recognition of Single Sample.

Yanqiang Zhang; Dongmei Sun; ZhengdingQiu proposed the real-world applications, one sample biometric recognition may produce subpar recognition results. We describe a unique feature level biometrics fusion method to address this issue by fusing the palmprint and middle finger picture, both of which may be obtained from a single hand image. The pictures of the palmprint and middle finger are first used to determine the local embedding subspaces using a manifold learning technique, and the concatenated feature is then extracted using principal component analysis (PCA). This would result in good performance since the local structures of individual biometric models would be kept while the redundancies between them would be minimized. The testing findings showed the average recognition rate of score level fusion and single modal biometrics, in comparison to recommended strategy received a considerable boost, reaching 98.71%. To show the effectiveness of the suggested fusion strategy, performance comparisons of the cumulative matchcharacteristic (CMC) curves for various recognition algorithms were also made.

C. The Federal Bureau of Investigation uses forensic biometrics from images and video.

Nicole A. Spaun proposed According to the forensic Sound, Live feed, and Photogrammetric Unit employs forensic examiners who carry out tasks including human identification (from images and videos), which includes height estimation and comparisons of the face, ears, hands, and feet. Exams are carried out without the use of automated biometric software. The amount of case, it is predicted that automated biometrics would improve examination process efficiency and give statistics and likelihood rates that may be used as evidence in court. It provided funding for research initiatives on ear and facial individualization in order to create such biometric systems. The planning more study on hand, ear, and face biometrics.

III. Biometrics Implementation

Unique identifying systems with high operational accuracy are definitely needed. Biometric authentication is one approach for this, where the distinct traits that are mostly unchanging and unforgeable are all being investigated. There are several such characteristics, like the well-known eye, palm, or optic. All while these technologies do have weaknesses, they nonetheless provide significantly better safety than knowledge- or ownership ones. Various categories may be used to classify biometric security methods, but from the viewpoint of the reader, three things stand out: the amount of the gadget requires physical touch to work, and the recognition period (which includes the level of user cooperation/effort, any additional time required for location or other recognition operations. Regarding the consumer, the accuracy and security are the key factors, which ensure a negligible amount of erroneous acceptance. Since many users have hygiene issues about devices that many other users also contact, contactless technologies are frequently selected. Although this concern unfairly disadvantages biometric identification methods, user acceptability is nevertheless a crucial element in the effective implementation of such system. Dentification time is often minor compared to the entire access cycle,but it depends on the user's amount of cooperation, which implies that it might vary widely. The performance of the algorithms in the systems now in use is often under a second, but no longer than a few seconds. Improper system utilization is the source of the problems. A person finds an only one refusal irritating, and numerous failures may require the action of the guard force based on the safety rules in place, having caused backups in the entrance waiting list and significant disadvantage for the telecommunication services. But even so, consumers must acknowledge that these instances will everyone in a while give rise and may not be totally eradicated. Various surfaces and indications may assist the user in this. By eliminating some degrees of freedom, we can lower the likelihood of inaccuracy. Indications with restrictive materials to restrict freedom levels to one help the operator, making failed identification with that technology very uncommon. Hand geometry identification is an excellent illustration of this. On the other hand, this implies an increase in the need for physical interaction, which might result in user unhappiness given the previously mentioned concerns.

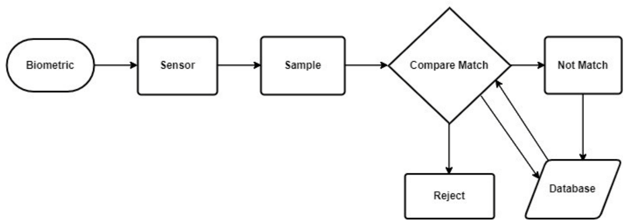

Fig: 1. Biometric system

IV. Biometric Technologies Comparison

The preceding point's biometrics remedies may be categorized and compared using a variety of criteria and measures. Such an analogy will give guidance when coordinating the installation of a new technology and aid in outcome prediction.

- FAR: This demonstrates how frequently a system will identify an unauthorized user as authorized, weighed in percentage.
- FRR: This demonstrates how frequently the system will treat a legitimate user as anunauthorized one and deny access calculated as a percentage.
- GFRR: This illustrates the FRR of a device in real-world conditions, including user mistakes, with the assistance and expansions of [1] ABI's research %-based measurement.
- FTE: This demonstrates the number of persons that might not be registered in the system and are thus unable to utilise it. calculated as a percentage.

- SPOOF OF RISK: It demonstrates how easy the system may be thwarted by various means (for example, displaying simply a picture of the fingerprint to an optical fingerprint scanner instead of a real one).
- SAMPLE LIVE DETECTION: This demonstrates if the system can tell the difference between a real user and a spoofing attempt.
- ACCEPT USER: This demonstrates a user's overall acceptance of the technology, together with their readiness to cooperate and any misunderstandings or anxieties that may have affected their acceptance.
- REQUIREMENT CONTACT: This demonstrates if the user must remain in close proximity to the gadget in order to carry out the identification.
- BIOMETRICS STABILITY: This demonstrates if the sample evolves ovetime and whether any outside influences may be present.

V. Problem Statement

These issues inevitably lead to another one, which is that choosing a biometric solution for a security project is totally based on opinion. For instance, a well-known partner may advise something, or a consumer may choose for a well- known company's well-publicized system. The whole distribution chain is characterized by this ignorance. Manufacturers make claims about their goods, distributors buy them based on arbitrary pricing and value standards, and designersandpotential customers utilize this information to choose the system. No independent, trustworthy sources exist that could offer information on whether the system is capable of carrying out a specific job or not. Even safety firms and specialists are bumbling throughout the dark and frequently carry out the necessary checks itself. However, the majority of these businesses short in time, finances, and expertise needed to conductsuch tests in a logically sound and repeatable manner.

Geometry recognition in hands	Unique alterations	Personal verification, tracking attendance	sensitive innovation

VI. Conclusion

Human identification by biometrics is based on physiological and behavioral traits. Condensed biometric scanners come in many different varieties, computers can analyze enormous volumes of data, and developing biometric authentication systems is readily affordable in today's technologically advanced world. In addition, the threat of terrorism still exists in the modern world, and rigorous security and monitoring measures have emerged as a major worry. Because biometric technologies outperform traditional security measures, they are now a wise alternative for authorization, employee identification, and access control. This article provides key facts about biometric technology to assist novice researchers in selecting a subject in this area based on their preferences. Information has been provided on everything from the fundamental design of the biometric system to recently developed biometric technologies. Researchers have proposed two distinct state-of-the-art designs for access control biometric systems (uni-modal and multi- modal). One must have finally come to the conclusion that a multi-modal biometric system offers greater accuracy than a uni-modal one.

***Abstract*—Annually, more people are admitted to hospitals, and some of them require routine blood pressure checks from health professionals. In order to ensure that the results are correct, the medical team must usually visit to the person and take many readings during each session. As a result, Malaysian hospitals, tracking procedures need to be made simpler. The Hypertension tracking system powered by the internet of things used in this study is created to directly monitor patient hypertension. In this project, the Raspberry Pi serves as a portal for viewing the hypertension number online. The system can transmit data from a blood pressure monitor across a network using a USB TTL serial connection that is connected directly to a Raspberry Pi, according to test results. The WhatsApp app and email platform both allow users to continuously monitor their hypertension. Additionally, the technology can precisely measure hypertension while the person is seated.**

Keywords*— *Hypertension, Email, Internet of Things, Raspberry Pi, WhatsApp.

I. Introduction

In its most latest report, the National Compliance Department noted that several Malaysian hospitals, ETD were overloaded, overworked, underpaid, and inadequately provided. The Department of Health is under enormous pressure to provide health care to all Malaysians towards the best of its abilities as the amount of patients keeps rising. Therefore, it is necessary to streamline the monitoring procedure within the Malaysian hospital. Having an online tracking system that displays every situation in engineering is simpler. One approach is to keep an eye on the patient's condition via the Internet of Things. Many technologies are being created and used today to improve the effectiveness of hospital administrators. An Internet of things hypertension tracker was created to assist hospital workers in tracking individual a patient's blood pressure reading. This will improve how doctors take decisions based on medical status in real time and decrease the reliance of patients on medical staff. For disabled people who may find it difficult to travel to the hospital to examine on their status, an Internet of things hypertension tracker is also helpful. The system has the capacity to move the location of medical services from the patient's house to the clinic. The hypertension trackingtechnique has recently experienced extensive research and developed from several types, including digital, aneroid, and conventional healthcare devices. It was suggested to use an Arduino-based health tracking system, where data is transferred to a computer for analysis using Software simulation. The Raspberry Pi module served as the processor in this system that sent the server the status of a patient's health tracking. The data was provided to a website that updates every 60 seconds, suggesting a healthcare tracking system. In contrast to many other works that employed databases to track the performance of the built system, this approach sends output to mobile applications and Email rather than a personal computer. The proposed method in this research is more mobile, allowing the doctor or hospital personnel to check on the patient whenever necessary. The remainder of the essay is structured as follows. The summary of the research methodology employed in this work is described in Section 2. Section 3 elaborates on the conclusions and analysis, and Section 4 is where the author draws a conclusion about the article's results.

II. Study Methods

Both computer and network execution are part of this project. Figure 2a flow chart shows the structure of the system that was created. The Raspberry Pi, which controls the entire system, is capable of detecting data from the hypertension gadget and transmitting it over the internet so that users may examine it in the WhatsApp and email applications. Anyone with the authority to examine the relevant data on the server can view this application.

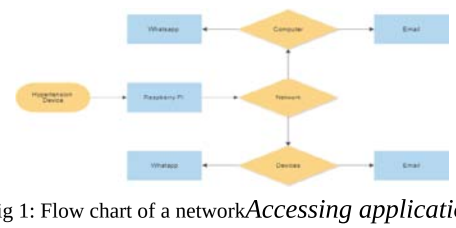

Fig 1: Flow chart of a network*Accessing applications*

A few software programs have been employed to ensure the project's effective completion and execution. A tracking tool called H-term is applied to read and view the analog data sent from a hypertension tracker to a personal laptop. The display of the H-term software can consistently

DOI: rp-9788770040723.034

show three different sorts of data on the hypertension tracker. Another piece of software used in this project was Putty, which was employed as a system file sharing tool. The software used to run the programme on the Raspberry Pi is called PuTTy. To utilisePuTTy, one must confirm that the Raspberry Pi's IP address has really been verified and entered properly. To ensure that the PuTTy and the Raspberry Pi device can connect, this is done. It demonstrates that the Python scripting language is run using the PuTTy technology. If a user turns on the hypertension monitor, the system activates. The user must then wait for the device to detect their hypertension. Before being sent to email and WhatsApp, the results will first be presented in the Juice SSH program. A helpful Android software that makes it simple to operate Linux servers is called JuiceSSH.

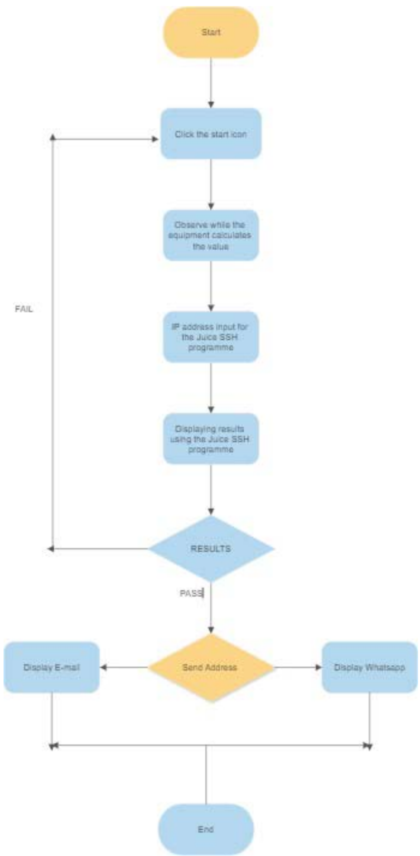

Fig 2: Flow Chart

A. *Structure of the devices*

The information from the hypertension sensor is sent to a personal laptop using a Universal Serial Cable to TTL Wired connection. In this project, there are two ways to access the internet: using an Ethernet connection and a wireless adaptor. In this design, a Raspberry Pi model B+V1.2 with 40 General-Purpose Information pins is used. Linking the USB cord to the PC will provide the Raspberry Pi with the 5 volts it needs to turn on. The wrist-mounted hypertension tracker utilised in the experiment has the product code CK101. Using a USB to the Universal Asynchronous Receiver Transmitter cable, the hypertension information from Electrically Programmable ROM will be sent to the PC. Figure 3 shows the hypertension device used in this experiment.

Fig 3: Hypertension Device

III. Result and Discussion

The wrist-mounted hypertension tracker is linked to the Raspberry Pi with a USB wire. The WiFi dongle is then attached to the Raspberry Pi to provide internet access. The data must be transferred via a Bluetooth link in order to use the Networks.

A. *Results on WhatsApp and email*

It depicts the Whatsapp application displays, while it shows a screen grab of an Email. Basically, the hypertension values, a description of the findings, and a date regarding when the information came were all presented on both devices. According to the American Heart Association (AHA), hypertension is deemed to be normal if it is less than 120 mmHg and high if it is around 120 and 129 mmHg. The remainder is classified as systolic, stage 1, or stage 2. Based on the data, a summary is generated by the software according to each person's systolic readings, regardless of whether they indicate a healthy, lower, or high hypertension measurement

B. *Hypertension accuracy depends on user location*

When the data was collected, the user's hypertension was healthy. In the sitting posture, hypertension appears normal. In the standing position, hypertension appears more, and in the laying position, hypertension appears down. When the user is seated and holding the device properly, the readings are most accurate.

IV. Conclusion

The establishment of an Internet of Things Hypertension tracking system utilizing a Raspberry Pi is discussed in this study. The system can read and transfer data to both the WhatsApp and Email applications, according to the results. The system has successfully undergone design and analysis. Future wireless connections between the Raspberry Pi andhypertensiontracker will allow for a more compact design. Additionally, the concept might be expanded to read additional medical devices like ECGs. Additionally, the system can combine many wireless technologies, including Wi-Fi, Multi-hop Wireless Systems, and Device-to-Device Connections.

***Abstract*—Plant seedling classification is a crucial task in the field of agriculture as it plays a significant role in the evaluation of the seedling quality and the prediction of plant growth and yield. With the advancements in computer vision and machine learning techniques, various methods have been proposed for automating this task, ranging from traditional machine learning algorithms such as decision trees and k-nearest neighbors to deep learning techniques such as Convolutional Neural Networks (CNNs). The choice of method depends on various factors, including the quality and size of the data, the computational resources available, and the desired level of accuracy. In recent years, deep learning methods have shown promising results in plant seedling classification due to their ability to automatically learn stratified representations of the data. Despite these advances, there are still significant challenges in this field, including the variability of seedling shapes, the limited availability of annotated data, and the difficulty of generalizing models to new species. To address these challenges, ongoing research focuses on improving the performance of existing methods and developing new methods that are more robust and generalizable. This proposed work deals with applying CNNs to the plant seedling dataset. The dataset contains 5545 train images and 794 test images, based on images of approximately 960 unique plants belonging to 12 species at several growth stages, when the models' convolution blocks were decreased, the reduced layers gave a validation accuracy of 93 percent, while the model without reduced layers provided a validation accuracy of 95 percent.**

Keywords—Convolutional Neural Networks (CNN), Deep Learning, Plant Seedling, Machine Learning

I. INTRODUCTION

CNNs are well-suited for plant seedling classification due to their ability to learn features from images and their effectiveness in image classification tasks. However, it's important to consider the specific problem and available data when choosing a machine-learning technique. The task of classifying diverse varieties of plant seedlings based on different characteristics is known as "plant seedling classification." Due to their capacity to automatically learn and extract information from pictures, convolutional neural networks (CNNs) are the popular choice for this purpose. However, depending on the issue and the data at hand, different machine learning models like K-Nearest Neighbors (KNN), Support Vector Machines (SVMs), and Decision Trees can also be used to classify plant seedlings.

Using decision trees, it is possible to categorize subtrees according to their size, form, and color. Decision trees may efficiently understand the relationship between the features and the target class by segmenting the data into smaller subsets based on the most crucial feature.

K-Nearest Neighbor (KNN) is a non-parametric classification method that can be used to categorize subtreesaccording to how closely they resemble known examples. The KNN algorithm can categorize a new subtree given a set of previously labeled subtrees by locating the k nearest neighbors in the training data and applying the majority class label.

By utilizing the spatial hierarchical learning of characteristics from photos, CNNs can be utilized to classify seedlings. To forecast the properties of a novel type of seedling, the network can be trained to recognize traits of the seedling, such as the form and texture of the leaves.

Support Vector Machines (SVMs), Random Forests, Naive Bays, and Artificial Neural Networks are additional methods that can be utilized for subtree categorization (ANNs). These methods can help in capturing intricate connections between things and target classes and in producing precise predictions based on learned models.

It is significant to remember that the technique used will rely on the particular situation, the data at hand, and the desired result. Synchronous learning is the process of using many methodologies and combining their predictions to produce more accurate predictions.

As can be seen from the above plot, The bar chart with the maximum number of images belongs to the class Loose Silky-bent. There is class imbalance with 5 classes having a really low number of images while 2 classes have a high number of images with the rest around the median.

Fig. 2 shows the class imbalance and can also be inferred from the pie chart, but this shows that it is not as steep as compared to the bar chart. It is advisable to normalize the count to give a better representation of the data present.

DOI: rp-9788770040723.035

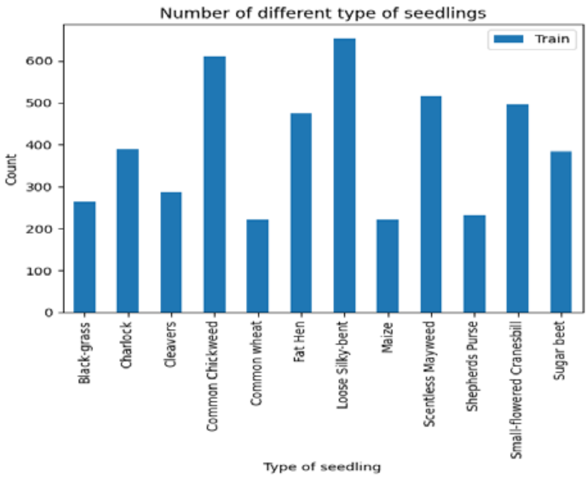

Fig. 1. A bar graph displaying the prevalence of various seedling kinds

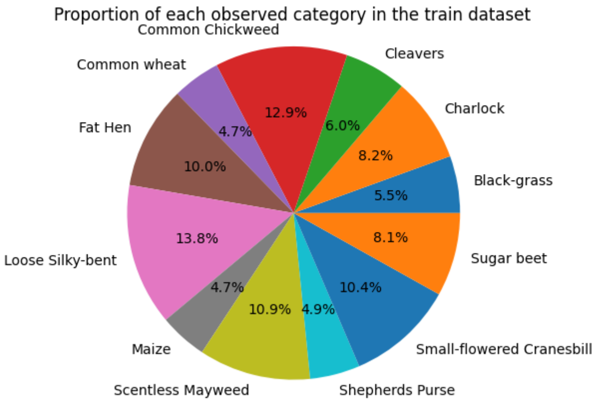

Fig. 2. Pie Chart representing proportions of each observed category in the training dataset.

II. Literature Survey

After surveying the available literature, we understand the architecture of learning methods, deep learning image models, transfer learning approaches using deep convolutional neural networks, and the methodology used to determine the classes of the plant seedlings.

A. *Convolutional Neural Networks have the following advantages:*

- Image Recognition: CNNs are particularly adept at classifying images because they can learn spatial feature hierarchies.
- Automated Feature Extraction: CNNs can recognize and learn about features automatically from input images, doing away with the requirement for manual feature engineering.
- Translation Invariant: CNNs can recognize entities in any location within a picture because they are translation invariant.
- Sparsity of Connections: CNNs are computationally effective due to their sparse connections, which enables them to process high-dimensional data such as images.
- Shared Parameters: By minimizing the number of parameters that must be learned, shared parameters in a CNN's convolutional layers enable the network to learn many features from various regions of the image.
- End-to-End Training: CNNs can be trained from beginning to end, increasing the automation and effectiveness of the learning process.

B. *Limitations are also there while using Convolutional Neural Networks, those are listed below*

- Data Diversity: One of the major limitations of current CNN-based methods is the limited diversity of the training data. Most existing methods use small and homogeneous datasets, which may not accurately represent the diversity of plant species and growth stages. To overcome this limitation, larger and more diverse datasets need to be collected and used for training the models.
- Transfer Learning: Another challenge is the limited availability of annotated data for training the models from scratch. To get around this problem, transfer learning—which involves fine-tuning previously trained models for the task—can be an effective strategy. However, the performance of transfer learning can be affected by the differences between the pre-trained model and the target task, and appropriate methods need to be developed to address these differences.
- Model Robustness: CNN-based methods can be sensitive to variations in the images, such as changes in lighting conditions and image resolution. To make the models more robust and effective in real-world scenarios, methods need to be developed to address these variations and improve the robustness of the models.
- Explanation and Interpretability: While CNNs have shown to be effective in plant seedling classification, they are often considered black box models, making it difficult to understand the reasons behind the predictions. To improve the transparency and interpretability of the models, methods need to be developed to provide explanations and interpret the decisions made by the models.

As a whole, while CNNs have shown to be effective in plant seedling classification, there is still much work to be done to overcome the limitations and gaps in the current methods and improve the performance of the models for real-world applications.

III. About the Dataset

The Aarhus University Signal Processing group, in collaboration with the University of Southern Denmark, has recently released a dataset containing images of approximately 960 unique plants belonging to 12 species at several growth stages.

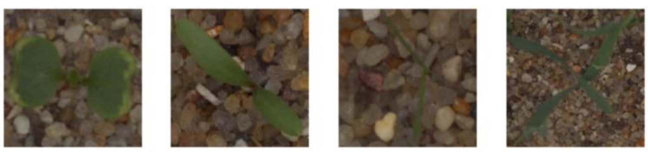

Fig. 3. Arbitrary selection from the data

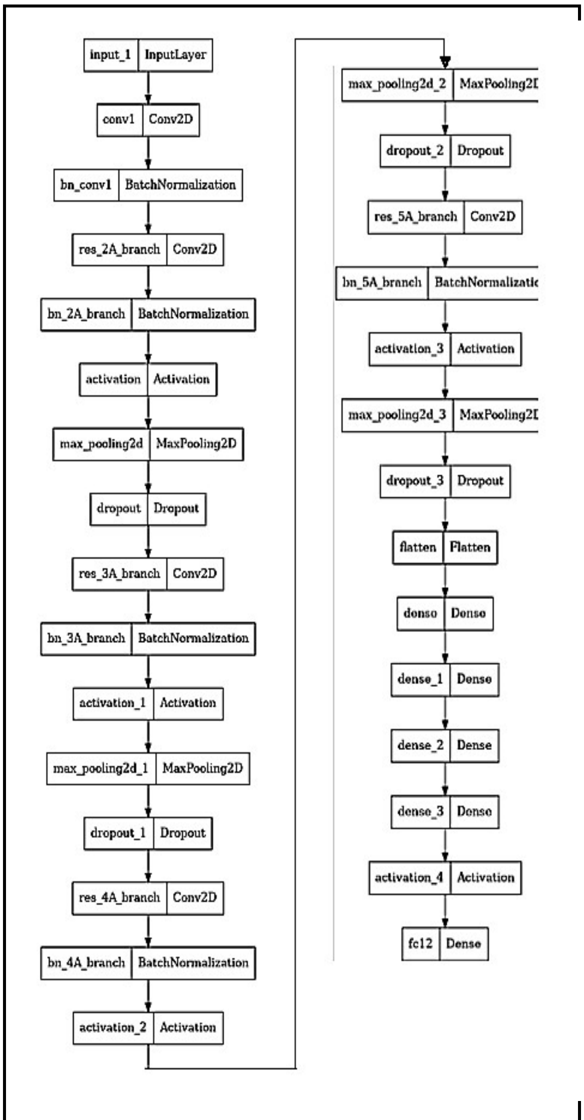
DOI: rp-9788770040723.035

IV. PROPOSED WORK

The proposed work for plant seedling classification using Convolutional Neural Networks (CNNs) involves the development of a deep learning model to classify images of plant seedlings. The process will start with the collection of 5545 images representing different species and stages of growth, which will then be preprocessed and divided into training, validation, and testing sets. The CNN architecture will be designed to extract hierarchical features from the images using multiple convolutional, max pooling, and fully connected layers. The model will then be trained using the training set, validated using the validation set, and finally tested using the test set. The results will be evaluated using various performance metrics, such as accuracy and F1 score, and compared with other methods. The trained model will be capable of automatically classifying images of plant seedlings and providing valuable insights into the quality and growth potential of the seedlings, making it a useful tool for farmers and researchers in agriculture.

V. MODEL ARCHITECTURE

C. General Structure



Proposed General Model Architecture

Model: "CNN"

Layer (type)	Output Shape	Param #
input_1 (InputLayer)	[(None, 150, 150, 3)]	0
conv1 (Conv2D)	(None, 73, 73, 64)	4864
bn_conv1 (BatchNormalization)	(None, 73, 73, 64)	256
res_2A_branch (Conv2D)	(None, 73, 73, 64)	102464
bn_2A_branch (BatchNormalization)	(None, 73, 73, 64)	256
activation (Activation)	(None, 73, 73, 64)	0
max_pooling2d (MaxPooling2D)	(None, 36, 36, 64)	0
dropout (Dropout)	(None, 36, 36, 64)	0
res_3A_branch (Conv2D)	(None, 36, 36, 128)	73856
bn_3A_branch (BatchNormalization)	(None, 36, 36, 128)	512
activation_1 (Activation)	(None, 36, 36, 128)	0
max_pooling2d_1 (MaxPooling2D)	(None, 12, 12, 128)	0
dropout_1 (Dropout)	(None, 12, 12, 128)	0
res_4A_branch (Conv2D)	(None, 12, 12, 256)	819456
bn_4A_branch (BatchNormalization)	(None, 12, 12, 256)	1024
activation_2 (Activation)	(None, 12, 12, 256)	0
max_pooling2d_2 (MaxPooling2D)	(None, 4, 4, 256)	0
dropout_2 (Dropout)	(None, 4, 4, 256)	0
res_5A_branch (Conv2D)	(None, 4, 4, 512)	6423040
bn_5A_branch (BatchNormalization)	(None, 4, 4, 512)	2048
activation_3 (Activation)	(None, 4, 4, 512)	0
max_pooling2d_3 (MaxPooling2D)	(None, 1, 1, 512)	0
dropout_3 (Dropout)	(None, 1, 1, 512)	0
flatten (Flatten)	(None, 512)	0
dense (Dense)	(None, 256)	131328
dense_1 (Dense)	(None, 256)	65792
dense_2 (Dense)	(None, 256)	65792
dense_3 (Dense)	(None, 256)	65792
activation_4 (Activation)	(None, 256)	0
fc12 (Dense)	(None, 12)	3084

Total params: 7,759,564
Trainable params: 7,757,516
Non-trainable params: 2,048

Proposed Work Architecture

VI. RESULTS

From Figure 4 and Figure 5 below we can observe that the model has arrived at the global minimum. It's excellent

DOI: rp-9788770040723.035

that the model isn't overfitting. However, the terrain is too uneven; the optimizer's momentum and learning rate may need to be changed.

Figure 6 Confusion Matrix, shows that our model is biased toward the loose silky bent plant seedling class.

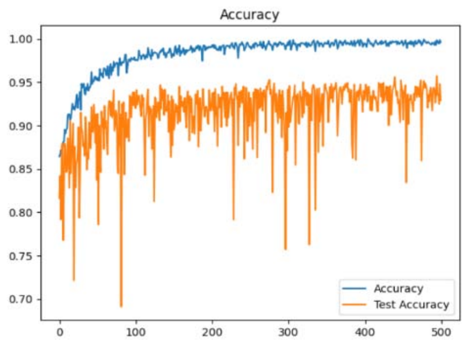


Fig. 4: Train Accuracy compared with Test Accuracy

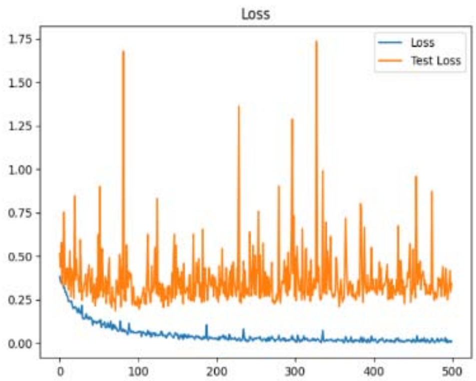

Fig. 5: Train Loss compared with Test Loss

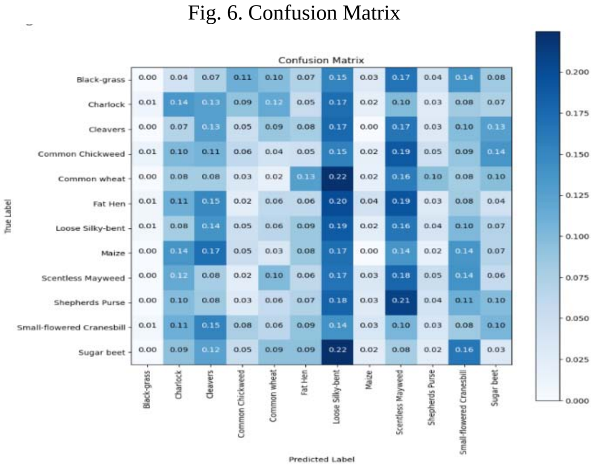
Fig. 6. Confusion Matrix



VII. CONCLUSION

The results from the plant seedling classification using Convolutional Neural Networks (CNNs) show promising performance, with a validation loss of 0.25 and validation accuracy of 95.80%. This indicates that the model was able to learn the representations of the images and make accurate predictions for the validation set. The loss of 0.01 indicates that the model was able to generalize well to unseen data and avoid overfitting, which is a common challenge in deep learning. The high accuracy of 95.80% indicates that the model was able to correctly classify a large percentage of the images in the validation set. These results suggest that the proposed CNN-based method is a promising approach for plant seedling classification and can provide valuable insights into the quality and growth potential of the seedlings. But more research is required to verify the findings and assess how well it performs in comparison to alternative approaches. The resulting test score was 85%.

I. INTRODUCTION(*CLOUD COMPUTING*)

Distributed computing is the cutting edge computational worldview. It is quickly merging itself as the eventual fate of conveyed on-request processing. By utilizing the idea of virtualization; Cloud computing is becoming the backbone of choice for a wide range of digital businesses. However, Internet-enabled business (also known as "e- Business") is now one of the finest strategies. Processing is being altered to a model that consists of administrations that are commoditized and delivered in a fashion similar to traditional utilities like water in order to fulfil the needs of web-enabled company. Regardless matter where the services are offered or how they are delivered, clients can access them based on their needs. The promise to convey this usefulness figuring has been made by a few processing ideal models.Distributed computing isonesuch dependable processing worldview.Distributed computing engineering comprises of a front end and a back end. These two closures are associated byInternet or Intranet. The front end involves customer gadgets like slight customer, fat customer or cell phones and so forth The customers need some interface and applications for getting to the distributed computing framework. The back end comprises of the different servers and information stockpiling frameworks. There is likewise a server called "Focal Server". A focal server is utilized for controlling the cloud framework. It additionally screens the general traffic and satisfying the customer requests continuously.

II. CHARACTERISTICS OF CLOUD COMPUTING

A. *Shared Facilities*

Uses a virtualized software approach to share physicalresources including networking, storage, and services. Regardless of the deployment option, the cloud infrastructure aims to maximise the use of the available infrastructure among a number of users.

B. *Flexible Provisioning*

Enables the provision of services in accordance with the needs of the current market. Software automation is used to carry out this task automatically, allowing for service growth and contraction. capacities along with appropriate. While performing this dynamic scaling, high standards of reliability and security mustbe up held.

III. RELATED WORK

- **Yong Yuet**has suggested this paper. A server that keeps information, a cloud provider, for example, can show a validator that such data is, in fact, being stored by the information owner thanks to a technology called remote information trustworthiness checking (RDIC). As most of these advances depend on the expensive open key foundation(PKI), that would potentially restrict the deployment of RDIC, they have an issue with advanced key management. A number of RDIC conventions have been published in writing up to this point. In this article, we propose another enhancement of the character-based (ID-based) RDIC convention in order to decrease the public key validation structure's complexity as well as the cost of establishing and maintaining it in RDIC systems that use PKI. We formalise RDIC based on ID, which has no information security against an outside verifier and no defence against a rogue cloud server, and its security model. The suggested ID-based RDIC protocol states that the validator is not provided with any RDIC protocol data.It is demonstrated that, in contrast to the conventional collection paradigm, the unique technique achieves zero information protection

DOI: rp-9788770040723.036

from a verifier and is secure against the malicious server.Consequently results of a thorough security research and implementation show that the recommended convention is clearly secure and useful for usage in actual applications. In this work, we investigated character-based distant information trustworthiness verification, a distinct method for secure distributed storage.

- **UsmanWaziret**has proposed this paper Global clients can access dispersed assets thanks to distributed computing. The flexible engineering used in distributed computing provides organisations in many locations with services as needed. However, there are a lot of challenges with cloud administrations.

Different approaches have been suggested for distinct types of cloud administrative challenges. In order to overcome the challenges with SLA, this study evaluates the many models for SLA in distributed computing that have been developed. Performance issues, customer satisfaction issues, security issues, profitability issues, and SLA breaches. We go through SLA design in distributed computing. The SLA models that have been suggested for usage in several cloud management models, including SaaS, PaaS, and IaaS, are then covered. Tables are used to explain the benefits and limitations of existing models in addition to this section. In the final section, we conclude and signal the conclusion. In this post, we reviewed various SLA models used in a setting of cloud applications. Some of the devices can provide excellent customer data protection, while another portion of the models can charge SLA infractions. Some of these boost customer confidence, while others enhance displays.

- **PritiNarwalet**has published this particle on Distributed computing is another transformative along with dynamic stage that utilizes virtualization innovation. In Cloud figuring climate, Every application may function in a separate environment called a virtual machine thanks to virtualization, which isolates the equipment framework components in programming. The hypervisor distributes numerous clients hosted on the same server in virtualization. Despite the fact that it gives many advantages like asset sharing, cost-proficiency, superior executioncalculability and diminishing in equipment cost however it additionally forces various security dangers. Risks can have an impact on a virtual machines (VMs) either directly or indirectly through the virtual machines in which the Hyper-visor supports. This study uses a game theoretic method to give an audit of all potential security risks and associated mitigation strategies. Due to the free and important dynamic character of cloud clients, where each player would seek out the optimal arrangement in a secure manner is handled, game theory may be used as a safeguarding endeavour.
- **Nitin Kumar** Sharmaet.al has proposed this paper Quality Based Access Control (ABAC)is a kind of models that are planned with the intention of overcoming the drawbacks of outdated accessible methods of control (DAC in addition to this MAC and finally RBAC) and combining their advantages. Attribute - based access bases admittance limitations on the non-exclusive qualities of drugs. Many reputable security strategies tie access decisions to credits. ABAC models may be used to find security measures, which can then be properly classified and handled using OWL. In OWL, we have described models, places, information, and security measures, and a justification was used to decide what is allowed. This research, we describe a technique using Web Ontology Language to handle the Aback model (OWL). Utilizing the EYE reasoned, which derives the intelligent relationship and concludes the entrance reward for each described action,the need of strategies is completed. In this work, we have demonstrated how the Web Ontology Language may be used to handle the Attribute Based Access Control paradigm (OWL).
- **ZiadIsmailet**has suggested this paper. Critical security issues have been introduced by recent advancements in distributed computing to assure the categorization, dependability, and accessibility of information that has been appropriated. Usually, the client and the cloud provider agree to a Service Level Agreement (SLA). Check the cloud provider's adherence to the SLA's information reinforcement criteria for still another benefit. The accuracy and accessibility of updated information may be thoroughly examined using a variety of security mechanisms. A client or a self-sufficient component, which we'll call the verifier, may be given this responsibility. However, confirming the availability of information incurs additional costs, which may prevent the customer from completing information confirmation on a regular basis. To choose the best information check technique, It may be possible to determine the connection between the verifier and the cloud provider. Finally, we show how we assess the model's boundaries and mathematically validate our model using a contextual analysis.

IV. EXISTING SYSTEM

The notion of VM scheduling based on resource monitoring data derived from previous resource utilizations (including PMs and VMs), and the resource data are categorised using the optimizationmethods K-NN and NB, thus scheduling is performed. A classification model makes an effort to infer a conclusion from observable facts. A classification algorithm would make an effort to predict the value of one or more outcomes provided two or many sources. Results that potential labels that might be used on a dataset. The two methods of machine learning are supervised and unsupervised. In a supervised model, the classification algorithm is fed a training dataset. The k-nearest neighbour approach is a non-parametric tool for algorithm likes regression and classification (k-NN). In both scenarios, the input consists of the nearest neighbor training instances in the feature space. Whether k-NN is used for classification or regression, the outcomes will change.

V. PROPOSED METHODOLOGY

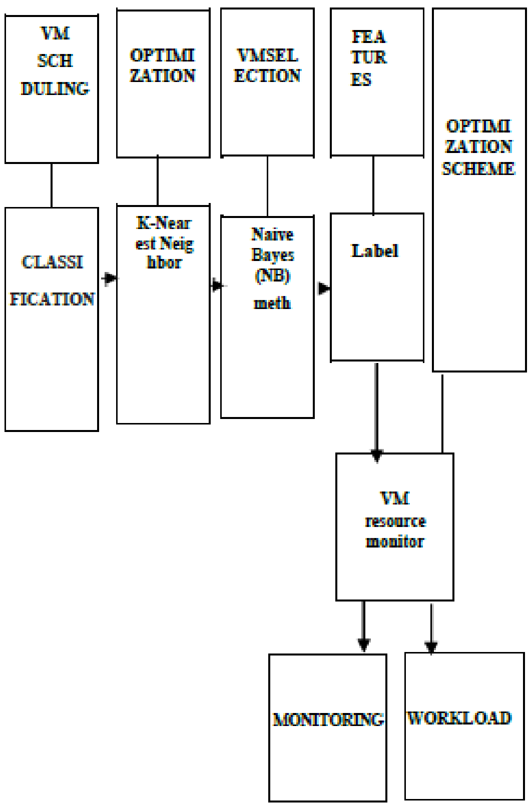
A idea seems to be present the concept of VM scheduling based on resource monitoring data taken from previous resource utilizations and to assess previous VM

DOI: rp-9788770040723.036

usage levels using two classification techniques such as PSO in order to schedule VMs while maximising performance. The suggested VM scheduling technique improves the VM selection by gathering real-time monitoring information and examining physical and virtual resources during the period. The goal is to improve VM scheduling by including factors relating to real VM use levels, so that VMs may be deployed while reducing the penalization of overall performance levels.

A. VM Scheduling

By relying on continuous dataset observation information collects and study of actual and virtual assets, the recommended calculation improves the VM determination phase. We want to improve VM planning. VMs may be put by limiting the punishment of generally speaking execution levels by combiningcriteriarecognised with real VM use levels. The upgrading plans include study on the widely disseminated virtual machines (VMs) to incorporate (a) higher utilisation levels and (b) lower presentation drops. A checking engine that accepts the usage of assets online while gathering information from virtual machines The motor is made to gather stretch-based framework information and save it in an internet-based cloud administration so that it is accessible for information management. Information from each brief moment (for instance, 1 second) is recorded.



VI. Classification Algorithm

A. The K-Nearest Neighbour Method

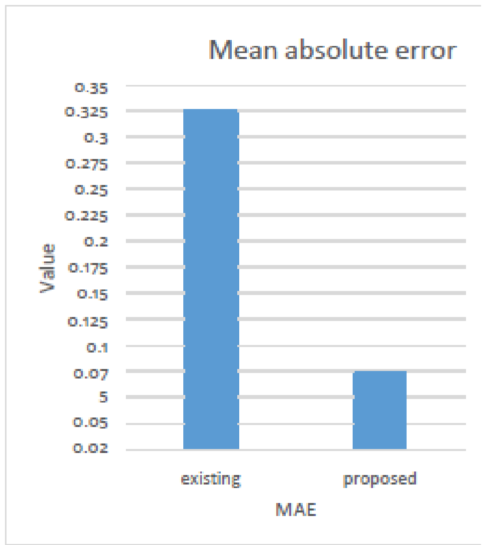
A fundamental calculation called K-closest neighbour preserves all examples that are already known and creates new cases based on a similitude measure supervision. K-NN has been used for quantitative evaluation and examples. A non- parametric technique for characterising and relapsing is the computation of K-Nearest Neighbours (KNN).

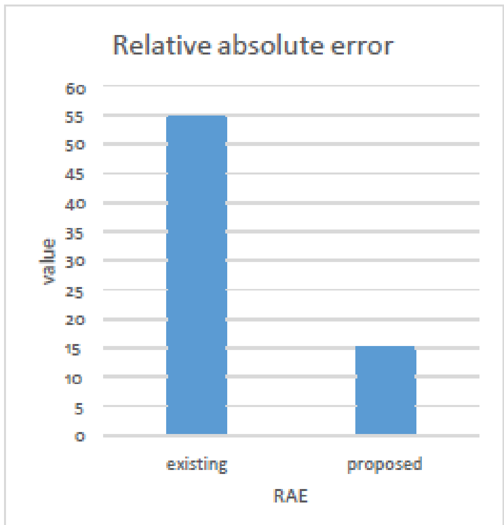
B. Optimization Scheme

These development plans seek to identify the PM's asset heaviness as indicated by the VMs' asset usage. This will show details on the general condition of transmitted VMs, such as whether a responsibility is running or not. To do this, we provide two upgrading strategies. The KNN is used to characterise the order in which the VM state for its current asset consumption. Before aggregating the data using AI techniques like K-NN, the virtual machine asset utilisation dataset are first acquired and confirmed.

VII. Experimental Setup

The outright mistake is characterized as the outright worth of the contrast between the deliberate worth and the genuine worth. In this way, let:





ea = the outright mistake ,

xm = the deliberate worth ,

xt = the genuine worth .

Finally,formula to recording a clear error is:

DOI: rp-9788770040723.036

$$ea = | xm - xt |$$

CONCLUSION

Various virtual machine location computations were used for planning by selecting actual machines based on framework information (such as CPU, memory, and transfer speed) in the cloud framework. Real-time VM asset utilisation levels are not taken into consideration in the current VM scenario. Furthermore, a prediction is given for a particular VM scenario based on the previous VM usage experiences. After that, the VM use is described, information is generated to calculate the anticipated VM asset consumption and place VMs as needed. A calculation that allows VM scenario as per PM and VM usage levels was offered, as well as a computational learning approach based on the notion of analysing historical VM asset use as per authentic data to speed the PM determination stage. In addition, a VM arrangement calculation based on continuous virtual asset checking was provided, in which AI models are used to prepare for and profit from previous virtual machine asset use. An observing motor is therefore accepted with asset utilisation information. By using KNN, the real machine's count is reduced by four. The task completed by 28 real computers when using pre- selected VM for work is reduced by 24 actual machines when using KNN.

***Abstract*— Thievery and misplacement of luggage are two of the major exasperating and inconclusive troubles faced around the globe by the people who travel a lot. Many innovations were put in place to solve this problem, but they were unsuccessful and lacked in implementing progressive technologies. This work is an advanced approach to prevail over such concerns. Unlike the existing systems, this system equips an idiosyncratic and coherent property of the SMS (Short Message Service) controllable location tracer and motion detection of the luggage or the bag. Which can be turned on as per the need of the user. The system further integrates a GPS (Global Positioning System) which sends the coordinates as SMS. This proposed system is incorporated with existing technologies to get to the button of the above discussed obstacles faced by the user in the most efficient and peculiar way.**

***Keywords*—Arduino UNO, SMS, GSM module, GPS module, Orientation, anti-theft.**

I.INTRODUCTION

Data released by the Delhi Police show that over 70% of cases of baggage theft at Indira Gandhi International Airport involve items accidentally left behind in the trolleys or in the taxis by passengers involuntarily. According to a senior GRP Official, approximately 84% crimes on Mumbai railways reported in the year 2021 were of theft. Tourists have always been obvious targets for thieves. In 1950, at the commencement of the jet age, just 25 million people took foreign trips. By 2019, that number had reached 1.5 billion, and the travel and tourism sector had grown almost too big. These statistics give us a sign that frequently tourists are at risk of theft, exclusively bag theft, which is one of the foremost misdemeanours against tourists.

This work has been proposed after numerous analysis on the disputes encountered by the user with their luggage while traveling around like their bags has been missing or stolen because of the misplacement or because of some carelessness while transporting it, [1] and one of the major issues we received from the user is that they demand to depend on others to take care of their bags when they are not available at that particular places, so they are depended on some intruders to take care of their bag, which is a perilous process. People who lead their life in metropolitan cities are frequently prone to thievery and misplacement of their bags because of their frenetic schedule. The presently usable smart bag system particularly allows the user to access its location whenever it is missing through a real time location detector, but does not contribute any kind of comprehensible anti-theft features [2,3,4]. The put forward system serves a solution for concluding the cited issues adequately.

The proposed work yields an effective solution for luggage security. The system is more favourable to people in metropolitan cities who carry expensive things. Gadgets for their day-to-day activities and some for special things such as an application of the internet of things. The user entirely controls this system with the help of SMS [16,17]. In this system, a signal is sent through an SMS since the primary target of the system is to make it convenient for the users to ensure maximum safety, such that no extra applications are required to control the system which may lead to unwanted malware entering the phone. This system is also incorporated with the motion detection which provides extra protection [13,14]. The user will be able to control all the above things with a very basic phone. This ensures that the user does not need to buy any special device.

II.LITERATURE SURVEY

Nagar M et al. have done research on implementation of GSM and GPS modulebased tracking systems with an emphasis on easiness in installation in [2]. The authors claim it to be a "plug-and-play device" owing to the simplicity it provides for the user. MNH Raimi et al.have implemented a smart bag which has a solar panel with it for both powering the system and charging devices in [3]. Object tracking feature, implemented using GPS, is present in this project. The author abbreviates it as 'SVB'. E Terence et al.have made a project which solves the strain of carrying heavy bags in [4]. This system also incorporates a GPS tracking system with GSM acknowledgement to the user. A. Ifeoluwa and I Francis have implemented a GPS tracking technology with the main intention of providing security to Nigerian school students in [5].It is told that this project could be considered as a business-to-government (B2G) model. NavyaAnanthula et al. have proposed a system base of which is a GPS based women's safety system that consists of dual-alerts that is voice module and message which is sent through GSM to the predefined mobile number in [6]. The entire system is

DOI: rp-9788770040723.037

activated with the help of a dedicated button. SuvarnaLakshmi et al. have made a research on a device mainly intended in providing safety to women in [7]. This is implemented using a GPS-GSM tracking system with audio and image capturing of the culprit. M. V. Singh et al. have implemented a GPS tracking device with target users as students in [8]. This device has an alerting system which reminds the users about the books to be arranged into their bags. Sunil K Punjabi et al. in [9] have proposed a system for women and children which allows immediate responses to any harassment in public places, societies, etc. It has a pressure switch which sends an SMS when pressure is applied at critical instances.

III. FUNCTIONING OF PROPOSED WORK

The whole system is controlled using the SMS system through the GSM module. As a result, the system must only execute commands issued by the owner of the bag. To do this, each unit of the system is given a unique password during the initial step of system setup. An Arduino UNO, being one of the most conveniently programmable and effective development board, is programmed with Embedded C to control all the modules connected to it. A GSM module is connected to the Arduino UNO, and it receives commands from the user through SMS and transfers them to the Arduino UNO's digital pins. To increase the system's applicability, it also sends an SMS to the user with information on possible threats as well as real-time geographic coordinates. There are several ways to implement position tracking using a GPS module, and it has numerous uses [5-8]. A GPS module is connected to the Arduino in order to collect real-time position coordinates. The precision and reliability of GPS systems are enhanced in numerous ways [9,10]. Gyroscopes are employed in a variety of applications [11,12,13]. They are getting better as technology develops [14]. This module is additionally linked to the system and provides real-time changes in the orientation or location of the bag when it is secured by the user, detecting changes in all six axes in three dimensions. A burglar alarm is linked to the system, and if there is any change in position, the alarm is activated, alerting the surroundings and sending an alert to the user through SMS. The preceding is depicted as a block diagram (Figure.1)

Whenever anyone tries to move the bag when it is locked by the user, the user receives an SMS warning. The burglar alarm in the system is also activated, and the people in the vicinity get notified of the theft. The system was designed such that motion detection begins only when the user sends a command to the system of their choosing. This is done to ensure that the user does not receive a warning for moving their luggage by themselves. A buzzer is rung for 2 seconds to notify the user that the system has been enabled. There are many additional equivalent features that may be enabled from anywhere in the globe using the network through SMS [15,16]. Users can replace the initially provided passwords with relevant terms which are easy for their remembrance. When the activation instruction is received from the user, the gyroscope is activated to alert the user of the bag's orientational changes. The GPS coordinates are delivered through SMS when the instruction to get location is sent. This is useful for guaranteeing the bag's security even when the user is not there. Additionally, specific commands are given for this system to assist the user with the system. The alarm will be activated when the command to instantly find the bag is sent, making it easier for the user to locate the bag in the nearby local places. It also keeps the user informed of any changes in the bag's orientation. Similarly, all of the system's digital outputs will be conveyed to the user via SMS in linguistic structure. The messages contain the necessary data, so that the user is kept up to date on all relevant information. This assures the bag's safety. When the user needs to grab the bag, the lock may be temporarily deactivated by disabling the gyroscope using a simple command, allowing the user to access the bag. When the system is deactivated and free to move, the user will be notified with a beep sound via the system's alarm, ensuring that the user does not get into any trouble.

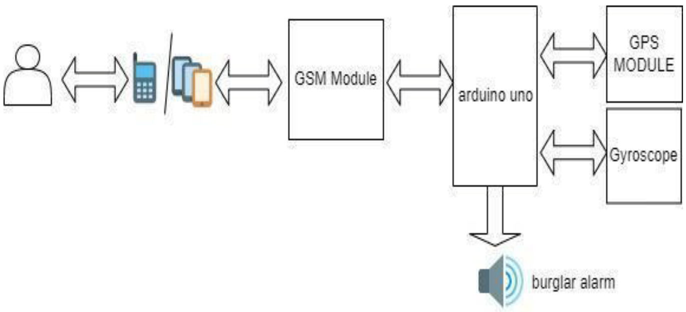

Fig. 1. The figure portraying the process flow of the system

IV. FLOW CHART

The flowchart broadly comprises two parts, namely the initialisation part and the loop part. In each process described below, these two parts are described.

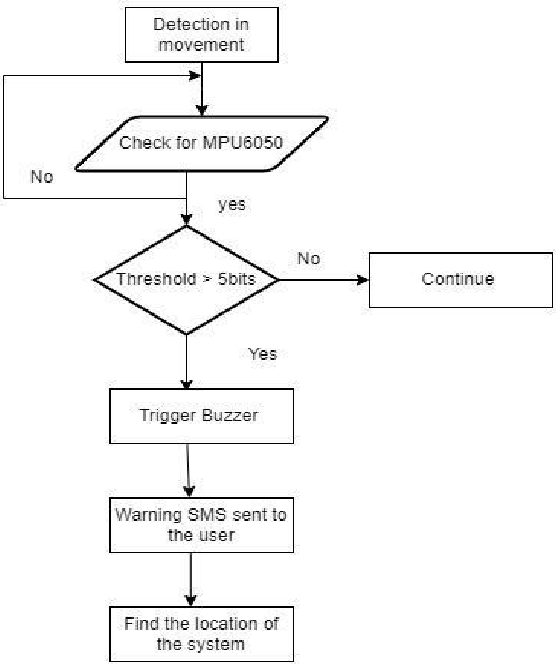

Fig. 2. Complete flowchart of the anti-theft bag system

DOI: rp-9788770040723.037

In Figure. 2, the GSM module is initialised by connecting its transmitter and receiver pins to the microcontroller's digital input pins. During initialization, the module attempts to connect to the GSM frequency band. The system is set up to run in SMS mode. The methodology for dealing with received messages has been established.

These parameters in the startup section are accomplished through the utilization of AT commands. A variable is declared in the loop and is used to record the received messages. All the characters within the string of received messages are capitalised. The pre-defined instructions are compared to the recorded messages. When the SMS received contains the word "LOC," the geographical coordinates are sent to the user via SMS. When the received SMS contains the word "FIND," the buzzer is activated for a limited period of time. The motion detection begins, Whenever the SMS received by the system is "ON ". The system then enters a loop in which variations in orientation are continually monitored.

The messages received are also updated on a regular basis in this loop. When an SMS is received by the system is "OFF" the system disables the motion sensing by interrupting the loop. This module serves as a conduit between the user and the protection system.

In Figure 3, the gyroscope is initialised by connecting its serial clock and serial data pins to the microcontroller's analogue inputs. The serial connection between the microcontroller and MPU6050 is established during the initialization process. The MPU6050 has a 0 to 63 Hz high-pass filter and a motion detection duration of 20ms. When the system is turned on through the command received from the user, motion detection begins inside the loop. When the change in orientation detected exceeds a threshold of 5 bits, it is considered as a change in motion of the bag, the user will be notified about movement in the bag through SMS. Following the previous step, this will activate the buzzer by digitally programming the buzzer's pin as high, enabling the user to catch the burglar red-handed. The flowchart in Figure 4 shows how the location retrieved from the GPS module and the data is transmitted to the user. When the user sends an SMS with the keyword "LOC," the position of the bag is communicated to the user in the form of coordinates for latitude and longitude. When the GPS does not acquire a proper signal, it takes some time to locate the correct coordinates which must be communicated to the user, and data from the GPS is also necessary when there is movement detection in the system to alert the user about the theft and the location of the crime. The system has some pre-defined text that must be delivered to the user through SMS based on the function invoked by the user. The above-mentioned combination of GPS and GSM has yielded numerous favourable performance [17,18]

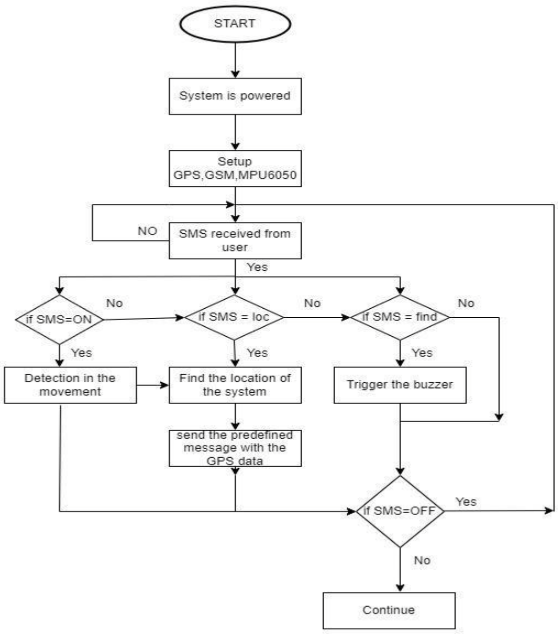

Fig. 3. Movement detection flow chart

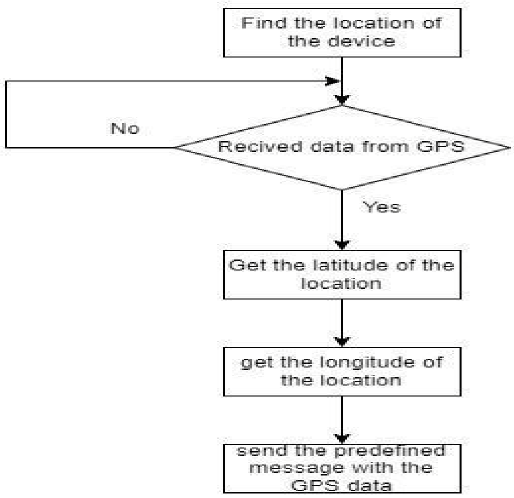

Figure. 4 Finding the location of the system flow chart

IV. RESULT

The presented results were taken out from the real time hardware testing in the period of the testing the final proto type of the proposed system and the the output results were further mainly classified into the different working states of the system which gives out the correct signals on the period of the large movement applied to the system while placed inside a bag and the classification of results are.

A. Initialization of hardware

In Figure5, all modules have been initialized. First, GPS is configured. The GSM is then connected to the global system network, as shown by the phrases "Connecting" and "Connected." The four "OK" phrases indicate that GSM is connected to the network, the module is set to SMS mode, received SMS is defined, and all unread received messages are recovered in that order. The phrase "MPU6050 detected"

DOI: rp-9788770040723.037

indicates that communication between the controller and the gyroscope has commenced.

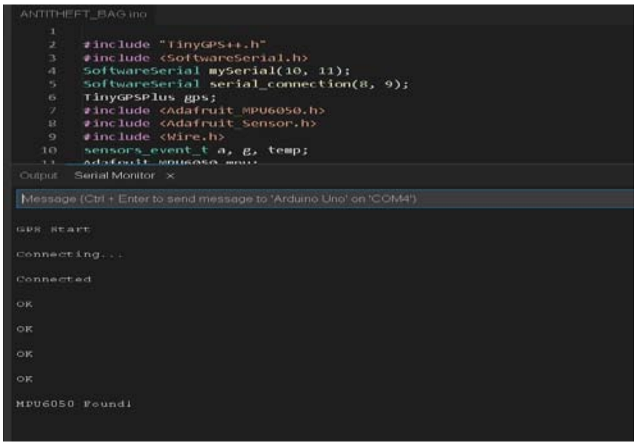

Figure.5 The initialization of the system

B. The ON function (activating the motion detection)

Figure 6(a) Figure 6 (b)

Fig. 6 User pressing the trigger button on phone

Figure.6labelled with (a) and (b) where (a) represents SMS app indicating theON function and (b) representing Serial monitor indicating the ON function .In Figure.6(b), the keyword beginning with "+CMT" specifies the phone number (which has been anonymized), as well as the date and time the message was received. Similarly, incoming messages are received. All phrases with "Ok" indicate that the message has been sent to the user. This is supported by the words in Figure.6(a). Similarly, remaining messages that are transmitted are marked. The line "Motion detected" indicates that somebody attempted to move the bag.

C. Detecting the location of the bag

Figure 7(a) Figure 7 (b)

Fig. 7 User knowing the location using simple command

Figure 7.labelled with (a) and (b) where (a) indicating SMS app indicating the LOC function and (b) indicating Serial monitor indicating the location of the system.

The keyword "LOC" in Figure 7(a) indicates that the user has sent the command to determine the position of the bag. The following phrase demonstrates how the bag's latitude and longitude are determined. The determined value is delivered to the user, as seen in Figure 7(b). There are several applications for tracking systems in this manner [19,20].

VI.HARDWARE IMPLEMENTATION

To implement the proposed idea, an Arduino UNO microcontroller, GSM module, GPS module, Gyroscope, phone, burglar alarm, and a 12 V, 1.3 Ah battery are used. These modules are controlled by Arduino UNO (microcontroller), and it is programmed using Embedded C in the Arduino IDE platform. The connections of the hardware modules are previewed in EasyEDA. The Gyroscope module makes use of the former, while the GPS and GSM modules make use of the latter. Figure 8 depicts the suggested system's architecture. The system is constructed in such a manner that all of the modules are powered by the Arduino UNO, which is supplied by an external power supply. The motion detecting capacity of the gyroscope is used here, as in prior publications [21,22]. The threshold is set low to avoid the detection of very small changes in orientation by accident or by Naturally induced acceleration.The GSM module's Rx and TX pins are linked to the Arduino board's digital pins, accordingly, so that signals are delivered and received through the allocated lines. And it is employed in SMS mode. Similar applications exist for GSM modules in SMS mode [22, 23].

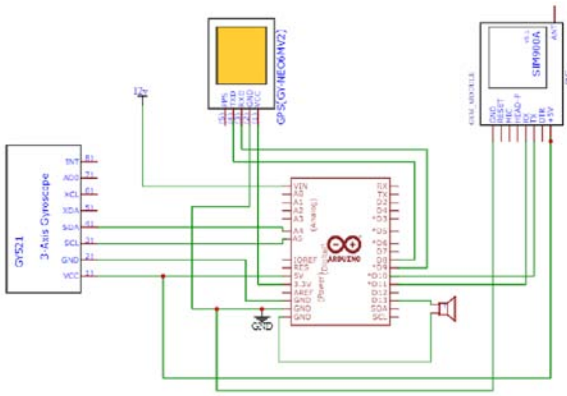

Figure 8 circuit diagram replicating the hardware which is used for simulation purpose

VII.CONCLUSION AND FUTURE WORKS

Anti-theft bags are currently available in the market, but they do not address some major and crucial issues. To address these shortcomings, a security system against bag theft using SMS controllability and a GPS location is designed. With this proposed paper, the rate of luggage theft or misplacement can be reduced in contrast to the existing scenario and systems. This also aids in finding people in critical instances such as getting lost. A basic cell phone that is a part of everyone’s life today is all that is required to manage the system and obtain information on lost or misplaced luggage. It additionally operates in locations with low network coverage. In addition to this, it benefits those who travel alone. This makes them more independent. Unlike other smart and handy bags, this method ensures additional security along with smart features. Instead of providing an image of the suspect, the proposed system provides the exact coordinates of the bag, which is more simplified but much more effective. This system may be incorporated with containers while shipping expensive items. To a much wider reaching extent, this offers security for all types and sizes of commodities. Unlike the existing security system, which catches the suspect when the bag is opened and sends a mail to the owner, instead of providing an image of the suspect, the proposed paper provides the position of the bag, which is simpler but much more effective. In industries, we may integrate this system with containers while shipping expensive goods. To a great extent, this system provides security for the commodities.

In the future, in addition to all of these functions, item detection within the bags may be added; they can also identify such that individual protection is provided to each thing present in the bag through SMS. In addition, instead of utilising the GPS module, alternative technologies can be used in the system to determine the position of the bag, as the GPS may lose signal and be unable to relay the location of the bag to the user in certain conditions.

***Abstract*—The implementation of licenceplate detection in smart transportation systems is discussed in this study paper. The suggested system makes use of character detection techniques as well as an unique method for eliminating shadows. The invention of an enhancedbinary approach for shade elimination that blends the Bernsen approach withGaussian filter and the incorporation of a character detection method utilising the Support Vector Machine (SVM) technique are the paper's two significant contributions to the area. The SVM approach concentrates on the whole licence plate rather than individualcharacters and obtains characterattributes from a stretchy mesh. The research also presents new methods forimprovinggrayscale photos and correcting image tilt. The proposedalgorithm is resilient to variations inlighting, viewing angles, position, size, and colour of license plates, making it suitable for use in complex environments.**

I. Introduction

An image is a column- and row-organized array, or matrix, of square pixels (picture elements). The most popular and practical method of sharing or distributing information is through images. There are a thousand words in a picture. Images clearly communicate information about the positions, dimensions, and connections between items. They depict geographical data that humans may identify as objects. Because of our natural visual and cerebral capacities, humans are good at extracting information from such images. Humans get about 75% of their information in visual form. Picture compression, image amplification and revival, and dimensionretrieval are the three main types of image processing operations. Many individuals are familiar with the idea of picture compression, which seeks to utilise less memory.

II. Literature Survey

[1] An intelligent strategy for checking the annualinspection status of motorcyclesbased on: license plate recognition

Techniques for recognisinglicence plates have beeneffectively used to manageparking lots, track down stolen vehicles, andregulate traffic. This study suggests alicence plate-based method for determininga motorcycle's annual inspection status usingphotos taken at authorized inspection locations and along the roadside. Ashardware platforms, a desktop PC and an UMPC (Ultra Mobile Personal Computer)with a web camera are both employed. A search window is used to scan integratedhorizontal and vertical projections, which are used to locate licence plate locations in photos. Additionally, a character recoverytechnique is used to increase the success rate. Both a back propagation artificialneural network and feature matching are used to recognise characters. Then, using the specified licence plate.

[2] An Efficient Method of License Plate Location in Natural_scene Image

This work proposes a novel and effectivealgorithm for the placement of automobile license plates. This method's goal is to efficiently locate license plates in spite of restrictions on LP distance, angle of view, lighting, and background complexity. This approach's contribution is that it combines the mathematical morphology method with the sliding concentric windows (SCWs) method to create a faster, more reliable method. Our method utilizes the colorinformation of LP toaccurately locate it. It iscapable of identifying multiple LP inanimage,and is less restrictive than other LP locationtechniques. Furthermore, it has a quickerprocessingtime,taking only 0.1 second, makingit suitable for real-timeapplications. 200 natural-scene car photos with various backdrops and ambient lighting were used totest the system.

[3] License Plate detection of movingvehicle

This study proposes an Egyptian license plate recognition system for moving automobiles. The suggested method takes an image from a digital video camera and extracts the distinctive elements of a plate from it. The suggested method detects the numbers and letters on a license plate usingamultilayer neural network. The system is split into two primary phases: the first is the training stage, during which a dataset is produced and the neural networks are taught for recognition. The second is the recognition procedure, which includes segments for words and numbers, detecting vehicles from a stream of frames, estimating plate positions, and plate recognition.

[4] Enhancement of license plate recognition performance using Xception with Mish activation function

The research's goal is to offer a reliable and efficient method for reading characters on license plates under challenging environmental situations. The proposed method was tested using four benchmark datasets, which are, FZU Cars, Stanford Cars, Application-Oriented License Plate(AOLP) and HumAIn 2019 Challenge.

DOI: rp-9788770040723.038

[5] A Method for Identifying Specific Vehicle Using Template Matching

A novel recognition method is proposed in this work to overcome the concerns brought up by the identification strategy that makes use of the previously discussed template- matching process. In order to further verify the algorithm's accuracy in object recognition, we applied it to a real road. Thefindings revealed a 99.6% accuracy rate, which is sufficient for practical application.

[6] Automated new license plate recognition in Egypt

The functional use of license plate recognition (LPR) is utilized by Automatic Vehicle Identification (AVI) systems. This research offered an original and simple technique for the LPR system of Egyptian automobiles. Database communication, plate region extraction, and plate characteridentification are the three key parts of the proposed method. A video stream was one of this system's most important advantages. Real-time functionality could be used without the need of extra sensors, such as infrared ones. Automated New License Plate

[7] A Survey on License Plate Recognition Systems

This study proposes an Egyptian licenseplate recognition system for moving automobiles. The suggested method takes animage from a digital video camera and extracts the distinctive elements of a plate from it. The suggested method detects the numbers and letters on a license plate using a multilayer neural network. The system is split into two primary phases: the first is the training stage, during which a dataset is produced and the neural networks are taught for recognition. The second is the recognition procedure, which includes segments for words and numbers, detecting vehicles from a stream of frames, estimating plate positions, and plate recognition.

[8] An edge:basedcolor:aided method forlicense plate detection

Detecting licence plates is a challenge that isexamined in this research. Some commonissues include poor imagequality brought onby poor lighting, moving vehicles, shifting viewpoints and distances, complex backgrounds, etc. It is suggested to use edge density and intensity variance to improveimages in two separate ways.

[9] CarLicensePlateDetection

This study examines automobile licence plate detection (CLPD) technology, whichuses car license plates to identify vehicles (CLP). Due to several applications, including crime prevention, electronic toll collection, intelligent traffic management, etc., car license plate detection (CLPDS) is a growing field of study. The suggested system employs adaptive thresholding to produce the binary picture after converting the colour input image to grayscale. The undesirable lines are then eliminated using an algorithm for unwanted lines (ULEA).Finally, the Sobel operator detects vertical edges to identify the license plate. For the purpose of detecting license plates in both the front and back views, experiments were performed. The experimental evaluation is done on 60 photos that were obtained from parking lots and the sides of roads.

[10]Autonomous Vehicular Surveillance using License Plate Recognition over Cloud Computing Architecture

For the purposes of vehicular surveillance, these cameras are inefficient, as a lot of them will be required to monitor vehicles effectively. These cameras capture meaningful images of license plates from their video feed, and upload these images to the cloud using a Vehicular Cloud Computing architecture. The cloud compares them to a database of license plates that are flagged by law enforcement. If the license plate is found to be flagged, then the respective law enforcement authorities are notified of the location of the car.

[11]Vehicle plate number localization using a modified GrabCut algorithm

A key stage in any vehicle plate number recognition system is to first locate the vehicle plate number. In this paper, they presented a modified GrabCut algorithm for localizing vehicle plate numbers. In contrast with the traditional interactive GrabCut technique, a modified GrabCut algorithm was designed to identify and extract vehicle plate numbers in a completely automatic manner. Finally, to evaluate the performance of the proposed technique, the localization accuracy is tested with a dataset of 500 vehicleimages with vehicle plates from different countries.

[12]Region-based license plate detection

In order to recognize a license plate efficiently, however, the location of the license plate, in most cases, must be detected in the first place. Due to this reason, detecting the accurate location of a license plate from a vehicle image is considered to be the most crucial step of an ALPR system, which greatly affects the recognition rate and speed of the whole system. In this paper, a region-based license plate detection method is proposed. These candidate regions are then analyzed and classified in order to decide whether a candidate region contains a license plate.

[13]Towards aMultinationalCarLicensePlateRecognitionSystem

A full-fledged image-based car license plate recognition system is described in the paper. The localization stage of the CLPR yields a plate clip followed by character segmentation and recognition. The recognition scheme combines adaptive iterative thresholding with a template-matching algorithm. Promising results have been obtained in the experiments with Israeli and Bulgarian license plates including images of poor quality.

[14]Vehicle license plate character segmentation

Auxiliary lines are added into the image to make the separated parts of each Chinese character to be an interconnected region. The noise regions will be eliminated after two fusing images are merged according to the minimum principle of gray values. Then, the characters are segmented by projection method and the final character images are obtained. The experimental results show that this method features fast processing and good performance in segmentation.

III. PROPOSED METHOD

DOI: rp-9788770040723.038

Our proposed method focuses on a solution for image disturbance brought on by varying outdoor conditions including shadow and exposure, as well as uneven illumination,which are typically difficult to successfully handle using conventional binary methods. We discussed the method of extracting features from alphanumeric characters, and applied a Support Vector Machine (SVM) to classify those features. The system's overall performance along with the effectiveness of every single element were also evaluated.

This paper presents several newcontributions to the field of image processing. Firstly, a novel technique for eliminating shadows from images is proposed, which combines an advancedversion of the Bernsen algorithm with theuse of Gaussian filter. Secondly, an algorithm for character recognition is presented, which uses Support Vector Machines (SVMs) to recognize characters in an address string, rather than just a single character.

Additionally, the most effective character feature extraction are evaluated in order to determine which ones are most useful in practical contexts. The paper also includes techniques for correcting image slant and enhancing image quality. Furthermore, the paper proposes an image tilt correction method for license plate pre-processing. Finally, the paper presents the results of experiments evaluating the performance of the proposed techniques.

IV. Implementation Modules

1. *License plate preprocessing*

In license plate recognition (LPR),preprocessing the image of the license plate is a crucial step. This process includes identifying the location of the license plate, correcting any distortions in the image, and segmenting the elements on the plate. The objective of recognition is to find regions of the image that resemble a number plate. However, variations in the image's orientation can result in skewed or distorted images. Therefore, adjusting the image tocorrect these issues before attempting to segment the characters is an essential step inthe process.

2. *License plate detection*

The connected component analysis (CCA)technique is used in the search for binary images that are connected in an eight- neighborhood relationship. Using theConnected Component Analysis (CCA) method, the picture is examined and its pixels are arranged into distinct clusters based on their connectedness.

3. *Character segmentation*

Character segmentation is a multi-step process that includes the following steps: 1) creating a white backdrop with black text on the licence plate picture, 2) resizing the plate to 100x200, 3) applying tilt correction and image enhancement techniques, 4) dividing the numberplate into two portions using a projective approach, then separating theelements from each area and, 5)standardizing the size of the characters.

4. *Character Recognition Algorithm*

The peripheral direction contributive density(PDC), the local direction contributive density (L-DCD), and the global direction contributive density (G-DCD) are examples of characteristics of the stroke direction that are used in a statistical procedure. The steps taken to achieve the G-DCD and L-DCDcharacteristics are described in thistechnique.

IV. Proposed Method Diagram

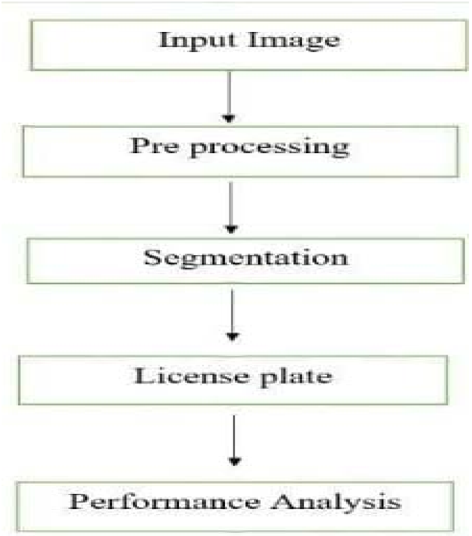

Fig.1 Proposed Method

5. *Experimental analysis*

The process of extracting features from binary characters is found to be simple and efficient, in comparison to grey-value characters. Oursystem, which can acquire images under various lighting conditions and environments, achieved an accuracy of 90.98%.

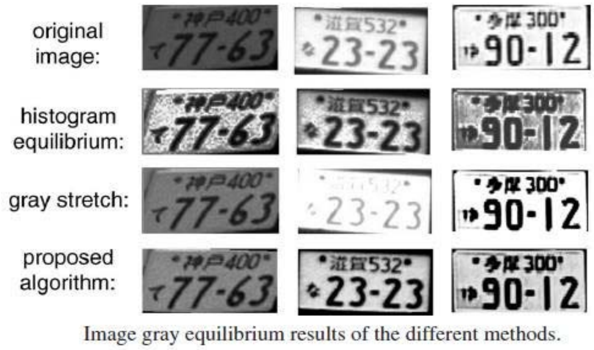

Fig.2 Image gray scale results

The performance of the system in terms of location, segmentation,recognition and overall performance was 96.96%, 98.23%, 98.01% and 93.45% respectively. To ensure optimal image quality, a step of grey equilibrium is included in the segmentation stage. In this study, we utilized a gray statistical method (GSA) to improve image quality.

V. Advantages

The License Plate Recognition (LPR) system operates as follows: When the system receives an input image, the initial step is pre-processing which includesactions such as making the image binary andeliminating noise. Then, using either frame location or character location methods, potential number plates are obtained fromthe picture. If the system is unable to locate any license plates, it will generate a "refusedrecognition" outcome. However, it ispossible for

DOI: rp-9788770040723.038

multiple license plates to be detected. After that, the system advances to the detection and segmentation phases. The segmentation step of the licence plate willbe completed if it can be recognised. If not, the system will consider a different possible licence plate.

Two assessments areperformed during the segmentation phase:one for a plate with a single huge number ona bright-white background and another for a binary alteration procedure. The first assessment concerns plates with a single big number on a white background. When the present approach fails to appropriately segment the plate, a different binary method is used in the second evaluation. While, text detection includes classifying characters into4 distinct categories.

The end result of the detection process is determined by selecting the best recognition method among the different methods used. To generate a legitimate licence number, all characterrecognition results are taken intoconsideration, as long as they conform to thestructural rules of license numbers outlined previously.

VI. Discussions

For a variety of reasons, including car park operations, surveillance systems in secured areas, and road system, its capacity to recogniselicence plates (LPR) is crucial. The many plate formats and the variable illumination.Outsideduring photogrammetry, including backdrop, lighting, speed limit, and camera-vehicle distance, might make this work challenging. Consequently, many techniques are confinedto specific situations such as constant lighting, predefined paths, and unchanging backdrops.

The identification and division ofthelicence plate, segmenting and normalising the characters, and character recognition make up the four key elements of an LPR system. For the whole system, thesuccess of the locating operation is essential since it directly affects the precision and effectiveness of the succeeding processes, however, this step is challenging to accomplish due to different lighting conditions and complex backgrounds.

VII. Conclusion

The three primary aspects of the license plate recognition (LPR) method presented in this work are: identifying the registration plates, dividing the tokens, and recognizing the licence tokens. The overall performance of the algorithm is 95.8%. The performance of identifying the plate, segmenting the characters and recognizing the characters individually are 96.96%, 98.23%, and 98.01%, respectively. Our system achieved satisfactory results for individual rates and overall performance. Even though the suggested method isdesigned to work with number plates from a certain nation, many of its components may be readily changed to work with licence plates from other nations. The improved binary algorithm is particularly useful in dealing with uneven illumination, a commonissue in plate detection, and can be adapted to various surrounding conditions. As license numbers are commonly composed of numerals and Roman letters, the suggested algorithm is suitable for any number plates that follow a similar composition.

VIII. Result

Fig.3. Output

As observed in the above diagram as shown the image of the vehicle is the input that was provided to the model andwegotthe number plate of the vehicle asthe output and the accuracy received was 95.8. The heat map represents confusion matrix.

***Abstract* — Osteoporosis is a chronic condition characterized by low bone density and an increased risk of fractures. It is a common problem among older adults and can significantly impact the quality of life and healthcare costs. Early diagnosis of osteoporosis is crucial for the implementation of effective treatment and prevention strategies. However, current methods for detecting osteoporosis, such as Dual-energy X-ray Absorptiometry (DXA), are not always reliable and can be inconvenient for patients. In this article, we explore the application of machine learning methods for osteoporosis detection and have evaluated it using a few models, like the Multilayer Perceptron, Convolutional Neural Network A - 3 Conv. layers, (16 32 64), Convolutional Neural Network B – 4Conv. layers, (32 64 128 128) and Convolutional Neural Network+ Dropout (over Dense Layer only) to see which one might give us the best result. We used a dataset of bone scans compiled and categorized by Mendeley data and used this data to train the models. Our results demonstrate that these models can effectively identify individuals with osteoporosis with some accuracy and sensitivity, some more than others. Overall, our study shows that the best-trained model found during cross- validation has an accuracy of 89.34%.**

Keywords—- Osteoporosis, Machine Learning, Deep Learning, Detection, DXA Scans, Bone Density, CNN, Multilayer Perceptron, classifiers

I. INTRODUCTION

Bones support our bodies and give us mobility. They preserve the health of our heart, brain, and other internal organs. Bone is a growing, living tissue. It is mostly composed of collagen, a protein that imparts strength and hardness and calcium, a mineral that offers a soft structure. A calcium deficiency can lead to the bones becoming weak and losing most of their power and rigidity. This leads to them breaking up most of the time, even in minor disturbances. This condition is called osteoporosis. Osteoporosis can cause spinal or hip breaks that may provoke budgetary weight and high depressing ness. As needs are, there is a prerequisite for the early examination of osteoporosis and expecting the proximity of the break. According to the World Health Organization, musculoskeletal problems account for up to one in three cases of disability globally and impact people of all ages. These ailments include more than 150 diagnoses, ranging from straightforward fractures that recover quite fast to chronic illnesses like osteoarthritis. Such musculoskeletal problemswill become more prevalent and their accompanying socioeconomic consequences will rise as the world's population ages. Over the next few decades, the significance of accurately detecting these conditions, frequently done by Bone X-Ray scans evaluated by skilled radiologists, will only increase. An automated method for swiftly and affordably identifying bone abnormalities from X-Rays would be extremely helpful given that there are so few qualified radiologists in the world, with only a handful an automated method for efficiently and affordably identifying bone abnormalities from X-Rays would be extremely helpful given that there are so few qualified radiologists in the world, with only a handful of them being found in underdeveloped nations.

Our main objective is to build a system that can predict from the input if said person has osteoporosis, i.e., his bones are normal or not, and for that, we will train our model using a dataset and effectively train the model to get better at predicting.

This machine learning project aims to experiment and provide different solutions employing various neural network architectures in a binary classification task. In particular, the dataset at hand is composed of 614 images representing normal (359) and osteoporosis (255), a standard image classification dataset for composing and improving neural network models. All the different phases of the work are developed in python with the TensorFlow machine learning library via Colab Notebook.

II. LITERATURE REVIEW.

A recent study conducted on detecting liver disease lesions used a very highly sought-after and upcoming CNN architecture, DenseNet which was trained with around 10000 real-time samples of liver Xrays. The resulting model had an accuracy of 98.34, higher than previous works due to DenseNet‘s unique dropout layer [1].

A couple of researchers from McMaster University in Canada along with a few researchers from other universities conducted a study by training a CNN to identify vertebral compression fractures but with a twist. Instead of using a pre-labelled dataset, they used active learning to decrease

DOI: rp-9788770040723.039

class imbalance and produce an effective image classifier. This reduced the cost and time required to train an ML model [2]. CNN was also used todetect lung nodule candidates by training the model with the LUNA16 dataset. This turned out to be a huge success and the results surpassed the previous SOTA approach. The model also was insensitive to the input sizes of the image making it highly useable across a wide range [3]. To make skin cancer detection easier and more accurate, work was done on combining well-known deep-learning models to extract features and then use those to train support vector classifiers. The resulting model was able to give an accurate prediction of 83.83% for melanoma classification and 97.55% for another classification [4]. Another Skin cancer detection proposal used a CNN on a dataset consisting of a whopping 129,450 images to effectively compete against 21 board-certified dermatologists to classify the images into two critical binary classes. The CNN performed as good as the doctors [5]. Researchers in china concluded that the deep learning model, DCNN, could not replace DEXA for BMD (Bone Mass Density) screening, however, it might be employed if a DEXA has not been performed but a lumbar spine X-ray is easily accessible [6]. Another proposal we came across tested a Multilayer Perceptron and Naive Bayes on 33 scans. The results showed that the Multilayer Perceptron outperforms the Naive Bayer classifier in every way [7]. A test was conducted between SVG and an EBP-NN (Error Back Propagation Neural Network) to see which was able to classify fractured and non-fractured bones accurately using a dataset which was preprocessed with wavelet transform to remove noise. The SVG outperformed the EBP-NN by 2% [8]. There was a test between an FEA model and a CNN model to test bone anonymities. Both were put to the test using a large database of artificially produced cancellous bone anatomy. The execution time difference between the FEA model and CNN was around 1000 times, from 32.1 seconds to 0.03 seconds [9]. This is one of the studies that helped us go with CNN architecture. Twenty machine learning techniques were evaluated based on their popularity and frequency in biomedical engineering challenges to divide subjects into two classes (osteoporosis and non-osteoporosis). The well-known 10-fold cross-validation method has been used to evaluate all classifiers, and the results were presented analytically. Their research showed that "age" and "weight" were rated as the most significant diagnostic criteria initially generating the feature set by a feature selection approach. It was evident that eliminating the "sex" diagnostic component did not affect the majority of techniques' efficacy [10]. Cruz et al. methodically gathered and condensed the main approaches used to categorise risk categories for osteoporosis, highlighting their issues and patterns. In conjunction with earlier studies like QUS and DEXA, methods that used AI principles for categorising risk groups were emphasised, concluding that developing a model utilising AI to forecast risk groups has frequently proven to be very beneficial for the patients in their treatment. A relatively new and non-invasive technique for determining bone mineral state at the peripheral skeleton is quantitative ultrasonography (QUS). In addition to bone density, QUS methods offer some structural data that may be crucial in assessing the risk of fracture [11]. The use of fuzzy neural networks (FNN) to identify postmenopausal women with osteoporosis was suggested in another proposal that we came across. This study used 100 postmenopausal women's dental panoramic radiographs from visits to their clinic for BMD evaluations at the lumbar spine and femoral neck. The results indicate that postmenopausal women with osteoporosis can be identified in the dental clinic using a combination of cortical width and shape by employing FNN. Fuzzy neuralnetworks combine the advantages of fuzzy systems and neural networks, enabling them to consider various characteristics and variables related to a condition and produce more accurate and dependable forecasts. Using the new FNN-based system, dentists can effectively identify postmenopausal women and then refer them for BMD testing to obtain an accurate t score and continue with their testing. [12]. A system to automatically detect and localisetumours as small as 100 x 100 pixels in gigapixel microscopy images with a resolution of 100,000 x 100,000 pixels has been developed in studies on employing CNNs for disease diagnosis, such as this one. On the tough lesion-level cancer identification challenge, their approach, which makes use of a convolutional neural network (CNN) architecture, achieves state-of-the-art results when trained with the Camelyon16 dataset. According to their reported results, CNN detects 92.4% of tumours compared to 82.7% for the previous best-automated method. [13]. A proposal conducted by researchers in Saudi Arabia led them to produce a model using Mask-RCNN that is trained to perform bone age assessment and classify them. Without changing the program's structure, they applied innovative methods like the whale optimization algorithm to handle various optimization challenges for real-world applications. The resulting model had a maximum accuracy of 99.2% [14]. A study was done on assessing how well neural networks have helped various healthcare operatives were documented in a survey, where it is noted that CNN, especially in the field of ML has had the most success in medical image classification among other ML-based solutions [15].

III. Data Pre-Processing

The first step is to load the dataset into the Jupiter notebook to start working on it. Assuming the images are stored locally, this is achieved via the os python library. A crucial first step for all types of machine learning applications is to check the dataset thoroughly and apply some kind of pre-processing even the best model cannot learn much from a poor, noisy and inconsistent dataset. Given the project's experimental nature, all images present in the original dataset are being considered, without any kind of manual removal of noisy samples. Anyhow, the images have different sizes and are stored in jpg format.

DOI: rp-9788770040723.039

Hence, in this case, pre-processing consisted of a resize of all images and a colour conversion, resulting in 250x250 grayscale images. These procedures aim to align the dataset, speed up the training and reduce the memory requirements without affecting the final results too much. This is achieved via a single custom function adopting the computer vision library Open-CV. Not much else applies to images in terms of data pre-processing, however, data normalisation can be employed. It consists of adjusting feature values to have them on a similar scale, this is proven to increase the performance and the training stability of the model, in particular of neural networks. In this case, grey scale pixel values ranging from 0 to 255 are normalized in the 0-1 range.

After this phase, images are stored in an array with shapes (614, 250, 250) and labels are represented in a separate array with shapes (614, 2). Labels are represented via one-hot encoding since classes are not related in any way and distance has no meaning.

Using 5-fold cross-validation, the risk estimate for each model is calculated. This enables us to train the model on several dataset subsets, produce five distinct predictors using a particular network architecture, and assess the overall model performance by taking into account the average loss and accuracy across all predictors. This is accomplished using a custom function that folds the images and their labels simultaneously shuffles the images and their labels, trains the model over four folds, and then tests it over the final fold five times. Naturally, the model weights are reset at the beginning of each training phase, thus five distinct predictors are generated. The function then returns the average loss and accuracy of the predictors as an overall evaluation of the learning algorithm with that fixed structure and hyper parameters.

IV. Model Set-Up

Each model is built in Tensorflow. Keras uses the same training loss function and optimizer. Since the approach only attempts to optimise the loss function, it is essential for the model's overall performance. A standard loss function for the binary classification task is employed in this instance, which is binary cross-entropy. The optimizer, which affects the network's updated weights, is also crucial. Adam, an expanded variation of stochastic gradient descent that has become the industry standard for deep learning and computer vision tasks, is employed in this situation.

The batch size and epoch count are additional important training factors. The batch size determines the number of samples the model runs through before updating its internal parameters. An epoch is a full pass over the entire training set, and the number of epochs defines the number of times the algorithm goes through it during the training procedure and so we set the batch size to 64 and the no of epochs to 15.

The accuracy and the zero-one loss are additional parameters that are offered when evaluating each model. The accuracy gives back the total number of accurate predictions across all samples taken into account, typically given as a percentage. The custom metric known as the zero-one loss merely counts the number of errors over the overall sample count taken into account.

The architectures we chose are as follows:

*Multilayer perceptron:*The multilayer perceptron is the first neural network architecture to be tested. It has six layers and is a feed-forward neural network. The first layer is a flattening layer, which converts the 100x100 2D input array into a 10000 by 10000 1D array to enable computations for the subsequent levels. Basic layers with dense connections make up the following four layers; the first has 100 neurons and the second, has 64. The Relu function, which is the most frequently utilised for hidden layers since it prevents the vanishing gradient problem during training, serves as the activation function for these layers. Only two neurons make up the output layer, representing the two distinct predictions' outcomes. The sigmoid activation function is utilised here, which outputs two values between zero and one summing upto one, representing the likelihood of either normal or osteoporosis.

The results were as follows:

MLP Metrics - 5-fold cross-validation estimate:

0-1 LOSS: 16.6 (over batch size = 64).

BCE LOSS: 0.5510249614715577

ACCURACY: 0.7221181392669678

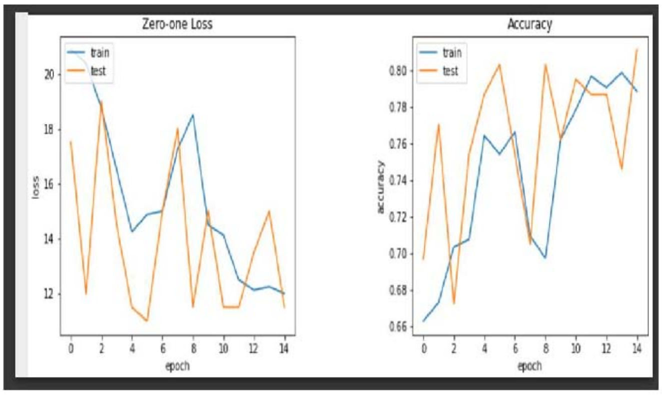

Fig 1. MLP Results

*Convolutional neural network A - 3 Conv. layers (16 32 64):*A convolutional layer followed by a max-pooling layer makes up the building block of a convolutional neural network; the whole network is made up of many blocks of this type. The number of applied filters, size of the kernel, and padding especially to prevent the shape of the picture from being altered during convolution must all be specified when building a convolutional layer. Three blocks with increasing numbers of 3x3 filters (16, 32, 64) were utilised for this model. The output must next pass through a flattening layer to become less dimensional before being fed to a dense layer made up of 512 neurons. Again, there are only two neurons with a sigmoid activation function in the output layer.

DOI: rp-9788770040723.039

The results were as follows:

CNN_A Metrics - 5-fold cross-validation estimate:

0-1 LOSS: 13.2 (over batch size = 64).

BCE LOSS: 0.5615522921085357

ACCURACY: 0.7696174907684326

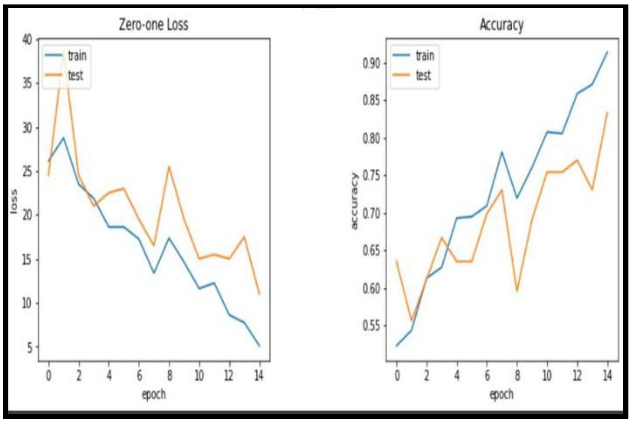

Fig 2. CNN (A) Results

Convolutional Neural Network B - 4 Conv. layers, (32 64 128 128): A second CNN can be defined to do additional research on this powerful architecture. This CNN is made up of four blocks that generate 32, 64, 128, and 128 filters, while the rest of the network is left unaltered. This ought to give the network additional strength and enable it to gather more information.

The results were as follows:

CNN_B Metrics - 5-fold cross-validation estimate:

0-1 LOSS: 13.1 (over batch size = 64).

BCE LOSS: 0.5430635213851929

ACCURACY: 0.7896695256233215

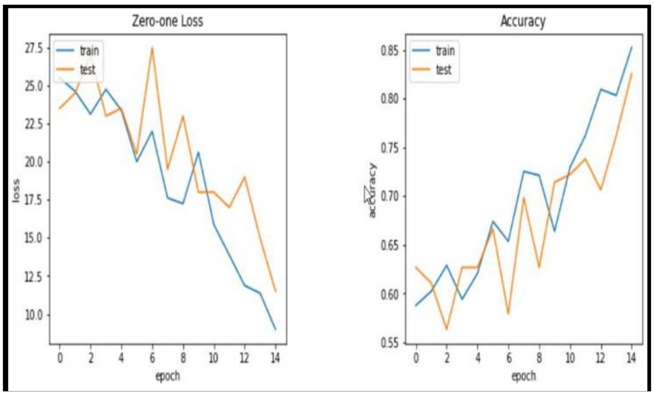

Fig 3. CNN (B) Results

Convolutional neural network + Dense dropout: Here we took the previous B model and added a dropout layer right before the dense layer and the dropout rate was set to 0.2.

The results were as follows:

CNN_dropout_dense Metrics - 5-fold cross-validation estimate:

0-1 LOSS: 11.0 (over batch size = 64).

BCE LOSS: 0.514670866727829

ACCURACY: 0.7984426307678223

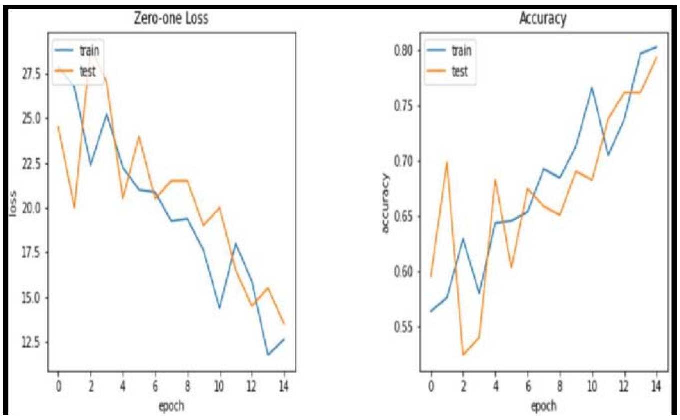

Fig 4. CNN Dropout over Dense layer, rate = 0.2 - Results

All the above graphs refer to a single step of the k-fold CV, graphs from other steps show a similar trend.

These results show that overfitting has been lessened but not completely avoided when compared to those CNN B. With dropout, this occurs around the 9th epoch as opposed to CNN B, when test loss started improving around the 7th epoch.

V. CONCLUSION

In the end, we performed a K-fold Cross Validation to pick the best-trained model and give out the best accuracy encountered. The result was as follows:

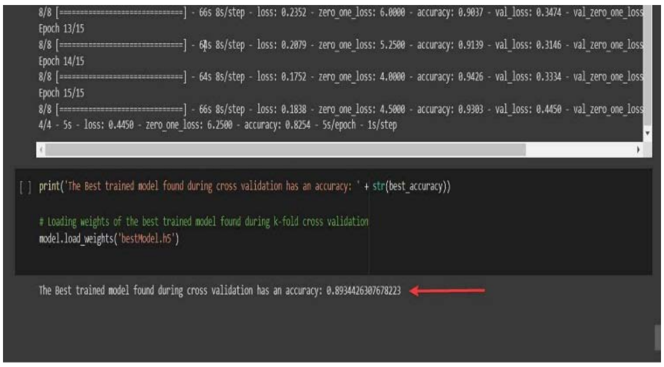

Fig 5. Accuracy of the model

The purpose of this research was to explore various neural network topologies and learn how to conduct tests and assessments using k-fold cross-validation that was statistically sound. Having stated that, the most recent models nearly attained a 90% accuracy. There is still room for improvement but our main goal for the next step of this research is to look at CNN models with a dropout layer

DOI: rp-9788770040723.039

and some particular architecture like DenseNet to take this to the next level.

***Abstract*–The increase in the Virus outbreak has caused a great deal of damage not only to the people around the world but also to the economy and the way we look at small things around us. From the year 2019, the world has seen different types of viruses. COVID 19, a horrific virus that put the entire world to an absolute stop. It caused widespread damage to the businesses, people, education, technology, medical and various other sectors. The Omicron which was a version of the SARS-COV-19 destroyed the immunity in most of the people. Recently the newer virus the H3N2 has also started its spread across India. When the cases were going sky-rocketing, the WHO came up with the idea that, when people stood at about 1-1.5meters it turned out to be safer for people. This process was coined as social distancing. Even though it is a very simple rule, a lot of people are not able to follow it because of the increased crowd around them. It has become very difficult to maintain it in places such as malls, markets, transportation stations etc. Using machine learning techniques, we have been able to monitor whether a proper distance is maintained between people.**

Keywords - SARS-CoV-2, Omicron, H3N2, Social Distancing, YOLOv3, Violation, Monitoring.

I. Introduction

The SARS-COV-2 surge started in December 2019. By March 2023 there had been 681,827,072cases in total and 6,813,670 deaths. The most effective method suggested by WHO (World Health Organization) is socialdistancing, which has become very difficult for people to follow. Manually people used to draw lines and circles on the roads, malls, worship places, which marked the territory for the people to stand and not cross it and as would violate the social distancing norm. We can never always blame the people for not following it as most of us were not prepared to face a situation beforehand. Human beings due to their mob-mentality often tend to roam to places with a large crowd.Placessuch as very narrow streets, malls, markets, eateries where the daily crowd is enormous,alwaysmaintaining social distancing is difficult. And especially during times such as the festivals like Christmas, Diwali, New year, the number of people who throng on the roads is humungous. Due to this there will be lot of people who might get infected, and here by, to maintain hygiene in such places by the health care workers would be difficult. The other viruses also demands such a selective isolation of the people in crowd to prevent the spread of the deadly virus, but physically monitoring all the time is a tiring process.

We considered the health care workers who would be on the field monitoring social distancing the whole time. Asthey are very near to the public the chances of their health getting deteriorated is very high. Our main goal was to terminate this problem. Thus, a technology that would monitor this at a remote location could be helpful to them.

Keeping all this in mind we have come up with a very simple system where the proximity of the people is determined using the deep learning mechanisms. We monitor the live video streaming camera, or even a recorded video or photo and detect the proximity of people and alert immediately if there was a breach.The system that we have made not only displays efficiently the number of people who are not following the social distancing but also helps to safely control the spread of the SARS-COV-2 virus.

II. Literature Survey

With the Indian population over 1.3 billion, it is becoming very difficult to monitor social distancing with minimal technologies. The works done by those researchers has helped the government to maintain social distancing to a bit. Technologies such as machine learning, deep learning and artificial intelligence are used by many tech-enthusiasts and they have easedout the process. In this section we will analyze different projects undertaken by different researchers.

Initially we had investigated [1] which was monitoring the social distancing using artificial intelligence. The camera would capture the images or the live stream. Then using R-CNN methodologies, it would detect the images present in the image or the video after which the distance is calculated using the distance matrix. Then the people are highlighted and shown is the distance is violated or not.

[2] [3] used image processing methods. Edge detection where, the edge of each object on the image is considered and if the edge of the two people cross the threshold level, we say that it was a breach of social distancing. Even though edge detection is a very efficient methodology, it is not very accurate while giving out the results. Another approach that we saw was [4] training the datasets using the Microsoft Common Object in Context (MS-COCO) for the image segmentation. This proposal also gave a proper measurement of the distance between them. [5] also followed a similar method. But instead, it identified the triggered areas where the spread of virus could be higher and instantly gave a warning that the following place was at risk. By this people could restrain themselves from going there.[6]used the centroid to find out the distance between the people and detect the social distancing.

DOI: rp-9788770040723.040

[7] uses UAV(unmanned Ariel Vehicle) which is similar to a drone which captures the real time images and searches for the pedestrians. They are marked on a map and the distance is checked. [8] similarlyused Artificial Intelligence for the monitoring Social Distance where, CNN and Convolution Long Short-term memory ConvLSTM was used. [9] used CNN methodologies which proved to have 98.5% accuracy. [10] took a different approach for this and used the IoT (Internet of Things) for detection. VidMask was used by few projects like [11] for training and detecting people with masked faces and then detect social distance. [12][13] used the deep learning concept. [14] had a special feature of identifying the people in the low light as well. [15] gave us the inspiration to work on this project. It explained the importance of social distancing and the various effects it has if not followed properly.

The major implication that we noticed from all the above projects was that none of them had a proper alert system. The above proposed methodologies just display on the screen of a recorded video the number of violations that have occurred. Due to this the security officer or the person who is governing the system might know that the social distance is violated, but the people who are standing there will not be knowing. Thus, we have inculcated the knowledge from the previous projects and the idea that we had come up with. They are

- Instant sound alert
- Instant WhatsApp message alert

Instant Sound alert is a feature that gives out a beep sound for about 2 seconds whenever there is a security breach in real time. As soon as the people in the given locality cross the threshold distance, a wide awakening sound is heard that could help people adjust themselves from where they are standing immediately.

Sometimes when the security officers are not viewing the camera from the security room, it would be difficult to keep a track if there has been a breach or not. Hence, sending a WhatsApp message to the group in which the security officers or the health care workers are present would make them attentive and help them clear out the crowd that is present. It can also be combined with the help of camera to see the exact person who violated the social distancing norms and take necessary actions on them.

III. Proposed Methodology

The proposed method makes use of image-processing techniques to track social distance in public spaces and workplaces. Cameras are placed in strategic locations, and video streaming is used to monitor the social distance. We can combine this solution with the security camera systems at workplaces, factories, and retail locations so that we can monitor whether individuals are maintaining a safe distance from one another. Utilizing the YOLO (You Only Look Once) Object detection technique that accurately identifies a person's class as input. Here is a stream of video. We track the objects in accordance with their movement by utilizing Object Tracking. The individual who disobeys the social distance rule is depicted by the RED bounding box elsewhere with a GREEN box's perimeter.

Majorly there are 3 main steps in doing this:

Person Identification: The initial step of identifying a person in the given camera or a video stream was done with the help of the YOLOv3. It is an object detection algorithm, whose purpose is to identify unique objects with help of training. The weights that were used had distinctive ability to filter out rest of the parts in the image and correctly mark the human beings in the video. The imutils library does the basic image processing. Using CNN or R-CNN could have slowed down the process of training as it would have very less frame rate for comparison as contradictory to the YOLOv3 that has been used. In order to make sure that same person is not detected twice and the exact person is detected throughout the video, we give out a class id to each of the person in the video individually. Thus, it will be their identification and even if the person moves out of the frame and comes again, it will again track him as the same person and not a different person. The box that is drawn around the person using the coordinates X, Y. As the person moves inside the frame, the coordinates keep getting updated and the box around the person also will change accordingly.

Detection of Social Distancing Violation: Once the detection of people is done, the next step would be to accurately check the social distance between each people. We then initiate by setting the minimum confidence and the minimum threshold values. The confidence level indicated how accurate does the system detect the person. Minimum distance (MIN_DIST) is given as 50. The MIN_DIST is calculated with the focal length(F) multiplied with the width(W) whole divided by the pixels occupied(P).A dot is drawn inside each of the box exactly at the centroid. When the centroids of two people’s boxes reaches below the MIN_DIST, we then say that the social distance is violated.

The centroid is first identified by using the width, of the height of the box that is detected around the person. Then the non-maxima suppression is applied, which makes sure even though two boxes overlap each other, they are not losing their unique identity. After which, we check if the centroids of two boxes are greater than or lesser than the MIN_DIST. Then we detect if there is a breach in the protocol.

OpenCV2 is used for the camera input. It also works similarly to the video feed. Where the camera opens and we can then detect the person. The video feed could have two different camera angles:

Checking the protocol from close distance: This surveillance camera provides a very zoomed-in view of persons around from a very close distance. We recognize the individual from the video monitor and ensure that they are far enough away to be safe.

Checking the protocol from a bird’s eye view:From a very far away distance, each person's distance from the other is calculated.

*Violation Alert System:*The major part of the project is providing the right alert to the people and the health care workers. This will ensure that the people will immediately change their positions and stay at a safer distance, that makes this project standout from rest of the projects. The alerts are given in 3 different ways.

*Alerts in the Video Feed:*Once the people are detected on the video feed or on the camera, a specific-colored light

DOI: rp-9788770040723.040

box would be displayed around them. Initially it would be green. If the centroids of the boxes cross the minimum distance, the color of the box will immediately change to red around the two people who are very close by. There will also be a section in the video labeled as “Social Distancing Violations” which will show the real time count of number of violations.

Sound based Alert: Video based alert would be helpful if the number of people is very limited and the space is very little. Example a video-based alert will be helpful in a queue of people standing at the billing counter or students sitting in the class. But when this combined with an alert sound such as a beep when there is a violation detected will immediately bring in a sense of tension amongst the people and help them stand in their appropriate positions. We had installed the “Winsound” library and an alert at a frequency of 400 will be played.

*Alert in form of WhatsAppmessage:*Consider a situation where the health care workers are not present inside the security room and the number of staffs are limited or the system is installed inside a SARS-COV-2 contaminated ward in a hospital. In such circumstances, a video feed alert might not be very effective. A sound alert could work but not perfectly. Therefore, we have introduced personalized WhatsApp message that would be sent to the person in the ward that violation has occurred. If all the health care workers are in a WhatsApp group, a message saying violated would help them regulate the people and make them stand in a safe position. For this we have used the library pywhatkit. Instant message would be sent in real time if the system detects that there was a violation.

The combination of Video based alert, sound alert and a WhatsApp message would also benefit the specially abled people to maintain the social distancing.

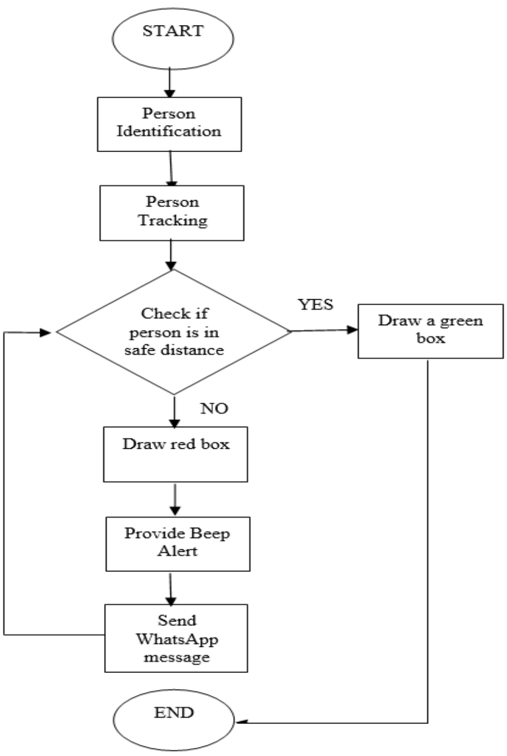

Fig 1: Flowchart of the project

IV. Benefits

The following are the benefits of using our project:

*Help the health careworkers:*Our project’s main motive was to help the public health workers. Usually in crowded places, it is the job of the workers or mark each space with dotted lines as to mark the distance for social distancing. But it eventually becomes difficult as when the crowd increases it becomes for the people to handle so many people. Thus, we have used the monitoring using the surveillance camera to ease out their process and take care of the health of the people.

*Lower the spread of SARS-COV-2:*The major purpose the WHO or The World Health Organization started the concept of social distancing was to govern the escalations of the deadly virus. As it was widely accepted by the people, but very poorly followed, the model we have made can help to effectively follow it.

*Increase the economy:*Due to SARS-COV-2 India as a country lost its entire economy. The project helps to remove the lockdown present in the country. Due to this, even though there is SARS-COV-2, people tend to go to crowded places like restaurants, malls, offices, and educational institutions.

Timely Alerts: The system maintains a proper record of the number violations that occurred to make sure that the institution can keep track of the progress. Whenever a WhatsApp message is sent in the group, it notes it down in its database.

V. Discussions

The major discussions while making this project was done to see, how much helpful the project was going to be for the health care workers. We had spoken to many Health care workers and then we had decided that something had to be done to remove their plight. Thus, we devised this project. There were discussions as to this project using Deep learning or image processing. Image processing becomes easier to do as it consists of less complex mechanisms. As the complexity is less, we can easily perform more integrated components to the project. We can add many datasets to it and check the accuracy of the project. Yolov3 was used in place of the traditional CNN and R-CNN. This is because, R-CNN and CNN are comparatively slow when each frame must be detected frame by frame. Yolov3 is around 8 times faster compared to them. The major difficult that could arise while making the project was how to connect it to a camera and lively capture the movement of the people in the crowded place. OpenCV2 library came handy for us to effectively view the camera mode and capture the live feed. Later the introduction of the messaging feature that was guided by our guide was added. All the feature makes the project very seamless and was done with the motive of making the people around us feel safe.

Specially abled people find it difficult to adapt to the new norms that is being laid by the WHO (World Health Organization). Thus, alerts based on personalized experience will help everyone be safe from the deadly virus safely.

DOI: rp-9788770040723.040

As the WhatsApp is used to provide mobile alerts, we have made sure that the system is highly secured and there will not be any invasion of privacy or leakage of mobile numbers to third party and will be safe to be used by everyone.

VI. RESULT

The following images depict the expected result that we achieved when we ran the application.

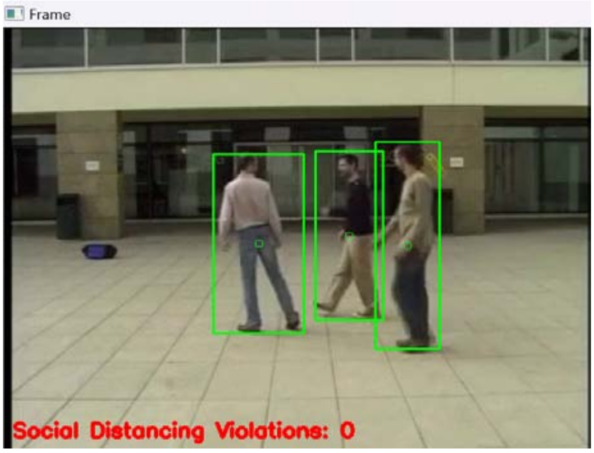

Fig 2: Initial Detection

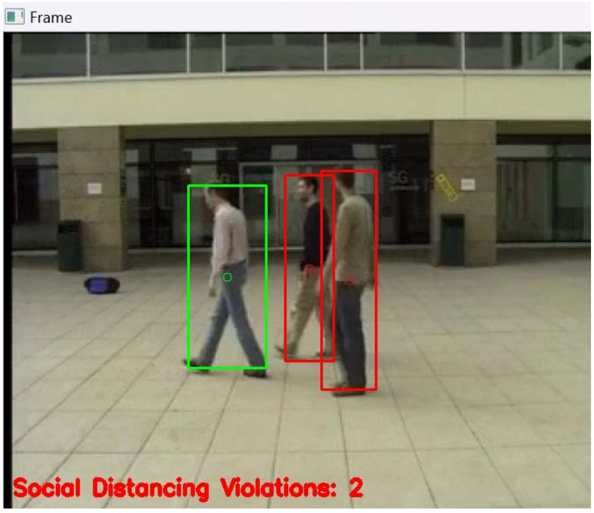

Fig 3: Violation Detected

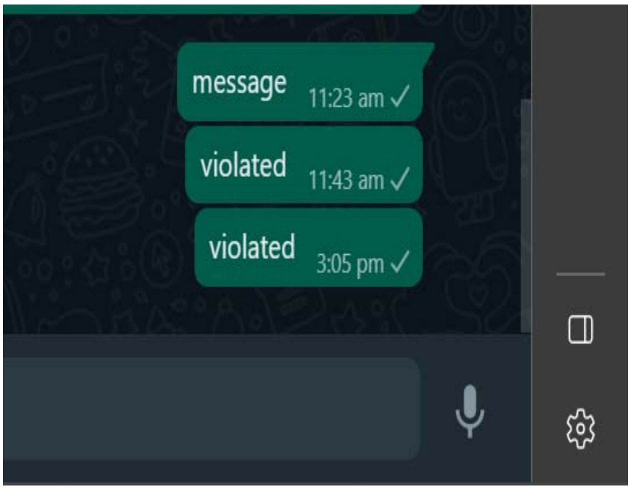

Fig 4: WhatsApp text sent

The above image displays the real time video that was taken and then monitors using the YOLO algorithm to see how many people are exactly following the social distancing norms and how many violations are being made.

The first image (fig 2) displays at a normal condition where the people are standing 1-1.5 meters away from each other and thus, there are no violations. The second image (fig 3) displays that 2 violations have occurred and this is because the people have crossed the minimum distance with themselves.A message is also sent to the group (fig 4). Using this information, we can control the violations. The predictions that came were 100% accurate.

VII. FUTURE ENHANCEMENTS

As technology keeps developing andthe virus getting stronger every day, the following system might not be useful in long run. For this we have planned for few enhancements such as instead of sending a WhatsApp message to the groups, we could send a personalized message to each person's mobile phone saying that they have violated the protocol. This will help in more personalized control of the violation and increase the privacy as well.

We have also planned to use this for the betterment of the society by providing it to the nearest hospitals so that people around us feel safe and SARS-COV-2 could be destroyed completely.

VIII. CONCLUSION

The major motive to consider this project was for a social cause.SARS-COV-2 is a deadly virus which is highly contagious. It easily spreads through air, or even skin contact. Our primary goal in implementing this project is to alleviate this problem, and as a result, our algorithm will subtract social distance between individuals. Since Health care workers are the ones who work every day, this aids them.As there is increased crowding in areas like malls, theatres, beaches, etc., it is difficult to identify those who are keeping social distance and to encourage them to do so. As a result, our model will use a camera to identify every individual in these public spaces, closely observe them, and slap a red mark on anyone who is too near to another person. Also, the YOLO method for our image processing model. Our methodology will thus primarily benefit Health care workers and aid to lower the number of COVID cases.

***Abstract*—Depending on whether they are "service reservoirs" for local storage of treated water, "lakes" that occur naturally and are used for drinking water, or "man-made" reservoirs built by constructing a dam across a valley, water reservoirs vary substantially in size and shape. The technique used to gauge reservoir water levels will vary based on the kind of reservoir being observed. A service reservoir's capacity is often known, and level monitoring allows for control over the flow through the reservoir and the pace of water withdrawal to guarantee a steady supply of water. As reservoir water levels drop due to water demand, level monitoring may be used to activate pumps as necessary to replenish them. In India, there is a serious problem with access to clean drinking water. It could soon start to resemble a global emergency. Therefore, it is crucial to save water. Water waste is increasing daily as a consequence of the pervasive issue of regulating the water level of above reservoirs in home-based water tanks. We all understand the importance of water to us, however. By collecting data on previous water levels and providing a graph that forecasts the reservoirs' future water level, a simple water level checker may manage this issue. Measurement and management of reservoir water levels are done using a Reservoir water level checker(RWL).**

Keywords*— *gauge, service reservoir, level monitoring, forecasts, reservoir water level(RWL) checker

I. Introduction

Cities rely heavily on dams for their water supply, as well as for flood control and river navigation. The vast majority of dams are built to accomplish many goals and therefore have many benefits. It is necessary to create some kind of connection between metering systems and computer models in order to help regulate the intricate systems of hydropower plants. Dams are typically monitored via conventional surveillance methods and water management, with the exception of certain dams' automated monitoring of water levels. Because so many people depend on dams and mayhave opposing interests, managing water resources via dams becomes challenging. Areas that are densely populated are affected by this. Dam monitoring is a laborious and drawn- out process that has to be improved gradually. Areas that are densely populated are affected by this. Dam monitoring is a laborious and drawn-out process that must be improved gradually. Areas that are densely populated are affected by this. Dam monitoring is a laborious and drawn-out process that has to be improved gradually. Using data sent to a control panel, a water level checker may determine if the water level in a body of water is high or low. Some water level indicators use float switches and probe sensors to measure water levels. The level of water in a RESERVOIR is detected and shown by the Water Amount Checker using a straightforward technique.

A reservoir's water levels are monitored and controlled using a water level checker. When water levels drop below a certain threshold, the control panel may also be set up to automatically operate a water pump and top them up.

II. Literature Survey

There are many studies addressing fuzzy or neural network control in water level control systems, and the field of water or liquid level control is quite active. Water level monitoring and control are required.

Through a variety of sensors, the whole dam and major pipeline are monitored here around the clock. These interconnected wireless sensor nodes provide data to a gateway by connecting to one another. Information is stored and made available to the observer online using common storage space, or "CLOUD". The most valuable naturalresource, water, will be saved through the use of IoT for the aforementioned reason[1].

Given that they are commonly used for agricultural reasons, it is clear that Remote sensor systems are a dependable precedent. The use of the web and its applications has grown dramatically in recent years. Since everyone's job is impacted by it, it would be difficult without the internet. In the same way, as today's widely used remote sensor systems, which include a CPU, storage, power supply, a phone, and at least one sensor, are low-power devices. Both have been merged in this application with the aim of acquiring information on the state of the water[2]. There are many studies addressing fuzzy or neural network control in water level control systems, and the field of water or liquid level control is quite active. Water level monitoring and control are required.

Water level detection is made simple by the ease of installation and low maintenance requirements of submersible pressure transducers (wet sensors). They are

DOI: rp-9788770040723.041

therefore commonly used for temporary installations as well as deployments in far-off locations. They need to be installed permanently and kept submerged at all times. It works by providing hydrostatic pressure to a strain gauge, which converts mechanical motion into an electrical signal that the station can subsequently detect.

As we can see, significant dam safety control nowadays is mostly dependent on measuring crucial variables like absolute and relative displacements, strains, and stresses in the concrete discharges through the foundation, etc., as well as visual inspections of dam structures. In certain dams, the gathered data is analyzed and contrasted with the findings from mathematical or physical models that help with a structural safety assessment.

Artificial neural networks (ANNs) have been shown to surpass conventional methods in the creation of models for predicting river flow. They are quick and versatile. By taking into account the previous operations the structure was put through, these networks may be used to characterize the dams' typical structural behavior. The vast network of neurons in the human brain is analogous to an artificial neural network, which is nothing more than a network of linked nodes. In this network, each circular node stands for an artificial network, and each arrow represents a flow from one node's output to another's input.

A dam may experience extreme water level variations during its lifetime as well as seasonal temperature changes. Delivering the right quantity of water while keeping the water head over a certain threshold is the most important part of water delivery. It is critical to provide the final consumers with the required volume of water at a suitable pressure. The overhead storage tanks are built with a constant water level in mind in order to sustain pressure. The daytime fluctuations in client demand affect the tank's output flow rate. Overflowor pressure drops at the end user are possibilities if water is given at a constant pace.

One such project on the Nile entailed the establishment of national geographical databases, geographical layers, hydro- meteorological parameters, data on the usage of water, and information on land use, the amount of cover on the land, and soil kinds. Acoustic-based Doppler current profilers and automated weather stations are two examples of contemporary monitoring systems that were put into place. For monitoring water flow, this kind of apparatus is suitable. In most rivers, a boat with a Doppler current profiler mounted is used to operate it. As a result, there is no longer a need for an expensive cableway to be built. Additionally, this project includes two buoys that will be used to measure the amount of water evaporation on Egypt's Lake Nasser and to verify the accuracy of satellite-based evaporation estimations. This data format was created in cooperation with the national water resource agencies and has been used by the majority of basin states. This generated data structure enables smooth and rapid data exchange once proper data-sharing techniques are in place. The creation of instruments for basin-wide evaluation, like the Nile DST, also needs a uniform framework [3].

The South-East River Trust, on the other hand, controlled the Teise River's water levels using a weir technique. A weir is simply a wall built across a river to alter the properties of the flow. Weirs are often erected across the breadth of rivers as horizontal barriers that collect water behind them while yet allowing it to gently flow over the top. Weirs are widely used to prevent flooding and to keep track of discharge. Another water level monitoring system was developed, and it is made up of an ultrasonic sensor, a PIC microprocessor, and a GSM module. The distance between the ultrasonic sensor and the liquid's surface is measured. This method suggests using the GSM to create a system for monitoring water levels.

When the water level reaches a critical level, a module that uses Short Message Service (SMS) to alert the person in control switches the pump off automatically. The water level may be checked as needed [4].

China is using computing methods to cut down on water waste and increase financial gains. Additionally, it ensures environmental protection and water cycle stewardship so that water resources may be passed on to next generations. By employing sensors that measure the volume of water in the tank, they automated the pumping of water into tanks using Arduino-based devices. An LED display will alert the user of the condition while the pump mechanism will work automatically based on the water level. To automate water extraction from the sump tank, this system is simply expandable. The same technique may be used to monitor how much water is in the sump using sensors, but if the system notices that there is not enough water, it will stop the engine from running to prevent dry running. To alert the user of the issue in such a situation, an alarm sound may be enabled [5].

The handler commands the gate to open and shut under the manual dam control method currently in use. This permits both unequal water distribution between the two residences as well as human error, which might cause floods orexcessive water waste. Their proposed approach removes these possibilities by providing an automated dam control system. In part, the whole system is self-powered. Because of the architecture, the system is self-sustaining and uses energy collecting.

Systems for remote data collection and monitoring are practical and efficient instruments for monitoring and collecting data from bulk storage tanks. Such systems are helpful in businesses that are designated as safety essential systems and measure the liquid within the tank, which is of utmost importance. The design and preliminary testing findings of a low-power wireless system for tank-level monitoring using ultrasonic sensors are presented in this study[6].

In this system, the water pumping process has been automated using an Arduino board. The Arduino can sense the amount of water in a tank, determine whether to turn on or off the pump, and show the status on an LCD screen. The device further keeps an eye on the sump tank's water level (source tank). Low sump tank levels will prevent the pump from turning on, protecting the engine from dry running. When the sump tank's level is low or if there is a sensor issue, a beep sound is produced[7].

An inexpensive optical water level sensor based on the fibre bending effect and an elastomeric membrane is discussed in this work. The suggested sensor has a specific design that makes it easy to use, dependable, and affordable. It is appropriate for use in reservoirs, tanks, and the tubes of embankment dams. The sensor selects the suitable membrane and can measure the water levels up to 10 m or more using a typical single mode fibre. The creation of the sensor, a theoretical modelling, and the outcomes of lab and field experiments are all covered in this essay. A real-time monitoring system based on optical time domain reflectometry has been using seven sensors that were put in an embankment dam[8].

The system, which consists of several sensors, is used to measure the water's physical and chemical characteristics. They measure the water's characteristics, including its temperature, PH, turbidity, conductivity, and dissolved oxygen. The core controller is capable of processing the measured data from the sensors. They have used the raspberry PI B+ model as a core controller. Finally, cloud computing may be used to see the sensor data online[9].

In this project they have used Zigbee 802.15.4, a 74HC14 inverter, water level sensors, and GSM technology to monitor the water level. Water quality sensors like turbidity sensors and dissolved oxygen sensors may also be used to check the water's quality. In this monitoring system, sensors check the pH level, temperature, turbidity, dissolved oxygen, and water level at predetermined intervals. This strategy would aid in lowering household energy usage and water overflow[10].

In this research, they suggest an Internet of Things (IoT) based real-time water level monitoring system. Their prototype is founded on the notion that, particularly in disaster-prone locations, the water level might be a crucial factor in determining the likelihood of flooding. The requiredparameter is detected using a water level sensor, and if the water level meets the parameter, a real-time signal is sent to a social network like Twitter. Data repository configuration was made on a cloud server. On the remote dashboard, the water level measurements are shown[11].

In order to monitor the water level, the system employs an ultrasonic sensor, an AT89S51 microcontroller, and a SIM300C GSM modem. When asked through SMS, the system may test the water level and provide a measurement report. This system may be installed in a variety of locations since, depending on the installation requirements at those locations, it just requires the first configuration through SMS[12].

An ultrasonic sensor, PIC microcontroller, and GSM module were used to construct a monitoring system for measuring water levels. The distance between the ultrasonic sensor and the liquid surface is measured. With the integration of a GSM module, this system shows the construction of a water level monitoring system that will send a Short Message Service (SMS) alarm to the person in charge when the water reaches the critical level, which will cause the pump to automatically switch off. At any time, it is possible to check the water level[13].

In order to prevent many steps and make the process simpler and faster, they utilised a control approach in this study that validates the hardness of the supply water at the very first phase. The typical process station will also squander a significant quantity of water at each stage of the filtration process. Such wastages can also be reduced in the planned job by employing an effective control method. The experimental investigation carried out using the suggested technique investigates the water saved during the clear water operations as well as the processing time needed for the feed water[14].

This study uses the Linear Discriminant Analysis (LDA) method to show an assessment of the water quality. The Water Quality Index is calculated using a weighted arithmetic index approach (WQI). The final major WQI dynamics are known at that point, and the LDA is connected to the dataset. The LDA then performs Light Gradient Boosted Machine (LGBM) classification after forecasting the WQI. The LGBM classifier is then engaged to assign a water quality label. On a dataset connected to Gulshan Lake, the suggested LGBM with LDA approach is shown and assessed. The results reveal 100% classification accuracy for the Light Gradient Boosted Machine classifier system and 96% prediction accuracy for the LDA, which indicates consistent interpretation connected over the futuristic models[15].

III. Basic Schematics

The main goal of this project is to completely automate the regulation of water levels near all dams using a centralized server [7]. Each dam is first considered to be a single node. Acentral command center, which can keep track of each node's activity, is connected to several of these nodes.

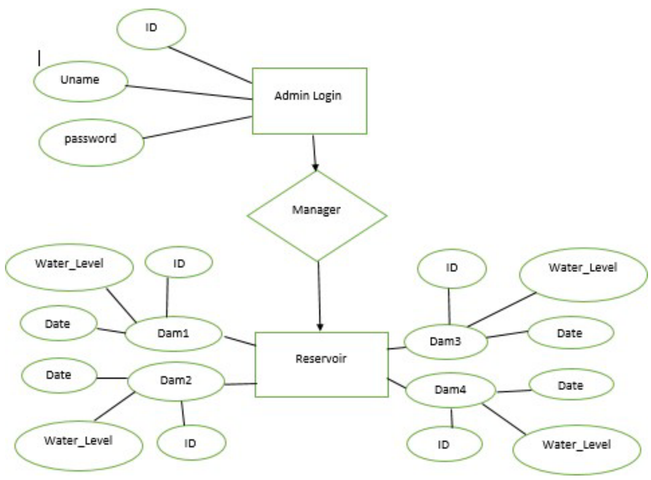

Fig. 1. Basic Schematic diagram

From the Figure 1, we can see that initially, we will have an Admin node with its own ID, Uname, and password. Only the admin will have total access to the database and the data being entered. All scraped data will be placed into the local host to preserve it and utilize it to anticipate water levels.

The admin node is then linked to a common manager, which collects all scraped data, saves it, and manages Dams data on the local host. At regular intervals, it collects all of the IDs, water level data, and dates. This is used to forecast reservoir water levels.

The manager is then linked to numerous nodes, each of which has information on a Dam. Details such as water

DOI: rp-9788770040723.041

level, ID, and date are required to assess and anticipate before a calamity occurs in the near future using the old stats.

Because the project is modular, we can add additional modules and use them on a large scale. This device is so simple to use that it can assist individuals in the area to evacuate promptly in the event of a disaster.

IV. Water Level Tracking Implementation

The monitoring of reservoir water levels is required for assessing and forecasting a disaster-avoidance plan. The water level was calculated at four distinct sites to test the treatment's efficacy. The procedure consists of four steps:

A. *Web Scraping using BeautifulSoup*

Web scraping, web harvesting, or web data extraction are all terminology for an automated technique of obtaining vast amounts of unstructured data from websites. The user can extract all of the data on specified sites or specific data as needed. The obtained data can be saved in a structured manner for further study.

Web scraping Using BeautifulSoup involves the following steps:

- Locate the URL of the webpage you wish to scrape.
- Examine the specific elements before selecting them.
- Write the code to obtain the content of the chosen components.
- Save the data in the appropriate format.

With this, we collected the required Table data regarding the Dam. The Data collected is stored in a local host called Phpmyadmin using an Apache distribution called Xampp.

B. *GUI Designing using Tkinter*

Tkinter is a typical Python interface for the Python-bundled Tk GUI toolkit. Python was chosen to build the GUI since it is the fastest and most straightforward way to develop GUI apps. Making a GUI using Tkinter is a straightforward process.

To make a Tkinter app, follow these steps:

- The module is being imported Tkinter
- Make the primary window (container)
- Add as many widgets as you like to the main window.
- On the widgets, use the event Trigger.

The Figure 2 , shows the GUI we designed to project.

Fig. 2 GUI of login page

We first created a login page for both admin and user to access the app. In the Figure 3, after login we have options to choose between reservoirs .

Fig. 3 Options tab for reservoirs

V. Results

After all of the reservoir data has been web scraped and saved on the local host, we can examine the reservoir information in the GUI. We will initially have a login for admin and user, then after logging in, we will be able to pick between reservoirs and click go. This is seen in Figure 4.

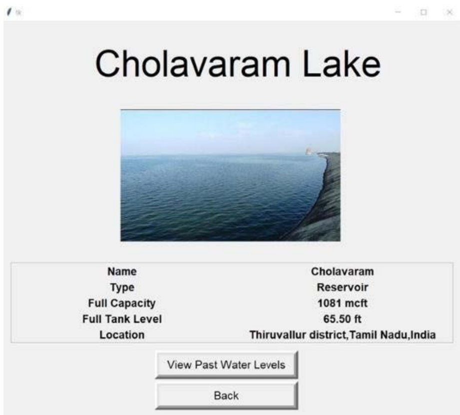

Fig. 4 Data regarding the lake

After clicking go, the newly created page will display reservoir data and give us the choice to "see prior water levels." Using this option, we may view the water level plot for the previous 100 days. This is seen in Figure 5.

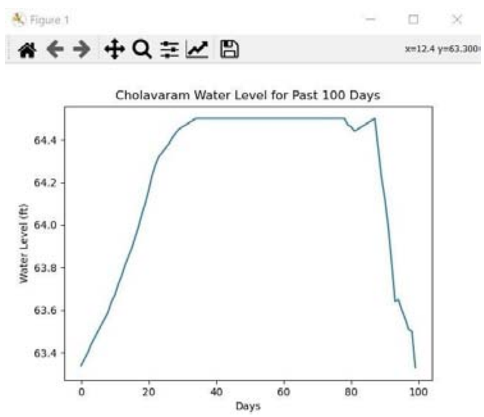

Fig. 5 Plot for water level for the past 100 days

DOI: rp-9788770040723.041

The Figure 6 shows the output of the reservoir water level.

Fig. 6 Shows the data collected from the last 100 days

VI. CONCLUSION

This project is intended to suit the needs of a reservoir water level checker. It was created in Python with the backend DBMS so that the data input is saved in the DB file and the data stored is utilised in the rwl checker while keeping thesystem specifications in mind. We utilised a simple data entity relationship diagram to create the system. The rwl checker has all of the characteristics of a true water level indication device. This short project taught us how to connect to a database using Python.Overall, the project teaches us important skills such as:In creating the system, system analysis and design approaches such as data flow diagrams are used.

***Abstract*—Electric vehicle (EV) charging stations powered by renewable energy sources, such as solar power, can significantly reduce carbon emissions from transportation. In this paper, we propose a smart electric vehicle charging station that utilizes solar power to charge EVs. The proposed system integrates solar panels, battery storage system, and electric vehicle charging equipment to provide a sustainable and efficient charging solution. Additionally, a smart charging system optimizes the use of solar energy and manages the charging sessions to avoid peak demand periods. We describe the system design, implementation, and benefits of a solar-powered smart EV charging station.**

***Keywords*—solar panel, BMS, IOT, EV charging station.**

I. Introduction

With the increasing demand for electric vehicles (EVs), the need for electric vehicle charging stations is growing rapidly. However, the use of traditional electricity sources to power these stations results in significant environmental impact and contributes to the global carbon footprint. Therefore, the implementation of renewable energy sources, such as solar power, is becoming increasingly important.

The combination of solar power and electric vehicle charging stations offers a sustainable solution that can significantly reduce carbon emissions and promote the use of renewable energy sources. The integration of a smart charging system allows for efficient management of the charging process, optimizing the use of solar energy and avoiding peak demand periods. This paper proposes a smart electric vehicle charging station that is powered by solar energy and includes a smart charging system.

The paper is organized as follows: The first section provides an overview of the current status of electric vehicle charging stations and the use of solar power as a renewable energy source. The second section presents the proposed smart electric vehicle charging station and its components. The third section discusses the implementation of the proposed system. Finally,the conclusion summarizes the findings of this research paper and discusses the potential for future research.

II. Current Status of Electric Vehicle Charging Stations and Solar Power

The increasing demand for electric vehicles has resulted in a significant increase in the number of electric vehicle charging stations globally. According to the International Energy Agency (IEA), the number of publicly accessible electric vehicle charging points reached over 1.3 million worldwide in 2020. However, the majority of these charging stations rely on traditional electricity sources, such as coal and natural gas, which contribute to greenhouse gas emissions.

The implementation of renewable energy sources, such as solar power, can significantly reduce the environmental impact of electric vehicle charging stations. Solar power is a clean and renewable energy source that can be harnessed to provide electricity to charging stations. The use of solar power in electric vehicle charging stations not only reduces carbon emissions but also reduces the reliance on the traditional electricity grid, providing energy security.

III. Methodology

A. *Block Diagram*

- The grid-based photovoltaic charging system is an innovative future technology. The photovoltaic charging system is shown in the architecture, which was developed after various studies.
- The above design shows that a DC-to-DC converter and a DC-to-AC converter both produce two stages. The dc bus is more important since it interfaces with additional dc power devices, as well as the PV array and energy storage batteries of electric cars. The fact that the DC bus is meant to connect the PV array, the ESU, the EV battery pack, and other dc powered devices emphasizes its importance.

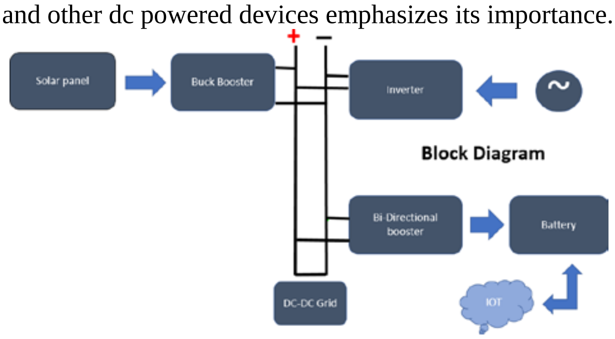

Fig. 1. Block Diagram

DOI: rp-9788770040723.042

- Standalone PV charging system: With an off-grid station, power is provided directly to the batteries of an electric car. Connection to the power grid An Energy Storage Device (ESD) unit is connected to the charging system to deliver electricity to the EV battery continuously during the night.
- We'll build an Internet of Things project in which the ESP8266 will track its own battery level using the BlynkIoT Cloud. We can monitor sensor data, battery charging/discharging status, battery voltage, and battery % in order to quickly recharge it. This is a simple method that makes use of a voltage divider circuit and the analogue input on the NodeMCU ESP8266 board.

B. Lab Setup

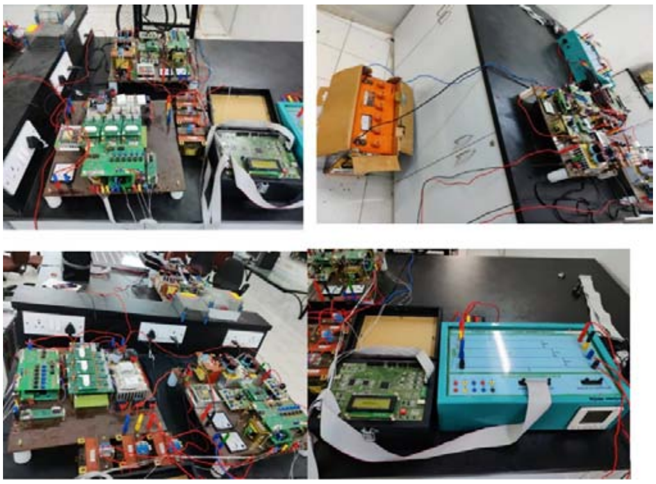

Fig. 2.Lab Setup.

- Solar panel

The solar panels are used to harness solar energy and convert it into electrical energy to power the EVCS. The number and capacity of solar panels depend on the expected charging demand, the geographic location, and the climate conditions.

- Energy Storage System

The energy storage system consists of batteries that store the excess solar energy generated during the day and use it to power the EVCS during the night or periods of low solar irradiance. The energy storage system also provides a buffer to balance the energy supply and demand, and ensure stable and reliable charging services.

- Energy Management

The energy management module is responsible for monitoring and optimizing the energy flows in the system. It uses real-time data from the solar panels, energy storage system, and EV charging stations to predict the energy demand and supply, and adjust the charging rates and schedules accordingly. The energy management module also ensures the safety and stability of the system by regulating the voltage and current levels, and preventing overloading or short-circuiting.

- EV Charging Stations

The EV charging stations are the primary interface between the EVs and the EVCS. The proposed system supports different charging standards such as AC, DC, and fast charging, and can accommodate multiple EVs simultaneously. The charging stations are equipped with sensors and communication devices that enable real-time monitoring and control of the charging process.

C. Battery Management System

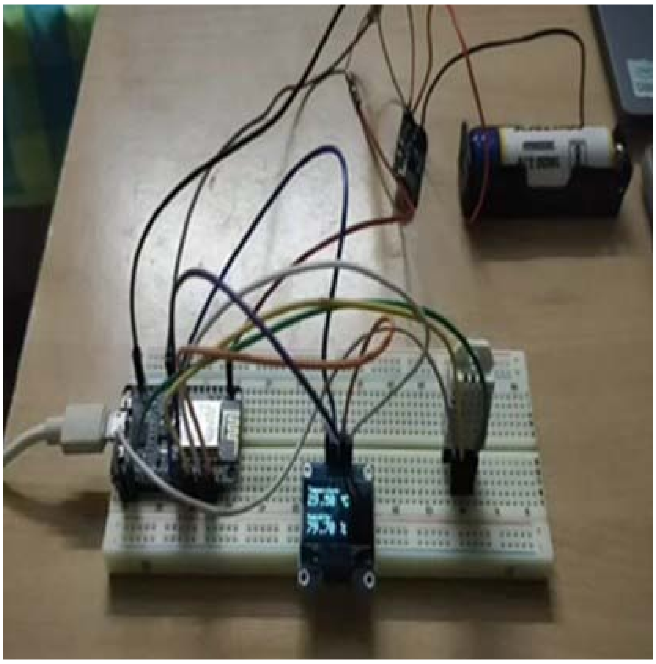

Fig. 3.Battery Management Setup.

- Smart Control System

The smart control system is the brain of the proposed EVCS. It integrates various advanced technologies such as IoT, AI, and cloud computing to optimize the system performance, enhance the user experience, and providevalue-added services. The smart control system consists of four main modules: energy management, charging scheduling, user interface, and communication and security.

- Charging Scheduling

The charging scheduling module is responsible for man- aging the charging sessions and optimizing the charging efficiency. It uses data from the EVs, such as battery capacity, charging status, and location, to prioritize the charging sessions and allocate the available energy resources efficiently. The charging scheduling module also provides real-time updates to the users about the charging status, estimated time of completion, and charging costs.

- User Interface

The user interface module provides a user-friendly and interactive interface for the customers to access the charging services and manage their accounts. It includes a mobile app and a web portal that enable customers to reserve charging spots, track the charging progress, and pay the charging fees. The user interface module also provides personalized recommendations and incentives

DOI: rp-9788770040723.042

based on the user's preferences and behavior.

IV. Implementation

Fig. 4.Mobile Dashboard.

The implementation of the proposed smart electric vehicle charging station involves several steps:

a) Feasibility Study: Evaluate the solar energy resource at the location, the expected demand for the charging station, and the required capacity of the battery storage system.

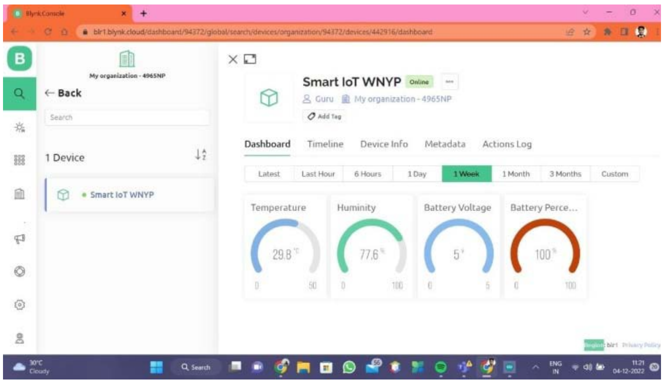

Fig. 5.Website Dashboard.

b) System Design: Develop a design that integrates the solar panels, battery storage system, and electric vehicle charging equipment. Determine the capacity of the solar panels and battery storage system needed to meet the expected demand for the charging station.

c) Equipment Selection: Choose the solar panels, battery storage system, and electric vehicle charging equipment that meet the project's requirements. Consider the efficiency, durability, and cost of the equipment.

d) Installation: Install the solar panels, battery storage system, and electric vehicle charging equipment according to the design specifications. Ensure that the installation follows safety regulations and industry standards.

e) Smart Charging Implementation: Integrate the smart charging system that manages the charging sessions, optimizes the use of solar energy, and communicates with the electric grid to avoid peak demand periods. The smart charging system can be implemented using a variety of technologies, including energy management systems, intelligent algorithms, and cloud- based platforms.

f) Testing and Commissioning: Test the charging station to ensure that it meets safety regulations and industry standards. Commission the charging station to operate efficiently and sustainably.

g) Monitoring and Maintenance: Monitor the performance of the charging station and maintain the equipment to ensure long-term efficiency and sustainability.

V. Benefits

a) Sustainable and Environmentally Friendly: The pro- posed system uses solar power, which is a renewable and clean energy source. It reduces the carbon footprint and contributes to mitigating the climate change effects.

b) Cost-effective: The use of solar power can reduce the operating costs of the EV charging station and increase the return on investment. The energy storage system can also reduce the peak demand charges and provide ancillary services to the electric grid. •

*c) Efficient and Reliable :*The smart control system can optimize the energy management and charging scheduling, and provide real-time monitoring and control of the chargingprocess. It ensures the efficient use of the available energy resources and the reliable operation of the system. •

d) Scalable and Flexible: The proposed system can accommodate different charging standards and protocols, and can be scaled up or down based on the demand and the availability of solar energy. It can also be integrated with other renewable energy sources and energy storage systems.

VI. Drawbacks

a) Initial Investment: The installation and setup of the EV charging station and the solar panels require a significant initial investment. The cost may vary depending on the size, capacity, and location of the system.

b) Weather Dependency: The efficiency and performance of the solar panels depend on the weather conditions, such as sunlight intensity, cloud cover, and temperature. The system may not generate enough energy during periods of low solar irradiance or extreme weather events.

c) Space Requirement: The installation of the solar panels requires a significant amount of space, which may not be available in some urban or densely populated areas.

DOI: rp-9788770040723.042

The charging station may also require additional space for parking and infrastructure.

d) Maintenance and Operation: The maintenance and operation of the EV charging station and the solar panels require specialized skills and knowledge. The system may also require periodic inspections and repairs to ensure the safety and reliability of the system.

VII. Conclusion

The project addressed the design and development of an IoT-based battery monitoring system for electric cars in order to ensure that online monitoring of battery performance decline was achievable. The objective is to establish the feasibility of the underlying premise of the notion. As part of the system development, the hardware for the battery monitoring device and a web-based battery monitoring user interface are being created. The system may offer information such as position, battery life, and time through the internet by integrating a GPS system to identify the coordinate and display it on the Google Maps application. The system may be developed further by integrating new capabilities. The technology may be utilized in smartphones by developing them.

***Abstract*—In this study, a Convolutional Neural Network (CNN) is used to classify potato leaf illnesses using Deep Learning. The suggested approach entails preprocessing the leaf image data, training a CNN model on that data, and assessing the model's success on a test set. The experimental findings show that the CNN model, with an overall accuracy of 99.1%, is highly accurate in identifying three kinds of potato leaf diseases, including Early Blight, Late Blight, and Healthy. The suggested method may offer a trustworthy and effective remedy for identifying potato diseases, which is essential for maintaining food security and minimizing financial losses in agriculture. The model can accurately recognize the various disease types even when there are severe infections present. This work highlights the potential of deep learning methods for categorizing potato diseases, which can help with effective and automated disease management in potato farming.**

Keywords* — potato leaf disease classification, deep learning, convolutional neural network, image processing, computer vision, plant disease diagnosis, agricultural technology, crop protection

I. Introduction

Potato is a vital food crop globally and a significant source of income for farmers. However, potato crops are susceptible to various diseases that can cause significant yield and quality losses. Leaf diseases are among the most common and destructive of these diseases [1]. Early detection and accurate diagnosis of these diseases are essential for effective disease management and control. Traditional methods of disease diagnosis rely on visual inspections, which are subjective and time-consuming. In recent years, there has been a growing interest in the use of deep learning techniques for automatic disease detection and classification.

The potato, **Solatiumtuberosum**, as in Fig. 1 is the fourth-ranked food crop used to feed an increasing global population because of its adaptability in cultivars and high complex carbohydrate content. For the dining and the processing market, potatoes can be kept for a long time, but storage disease issues are common [2]. Wherever potatoes are produced, diseases both in the field and during storage can be a limiting factor in the ability to produce them sustainably and profitably.

Fig. 1: Potato **(SolatiumTuberosum)**

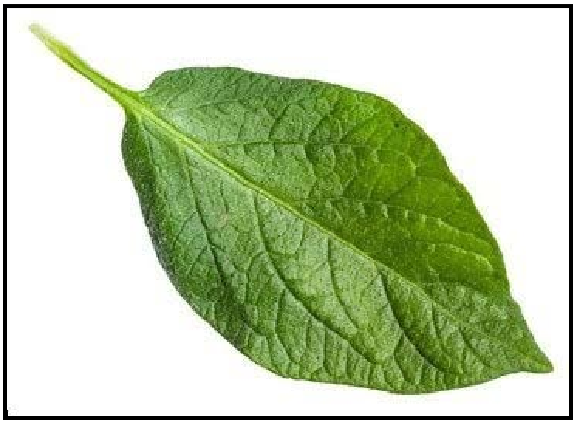

Fig. 2: Healthy Potato Leaf

In this study, we suggest a deep learning method for categorizing potato leaf illnesses. In particular, we investigate the application of convolutional neural networks (CNNs) for the automated detection and classification of various potato leaf diseases.The primary goal is to develop a precise and useful method for the early detection and classification of potato leaf diseases so that farmers can act quickly and control the disease. The suggested method has the potential to greatly increase the effectiveness and accuracy ofmanaging potato leaf disease and increasing crop yields while minimizing financial losses.

DOI: rp-9788770040723.043

As, due to its capacity to extract intricate patterns and features from sizable databases, deep learning has become increasingly popular in recent years. Deep neural networks known as convolutional neural networks (CNNs) are frequently employed for picture classification and recognition tasks. They can learn hierarchical representations of images, which makes them especially suitable for this job.

It is built with the intention of detecting or identifying the various diseases that can affect potato leaves, because Convolutional Neural Network (CNN) can identify them with ease while the human eye cannot. Unbelievably, some pre- trained Neural Network Architectures have error rates of about **3%**, which is even lower than the best **5%** error rate of human vision. **5.1%** was determined to be the human top-5 error on large-scale images, which is higher than pre-trained networks [3].

II. Literature Survey

Singh et al. (2015) [4] - performed a review of the literature on various image processing techniques for detecting leaf disease. The writers wanted to speed up identification and detection of plant diseases while lowering the subjectivity that comes with naked-eye observation. They presented an algorithm that uses picture segmentation to automatically identify and categorise plant leaf diseases. The impact of HSI, CIELAB, and YCbCrcolour spaces on disease spot detection was examined by the authors. To identify the disease spot, the Otsu technique was applied to the colour component after an image was smoothed using a median filter. The suggested method was not put to the test on any datasets.

He et al. (2015) [5] - deep residual networks were discussed in relation to image recognition challenges. As shallow representations for image retrieval and classification, VLAD and Fisher Vector are cited in the paper's literature review as related concepts. The writers also covered the advantages of encoding residual vectors over original vectors for vector quantization. The Multigrid method was also mentioned as a method for solving partial differential equations (PDEs) by reformulating systems as subproblems at multiple scales, where each subproblem is accountable for the residual solution between a coarser and a finer scale. This method is used in low-level vision and computer graphics.

Islam et al. (2017) [6] - suggested a method to identify diseases from images of potato plant leaves by combining image processing and machine learning. The authors classified diseases using the 'Plant Village' database of openly accessible plant images. Using the suggested method, the research classified 300 images of diseases with a 95% accuracy. The paper also highlights how crucial contemporary phenotyping and plant disease detection are to assuring food security and sustainable agriculture.

Velmurugan and Renukadevi (2017) [7] - describe a research on the creation of software for the automatic detection and classification of plant leaf diseases. Only a few methods were suggested for particular databases, such as satellite images, leaf sets, maps, faces, fingers, etc., the authors discovered after conducting a literature review. The research suggests a novel algorithm that, with 94% accuracy, canidentify and categorise the diseases under study. The processing process consists of four major steps: colour transformation, masking of green pixels, segmentation, and computation of texture statistics from the SGDM matrices. The suggested method was tried on a database of about 500 plant leaves, and the outcomes support the robustness of the suggested algorithm.

Dasgupta et al. (2019) [8] - address the issue of food scarcity in developing countries, particularly in India, due to potato production being affected by diseases such as Early Blight and Late Blight. To tackle this problem, the authors propose the use of deep learning and transfer learning techniques to develop a model capable of accurately detecting these diseases in potato plants. The literature review section of the paper delves into the The fungus AlternariaSolani is responsible for the early Blight disease. The disease has a polycyclic life cycle and requires free water to germinate. Early Blight primarily causes the premature defoliation of potato plants.

Cecilia et al. (2019) [9] - share a research on the use of image processing methods and machine learning algorithms for spotting pests and diseases in blueberry plants. Since there was no openly available database for this kind of fruit, the authors created their own database of images. The research used a variety of filters, including addWeighted and Gaussian Blur to enhance the details in the images and medianBlur and Gaussian Blur to remove noise. Utilizing both normalised and unnormalized versions of algorithms like HOG and LBP, traits were extracted. Using Deep Learning, the findings revealed an accuracy index of 84%. The report does not, however, contain a literature review.

Iqbal and Talukder (2020) [10] - investigated the use of image processing and machine learning methods in identifying and classifying diseases of potato leaf. In order to find diseased regions, the authors processed 450 images of healthy and diseased potato leaves from the freely accessible Plant Village database using image segmentation methods. To differentiate between the sick and healthy leaves, they used seven classifier algorithms, with the Random Forest classifier having the best accuracy (97%) rate. The study also included a review of prior studies that used machine learning and image processing to identify plant diseases.

III. Proposed Methodology

Data collection, pre-processing of the data, data augmentation, and disease classification make up the main four stages of the methodology described in this paper. Fig. 3 mentions the graphical representation of procedure for classifying different diseases of Potato leaf, step by step. So, the four mentioned steps are:

A. Data Acquisition/ Data Collection and Description

Different image resolutions and sizes have been obtained from dataset uploaded on ‘Kaggle’, known as Plant Village by ArjunTejaswi which contains plant diseases of around 15 types. The dataset contains about 20,600 imagesof which 2152 images belong to plant ‘Potato’ andcategorised as Healthy,

DOI: rp-9788770040723.043

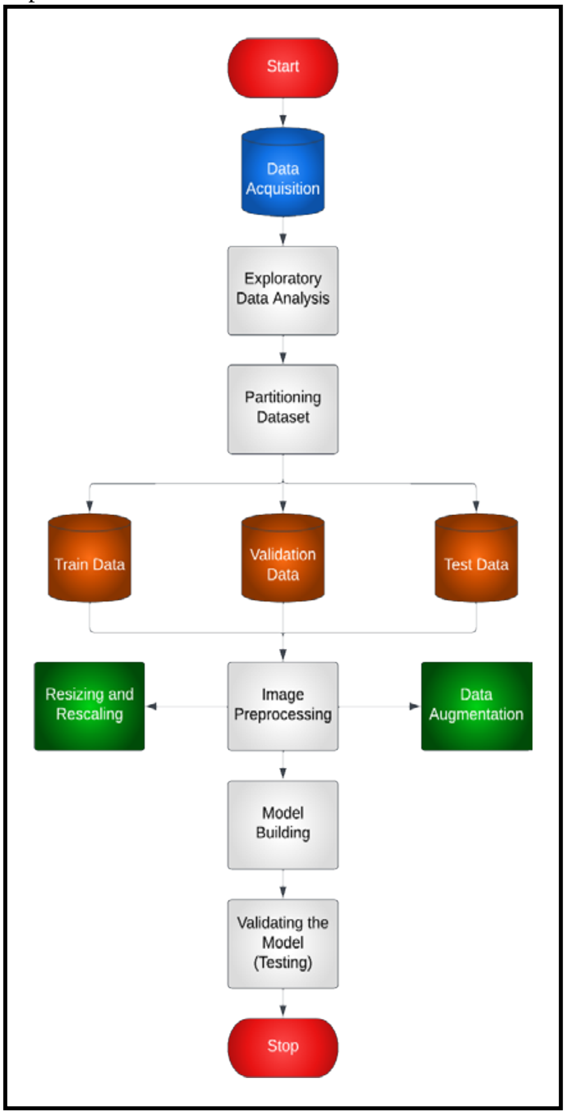

Fig. 3: Methodology Flowchart

Early-Blight, and Late-Blight as in Fig. 4 [11]. The dataset is arranged in Joint Photographic Experts Group data format (.jpg file).

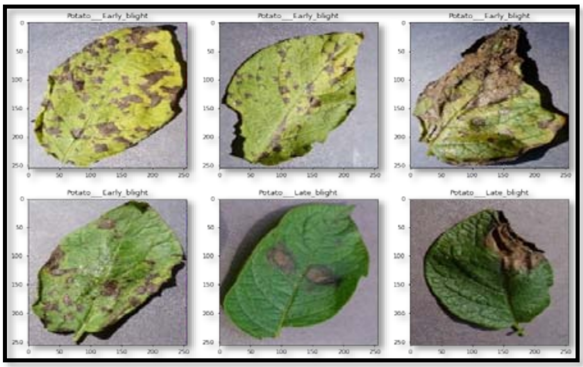

Fig. 4: Images of Potato Leaves with different Diseases

B. *Preprocessing*

The potato-disease dataset is divided into three classes. These classes include Early-blight class (1000 images), Healthy class (152 images) and Late-blight class (1000 images). Hence, the dataset was divided into **46.4%**, **7.06%** and **46.4%** respectively.

The splitting of the dataset for training (70%), testing (15%) and validation (15%) is carried out. Before splitting the dataset, images of dataset were divided into batches for the ease of splitting the dataset. Also, specific functions like: ‘prefetch’ – loads next batch of images into CPU when GPU is busy training the images, ‘cache’ – saves time while reading the images; were applied for better use of resources of the system being used.

The CNN model is practiced on the train set. The validation set is used to fine-tune the hyperparameters (i.e., the design) of a classifier, while the test set provides an objective assessment of the final model fit on the training dataset [12]. Noise in the picture can first be reduced by removing any unnecessary parts. If there is too much disturbance in the image, it won't be used [13]. Pictures collected from various sources and of varying sizes must be resized to **256x256** pixels for the dataset's standardized input photos. The batch size of **32**.

C. *Data Augmentation*

In contrast to the shallow networks used in machine learning, deep learning (Deep Network) needs a lot of data. Machine learning and deep learning frequently encounter issues with a lack of training data and an imbalance in the quantity of data for each class [14]. Data augmentation is the approach taken to solve this issue. Data augmentation is a technique for modifying data without changing its initial meaning. 5100 datasets are still insufficient for this research to achieve optimal performance, necessitating the use of data augmentation. The augmentation factors in this study are generated by the automatic application of simple geometric transformations like translations, rotations, scale changes, shearing, vertical and horizontal flips.

But for this dataset, only the rescaling and resizing of images (**1/255**), horizontal flip, vertical flip and random-rotation of **0.2** degrees is used as the leaves do not have high number of features to be considered.

D. *Disease Classification using CNN*

ML (Machine learning) in Artificial Intelligence (AI) includes DL (Deep Learning), also referred to as deep neural learning or deep neural network, with more levels than machine learning. Its state-of-the-art abilities in a variety of fields, including object detection, speech recognition, object categorization, and picture classification, have been enhanced by deep learning techniques [15]. Convolutional Neural Networks are one of the most popular deep learning courses. In some studies, CNN have been used to detect plant diseases based on the condition of the leaves [16]. CNNs, or Convolutional Neural Networks, usually have a few multi- layer convolutional layers that are arranged according to functions. One or more fully connected layers that are typical of a neural network commonly follow the subsampling layer. The input for the following feature layer is a feature collection that is contained on the preceding layer in a small area. CNN has a lot of expertise with computer vision issues. Compared to ANN (Artificial Neural Network), sharing parameters is one of its features, which lowers the number of parameters needed for the

DOI: rp-9788770040723.043

model. Additionally, CNN's features are of very high standard content. Softmax is the final output layer as we perform multiclass categorization. The sample model of CNN can be visualized in Fig. 5 [17] as given below.

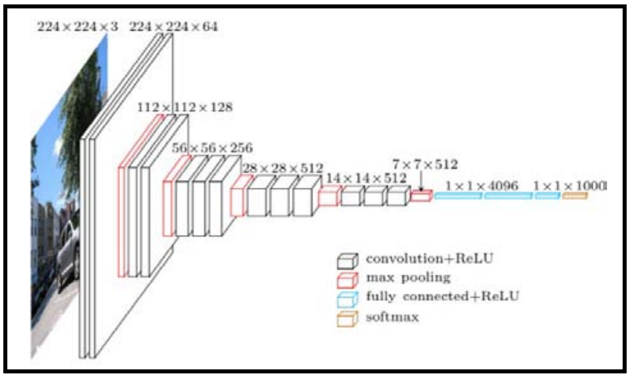

Fig. 5: Convolution Neural Network (CNN)

In our research, we created a feature map by applying convolution to the input picture through a convolution filter. As a convolution filter, a 3x3 filter is employed. For this procedure, padding = "valid" is used. When padding is "valid," it must reflect zero padding. 5 convolution layers (C1, C2, C3, C4, C5) with a kernel/filter size of 3x3 and a subsampling layer (S1) with a max-pooling frame of 2x2 are included in the CNN model.

The input picture with varying sizes is convolved with 32 filters with no padding in the first convolution (C1), producing 32 features that are 254x254 in size. During the training process, the algorithms will learn these parameters. Rectified Linear Unit (reLU) are utilised as the activation function in each convolution layer. It makes the pictures' nonlinearity greater. These characteristics produced by the C1 layer.

64 convolution filters are applied to the features map from the preceding layer in the second convolution layer (C2) to create 64 convolved features maps, each measuring 3x3. The second subsampling layer (S2), which employs max-pooling and a window size of 2x2, receives these features. As a result, 18496 shared features maps, each measuring 125x125, are produced.

The third convolution layer (C3) uses 64 filters to create 64 feature maps, each measuring 3x3. The features are passed to S3, the third subsampling layer, which also employs max pooling with a window size of 2x2. The result is the creation of 36928 shared features maps, each measuring 60x60.

There are 64 filters used in the fourth convolution layer (C4), producing 64 feature maps, each of which is 3x3. With a window size of 2x2, the fourth subsampling layer (S4), which employs maximum pooling, receives these generated features. Consequently, an image of 36928 pooled features with 14x14 pixels is produced.

64 filters are used to create 64 feature maps, each measuring 3x3 pixels, in the fifth and final convolution layer (C5). These features are passed to the fifth subsampling layer (S5), which also employs maximum pooling and a window size of 2x2, using these features. The result is the creation of 36928 shared features maps, each measuring 3x3. So, no dropout layer is employed. Dropout is a regularisation method that lowers overfitting. Only the model's training step uses dropout. Dropout disables some randomly selected neurons' capacity to activate downstream neurons on the forward pass and does not apply any weight updates to the neurons during the backward run. This ignores the neurons during the training phase in line with the dropout rate.

The model adds a flatten layer as it flattens the data into a 1-dimensional array for entry into the following layer [18]. Following that, a dense layer with 64 nodes receives the produced features. A dense layer with 64 nodes feeds these generated characteristics. There are 1,47,520 parameters total here. Finally, for the classification, we used a second dense layer with softmax activation and 4 nodes. Thus, there will be 195 factors in total.

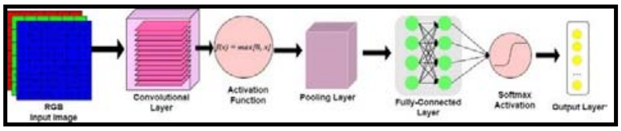

Fig. 6: CNN Architecture of the Model

The algorithm has a total of 277,891 trainable factors and are same shown in Table 1, below.

TABLE IDEPICTION OF LAYERS AND ITS PARAMETERS INVOLVED DURING TRAINING THE MODEL

Layers	Parameters
Conv2D (C1)	896
Conv2D (C2)	18496
Conv2D (C3)	36928
Conv2D (C4)	36928
Conv2D (C5)	36928
Dense (1)	147520
Dense (2)	195
Total	**277891**

IV. RESULTS AND DISCUSSIONS

A. *Training Process*

The CNN model is created, and then the Adam optimizer is used to build the model. It is a highly effective optimisation method used for deep neural network training. It incorporates the benefits of two optimisation techniques, RMSProp (Root Mean Square Propagation) and AdaGrad (Adaptive Gradient Algorithm). The five-layer Convolutional Neural Network architecture model was used for the dataset learning exercise. The study's period specification called for 50 epochs, a 32- batch size, and a learning rate of 0.01 to enhance the model's performance. The suggested method's algorithm searches for values in the image dataset as part of the learning process in order to recognise new images. Each epoch phase's value must correspond to the value of the picture being trained. To calculate the loss and accuracy values, the outcomes of the epochs will be recorded. The accuracy value indicates how accurately the system classifies objects, and the value of the loss gained must be close to or equal to zero. Loss is an indication that the model has a poor value.

In both plots of Fig. 7, the findings of the Accuracy and Loss values are displayed. obtaining values that are near to

DOI: rp-9788770040723.043

one and other to zero. While training, the early and later epochs show more fluctuation values. After the 250th epoch, the training dataset's accuracy, which includes the original images, achieves **98.189%**.

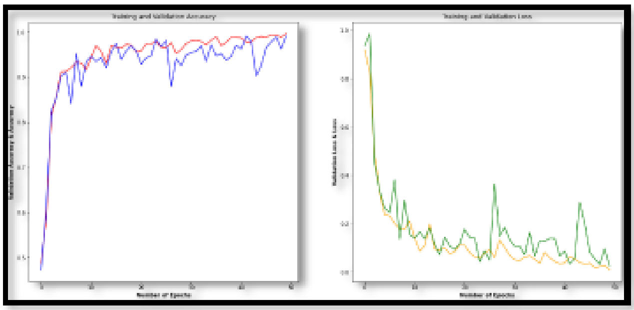

Fig. 7: Accuracy and Loss recorded while training the Dataset

B. *Testing Process*

Following the training procedure using the generated dataset, we retrieve the remaining part of the dataset i.e. testing dataset to be tested with the model. The testing accuracy is recorded as **99.18%** and testing loss as **2.48%**. Refer, to the Fig. 8 below for results.

The learning rate is 0.01, the batch size is 32, and the training period using the epochs parameter is 50. The CNN needed 7000 seconds, or approximately 1.9 hours, to complete 50 epochs at an average speed of 104 seconds per epoch.

Also, the model trained and tested is **capable of signifying** the **confidence** up to what extent it is able to classify or predict the disease.

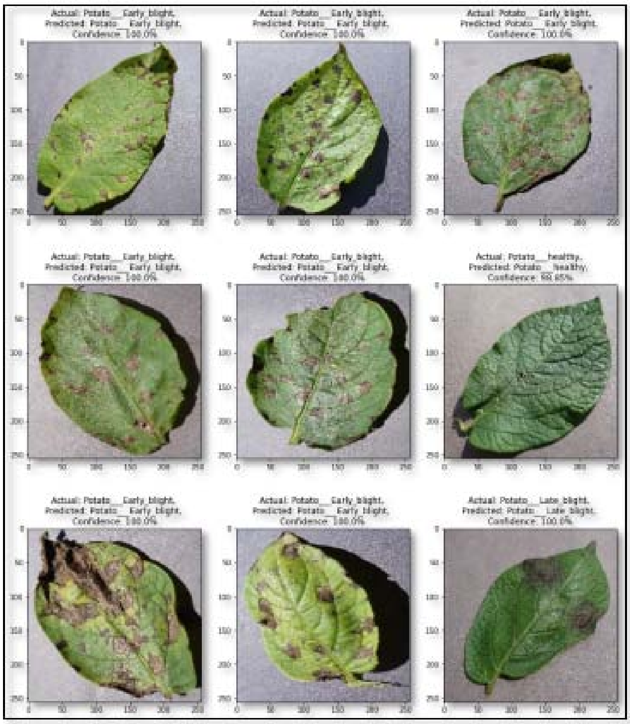

Fig. 8: Testing the Trained Model on Test Dataset for Accurate Classification of Disease

When assessing the model's accuracy with a leaf image object, it is crucial to keep in mind that image noise willresult in subpar classification results. By cutting out everything, but the desired leaf object and ensuring that there is only one leaf in each frame, noise can be removed from a picture.

V. Conclusion and Future Work

In this research, we suggested a deep learning strategy for categorising potato leaf diseases using a CNN (Convolutional Neural Network). Pre-processing the leaf images, training a CNN model on the pre-processed data, and assessing the model's performance on a test set are all steps in the suggested approach. With an overall accuracy of **99.18%**, the experimental findings showed that the CNN model was highly accurate in classifying four different potato leaf diseases, including Early Blight, Late Blight, and Healthy.

The suggested method may offer a trustworthy and effective means of diagnosing potato disease, which is essential for ensuring food security and minimising financial losses in agriculture. This approach can be further extended to other plant species, enabling early detection of diseases, and facilitating prompt interventions to prevent further spread.

Overall, the findings of this research show the efficacy of deep learning-based methods for identifying plant diseases and their potential to revolutionise the agricultural technology industry [19]. The proposed approach can assist farmers and experts in the early detection of diseases and timely implementation of control measures, thereby improving crop yields, reducing losses, and contributing to global food security.

Furthermore, the proposed deep learning-based approach offers several advantages over traditional methods of plant disease diagnosis. Unlike manual inspection, which is time- consuming and prone to human error, deep learning-basedapproaches can provide accurate and consistent results with minimal human intervention. Additionally, this approach can process large amounts of data in a short amount of time, making it ideal for real-time monitoring and detection of plant diseases.

While the proposed approach achieved high accuracy in identifying potato leaf diseases, further research is necessary to investigate its performance on other plant species and under different environmental conditions. Additionally, the proposed method can be further improved by incorporating additional data sources and developing more complex models.

In conclusion, this study demonstrates the potential of deep learning-based approaches for plant disease diagnosis and management. Early detection of potato leaf diseases is made possible by the suggested technique, which can have a significant impact on crop protection and global food security. With further research and development, this approach can be extended to other crops and environmental conditions, enabling the development of more effective and sustainable agricultural practices.

***Abstract*— English has now become a global language and is commonly spoken even amongst non-indigenous English societies. Grammar can be understood as an arrangement of words to form proper and meaningful sentences. English has a vast vocabulary and hence grammatical errors and typos are likely to happen for an average person. It is therefore important to have a medium that can help correct these errors and in doing so can help users improve their writing skills. The proposed work called Gramcorrector is an application that does both Grammar & spell correction. The availability of large volumes of data and good compute power paved the way for the development of such deep learning models. Gramcorrector is based on the Gramformer model, which uses the state of art transformer architecture. The core of this application is a Grammar & spell corrector model that has the capability to understand the intent of the sentence, identify all the possible errors and also apply accurate corrections. The corrected sentence or paragraph is displayed in the application UI along with the edits made on each sentence. This helps users to learn from their mistakes and also to improve his/her proficiency in English.**

***Keywords*— Grammar Correction, Natural Language Processing, Deep Learning, Transformer, SymSpell, Gramformer**

I. Introduction

English today has become a global language for communication. As a result, the number of English speaking people is increasing drastically even among the non-native communities. Learning the syntax and semantics of the English language is asignificant barrier for non-native speakers since it is a language with a big vocabulary as well as pre- defined grammar rules. This is made much more difficult when there aren't enough resources available to non-native English-speaking communities' education institutions to successfully teach the languages. Another significant barrier for amateur English language learners is the absence of proper contact with knowledgeable and deep English speakers. [1]

English is mostly learned by international students in academic settings including schools, universities, and other related institutions. Additionally, these students are more likely to engage with native speakers, which facilitates effective learning. On the other hand, educational institutions that help non-native groups learn English typically have few resources and a shortage of staff members who have the necessary training to impart English language instruction. The effectiveness with which the pupils learn the English language is directly impacted by these issues.

It is highly probable that non-native pupils who are enrolled in a school in a nation where the language is widely spoken will not have the chance to interact freely among native speakers. When given the chance to interact with native speakers, fresh language learners are often cognizant of and reluctant to use bad sentence structure and grammar. This not just impedes the process of learning but also has an impact on the pupils' self-confidence. Unrestricted and unfettered access to conversationalpractice significantly enhances and accelerates language learning. Moreover, this also prepares the users/students for effectivecommunications. Therefore, it is important to develop a system that addresses this scaled educational problem and also offers an unrestricted chance to learn English quickly and effectively.

Artificial Intelligence (AI) techniques are widely used today to solve grammar and spell correction [2]. With the development of Deep Learning (DL) architectures in NLP, rapid advancements were made in this area. The complex architectures such as Transformers have enabled models like Gramformer that work well on such problems. Gramformer can take as input any sentence or a group of sentences (2 or 3 sentences at max), apply grammar and spell correction and output the result. Gramformer works well when the number of input sentences or the sentence length are small. As sentences get bigger, the accuracy of the predictions also goes down. The proposed work identifies and addresses the shortcomings in such existing models and develops a new model that is more effective for grammar and spell correction.

The system developed in the proposed work consists of a UI where the users can type in or paste any text which needs to be evaluated. The text size can vary from a single sentence to a few paragraphs. The system uses deep learning to identify and correct both spelling and grammatical errors in the input text. The corrected text will be displayed in the UI. The UI contains an additional section that lists the edits or corrections made on each sentence in the text. This is useful for the users to understand their mistakes and learn from them. Thus, the proposed work can improve the language skills among users and in doing so effectively

DOI: rp-9788770040723.044

eliminate the aforementioned barriers to language acquisition in English.

II. Literature Survey

Every language has a predefined set of rules in which words can be arranged, called grammar. Following proper grammar is important in all languages to convey the required information. English is a language having a large vocabulary and as a result there can be frequent errors related to grammar and spelling when writing in English. Having a system that can identify and correct these errors is hence important. Such systems help users to see their mistakes, learn from them and in turn improve their language skill. At present, there are tools like grammarly that serve the need, but they still miss out on several errors and might sometimesconvert a grammatically correct sentence to an incorrect one. So, grammar correction is indeed a domain that still needs a lot of improvement.

In the English language, the same words can have different meanings depending on the context it is used. It is hence important for the system to have intelligence to understand the context and to make appropriate corrections. Intelligence stands the capacity to pick up information and abilities, and also to use them to solve a well-defined problem [6]. As described, it is difficult to find human intellect to teach English to non-native speakers. So it is key to develop an AI to overcome the lack of human resources. Even Though a few AI based solutions have emerged for the same cause, AI has never been successfully used to create cutting-edge instructional technologies. This is proven by looking at research literature that clearly describes the practices for promoting high-quality education as well as conversational language learning systems.

The authors of [4] argue that as new applications of AI are discovered and difficulties in educating and learning arise, a direct impact of AI on the subject of education is quickly approaching. The authors also mention how the area of education will be affected by the present wave of AI developments and how it will be changed in the future by new technologies and even the processing power of intelligent devices, one of which this research effort is modelled on. The success stories that have been achieved via the use of AI applications in education are highlighted by the authors in [8]. The outcomes are clear in the promotion of self-learning or self- development, virtual classrooms or laboratories, innovative schools that offer alternatives to traditional curriculum to all students, as well as virtual teaching [9]. In a study delivered to the Joint Research Centre of the European Union, the authors of [10] discuss the effects of AI on learning, teaching, and education. The adoption of customized and proactive students learning spurs the creation of ITSs based on AI algorithms [11].

English dialogue accompanies the Spanish dialogue in [12]. (EDC). The suggested EDC system supports elementary pupils in learning English as their second language of choice by taking the English language into account. The EDC approach motivates students by dividing English language instruction into two segments, namely the teaching phase and the discussion phase. The authors perform a pilot study to gauge the effectiveness of the EDC system. The findings indicate that the study's participants benefited from it. Additionally, theauthors note that most participants favoured the teaching phase over the conversing phase.

In [15], a more consistent body of research is given. The authors evaluate the 250 participants' English language acquisition using the Rasch model. Similar to [16], authors conduct research to look at how reading comprehension among non- native English-speaking students who are studying the language relates to lexical and grammatical understanding. 825 students who undertake the English as a Foreign Language (EFL) exam are included in the research. On the basis of grammar and vocabulary, the authors divide participants into high skills and low intelligence readers using a multi-layered neural network (NN). The study described in [17] is characterised by artificial language learning (ALL). As it focuses with the linguistic systems and researches the ecological validity of assessments of natural language ability, ALL examines language concepts as well as language development. Thus, it is clear from the analysis of current approaches that a fresh approach to enhancing language acquisition is feasible.

A neural network may be created in a manner similar to other Machine Learning applications to process unstructured text input. However, text data's large dimensionality will be a significant factor to consider while developing a solution. Neural network manipulation of high dimensional objects is challenging. Language modelling is the next significant NLP issue to be addressed. Any word sequence is given a probability by a language model, which is a probabilistic model. Learning a language model that gives strong probability to very well sentences is regarded as the task at hand.

The input of the neural network, that is the text data has to be converted to numerical form like vectors so that the network can process the data. The text data may be described mathematically using word embeddings, in which each word is represented by a higher-dimensional vector. Thus, the relationship between the words may be determined with the use of these word embedding approaches. Word embeddings are, in essence, learnt representations in which words with similar meanings have similar representations.

Word embedding can be done using standard techniques such as one hot encoding, count vectorizer etc. Each unique word in the corpus constitutes a dimension of the final word vector in a single hot encoding. Every dimension could have a value of zero or one when creating word vectors, depending on whether the word is present or not. Asentence is vectorized in Count vectors depending on the number of words in the sentence. Regarding word embeddings, the full vocabulary may be taken into account, or it may be limited to a select few top terms that are taken into account depending on its frequency. This gives control over the created word vector's dimensionality.

Apart from the standard techniques, pre-trained word embedding models can also be used to generate word vectors. These models are trained on large volumes of data and hence such models RNN+ LSTM + Transformer comparison

DOI: rp-9788770040723.044

There also exists python libraries that assist in correcting grammar. These libraries take in the input sentence, apply respective algorithms and return as output either the corrected sentence or the list of possible edits. Gingerit is an open-source python library that can be used for correcting grammatical errors. It is a wrapper around the gingersoftware.com API. Ginger software is an AI- powered writing assistant that corrects texts, improves and boosts the style and creativity of writing. It corrects spelling, punctuational and grammatical errors. The major drawback of Gingerit is that it is dependent on gingersoftware.com API. Updates in this API can cause the library to stop functioning.

Gramformer is a different open-source python library that can detect, highlight and correct grammatical errors. Gramformer exposes three separate interfaces to a family of algorithms used for detecting, highlighting and correcting grammar errors. Gramformer is a generative model even though its goal is to post-process generative model results. In general, all generative models have an uncontrollable tendency to occasionally produce erroneous text. A quality estimator (QE) is therefore introduced to ensure that the gramformer grammar fixes (and highlights) are as accurate as feasible. To return just the top-N candidates, it calculates an error correction quality score and applies it as a filter on the candidates.

According to the official documentation some of the use cases of Gramformer includes post- processing machine generated text, Assisted writing for humans, Custom Platform integration etc.

The major shortcomings of the Gramformer library is in dealing with multiple sentences. When more and one sentence is fed to the Gramformer model, the performance drops rapidly. Also, Gramformer is not efficient at correcting spell errors and in some cases, the incorrect spelling errors can lead to the model not being able to correct grammar.This objective of the research is to address these issues observed in the existing work.

III. Methodology

A. Grammar Correction Application

Grammar correction application is one that helps the user check for grammatical errors in the text they type. The text can either be a sentence or a few sentences or even paragraphs. The users can type in or paste or text for which they perform grammar checks. The application pre-process the input text and uses a deep learning model to check for grammatical mistakes and correct the input text. The corrected text along with the list of corrections for each sentence in the text are displayed in the application UI. The list of corrections for the input text helps people to understand their mistakes and in turn help them improve their language. Fig 1 shows the architecture of the proposed grammar correction application.

The application makes use of the Gramformer model at its core for performing grammatical corrections. One limitation of using the Gramformer model is that it fails to do well when dealing with text having multiple sentences. Gramformer, on the other hand, works well when the text contains only a single sentence. For real world scenarios, the user inputted text can have multiple sentences and or even a few paragraphs. This application assumes that the grammar of a particular sentence is independent of the other sentences in the text. Taking this assumption into consideration, the input text is tokenized to separate out each sentence in the text. This process is taken care of by the "Sentence tokenizer" component shown in Fig. 1. This component uses the sentence tokenizer function in NLTK library to split the input text to different sentences. This function loads a saved tokenizer model for the English language and uses the model to generate a list of sentences. The model uses whitespaces and punctuation marks to tokenize sentences. It also realigns punctuation that falls after the period but should otherwise be included in the same sentence.

The second limitation of the Gramformer model is in correcting spell errors. Gramformer is able to correct some words that are spelled incorrectly but it fails to do so for the majority of the words, especially those words that are not frequently used. The typo related errors can have a significant impact on the grammar. For example, a word having spell error "ther" can be corrected to "there" or "their" or be used as it is. Using any of the mentioned words will have a different impact on how the Gramformer model treats the sentence. Hence, it is important to have a check on the typo errors in the words belonging to the input text.

To handle spell errors, the Symspell module was added to the pipeline. Symspell is yet another open-source python library for spelling correction and fuzzy search. It makes use of the Symmetric Delete spelling correction method, which lessens the difficulty of creating edit candidates and looking them up in dictionaries for a certain Damerau-Levenshtein distance. Compared to the conventional method of deletes, transpositions, replacements, and inserts, it is six orders of magnitude quicker and language agnostic. In contrast to other algorithms, only deletions are necessary; there are no transpositions, replacements, or additions. Deletes of the dictionary word are created by transposing + replacing + inserting the input phrase.

As mentioned, the input text will be divided into different sentences. Each sentence is made up of several words and each word has to be checked for any errors. NLTK library is again used here to tokenize the sentence to a list of words. Each word is then fed to the Symspell model which uses a look up dictionary to suggest alternative words if any error is identified. Among these suggested words, the word that is closest to the word having error is chosen. The following configurations are possible for Sympell module:

- Return the closet word to the error word
- Return back the original word if no correct words are found within an edit distance
- Avoid correcting words that follow a predefined pattern
- Maintain origins casing (for example the word pATTern should be maintained as it is without correcting it to pattern)

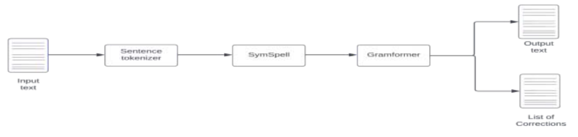

Fig. 1: Grammar Correction application architecture

The current implementation uses the second configuration that returns the original word if no matches are found within an edit distance of 2. Once the spell errors are corrected for each word, then the words are combined back to generate the original sentence. The new sentence will hence be free of spell errors. These corrected sentences are then fed to the Gramformer stage.The individual words present in the sentence; it is important to perform spell correction.

Once the spell correction is done for each sentence, it is then fed to the Gramformer model. Gramformer model is a pre-trained transformer model which is available as an open-source python library. Gramformer is a library that exposes 3 separate interfaces to a family of algorithms to detect, highlight and correct grammar errors. Also, to ensure the corrections and highlights recommended by the model are of high quality, it comes with a quality estimator. Gramformer can detect, highlight and correct grammatical errors. Gramformer is a generative model, and it has been noted that generally speaking, all generative models occasionally have a tendency to produce erroneous text that is impossible to control. Therefore, a quality estimator (QE) is introduced to ensure that the quality of the predictions (grammar correctionsand highlights) from the gramformer model remain as accurate as feasible. The error correction quality score may be estimated using the quality estimator, and it is used as a filter on the Top-N candidates to just return the top options.

Gramformer model takes in each input sentence and it has in-built functions to correct the grammatical errors as well as to return the list of edits made in each sentence. Having a sentence tokenizer overcomes one of the major limitations of the Gramformer model, where it was not able to do grammar correction properly if there are multiple sentences. With a sentence tokenizer component in place, the input text can contain any number of sentences since this component ensures that only one sentence is processed at a time. The application process and corrects one sentence at a time. The output from Gramformer stage is finally rendered in UI. The UI contains the sentence that is grammar corrected and also the list of edits done for each sentence. The list of edits helps the users easily understand the mistakes made in the input text, rather than having to compare both input text and corrected output to retrieve the list of corrections. The screenshot of the application is displayed in Fig. 2.

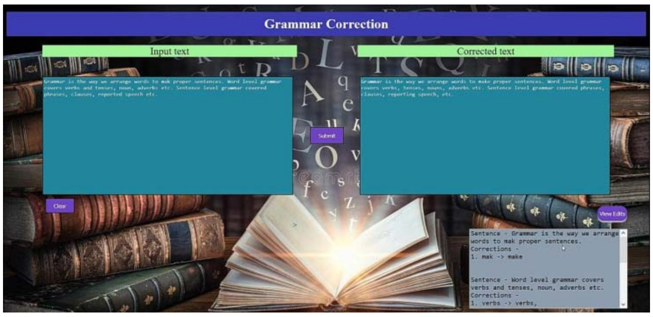

Fig. 2. Grammar Correction Application

The application was developed using the Flask framework in python, along with HTML and JavaScript. Flask is a web application framework written in python. The landing page of the application is as shown in Fig.2. The user has a text box under the ‘Input text’ section where they can either type in the required contents or copy paste from any document. Once done, they can click on the submit button to perform grammar correction. The corrected text will be displayed in the text box under the ‘Corrected text’ section. This text box is disabled and cannot be edited by the user. They can only view or copy the contents in the corrected text box. There is a clear button that can be used to clear the data from input text box, corrected text box and view edits window. The view edits button on thebottom right hand side of the screen can be used to view or hide the list of edits. The data in the ‘View Edits’ section will have the sentence and the list of edits made for each sentence is displayed right below it. This will be followed by the second sentence and so on. Thus, the application can be utilized to perform grammar correction and also view the errors in the input text.

IV. Results and Discussion

The grammar correction application can be used to both correct the grammatical errors and also view the corrections. It can correct errors in a single sentence, multiple sentences and even multiple paragraphs. Fig. 3 shows a few examples of input text containing just one sentence and the corrections made by the grammar correction application.

	Input text	Corrected text	List of edits
1	Matt like fish	Matt likes fish.	like -> likes fish -> fish.
2	the collection of letters was original used by the ancient Romans	the collection of letters was originally used by the ancient Romans.	original -> originally Romans -> Romans.
3	We enjoys horror movies	We enjoy horror movies.	enjoys -> enjoy movies -> movies.
4	Anna and Mike is going skiing	Anna and Mike are going skiing.	is -> are skiing -> skiing.
5	I walk to the store and I bought milk	I went to the store and bought milk.	walk -> went I -> milk -> milk.
6	I will eat fish for dinner and drank milk	I ate fish for dinner and drank milk.	will eat -> ate milk -> milk.
7	what be the reason for everyone leave the company	what is the reason for everyone leaving the company?	be -> is leave -> leaving company -> company?
8	Everyon is happy	Everyone is happy.	Everyon -> Everyone happy -> happy.

Fig. 3. Input text, Corrected text and list of correction for single sentence text by grammar correction application

From Fig. 3, the single sentence input text, the corrected text and the list of corrections can be observed. For sentences 1-4, the application was able to correct the errors such as using proper singular or plural form of the word and also adding fullstops at the end of each sentence. In sentences 5 and 6, the application was able to correct the sentence to maintain the past tense. Multiple corrections were also made for each sentencedepending on the necessity. For sentence 7, the application was able to rephrase the question such that it becomes more meaningful and correct the tense. It was also able to identify that the text is a question and added a question mark symbol at the end.

DOI: rp-9788770040723.044

For sentence 8, it was able to identify a spell error for the word “Everyone” and correct it accordingly.

	Input text	Corrected text	List of edits
1	How is you? Where is you going?	How is your work? Where are you going?	your work? is -> are
2	Because of new computing technologies, machine learning today are not likes machine learning of the past. It is born from pattern recognition and the theory that computers cans learning without being programmed to perform specific tasks; researchers interested in artificial intelligence wanting to see if computers could learn from data. The iterative aspect of machine learning are important because as models are exposed to new data, they are able to independently adapt. They learn from previo computations to produce reliable, repeatable decision and results. It’s a science that’s not new – but one that has gained fresh momentum. While many machine learning algorithms have been around for a long time, the abilities to automatically apply complex mathematical calculation to big data – over and over, faster and faster – is a recent development. "	Because of new computing technologies, machine learning today was not like the machine learning of the past. " ->

Fig. 4. Input text, Corrected text and list of correction for multiple sentence text by Gramformer model

Fig. 4 highlights one of the shortcomings of the gramformer model. Due to technical constraints, it was not made very complex or trained on a very large dataset and hence it fails to interpret certain sentences properly. Thus, it is not suitable for input texts having multiple sentences. In the first example, the first sentence “How is you?” is incorrectly updated as “How is your work” rather than correcting it to “How are you?” The second sentence is corrected properly. The second example hasseveral sentences and it makes the gramformer limitations clearer. Few of the words in the first two sentences are corrected and the remaining data is just ignored. The sentences towards the end of the input text are replaced with an empty string as shown in Fig. 4. This shows the importance of having the sentence tokenizer component.

	Input text	Corrected text	List of edits
1	How is you? Where is you going?	How are you? Where are you going?	is -> are is -> are
2	Because of new computing technologies, machine learning today are not likes machine learning of the past. Fig. 5. Input text, Corrected text and list of correction for multiple sentence text by grammar correction application

Fig. 5 shows the benefits of having the sentence tokenizer component. In a text having multiple sentences, each sentence is separated and treated independently. As a result, it can work around the limitations of the Gramformer model to deliver better results. Comparing Fig. 4 data with Fig. 5 data proves that the grammar correction application is able to generate more accurate predictions than the standalone Gramformer model. It can correct spell errors, punctuation errors and also take care of the grammatical mistakes. Hence this can be used by anyone who is willing to improve their language skills by understanding and learning from the mistakes.

V. CONCLUSION AND FUTURE WORK

English has a vast vocabulary and hence grammatical errors and typos are likely to happen for an average person. It is therefore important to have a medium that can help correct these errors. We proposed a new application called Gramcorrector that can help users improve their writing skills. The users can type in the required text and get it validated and also corrected in case of any grammatical errors. Transformer architecture has brought a lot of advancements in the field of NLP. As a result the proposed application uses a transformer based model called Gramformer to correct grammatical errors.. Corrected sentences and the edits made are displayed in the application UI. This helps users to understand the mistakes they made and in turn improve his/her proficiency in English. Even Though the application can handle the majority of language errors, there is a scope for further improvement, especially when dealing with spell errors. As a future scope, the spell correction module SymSpell needs to be improved so that it can suggest propercorrections also taking into account the context where the particular word is used in. Also, the training data can be enhanced to improve the vocabulary of this module. Similarly, the Gramformer model can be improved using larger datasets and also using more complex architecture such as GPT. Availability of good quality datasets in other languages other than English can also drive the development of this application towards such languages. This is also in the future scope of the Gramcorrector application.

***Abstract* -By steadily lowering carbon emissions from our planet,we can preserve a greener and safer world. The usage of electric automobiles,that utilize generated fuel for electricity,emits fewer emissions than a typical vehicle,and if renewable electricity is utilised, it is emission-free.,will generally result in a significant reduction in the mount of fossil fuel-powered vehicles on the road. Now adays, supercapacitors are frequently employed. These ultracapacitors or electrochemical double-layer capacitors are high-pressure, high-efficiency energy storage devices (EDLC). They can be quickly charged and discharged without sacrificing performance an extended length of time, which is one of their advantageous qualities that makes them perfect for use in energy storage systems. HESS, which incorporates multiple power reserve methods, can use a supercapacitor pack.**

I. Introduction

Electric powered vehicles (EV) of all types may be seen more frequently in modern deliveries, including electric-powered motorbikes, electric-powered scooters, and electric powered buses. The ecology and performance of each EV are the driving forces behind the increase in the number of them on the road. Therefore, EVs consume substantially less electricity and are less expensive to operate even though they are more expensive to purchase. In order to improve garage performance, it is important to Highly effective additives for electric energy storagein terms of their length, cost, cycle performance, longevity, power density, and energy density. By storing the energy from acceleration to deceleration, a hybrid energy storage system (HESS) made of battery and supercapacitor components could improve the overall performance of electric vehicles.

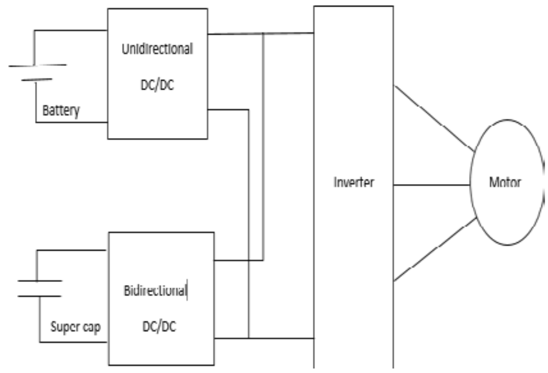
II. Existing System

Maximum amount of power may often be extracted from an ambient energy sourc e in two steps, followed by a DC-DC conversion.It is difficult to regulate the output at the same time because the input impedance of an energy harvesting circuit needs to be regulated for maximum power extraction.Due to its parasitic series resistance, the additional inductor results in a larger form fa ctor, higher price, and greater power loss.

III. Methodology

Applications forEV andHEVhave been present. Energy storage used an auto-motive application must meet a variety of criteria, including particular energy, specific power, efficiency, affordability, environmentalfriendliness, and safety.Specific energy allocation for EVs is prioritised because it affects the vehicle's range. However, since all of the energy in a HEV application comes from theenergy source and sufficient power is required to ensure vehicle performance, particularly during acceleration, hill climbing, and regenerative braking, specific energy becomes less significant and the first factor is specific power. Battery manufacturers frequently specify battery capacity (amp-hours), which is calculated as the number of amp-hours acquired after draining the battery from a fully charged condition until the terminal voltage hits the cut-off voltage.The specific energy of an ultracapacitor is in the region of a few watt-hours per kilogramme. However, it has a far higher specific power than any battery, up to 3 kW/kg. It is challenging due to their low specific energy density and reliance on the SOC to use ultracapacitors alone as an energy storage for EVs and HEVs.The ultracapacitor's load levelling effect reduces the battery's high-current charging during reverse braking as well as high-current discharging from the battery, which greatly extends the battery's life and energy capacity. We attached the lithium-ion battery and ultracapacitor for that reason.

Block Diagram



IV. Components

DOI: rp-9788770040723.045

A. Super Capacitor

Super-capacitors, a novel technology in the field of transportation, are suitable power components for HEVs' energy storage systems. They are dense in power is substantially superior to batteries and they have a lifespan of over 500,000 cycles.Ten times more energy can be held in a supercapacitor than can be in an electrolytic capacitor. Their quick adoption for automotive applications is a result of theirpower and life cycle properties, which are far superior to high power batteries.Two theories are put out in the literature to model the behaviour of super-capacitors. The first approach, which in accordance with the transmission-line model, suggests a circuit equivalent that uses distributed capacitance Ci and pore resistance Ri, which characterises the behaviour of the supercapacitor by means of an electrical equivalent circuit with two RC branches. C1 is modelled as a differential capacitor with voltage dependence., the first branch. It consists of a constant capacitor C0 and a variable capacitor Cv whose value changes linearly with voltage V1. Serial resistance comparable to R1 is R1. The two branches model is a simpler design and requires less simulated period than the first solution.

The major and rapid branch that replicates the predominate supercapacitor charging and discharging behaviour is represented by the R1C1 branch.

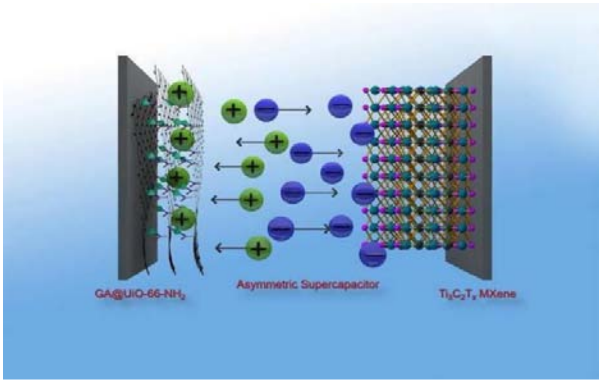


Fig 1. Schematic diagram of super capacitor

B. Lithium Ion Battery

By creating a difference in potential between two electrodes—one negative and the other positive—that are immersed in an electrically conductive ionic liquid known as the electrolyte, the lithium-ion battery operates on the principle of circulating electrons.The discharging phase of a battery occurs when a device is powered by it; during this time, electrons that have accumulated in the negative electrode are freed and move to the positive electrode via an external circuit.The opposite hand, as soon as the battery being charged, Electrons are moved back from the positive electrode to the negative electrode by the energy from the charger.Ion types, electrode substance, and related electrolytes are variable between the various battery kinds.For instance, a combustion engine vehicle's starter is typically powered by a 12-volt lead-acid battery that uses lead-based electrodes and an electrolyte containing lead ions. The lithium-ion battery uses lithium ions (Li+), which is how this technology got its name. A lithium-ion battery, like the one found in a vehicle like the ZOE, is made up of a collection of separate battery units (cells), which are interconnected and under the control of a specific electronic circuit.The battery's capacity, or the quantity of electricity it can store, is determined by quantity of cells, how big each cell is, and arrangement where they are placed.

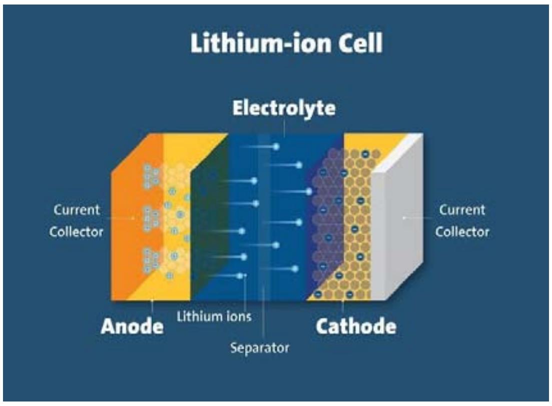

Fig 2.Schematic Diagram of Lithium IonBatteries

C. DC-DC Convertor

A circuit or electromechanical device called a DC-to-DC converter adjusts a direct current source's voltage level. Low to extremely high power levels.These days, electric vehicles are the principal applications for this bidirectional converter. Another name for It's a DC-DC.half-bridge converter.The circuit that results, which generally similar structure to the basic Buck and Boost structure though with the combined bidirectional power flow properties, is known as a dc-dc converter that operates both ways when the boost converter and the Buck are connected in opposition to one another across one another. It functions both ways.Automobile manufacturers typically use electric propulsion based on renewable energy sources rather than engines with combustion, which is the main source of emissions of greenhouse gases. Hydrogen is converted into electrical energy via FC, a clean, economical, and effective renewable energy source. A DC-DC boost converter must be used as the interface for power due to the requirements for driving, longevity, and Reliability of FCs and electric cars based on FCs

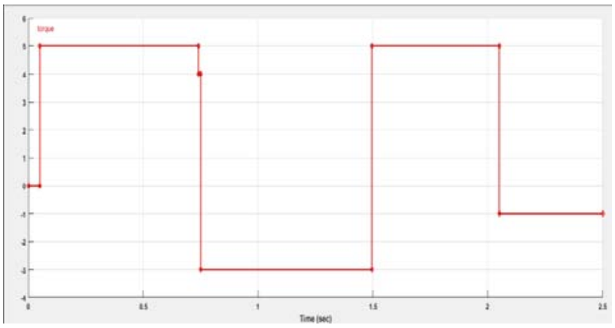

Fig 52. Measurement of torque

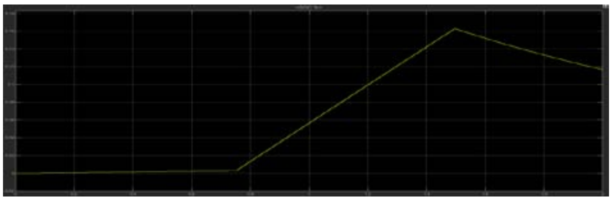

Fig 6. State of charge graph

VII. Conclusion

The hybrid energy storage system (HESS) design case for the application of a hybrid electric vehicle is described and analysed in this paper. A set of super-capacitors and a set of Li-ion batteries make up HESS. The design process seeks identify best device parameters in accordance with a suggested set of standards. It is also done to compare the two topologies for DC/DC convertersthat connect the To the DC, HESS connection. A traditional Buck/boost and DC/DC boost TL boost, buck/boost, and converter are two topologies were explored. According to the results, TL converters provide the optimum exploitation for high energy and high power densities, as well as decreased cost, weight, and volume in the vehicle, of battery and supercapacitor technologies. Models of batteries, supercapacitors, and Several DC/DC converter topologies are used using Matlab/Simulink. Results of the system performance and behaviour are obtained and discussed.

These results validate the TL topology's cost effectiveness and design assumptions.

Abstract— In the recent years, whole world has seen so many accidents due to drinking. Problem persists even after strict laws or policing. Hundreds of people lose their lives due to driving drunk or coming in the way of someone else who is driving drunk. Drunk drivers not only put themselves at risk, but also those in their vicinity. In this modern era the requirement of automatic device for alcohol detection is essential.With that goal in mind, we worked on an Alcohol Sensor for Vehicle Control using Arduino. We have used Arduino Uno, MQ3 alcohol sensor, a DC Motor (as car), piezoelectric buzzer, LED and resistors. This study developed a prototype of alcohol detection and engine locking system by using an Arduino Uno microcontroller interfaced with an alcohol sensor along with an LCD screen and a DC motor to demonstrate the concept. The system uses MQ-3 alcohol sensor to continuously monitor the blood alcohol content (BAC) to detect the existence of liquor in the exhalation of a driver. Results from testing the proposed system adequately matched the requirements for starting a car's engine once the level of alcohol detected in the breath of the driver is higher than the prescribed level that is permissible by law.

Keywords— Arduino, Alcohol detector, Parts per Million, USB.

I. INTRODUCTION

INDIA has earned the dubious distinction of having a greater number of fatalities due to road accidents in the world. Road safety is emerging as a major social concern around the world especially in India. Drinking and driving is already a serious public health problem, which is likely to emerge as one of the most significant problems soon.

These days, majority of road accidents are caused by drink-driving. Drunken drivers are in an unstable condition and so, rash decisions are made on the highway which endangers the lives of road users, the driver inclusive. The enormity of this menace transcends race or boundary. In India, the problem is being tackled by issuing laws prohibiting the act of drivers getting drunk before or while driving as well as delegating law enforcements agents to arrest and persecute culprits. However, effective monitoring of drunken drivers is a challenge to the policemen and road safety officers. The reason for this stems from the natural inability of human beings to be omnipresent as well as omniscience within the same space and time. This limited ability of law enforcement agents undermines every manual effort aimed at curbing drink-driving. There is therefore the need for an automatic alcohol detection system that can function without the restriction of space and time.In earlier executions of this project, a prototype of road accident avoiding system that havean alcohol sensor MQ-2 which detects the presence of alcohol in human breath was integrated with a PIC16F877/874 microcontroller which acts as the controller, and an LCD as the output. Other proposed systems for detecting drivers that are drunk so as to track them down have been 2 developed. The system uses Advanced RISC Machine (ARM) processor and MQ3 that detects liquor. The MQ3 sensor senses the intensity of liquor by means of an analog to digital converter which is inbuilt in LPC2148 ARM controller. Understanding the current situation regarding traffic safety, we have decided to go for an automated approach using Arduino UNO, as opposed to a traditional microcontroller approach. The Arduino system was selected over a microcontroller due to the following reasons:

- An Arduino board is cheaper in cost, thus reducing manufacturing cost.
- It is easily programmable, which offers flexibility regarding functionality.
- Due to the customizability of an Arduino Board, there is relatively lesser wiring and hence, lesser room for connectivity errors.
- The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.

The objective of this project is to implement a low-cost, scalable, and reliable alcohol detection system in the dashboard/steering wheel of a car. An alcohol sensor will continuously detect theBlood-Alcohol level of the driver and stop the car engine at any time when it detects a hike inthe level compared to the legal limit of consuming alcohol, as set by the government.

II. RELATED WORK

Nowadays in many civilized culture consumption of alcohol is taken as a tradition. The habit is coined with many occasions such as parties and celebrations [3]. Even a small amount of alcohol consumption can change the human behavior as well as his bodily behavior. This type of boddy inability to control can be highly dangerous and can involve car accidents which will risk the persons sitting inside the car also on the persons on the road [5]. Government made several laws like fine, cancellation of license etc. so that this can be minimized. The above mentioned problems shows that there is a need of simple, accurate and instrument to be used by the automobile manufacturers, vehicle users and so that vehicle will not start due to alcohol content in the air inside the vehicle [6,7]. The alcohol consumption is more in younger generation and they drink and cause accidents due to rash driving. Due to the alcohol consumption changes the bloodalcohol concentration and thus changes the body actions. There is a direct connection between blood alcohol and breathe alcohol concentration [4].

DOI: rp-9788770040723.046

By taking blood samples blood alcohol concentration can be measured and by using sensors breath alcohol content can be measured [7], [8].The first method is done by traffic policeman by taking blood samples of the drivers. The second method uses breath analyzers to sense the breath of the drivers. This method itself is not enough this can be integrated with the car system so that presence of any alcohol content in the vehicle also can be detected [9]. The proposed system is developed on embedded system using Arduino. Ashish Singh et.al [11] developed a alcohol detection system which facilitates the human driving system.

Deepak Garget. al [12] discussed on the development of alcohol detection system using various circuitry.

G. Sudha et.al [13] described in their paper on alcohol sensor based ehicle ignition control using Arduino UNO. Jagadeesh G et.al [14] in their paper explained the development of alcohol detector to minimize traffic accident cases based on alcohol consumption. Mrs. K. Niroshaet. al [15] discussed in their paper on amount of alcohol detection in vehicles and the system is developed using various sensors for the safety of people seating inside the vehicle.

III. Methodology

Main aim of this work is to develop a hardware to detect alcohol content in drunken driver while driving. Methodology describes the various steps that are followed in developing the prototype. It comprises various steps such as developing the hardware, simulating the circuitry through software, Testing the hardware for results.

A. Block Diagram

Block diagram of the proposed system is shown in Fig.1 which comprises following parts such as Power supply, Alcohol sensor and Ignition system on the input side. Indicating Unit, Alarm and DC Motor on the output side. Power supply consists of various sources for different sections of hardware.

Our system is powered with a 9V battery. A 5V DC supply as required by the microcontroller, sensor and display unit. While other components like DC motor require 1.5V and the LEDs need 2V. The Arduino Uno board has already been designed to operate without the use of transformer, the system can be powered via the USB connection from computer or with an external power supply of 7 to 12V. The External (non-USB) power can come either from an AC-to-DC adapter (wall-wart) or battery. Any voltage that is above 12V will make the control device to burn thereby destroying the board. Itis advisable to use voltage between 7 - 12V.

B. Architecture

Figure 2 illustrates the architecture of the system. For the purpose of ensuring the success of this project, we thought it best to simulate our circuitry and code before executing on any hardware. For our simulations, we used an online platform by Autodesk Education–Tinkercad.

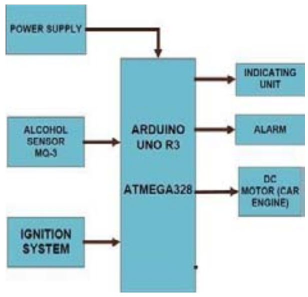

Fig. 1. Block Diagram arrangement

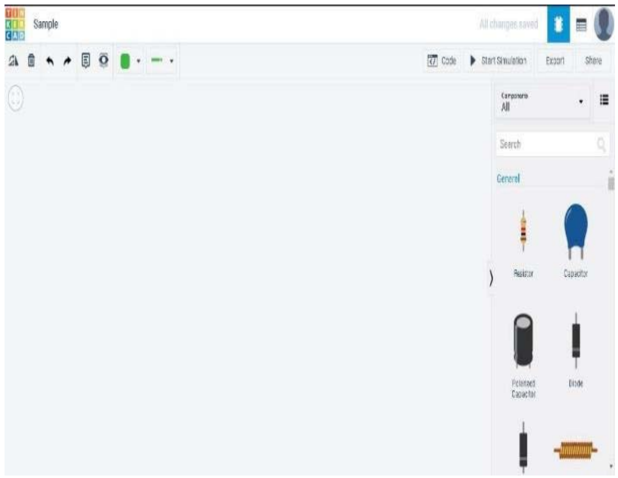

Fig. 2. Architecture of the proposed system

Tinkercad is a multipurpose educational online platform in which students, professionals and any curious minded individual can simulate and design – codeblocks, circuits and 3D designs. For the purpose of this project, we found it most hands-on and practical to use this website for designing and simulating our circuitry. There are multiple blocks of electric circuit designing components in a very diverse and vast library included on the platform, to name a few – resistors, motors, sensors, Diodes and other various electronic components. Here, we used the Arduino board (Arduino UNO R3) and were able to code the board for the simulations using the platform's in-built IDE (Integrated development environment).

C. Arduino Board

Arduinois an open-source hardware and software company, project and user community thatdesigns and manufacturessingle-board microcontrollers and microcontroller kits for building digital devices and interactive objects that can sense and control both physically and digitally. Its products are licensed under the GNU Lesser General Public License (LGPL) or the GNU General Public License (GPL), permitting the manufacture of Arduino boards and software distribution by anyone. Arduino boards are available commercially in preassembled form oras do-it-yourself. (DIY) kits.

DOI: rp-9788770040723.046

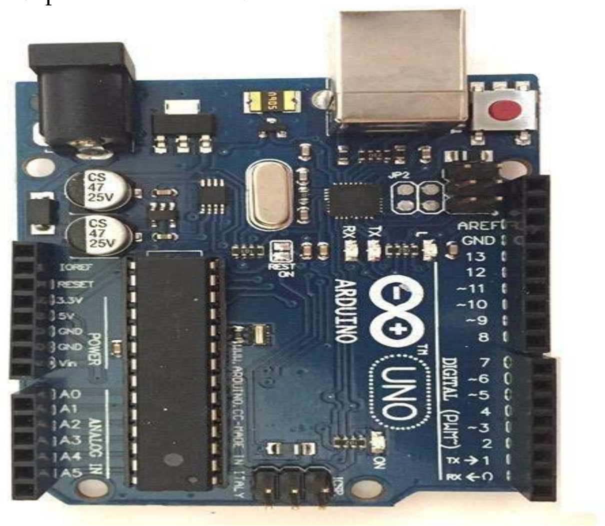

Fig 3.Arduino Board ATmega 328

D. Alcohol Sensor

Fig. 4. Alcohol Sensor- MQ3

MQ-3 gas sensor has high sensitivity to Alcohol, and has goodresistance to disturb of gasoline, smoke and vapor. It has fine sensitivity range around 2 meters. The sensor could be used todetect alcohol with different concentration; it is with low cost and suitable for different application. It has a clear interface type. On the sensor, port pins 1, 2 and 3 tends to the yield, GND and VCC independently.

MQ3 is a heater-driven sensor. That's why it is enclosed in two layers of fine stainless-steel mesh called an Anti- explosion network. It ensures that heater element inside the sensor will notcause an explosion, as we are sensing flammable gas (alcohol).

When SnO2 semiconductor layer is heated at high temperature, oxygen is adsorbed on the surface. In clean air, electrons from the conduction band in tin dioxide are attracted to oxygen molecules. This form an electron depletion layer just below the surface of SnO2 particles and forms a potential barrier. As a result, the SnO2 film becomes highly resistive and prevents electric current flow.

E. Connections with Arduino (Digital)

The module has a built-in potentiometer for calibrating the digital output (DO). By turning the knob of the potentiometer, you can set a threshold. So that when the alcohol concentration exceeds the threshold value, the Status LED will light up and the module will output HIGH.

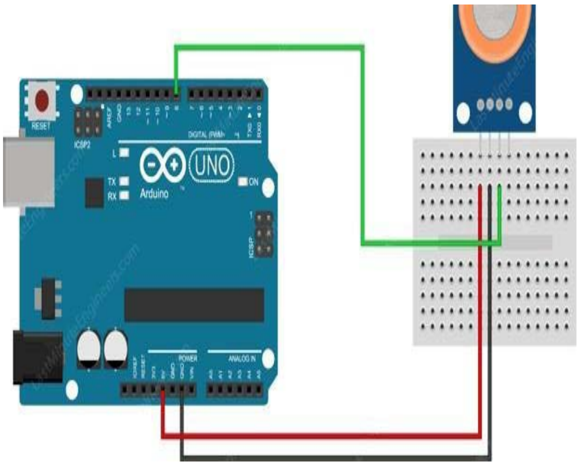

Fig. 5. MQ3 Connection with Arduino (Digital)

F. Piezoelectric buzzer

A piezo buzzer is a type of electronic device that's used to produce a tone, alarm or sound. It'slightweight with a simple construction, and it's typically a low-cost product. Yet at the same time, depending on the piezo ceramic buzzer specifications, it's also reliable and can be constructed in a wide range of sizes that work across varying frequencies to produce differentsound outputs.

G. System Flow Chart

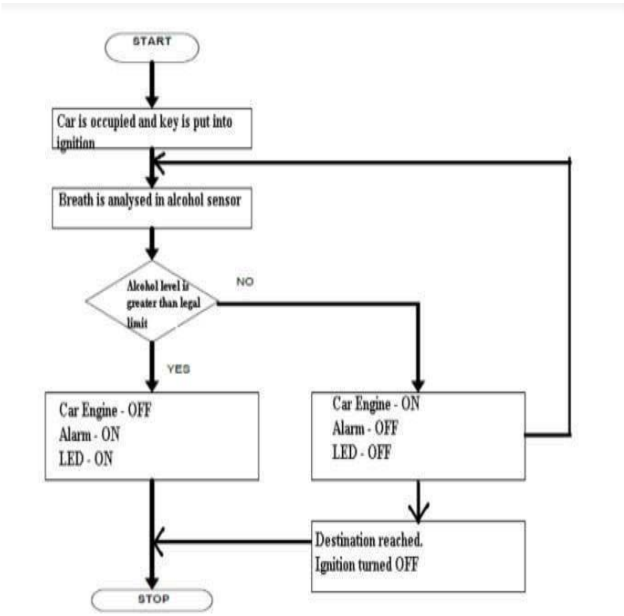

Fig. 6.System Flow Chart

Figure 6 shows flow chart of the system where when an alcohol sensor detect the presence of alcohol the ignition will start and simultaneously the LCD panel will show the presence of alcohol and buzzer will start ringing. In the absence of alcohol the ignition will start and buzzer will be silent.

IV. Result Analysis

The legal limit for alcohol percentage (permissible blood alcohol content) on a driver's breath is given to be 0.03% per 100 ml of blood, which comes out to be 0.03mg of alcohol per 100ml of blood.

DOI: rp-9788770040723.046

Now, considering ratios 0.03mg Alcohol: 100 ml blood

=> 0.3 mg Alcohol: 1000ml blood (1 litre)

TABLE I: SIMULATION RESULT

S.No	Readings	Actions
1	109	Engine ON, LED OFF, AlarmOFF
2	116	Engine OFF, LED ON, AlarmON
3	187	Engine OFF, LED ON, Alarm ON
4	42	Engine ON, LED OFF, AlarmOFF
5	90	Engine ON, LED OFF, AlarmOFF

Permissible Blood alcohol content is = 0.3 mg/L Toconvert that to parts per million :

We first refer to this formula -

%= mg/L ×(22.4 / M) ×((273+T) / 273) ×(1 / 10)×(1013 /P)

Where:

22.4 = The volume of 1 mol at 1 atmospheric pressure at 0ºC273(K): K stands for Kelvin, the unit used to measure thermodynamic temperature; as 0ºC Corresponds to273.15K.

T = The average temperature of the country assumed to be 25 degrees Celsius. 1013(Pa): One atmospheric pressure

P: denotes the atmospheric pressure at the point of measurement (Pa), which is assumed to be 1 atm on average, in India.

On substituting mg/L as 0.3mg/L in the above equation, we get:

% = 0.0159119%

Therefore,

PPM (parts per million) = 159.119

The above calculations tell us, that when the blood alcohol content reaches or crosses a threshold of 159.119ppm, the engine locking and alarm system will be engaged.

On experimentation, we find the above criteria to be matching and conclude the experiment to be a success.

Table 1 shows readings of simulation which respective action of LED, Alarm and Engine.

V. CONCLUSION AND FUTURE SCOPE

Drunken driving is considered as one of the major reason of accidents in worldwide. Drivers under the influence of alcohol shows a clear failure of perception recognition and vehicle control. This causes possibilities for hazardous situations and road accidents involving vehicles and pedestrians causing damage to both.

This paper defines the development of alcohol detection system for vehicle control using Arduino. The main important core element of this device is Arduino. Since the sensor which is used in the system has sensitivity of around 2 meters, it can suit to any vehicle and can easily be hidden from the suspects. The whole system has also an advantage of small volume and more reliability. As the growing public perception is that vehicle safety is more important, advances in public safety gaining acceptance than in the past.

The main advantage of the developed system is to control the number of accidents caused due to alcohol consumption. This system improves the safety of human beings and their property (vehicles, personal belongings in the vicinity of damaged area) and hence providing the effective development in the automobile industry regarding reduction in the accidents caused due to alcohol.

Implementing this project through Arduino allows global access to academics who might take up interest in this project and might want to update the system with new ideas, either innovative or with respect to execution and efficiency. This Arduino code can be accessed easily and built upon further.

This type of a system can also be used outside of the automobile industry, one such application could be automating exhaust fans in certain situations, like professional 10 kitchens, or in cases of fire, as the MQ3 gas sensor is also sensitive to Benzene, CH4, Hexane, LPG and CO. It can also be used for detecting gas leaks in factories by adjusting the impedances and sensitivity accordingly. Once a gas leak is detected the system can internally turn on exhausts and through the means of IOT, can shut down other appliances/devices which may potentially be cause for hazard

Abstract— *Federated learning* is a technique of decentralized machine learning that allows multiple parties to collaborate and learn a shared model without sharing their raw data. Our paper proposes a federated learning framework for intrusion detection in Internet of Vehicles (IOVs) using the CIC-IDS 2017 dataset. The proposed framework employs SMOTE for handling class imbalance, outlier detection for identifying and removing abnormal observations, and hyperparameter tuning to optimize the model's performance. We evaluated the proposed framework using various performance metrics and demonstrated its effectiveness in detecting intrusions with other datasets (KDD-Cup 99 and UNSW-NB-15) and conventional classifiers. Furthermore, the proposed framework can protect sensitive data while achieving high intrusion detection performance.

Keywords— Internet of Vehicles, Intrusion Detection Systems, Federated Learning, Machine Learning.

I. Introduction

With its ability to analyse large amounts of data and identify patterns that humans do not readily recognize; In recent years, machine learning has become increasingly popular as a methodology for intrusion detection. On the other hand, traditional machine learning techniques rely on centralizing data, which poses significant risks to individuals' and organizations' privacy and security. Federated learning is an approach of collaborative machine learning technique in which multiple parties collaborate and learn a shared model without sharing their raw data. This method addresses privacy concerns and allows for the inclusion of data from multiple sources, which can result in improved performance and robustness.

In this paper, we present the following.

1. A federated learning framework for intrusion detection using the CIC-IDS 2017 dataset.
2. The proposed framework employs SMOTE for handling class imbalance, outlier detection foridentifying and removing abnormal observations, and hyperparameter tuning to optimize the model's performance.
3. The proposed framework was evaluated using various performance metrics and demonstrated to detect intrusions in different datasets effectively.

II. Literature Review

Recent studies are looking at the application of federated learning in Internet of Things (IoT) networks for intrusion detection [1-4]. These approaches take advantage of the distributed nature of IoT devices to collect network data and train deep learning models in a decentralized manner. Doing so allows for real-time adaptation to changing network conditions and enhances privacy and security compared to traditional centralized methods. For instance, one approach proposed in [3] uses an efficient communication method and an on-device federated learning technique for deep anomaly detection of time-series data in industrial Internet of Things (IoT), where models are trained on individual IoT devices, reducing communication overhead and preserving privacy. Another ensemble multi-view federated learning technique for intrusion detection in Internet of Things (IoT) networks was presented in [4], which combines multiple views of network data to train an ensemble of federated learning models that detect anomalies in network behavior indicative of security attacks. In [2], a federated learning-based approach to anomaly detection for security attacks in Internet of Things (IoT) networks was proposed, leveraging decentralized data from multiple Internet of Things (IoT) devices to train a federated learning model that detects anomalies in network behavior. Moreover, [5] use deep reinforcement learning to create training data in IOV with prioritized experience and states, as well as a federated learning experience sharing mechanism to protect vehicle privacy. Other works propose specific applications of federated learning for different tasks, such as resource allocation [6], privacy-preserving learning models for vehicles [7], and outlier detection techniques for machine learning [8-10]. Additionally, the Synthetic Minority Over-Sampling Technique (SMOTE) proposed in [10] addresses the class imbalance in machine learning datasets, while [9] provides a comprehensive survey of outlier detection techniques for temporal data.

DOI: rp-9788770040723.047

Regarding blockchain and federated learning, [14] offers a hybrid architecture that combines a restricted blockchain and a locally directed acyclic graph (DAG) with a deep reinforcement learning-inspired asynchronous federated learning scheme. A blockchain-based federated learning pool (BELP) framework is presented in [15], allowing models to be trained without sharing new data and choosing the most suitable learning. Furthermore, [16] integrates federated learning and local differential privacy (LDP) for crowd- sourcing applications, [17] proposes a federated learning collaborative authentication protocol for shared data to prevent data leakage and reduce the propagation delay of data. Lastly, [18] introduces a semi-synchronous federated learning (Semi-Syn Fed) protocol to improve machine learning performance.

Our article emphasizes the use of the CIC-IDS 2017 dataset[11] for intrusion detection, which incorporates seven publicly accessible shared attack network flows that satisfy real-world requirements. While there is some missing and redundant data in this dataset, which can lead to significant imbalance and poor model performance [12, 13], these difficulties can be overcome by more stringent data preparation.

III. Proposed Framework

A. *Framework Proposed*

Our study explores the implementation of Federated Learning using two edge devices, namely Internet of Vehicles (IOVs), and a central server. The edge devices train their models locally using their own datasets, and only the trained model is transmitted to the central server. The central server combines the received models and trains a resulting model on its dataset.

To ensure data privacy, the original dataset is partitioned into three distinct parts, with each partition assigned to an edge device and the central server. Each partition adheres to an (80:20) training-testing ratio, which helps protect sensitive data while allowing models to learn from the collective experience of all edge devices. This partitioning principle serves as a secure and efficient framework for learning from distributed datasets, leading to the development of robust models that generalize well across different edge devices.

The models from the edge devices are pickled and transmitted to the central server. The central server trains a super global model with its share of the dataset, and the resulting trained model is then sent back to the edge devices as global model updates. This iterative process continues until satisfactory performance is achieved in the edge devices.

Overall, the study's approach to “Federated Learning” provides a practical solution for addressing the challenge of data privacy in distributed datasets while allowing edge devices (IOV’s) to contribute to the collective experience of training robust models.

*Figure 1.*illustrates the architecture of a federated learning-based Intrusion Detection System (IDS) in an Internet of Vehicles (IoV’s) network.The network consists of two Internet-connected vehicles (Edge Devices) that transfer models to a central server. The IDS is placed before the Controller Area Network (CAN) bus to monitor and analyze network traffic.

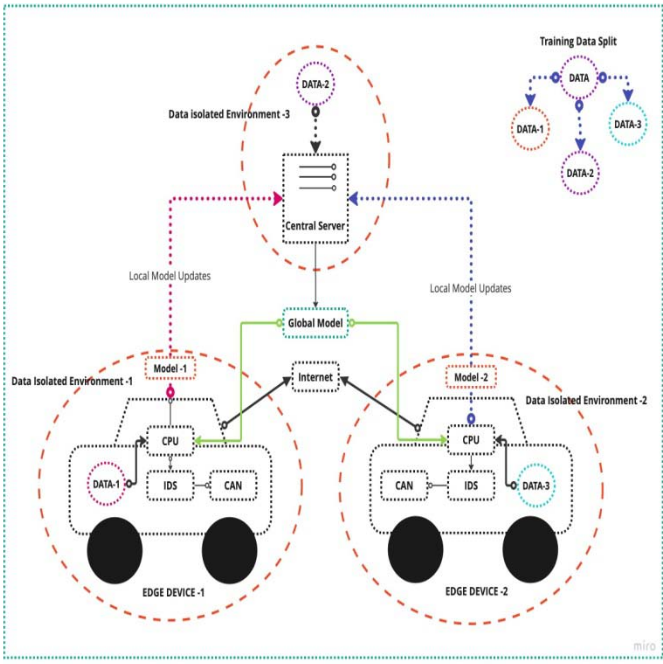

Fig. 1 IOV – Federated Learning Architecture

The edge device trains and optimizes the machine learning models using the preprocessed data and sends the model updates to the central server. The central server aggregates the model updates and sends periodic global model updates to the edge devices for retraining. This architecture enables distributed machine learning while maintaining data privacy and enhances the accuracy of IDS in Internet of Vehicles (IoV’s) networks.

B. *Description of the dataset*

CIC-IDS 2017 (Cyber Intrusion and Cyber Attack Intrusion Detection) is a dataset of network traffic data obtained in a controlled environment that is publicly available. It includes tagged network traffic data that may be used to train and test intrusion detection systems.

For the scope of our research, we used a different variant of the dataset that covers traffic like benign, DoS, port scan, brute force, web attack, bot, and infiltration.

Normal, non-malicious network activity is referred to as benign traffic. On the other hand, DoS attacks seek to make a network resource inaccessible to its intended consumers. Inspecting a computer's open ports for security considerations is referred to as port scanning. To guess passwords or keys, brute force attacks employ trial and error. Web-based systems, applications, or services are the targets of web-based attacks. A *bot* is a computer program that automates chores or performs activities on behalf of a user. Unauthorized access to a network or computer system is referred to as infiltration.

TABLE 1.Network Traffic Classes in the dataset "CIC-IDS 2017"

Si. No	Network Traffic Type	Quantity
1	Benign	22728
2	DoS	18984
3	Port scan	7946

DOI: rp-9788770040723.047

4	Brute force	2767
5	Web attack	2180
6	Bot	1966
7	Infiltration	36

From **TABLE1**, it can be inferred that the dataset is highly imbalanced (the "Benign" class has the most significant number of samples, while the "Infiltration" class has the smallest number of samples) and can have significant effects on the performance of the machine learning model trained on this dataset. We encounter this issue in the next section with specific pre-processing techniques.

C. Preprocessing Techniques

The proposed framework employs the Synthetic Minority Over-sampling Technique (SMOTE) to address the class imbalance in a dataset composed of seven distinct classes. The dataset consists of 22728 benign instances, 18984 Denial-of-Service (DoS) instances, 7946 Port Scan instances, 2767 Brute Force instances, 2180 Web Attack instances, 1966 Bot instances, and only 36 Infiltration instances. To obtain a balanced data set, we oversampled the minority infiltration class by generating 20000 synthetic instances. Similarly, the other classes, including Port Scan, Brute Force, Web Attack, and Bot, were also oversampled to 20000 instances each. The resulting balanced dataset allows a more accurate and representative evaluation of the classification models. Overall, the SMOTE technique effectively improves the dataset's balance, thereby increasing the reliability of the results obtained from the subsequent analyses.

Despite its effectiveness in balancing imbalanced datasets, oversampling can introduce outliers that may negatively impact the classification models' performance. The proposed framework employs Isolation Trees to identify and remove outliers in the oversampled dataset. Isolation Trees are decision tree that partitions data points based on their isolation depth, which measures the average number of splits required to isolate a data point. The algorithm identifies outliers as instances with high isolation depths, indicating that they are highly distinct from the rest of the data.

TABLE 2. QUANTITY OF NETWORK TRAFFIC AFTER PREPROCESSING

Si. No	Network Traffic Type	Quantity
1	Benign	20949
2	DoS	18984
3	Port scan	20000
4	Brute force	20000
5	Web attack	19152
6	Bot	19940
7	Infiltration	9105

By removing these outliers, the dataset (**TABLE2**) is better prepared for further analysis and modelling, as it reduces the risk of overfitting and improves the robustness of theclassification models. Overall, combining SMOTE with Isolation Trees provides a reliable and practical approach to handling class imbalance while ensuring the dataset's quality.

IV. RESULTS AND ANALYSIS

The study utilizes a Cat Boost model, gradient boosting algorithm that utilizes decision trees, as the classifier model for edge devices. The initial hyperparameters for the model are set to a base "depth" of 3, "epochs" of 50, and a "learning rate" of 0.50. To improve the model's accuracy further, the study applies grid search, a hyperparameter tuning technique that exhaustively searches over a specified set of hyperparameters. The search space consists of the "depth," "iterations," and "learning_rate" hyperparameters, where "depth" ranges from 3 to 7, "iterations" ranges from 50 to 200, and "learning_rate" ranges from 0.1 to 1. The resulting model exhibits a significant improvement in accuracy, demonstrating the effectiveness of hyperparameter**(TABLE 3)** tuning in optimizing deep-learning models for edge devices.

TABLE 3. ACCURACY OF EDGE DEVICE CLASSIFIERS

Si. No	Device	Base Model Accuracy	Hyperparameter tuned Model Accuracy
1	Edge Device 1	94.7 %	96. 251 %
2	Edge Device 2	95.5 %	96. 525 %

In this study, we transfer the best models from edge devices for the central server. It is crucial to note that only the models are transferred, not the data, thereby preserving the fundamental aspect of Federated Learning, i.e., "data privacy." The loaded models from the edge devices are used to create a supermodel utilizing the Bagging Classifier technique. This technique aggregates the predictions of multiple models to produce a single, more accurate model. The resulting supermodel exhibits better robustness than either of the individual edge device models, showcasing the effectiveness of ensemble methods for combining models trained on distributed data. We fit the central server's model using the partitioned dataset previously divided into three parts and validate it accordingly to ensure that the model is accurate and generalizable. The central server aggregates the model updates from the edge devices and broadcasts the new global model, which is then used for further model training on the edge devices. This process is repeated iteratively, allowing the global model to be continuously refined based on the new data collected by the edge devices.

TABLE 4.has the network traffic types and their corresponding confusion matrix labels.

	4	5	0	0	0	299	0	0
	5	2	0	0	2	0	643	0
	6	17	0	21	1	0	0	610
		0	**1**	**2**	**3**	**4**	**5**	**6**
	Prediction							

From the above confusion matrix (**TABLE 7.)**, it can be calculated that

a) Average Precision for central server: 0.963
b) Average Recall for central server: 0.9624
c) Kappa Score for central server: 0.953
d) Overall Accuracy for central server: 95.999 %

The results obtained from the confusion matrices indicate that the proposed federated learning framework demonstrated high accuracy and reliable performance in detecting intrusion attempts. The average precision and recall scores for all three devices were found to be above 0.96, indicating a low rate of false positives and false negatives.

The overall accuracy of the framework was found to be above 95%, suggesting a high level of accuracy in predicting intrusion attempts. The kappa scores obtained were also high, with all devices scoring above 0.95, indicating strong agreement between the predicted and actual classifications. These results suggest that the proposed framework is effective in enhancing the accuracy and reliability of intrusion detection systems in Internet of Vehicles (IoV's) environments.

TABLE 8.ACCURACY OF DIFFERENT CLASSIFIERS IN THE FRAMEWORK WITH CIC-IDS 2017 DATASET.

Si. No	Device	Accuracy
1	Edge Device 1	96.229 %
2	Edge Device 2	96.594 %
3	Central Sever	95.999 %

The above accuracy, precision, recall and confusion matrices are measured concerning testing dataset split, as mentioned earlier in "Proposed Framework."

In the results obtained in **TABLE** 8., the accuracy of the Central Server is slightly less than that of the individual Edge Devices. There are several reasons for this, including the fact that the Central Server model is created by combining the models of the two Edge Devices, which could introduce noise or inconsistencies in the data. Furthermore, we train the Central Server model on a smaller subset of the data than the individual Edge Devices, which could decrease accuracy.

However, Similar Trends (**FIGURE** 2.) are observed in **TABLE** 9. and**TABLE** 10. when the proposed framework is tested on different Datasets (KDD Cup -99 and UNSW-NB-15)We tested it on other network datasets similar to the CIC-IDS 2017 dataset to further validate the proposed framework and benchmark its performance. Specifically, we conducted experiments on the KDD Cup-99 [20] and UNSW-NB-15 [19] datasets, which also contain network traffic data and share some similarities with the CIC-IDS 2017 dataset. By testing the proposed framework on multiple datasets, we aim to assess its generalizability and effectiveness in a broader context. Through these experiments, we hope to provide a more comprehensive evaluation of the proposed framework and its applicability to a range of network traffic datasets.Despite different datasets used, similar trends can be observed in the accuracy (**TABLE** 9. &**TABLE** 10.) of the proposed framework when tested on the KDD Cup -99 and UNSW-NB-15 datasets, as shown in **FIGURE** 2. This suggests that the performance of the framework is robust and consistent across multiple datasets, thereby increasing its applicability and reliability in real-world scenarios.

TABLE 9. ACCURACY OF DIFFERENT CLASSIFIERS IN THE FRAMEWORK WITH KDD CUP -99 DATASET.

Si. No	Device	Accuracy
1	Edge Device 1	94.98 %
2	Edge Device 2	95.27 %
3	Central Sever	94.59 %

TABLE 10.ACCURACY OF DIFFERENT CLASSIFIERS IN THE FRAMEWORK WITH UNSW-NB-15 DATASET.

Si. No	Device	Accuracy
1	Edge Device 1	72.74 %

DOI: rp-9788770040723.047

2	Edge Device 2	71.63 %
3	Central Sever	71.53 %

To ensure consistency in our approach, we followed the same methodology as in the original experiment with the CIC-IDS 2017 dataset. This included using the SMOTE technique for oversampling, Isolation forests for outlier detection, and dividing the data into three sets for each edge device and the central server maintaining data privacy. By following this standardized methodology, we aimed to maintain consistency in the experimental setup and ensure that any observed differences in performance across datasets could be attributedto the nature of the data rather than differences in methodology.

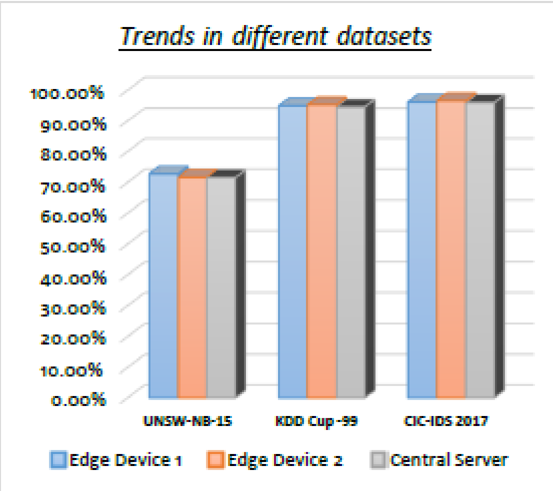

Fig..2 Trends Observed in Different Datasets

FIGURE.2 provides a comprehensive view of the comparative performance of the edge devices and the central server in terms of accuracy across the three datasets used in the study, namely CIC-IDS 2017, KDD Cup -99, and UNSW- NB-15.

The proposed framework was developed as an attempt to enhance the existing Intrusion Detection Systems (IDS). The proposed framework was rigorously tested against various conventional classifiers, including Naive Bayes, KNN, Adaboost algorithm, and Gradient Boost algorithm, to assess its efficacy (**TABLE** 11.) in improving the performance of IDS.

TABLE 11. ACCURACY OF DIFFERENT CLASSIFIERS WITH CIC-IDS 2017 DATASET

Si. No	Classifier	Accuracy
1	Proposed Framework	96.23 %
2	Random Forest	94.99%
3	KNN	86.21 %
4	Gradient Boost	63.68 %
5	Ada Boost	59.47 %
6	Gaussian NB	40.04%
7	Multinomial NB	31.18 %

TABLE 11., presents the accuracy results of different classifiers when tested on the UNSW-NB-15 dataset. The proposed framework achieved the highest accuracy of 96.23%, outperforming all other classifiers by a significant margin. The next best performing classifier was the Random Forest algorithm, with an accuracy of 94.99%. The K-Nearest Neighbor (KNN) algorithm achieved an accuracy of 86.21%, which is significantly lower than that of the proposed framework. The accuracy of the remaining classifiers, including Multinomial NB, Gradient Boost, Ada Boost, and Gaussian NB, was considerably lower, with values ranging from 31.18% to 63.68%.

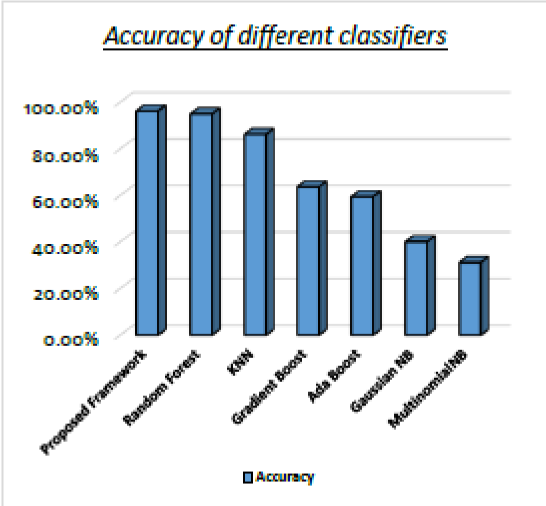

Fig.3. Accuracy of Different Classifiers

These results (**FIGURE.**3**)** indicate that the proposed framework is a highly effective method for "*enhancing*" the performance of Intrusion Detection Systems. The high accuracy of the proposed framework demonstrates its ability to accurately classify different types of network traffic, whichcan help in identifying potential security threats and preventing security breaches.

V. CONCLUSION

In conclusion, this study presents a promising approach for improving the performance of intrusion detection systems in IOVs through federated learning using an imbalanced dataset. The CIC-IDS 2017 dataset, comprising seven distinct classes, was preprocessed using Synthetic Minority Over- sampling Technique (SMOTE) and Isolation Trees to address the class imbalance and to remove outliers. The dataset was partitioned into three parts for two edge devices and one central server to ensure data privacy. The edge devices used a Cat Boost classifier model with hyperparameters optimized through grid search. The resulting model showed a significant increase in accuracy, highlighting the effectiveness of hyperparameter tuning. The edge device models were combined using the Bagging Classifier technique to create a supermodel that demonstrated better robustness. However, the central server model showed slightly less accuracy than the individual edge device models, likely due to noise or inconsistencies in the data or training on a smaller subset. Testing the proposed framework on other network datasets, such as KDD Cup-99 and UNSW-NB-15, provided a comprehensive evaluation of the framework's generalizability. The results showed that it effectively

DOI: rp-9788770040723.047

improved accuracy for different network traffic datasets. Furthermore, the proposed framework was compared with existing conventional classifiers, and the results demonstrated that it achieved the highest accuracy among them.Overall, the proposed framework presents a promising approach for federated learning in distributed networks while maintaining data privacy and enhancing the accuracy of intrusion detection systems.

Code Availability

The code for the proposed framework, which utilizes federated learning for intrusion detection systems on Internet of Vehicles, is available at the GitHub repository: https://github.com/abby1712/Federated_Learning_IDS_On_IOV.

***Abstract*—In democratic countries like India, voting is a fundamental right through which people choose their leaders. Traditionally, voting has taken place in centralized or distributed locations known as polling booths or stations. All citizens of India above the age of 18 years can cast their vote and choose their leaders. Voters go to polling booths and cast their votes under the supervision of an authorized person. Some of the main issues encountered with this traditional voting system include fewer voting percentages and false votes. To overcome these, an online voting web application is proposed in this paper. Any registered eligible voter can cast his/her vote through this application by logging in to the application. Before casting the vote, the application authenticates every voter on 2 levels. The 1st level of verification is carried through One Time Password (OTP) and 2nd level is through voter identification (ID) and any other government-issued ID cards such as Aadhaar, Permanent Account Number (PAN) card etc.,. The Aadhaar card is a government- issued unique identification card for every Indian citizen. Through this proposed online voting application, any eligible voter can cast their vote within minutes from any corner of the world by logging into the application using a gadget (mobile, laptop, tab, etc.,) connected to the internet. The main objectives of this document are to increase vote rate and reduce false votes. The conduction of elections through this application also reduces the workforce.**

Keywords—Encryption, One Time Password (OTP), Online voting system (OVS), Security, Web application.

I. INTRODUCTION

As per the International Institute for Democracy and Electoral Assistance (IDEA), Rwanda has reported 98.15%, the highest voter turnout or record during the recent national election conducted in the year 2017 [13]. Laos recorded 98.02%, the 2nd highest voter turnout in the year 2021, during theparliamentary elections. Turkmenistan recorded 97.17% of the voting, during the Presidential elections conducted in the year 2022 and Singapore recorded 95.81% of voting in the year 2020 during their Parliamentary elections. Haiti has recorded 17.82% of voting, the lowest voter turnout during the 2015 Parliamentary elections. Afghanistan recorded the 2nd lowest voting percentage in the year 2019, during the Presidential elections. Algeria, during the 2021 Parliamentary elections recorded 23.03% of voting.

In India, between 1951 and 2019 parliamentary elections conducted so far, an average of only 51.94% voting has been recorded. India is a rule-based country with a population of 1.4 billion [13]. The Government of India includes "all communities, individuals and institutions". Every citizen of India aged 18 years and above is an eligible voter and has the right to vote and choose their leader. The voting system started in India in the 18th century [1]. In the traditional voting system adopted in India, a voter will only be able to vote if his or her name is enrolled in the list of voters. This is done by providing a voter ID card issued by the Election Commission of India (ECI). Since many years till today, elections are being conducted in each country differently. Some of the most common ways of conducting elections around the world are paper voting, electronic voting machines, live recording electronic voting machines and optical voting machines.

The paper-based voting system or paper ballots was the first voting system introduced in 139 BC in Rome. Paper ballots or election ballots were first used in Rome in the year 139 BC to conduct the elections. In the paper-based voting system, the voter receives a blank ballot. The voter uses a pen or marker to vote for the candidate. Although paper ballots are easy to make and can be retained for verification, counting these paper ballots is a time and labor-consuming process [10]. This type of voting system was followed and is still in use in most of the developed countries like the United States of America (USA), France etc., [14]. This method is the most popular way of voting in most developing countries like India and African countries like Kenya, Botswana etc. [14].

The Electronic Voting Machine (EVM) was invented during 1990 in India by a team led by V. Hari Prasad. During 1998, elections were conducted using EVMs. These EVMs do nothave any mechanism to verify the identity of the voter before voting, therefore the fake voter can vote more than once. It takes a lot of effort and time to implement this sort of voting mechanism. There is a possibility of tampering with EVM during production and votes can be manipulated to change the result [8].

Recently, general elections were held in India in seven phases from 11th April to 19th May 2019 to elect members of the 17thLokSabha using EVM. Votes were counted and the results were announced on May 23rd.Around 912 million people were eligible to vote during this election, but only 67% of voting was recorded. However, this is the highest-ever voter percentage recorded, as well as the highest female voter turnout ever recorded in India during general elections [2].

DOI: rp-9788770040723.048

In Brazil, direct recording EVMs were used massively in 1996, where all the elections in Brazil were conducted using these machines. The device is integrated with a keyboard, touch screen, or buttons. The voters can ballot their vote by pressing the buttons and this machine in parallel counts the votes casted [6]. Whereas the voter must come in person to the place where the elections are conducted. Also, this voting mechanism is a time and labor-consuming process. Furthermore, there is a possibility of equipment failure.

The earliest optical-scan voting system was introduced in the USA during the 1960s. To scan ballots, it employs optical mark recognition scanners. The voter can cast the vote by filling the circle corresponding to their favorite candidate on the ballot. Then the machine considers the boldest mark on each ballot as a vote and counts. This machine counts votes very quickly. However, if the voter doesn't fill the circle properly, those voteswill end as erroneous optical scan results. Optical voting systemwas used until the 19th century [15].

A.D. Rubin's 2002 study states that an online voting system is a better option for voting which would increase the voting percentage. The verification of the Aadhaar [23] card is the security measure used in their study. As a part of the proposal, the authors tried to build a secure online voting system. This system is free from unauthorized access while voters casting their ballots [6], [18].

HimanshuAgarwal and G.N. Pandey, 2013 study states that the online voting system needs to have high security and reliability compared to that of traditional existing voting systems. To achieve this the authors proposed OTP, which would let the authorized user vote only once [5].

Ch. SaiPratap, D. Sumanth Rahul and Jithina Jose (2020) study states how an online voting system would bring an impact on the nation's development. This system monitors voting programs in a less complicated way and is safe to use. Their approach is better and faster than the traditional voting systems. This online voting system ensures transparency and continuity and maintains accurate voting procedure using Aadhaar that provides each voter with a special ID to avoid security breach. It allows a voter to vote from any location around the globe [1],[2]. From the year 1973, many countries including the USA, Belgium, Japan and Brazil began to adopt electronic voting, also known as E-voting, for their official elections.

II. Methodology

The proposed online voting application verifies the registered voter through OTP while voting [11]. The user interface of this application is implemented using Hypertext Markup Language (HTML) and the backend of this application is implemented using Cascading Style Sheets (CSS), Hypertext Pre-processor (PHP).

The architecture of the proposed online voting web application is represented in Figure 1 and the workflow of the online voting application is given in Figure 2. As an initial step, the voter needs to register in the portal. After registration, the user can log in to the portal using the credentials. Then, the application generates OTP and sends it to the registered mobile number of the voter [4], [11]. After the user enters the OTP and the application validates, the user can cast their vote [11]. After the voting, user votes are stored in the database for counting purposes.

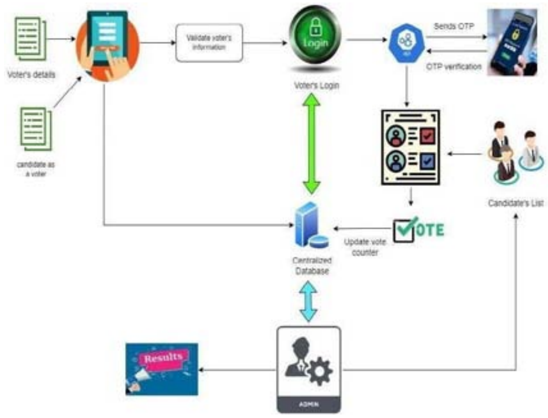

Fig. 1. Architecture of the online voting web application.

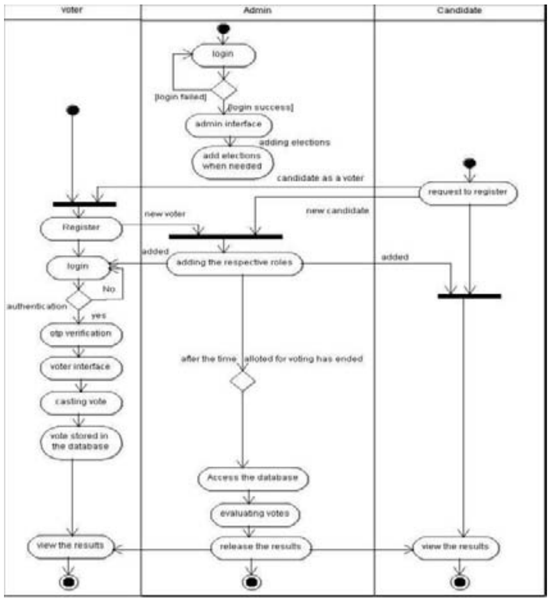

Fig. 2. Workflow of online voting system application.

The Admin/ECI is the official body responsible for registering the voters and manages the candidates during elections (refer with: Fig. 2). After the conduction of elections, the admin publishes the results in the application, which can be viewed by voters and candidates[4].

III. Results and Discussions

The proposed online voting web application will manage voter information, allow voters to login and exercise their right to vote online. This application integrates all the functions of the voting system. Each party's votes can be tracked through this application and the total number of votes for each party is counted. The database maintained by ECI through this application stores all the names of voters with their details [12].

An Indian Citizen aged 18 years and above should register in this application. Then the voter will be allowed to vote after logging in with his username and password and OTP verification. Each registered user will be allowed to vote only once. The details of the votes are stored in the

DOI: rp-9788770040723.048

application's database and the results can be published after elections [12]. Through this online voting system, voting turnout will increase, as the registered user can vote from any corner of the globe using the gadget connected to the internet. This application helps in reducing the cost and time of the voting process.

Fig. 3. Sign-up page.

Figure 3 represents the registration page of the online voting application. By entering the details such as username, contact, password, and retype password in the respective field's user can register. Once the user gets registered successfully, the registered user data is stored in the application's database [19]. The password will be stored in an encrypted format [4]. The encryption is carried out by applying Secure Hash Algorithm (SHA1) [20].

Fig. 4. Login page.

After successful registration, the user can log in to the portal [4]. Figure 4 depicts the website's login interface, where the user or administrator can log in. This page contains the fields Contact No., and Password, as well as the "Login" button. If the user does not have an account, then the user is redirected to Figure 3 for registration [4].

Fig. 5. OTP verification page.

Figure 5 illustrates the OTP verification page. An OTP will be sent to the user's registered mobile number. After verification, the page is redirected to Figure 9[11], [24], [21].

Fig. 6. Admin home page.

Figure 6 shows the Admin Home Page of this application. The admin dashboard displays the number of elections that are currently taking place. This page has details like election name, the number of candidates, the starting and ending dates of the elections, the status of the elections, and an action button for viewing results after the elections. The admin can only add election and candidate details and can publish the election results.

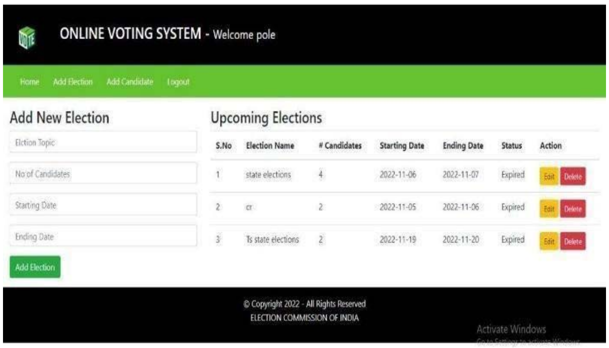

Fig. 7. Election Page.

Figure 7 depicts the Election Page of this application, which contains the details of upcoming, ongoing, and completed elections. On this page, the admin can check, add, edit or delete election details. While adding the elections the admin needs to fill up all the required details about the elections (refer Fig. 6).

Fig. 8. Candidate page.

The Candidate page of this application is shown in Figure8. The admin can add candidates and edit or delete the details of the candidates on this page. The details such as candidate name, party name, and party symbol of each candidate will be collected from the respective party candidates by the admin [12].

Figure 9 represents the voter's page. The voter page displays the current elections, by which voters can vote. A voter can cast the vote only once, through this application.

DOI: rp-9788770040723.048

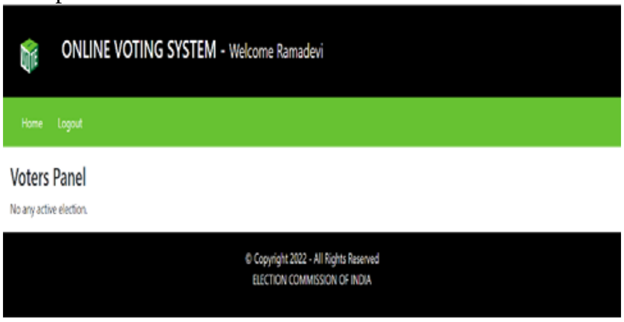

Fig. 9. Voter's page.

IV. CONCLUSION

In this paper, a secure online voting web application is proposed. This application has 2 levels of authentication through OTP, voter ID and any other government-issued ID card. This application is secure compared to the traditional voting system. With the application features, it is easier and convenient for the voter to use. A gadget with an internet connection and valid credentials is required for the user to vote securely from anywhere in the globe. This application also increases transparency and reliability in the voting system as all the details of the registered user's data are securely stored in the application database. As future enhancement, few more security features related to authentication, and authorization features can beadded.

Abstract—In recent times, augmented reality (AR) has emerged as one of the most promising technologies that can provide a high degree of adaptation and independence to facilitate the transfer of knowledge in the majority of different sectors. AR is being used in the process of projecting objects into an augmented environment to demonstrate to customers how those objects will seem in the setting of their choice. Even though there have been and will continue to be significant advances made, the visuals are still being projected in a three-dimensional environment. In order to circumvent this process and project a live image that has been caught in reality, an innovative strategy that makes use of modified machine learning algorithms is currently under consideration. Additionally, a brand-new method known as the "universal clipboard" is suggested, which makes it much simpler to copy and paste photographs between different devices.

Keywords—Augmented reality, Machine learning, Unsupervised Learning, Deep Learning.

I. INTRODUCTION

As technology keeps getting better, more and more people's daily tasks are being done digitally, which makes life easier in every way. Even if a lot of shortcuts are shown to people, there are still a lot of things that are easy but annoying to do. Different ways that Photoshop can be used to change documents. This got us used to the drag-and-drop feature, which lets us add records to an online site or link them to our emails by dragging them from where they are to where they should be on the web. It is a feature that saves minutes of time that would have been spent browsing through the pop-up window, which doesn't let us switch to a different screen until the file is chosen or the user quits. All in all, Augmented Reality can be very interesting and help you see things from a different point of view. The goal of the project is to change how people interact with and understand the real world by adding virtual information to their immediate surroundings and how they interact with the real world as a whole. Users use the drag-and-drop feature all the time to add records to an online site or link them to our emails. Users do this by dragging the records from where they are to where the web application is. But if users could copy and paste things from the real world onto digital screens, it would save us a lot of time and make our work easier. Expanded reality lets us copy and paste things from the real world into our high-tech screens with just a few clicks.

Through different features on our screens in the digital world, augmented reality has made our experiences better. But the idea of bringing real-world objects into the digital world changes the way users think about and use Augmented Reality Apps in a few big ways. Real-world objects can be pasted by clicking on the object's snap, getting its background, and then sharing it with your desktop. This can be a time-consuming process. With this Augmented Reality app, you just point your camera at the object you want to select. This saves time because the user doesn't have to snap, mask, save, or switch windows. This is a really efficient AR copy-paste Photoshop tweak. AR is the intelligent use of a real-world environment in which items are. AR is often described as a system with three key features: a mix of real and virtual worlds, interaction in real-time, and accurate 3D modeling of both real and virtual objects. The extra sensory information can be helpful, or it can be dangerous. This kind of involvement is always tied to the real world in a way that makes it seem like an immersive part of the vital environment.

Our application has 2 features: Using Augmented reality and machine learning - their project and process images in our application. For processing, Human-computer interaction (HCI) and interface design use commands like "plan," "cut," "copy," and "glue" to transmit information between processes. The cut command takes the information you've chosen out of its original position, while the duplicate command makes a copy of it. Both situations store selected data temporarily (the clipboard). The information from the clipboard is subsequently incorporated whenever a glue command is issued. Machine learning can now reliably locate people and objects, automatically eliminate the backdrop (background removal), and communicate the output to a computer. Considering image projection, AR has so far been utilized to bring enhanced visuals into the actual world. AR Cut & Copy works in reverse, digitally translating tangible objects. This study presents a novel approach to using augmented reality to make life easier by making things happen at the fingertips of a human being. It helps in visualizing objects without the tedious efforts of moving as they use coordinates and SIFT.

II. RELATED WORK

Gang Wang[1] has proposed a system Prior to performing saliency detection, a background estimate is

DOI: rp-9788770040723.049

applied. To gather background information, they use the bounding boxes approach. The model the saliency, there are 3 background works that are primarily addressed, including background connectivity prior, background contrast prior, and spatial distribution prior, enabling the proposed technique to emphasize the salient item as a whole and reduce background clutters.Experiments on two benchmark datasets show that our solution beats 11 leading methods while being more efficient than the majority of them.

They increase convolutional neural network pooling in order to identify prominent items. On the bottom-up route, they develop a global guidance module (GGM) using a U-shaped architecture to supply layers at various feature levels with salient item location information. To combine coarse-level semantic information with fine-level top-down route characteristics, they offer a module for feature aggregation (FAM). Following top-down fusion processes, FAMs are able to readily fuse coarse-level GGM data with features of several scales. These two pooling-based modules enhance detail-rich saliency maps by refining high-level semantic properties. In comparison with the other models, they find significant objects with sharper characteristics more effectively. Our approach handles 300 *400 photos at above 30 frames per second[3]. They determine how to extend the function of pooling in convolutional neural networks. Some instances, this disregards the crucial spatial information of the whole input picture.

Bi-DAINet[6] This research presents the Bi-directional Discard-Accept-Integrate Network, often known as the Bi-DAINet, for SOD. To begin the process of incorporating multi-scale feature maps into the network, they begin by constructing a Discard-Accept-Incorporate (DAI) module. In order to reduce the amount of congested noises, the DAI module will remove any redundant information from the layer below it, pull useful information from the layer above it, and then integrate the remainder. They construct a CNN that is capable of enforcing message flow in both the low-to-high and high-to-low directions. Foreground and background regions may be inferred using bi-directional networks. A saliency map that contains fine-grained boundary predictions is produced as a consequence of these findings. A supervising role is played by the edge-preserving loss function in object edge prediction. The effectiveness of our method is shown across five important criteria. They examine the contributions made by every Bi-DAINet component.

For this goal[9], the context-aware refining approach of angular embedding is used. The experimental findings demonstrated the effectiveness of the suggested framework. Moreover, a comparison of the framework with several cutting-edge deep learning-based approaches revealed that it may provide similar and intriguing outcomes.

This study[15]FanjieMenga introduces a novel fusion methods pictures by integrating object area recognition with the Non-Subsampled Contourlet Transform (NSCT). Saliency detection creates the IR image's saliency map. Second, a free areas removal approach extracts the IR image object region. Third, NSCT decomposes source pictures and uses distinct fusion algorithms for low- and high-frequency sub bands. Inverse NSCT generates the principal fused picture. Integrating the original fused picture with the object area yields the final fused image. they compare our technique to others using numerous criteria and find that it improves fused picture quality.

TiantianWang[16] proposes a unique Localization-to-Refinement network. A contextual module is used in the Recurrent Localization Network to weight feature mappings at each point. A recurrent technique is also suggested to obtain contextual information for repeatedly enhancing the convolutional features. A refinement module is used in the Boundary Refinement Network to learn local context knowledge via efficient transmission.

HolgerCaesar[18] discusses When they compare the mean entropy of various datasets, they discover that it demonstrates COCO-linguistic Stuff's richness. They are presently investigating how well a contemporary semantic segmentation algorithm works on COCO-Stuff. They evaluate performance across things and thin classes in the hopes of establishing a baseline for future studies on this dataset.

Projected Augmented Reality is a technique that uses projectors to directly overlay digital material on real things. When texts are projected as AR contents, readability is one of the most important considerations. As a result, numerous projector-camera systems for increasing projected content readability have been developed, in which projection settings are modified based on estimated legibility from taken pictures of projected contents. In this study, NaoyukiKazuta[23] introduces a unique approach for determining projected content readability that accounts for the influence of a patterned projection surface by exploiting edge information in collected pictures of projected contents.

IvonaTautkute[24] proposes a multi-modal search engine, which mixes the linguistic inquiries in this study. Our engine's purpose is to retrieve inside items. Their project enables customers to snap one picture of a room and receive products that are similar/aesthetically shot with a high recall. It also enables you to return goods that complement one other visually and artistically. To do this, our technology combines the findings gained via textual and visual modes. We enhance the mean common score from recovered products around 11 percent thanks to our blending method. Our work is being developed into a Web-based application that will be made available to the public.

ShreyashJoshi[27] presented a smartphone application to allow clients who purchase interior items online virtually view how their space would appear after buying the product.For augmented reality, it makes use of Google ARCore. The picture from the device camera will be accepted as input by ARCore. It will detect planes and then digitally overlay 3D models of the product over the picture, displaying it to the viewer in real time.This will provide a nearly genuine experience of putting the product in the user's house. Products such as wall art, furniture, accessories, and electrical equipment may be shown. The application's intelligence will give appropriate recommendations to the user to assist in the purchase of connected things. This will assist a person in decorating even an empty room from the ground up. The Apriori algorithm was used to propose goods to the user during

DOI: rp-9788770040723.049

association mining. This algorithm will discover the most commonly purchased set goods in order to provide recommendations.

Smartphones may show virtual things into the physical environment at a precise area indicated by a marker thanks to the augmented reality capability. In order to view a 3D home design[33], this study creates a smartphone application for augmented reality. A marker is selected on the floorplan picture that was taken by the smartphone camera, and it is then sent to the server. The server-side application recognises the corners of the picture and generates a vector with 2D coordinates using deep learning and integer programming methods. Utilizing Unity 3D, the client application on the smartphone creates a 3D home model using the 2D coordinates. The model is then overlayed using Vuforia over the floor plan picture marker. According to test findings, it is possible to generate 3D home models that are somewhat accurate and that correspond to the given layout. The augmented reality programme provides a different way to look at a floor plan so that a user may comprehend and interact with the design more fully.

In Ivonatautkute[36] research, they present a multimodal search engine to find objects from a multimedia library that are aesthetically related to the query by combining visual and linguistic clues. Our engine aims to make it possible to quickly retrieve fashion items like furniture or clothing. They merely consider it as an extra detail of the picture in the search and do not account for the situation in which a user searches for "the same blouse but in denim." By modeling contextual connections between aspects of various modalities using a combined neural network architecture, our unique approach, named DeepStyle, addresses these drawbacks. On two distinct, difficult datasets of clothing and furniture, demonstrate the resilience of our strategy. On the evaluated datasets, the engine beats the other approaches by above 20 percent. It is offered via a Web-based application and has been commercially implemented.

These two topics took up the majority of PoonpongBoonbrahma's[38] study. The first involves creating a sizable, stable 3D model or altered by participants who can do collaboration utilizing AR technology and a multiple-markers idea. Creating a smartphone plan for collective augmented reality creation.

Through the use of augmented reality technology, Kaimaris's[40] suggested apps seek to digitally resurrect cultural heritage sites and aid the user in locating locations where areas of interest are partially or completely obscured. Tourists utilize these programmes, which are loaded on mobile devices like smartphones and tablets, to enhance their surfing. The inserted virtual objects into rangu using augmented reality technology are typically 2D or 3D reproduction which serves as the additional objects in space or points of interest that help the user get around more easily and thus revitalize the environment. The most well-known frameworks are also addressed in detail in this article. This report includes data that was experimentally gathered from a number of minor projects that were tried on a variety of expensive and inexpensive equipment.

III. System Architecture

The system architecture of an application refers to the high-level structure of the software, including its components, modules, data stores, and the relationships between them. It provides a blueprint for the design and implementation of the application and helps in determining how the different components will interact with each other.User Interface (UI) component is responsible for presenting the information to the user and receiving input from them.

The UI can be built using react native/Expo user interface elements for mobile applications.Application Server component is responsible for processing requests from the user interface, accessing data from the database server, and returning the results to the UI. The application server can be built using technologies like react native,python.In this the local server act as a database to store the processed imageand then for copy and paste features use predefined python libraries like screenpointer and paste.

For API (ARcore/ARkit) calls our application typically have the components like client,api gateway,API endpoints,And store area.The client component is responsible for making API request to the server and presenting the data to the user.The client can be a mobile application.The API Gateway component serves as the point of entry for API requests and is in charge of forwarding them to the proper API endpoint. Additionally, the API gateway is capable of handling operations like request/response transformations, rate restriction, and authentication. This component, known as the API Endpoint, handles processing API calls and returns the desired data. Building API endpoints is possible with the use of tools like Python.After that our application projection is done use that APIs.

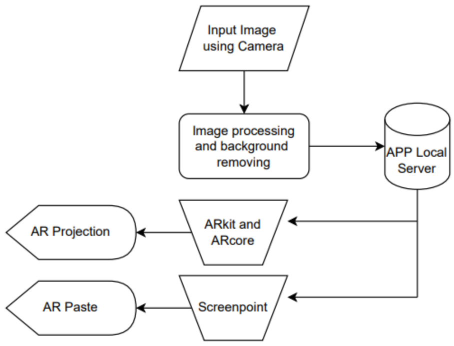

Fig. 1. System Architecture

IV. Methodology

A. Mobile Application - Expo/React Native

Expo is an open source framework which comes handy for developers who want to create native universal applications, i.e., android, iOS and the web. The hosted service is known as EAS - Expo Application Services. The applications are coded in javascript and React which has many universal libraries. Expo has a large variety of perks considering one can use it individually or as a team work.

DOI: rp-9788770040723.049

There are many functionalities in expo like camera, location, gyroscope and other useful features in the form of packages.

To install packages, the commands used are :

1) Expo SDK package : npx expo install
2) Camera : npx expo install expo-camera
3) To import into code : import {Camera} from 'expo-camera'

B. Object detection / Background removal

In order to identify unique areas or items that individuals are likely to focus their eyes on in visual situations, saliency detection models the human visual attention mechanism. For this visual job, contextual information is crucial[2].Traditional approaches use specifics concurrently or divided, but their capacity to identify the essential prominent objects in complex scenarios is constrained by the absence of high-level semantic information. As the extraction is in a higher level of systematic news, convolutional neural networks (CNNs) fortunately considerably encourage the models which can detect objects using salient object detection (SOD)[3].From a high level perspective, there are three basic methodologies for saliency detection: bottom-up, top-down, and mixed[9].The main challenge is accuracy of object localization has always been impacted by the complexity of the settings and the variety of the targets themselves. CNNs' deep feature layers are more semantically rich than their shallow counterparts, which is better for object location. The retrieved deep features require a clear separation between the salient regions and the background in order to correctly discover whole objects[14]

- *Deeplab:*Deeplab is an independent service that is in charge of managing the salience detection as well as the background removal tasks. Deeplab makes available an application programming interface (API), which allows you to run our Visual Relationship Detection (VRD) demo on your own photos by using an environment that is controlled by programming instructions. The VRD Application Programming Interface (API) is built using a REST-based architecture and makes use of the standard HTTP response codes. In addition to that, it accepts requests with form-encoded contents, gives results in JSON format, and supports the format.

C. Augmented Reality

The term "augmented reality" refers to techniques and technology that realistically incorporate virtual items into a series of actual photographs taken with a device's camera In contrast to VR. The customer is completely submerged in a digital world. It often takes place in a 3D environment and seeks to add some virtual content to the real world while still providing them with more choices. Virtual objects are designed to provide the user of an augmented reality system with relevant and context - dependent information. Utilizing technological devices with camera sensors, such as glasses, smartphones, tablets, etc., makes this combination conceivable[26].Language and visuals are the most common forms of human information transmission in everyday life, followed by scientific texts.75% of the information that people acquire visually are got by images[31]

- *AR Paste:*Photoshop is the software to be used in this project. Given that the user should transfer the captured image from the phone to the software, user have certain procedures to follow : Firstly, the image is captured by the camera of the device. When the device is pointed towards the screen, the centroid of the picture (x,y) is found by the software using OpenCV SIFT. This module can also be called Screenpoint.
- *AR Projection* Augmented Reality is always portrayed as a headset being worn with a small field of view. But our approach is to use an external camera and project it on the device. The implementation is done using technologies such as ARkit and ARcore. This helps in seamless projection of the image in the desired location or spot. Our project aims to project with adjustable dimensions of the image as needed.

D. Local server

In contrast to a local server, which operates on a different system, a local server in an application is a server that runs on the same physical machine as the programme. Data for an application may be managed and stored on a local server.The local server component handles storing and retrieving data for the application while the application component is in charge of sending requests to the local server and displaying the data to the user. Python-based technologies may be used to create the local server.The main purpose of the server is to store the data and provide to the application when thers is a requested for the process is needed.This system architecture gives a local server in an application a simple layout. The unique specifications of the application being created will determine the components' exact locations and the nature of their connections. On the other hand, this architecture offers a solid foundation for creating a local server that can efficiently handle and store data for an application.

V. CONCLUSION

The surveyed papers have certain downfalls and some of them are Occlusion - two or more objects are too close and seemingly merge or combine with each other.Lighting difficulties - contrast amplification in image-processing applications. Time complexity is high. The suggested systems in the examined publications come from a variety of fields. It is challenging to maintain correct spatial registration of actual and virtual objects. Systems with high accuracy are mostly experimental results.Our proposed system will be an ensemble model which uses both image processing and Augmented reality.

***Abstract*—Agriculture is the backbone of our economy in India. Crop disease affected in leaves and stems are not identified and cured leads to the reduction in the crop production. If the diseases are identified at the earlier stage, we can safeguard the crops from major crop damage which in turn yields better crop production. Right in global economy, not only farmers do agriculture, many youngsters from corporate companies and many entrepreneurs enter into agriculture. Major problem faced by youngsters and entrepreneurs are identification of crop disease. But the youngsters did not have a well knowledge about the plants, crops or even the plant disease. Each and every time getting the input from the farmers or domain experts involves time, effort and money. The most common fruit liked by all categories of people is banana which is grown all over India. The banana leaves are affected by both bacterial and fungal disease which affects the growth of the plants. Farmers are able to find the remedial measures based on the experience but youngsters and entrepreneurs are unable to predict the disease. So to help the layman we are developing a mobile app which can detect the agriculturalist, banana leaf spot disease are identified in an early stage and recommend the remedies to cure the disease through voice assistance. The supervised machine learning algorithm - convolution neural network is very successful in identifying the image and classification of leaf spot disease. So in our proposed system Convolution Neural Network are used to detect and classify disease based on banana leaf spot.**

Keywords*— Banana leaf spot disease; Convolution Neural Network; Mobile Application

I. INTRODUCTION

Agriculture is the backbone of our economy and plays a vital role in living life. Crop harvesting helps the economy of a country and is also necessary for the survival of each and every human being. In the world economy, India is the second largest producer of various agriculture products and produces more than 280 million tons of crops. Agriculture forms more than 70% of India's export capacity. Agriculture not only supports food but also provides people with employment opportunities, resources and technology. Agriculture is a rich source of food, nourishment and medicine for everyone and everywhere in all walks of life for several thousand years.

Banana is economically important fruit crops occupies 20% of the total crop area of India. Banana cultivation and harvesting is an important source of income and employment for many Indian citizens. Bananas is a rich source of nutrition fruit and consumed by more than 400 million people and 13% of worldwide banana production is exported to other countries. The plant disease found on banana leaf is black sigatoka and pestalotiopsis which are caused by fungi species. The leaf spot disease grow inside banana organs and drains away the nutrients thereby reducing their ability to photosynthesis by affecting leaves.

Black Sigatoka is a banana leaf spot disease when infected leaves can die and reduces the yield. The leaf spot disease can be controlled by applying fungicides and removal of affected leaves. The banana plants should be maintained with an sufficient spacing and efficient drainage within the plantation to be maintained. The symptoms of Pestalotiopsispalmarum is a tiny yellow, brown or black discoloration of the leaves. The spots or discoloration are0.25 inches in size which grow much larger forming lesions. The spots will turn into grayish color with a black outline. The banana leaf with wilting and a drying appearance is also the symptom of Pestalotiopsis palm. The disease spread can be controlled by applying pesticides to the banana plants but infected leaves cannot be recovered will stay infected until the leaf dies. The most important fungal disease widely spread around the world are Sigatoka, pestalotiopsis and cordana. So we are detecting and providing remedies to this disease.

The banana leaf spot disease are identified by the farmers based on their domain knowledge but existing youngsters or entrepreneurs could not identify the disease. They depends on the expert to get the information and remedial measures. To help the novice users to handle the issue, we proposed a mobile app to detect the leaf disease and also inform the remedial measures through voice assistance. The proposed system predicts the banana leaf spot disease with improved accuracy and also provides remedies for the disease cure through voice assistance.

The main focus of the paper is to apply mobile captured banana leaf image on the trained convolution neural network model to detect banana leaf spot disease. Our proposed system detects banana leaf spot disease in different illumination, varying complex background, resolution, size, pose and orientation.

DOI: rp-9788770040723.050

The rest of the paper focuses on the related work of researchers to detect the banana leaf spot disease. Based on the summary of the issues identified in the state of art, a proposed system is designed and developed under the section materials and methods. The proposed system is trained and tested with real time multiple banana leaf images and the accuracy of the system is measured. Finally after the discussion of the results achieved the final work is concluded with future work.

II. Related Work

SahilGandhi[1] developed a project to support farmers for detection of banana leaf spot diseases using machine learning techniques. The project helped the farmers to detect diseases and carry out necessary precautionary measures to prevent further spread of diseases. K. Lakshmi Narayanan[2] proposed a hybrid convolution neural network (CNN) for banana leaf disease detection. The system guides the farmers to apply fertilizers for prevention of disease in the initial stages.

PriyankaV[3] designed a convolutional neural network (CNN) model to train 50 epochs of batch size 64 to classify banana leaf diseases. The proposed model produced an accuracy of 90% for training and 89% on testing which can be further improved by tuning the hyper parameters of the model.

N V K Ramesh;Mohanpradeep Reddy B [4], proposed a system which can detect the disease in tomato plant leaf. The system uses the simple deep learning technique to identify the disease.The main aim of the system is to uses simple technique and limited resources to detect the disease. The proposed system give an accuracy of 94% on average.

Ravi Kishore Kodali [5], designed a system using CNN for classification and identification for tomato plant leaf disease. The accuracy of the system varies from 76% to 100% based on the class. The proposed system classified nine disease class and one healthy leaf class. R Swathika and S Srinidhi.[6] providesa architecture using convolution neural network layer. This paper introduces a new module for paddy disease classification.The dataset for the module are taken from public platform consists of 3500 images and give an accuracy of nearly 70%.

Wondatir, Dila[7] proposed a conventional neural network model to automatically classify banana leaf spot disease. The test image is segmented into infected area by applying K means clustering and texture features of gray level co- occurrence matrix (GLCM) are extracted from the infected leaf. The system is trained by using convolution neural network model which used 615 banana images collected from Arba Minch banana crop farms and other image repository. The classification accuracy based on CNN model is 91.41%. The accuracy based on texture feature for class healthy, yellow sigatoka, and panama are 82.3%, 70.7%, and 63.5%. SonerKiziloluk[8] used several deep learning models such as DarkNet, GoogleNet, Inception, Resnet and ShuffleNet to classify disease of potato, banana, cotton, and bean plants. The applied standard CNN models increased the accuracy from 7% to 25% with the transfer learning method of 5 epochs.

Sophia L. Sanga [9] proposed a methodology for early detection of banana diseases based on deep learning models. The deep learning architectures used to develop models for banana leaf spot disease identification are VGG16, Resnet18, Resnet50, Resnet152 and InceptionV3. The accuracies are 95.41% for InceptionV3 and 99.2% for Resnet152 with a confidence of 99% from the real environment. The proposed learning model helped the small scale farmers to detect banana leaf spot diseases at the early stage to enhance productivity.

Pruthvi P. Patel and Dineshkumar B. Vaghela [10] proposed system which detect both plant disease and pest identification. The proposed system uses deep learning technique to detect both crop disease and pest. V Suma and R AmogShetty [11], proposed a system which uses CNN and semi supervised technique to identify the crop diseases and detect the sickness of the plant. The proposed system will detect the sickness status of 4 distinct classes.

Prof.D.D.Pukale[12] proposed a system to identify, detect and rectify the banana leaf disease. The system also updates about the banana leaf disease to the farmer. An analysis report is produced which includes the symptoms and remedies of predicted disease and given to farmers for further actions. The system developed is an alert system which will notify the farmer through alert message about banana leaf spot disease.

Prof.N.A.Auti,ShraddhaKadam,[13], used deep learning approach to classify banana leaf using LeNetrchitectures. The proposed system efficiently classify banana leaf disease and give the remedial measures to prevent the leaf from further damage and destroy. Prof.D.D.Pukale[14] proposed a system to identify, detect and rectify the banana leaf disease. The system also updates about the banana leaf disease to the farmer. An analysis report is produced which includes the symptoms and remedies of predicted disease and given to farmers for further actions. The system developed is an alert system which will notify the farmer through alert message about banana leaf spot disease.

Jihen Amara[15] predicted two famous banana diseases banana sigatoka and banana speckle in real scene based on deep neural networks under varying challenging conditions. BassemBouaziz proposed an automatic LeNet deep neural network to classify banana leaves diseases.

From the above papers reviewed, we can conclude many researchers have done banana leaf spot disease detection and classification using Convolutional Neural Network (CNN) and its variant of deep neural network learning algorithms. The main issue of Convolution Neural Network fails to capture the pose, view and orientation of images. The CNN model requires large training data to build up the model and fails to learn the spatial relationship of the features. The future work is planned to target the automatic severity estimation to help the farmers to recover the plants from the disease.

III. Proposed system

In this system, first the image of the banana leaf is taken by the camera on the mobile phone. The captured image is pre-processed to resize to fixed size. The output of

DOI: rp-9788770040723.050

the pre- processing will be the input for the Convolution Neural Network (CNN) including two layers convolution and max- pooling. Through this CNN model, the features are extracted and the model is identified.

The data sets chosen for the proposed model includes balanced 937 leaf images with high resolution of banana plants, both infected and healthy leaves. The source data-set originated from GIS & Remote Sensing Lab, Agricultural University, Bangladesh. The input images are for three common leaf spot diseases - cordana, sigatoka and Pestaliopsis with high resolution are taken for study. The data sets descriptions under study for each class are shown in table 1. The total images taken for training, test and validation are depicted in table 1.

TABLE 1: BENCHMARK DATASETS DESCRIPTION

Image Category	***Total Images***	***Train Images***	***Test Images***	***Validation Images***
Healthy	129	89	20	20
Cordana	162	122	20	20
Pestaliopsis	173	133	20	20
Sigatoka	473	433	20	20
Total Images	**937**	**777**	**80**	**80**

The sample images used for study to classify banana leaf images as healthy, cordona, sigakota and pestaliopsis are shown below in figure 1.

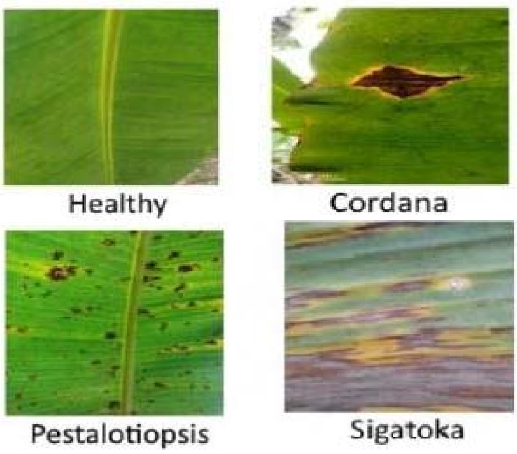

Fig.1. Banana Leaf Images

The hardware requirements may serve as the basis for a contract for the implementation. The hardware requirement for development are High Style Laptop with Intel Processor Core i3-4030U @ 1.90GHz with 8 GB RAM. The proposed system GUI is developed on Android Mobile Phone with high resolution camera facility to capture banana leaf image. The architecture of the proposed system is shown in figure 2.

A. Image Preprocessing

Image pre-processing is the initial stage for the classification of banana leaf spot disease. Image Preprocessing is applied to resize the image into standard size for efficient processing which in turn improve the image quality.

B. CNN Model Building

Convolution Neural Networks has three layers which are Convolutional layer, Pooling layer and Fully-connected (FC) layer. When the image data progresses through the CNN layers the objects shape and size are identified and forwarded to further layers till identifies the intended object. Convolution is the process in which the feature detector moves across theimage based on filter size. The filter size of 3*3 matrix is applied to the image area. A dot product is calculated between the input pixels and the filter and the resultant value is fed as an output array. The process is repeated until the kernel has swept across the entire image. The final output from the input image and from the filter is known as a feature map or activation map. CNN applies a Rectified Linear Unit (ReLU) transformation to the feature map.

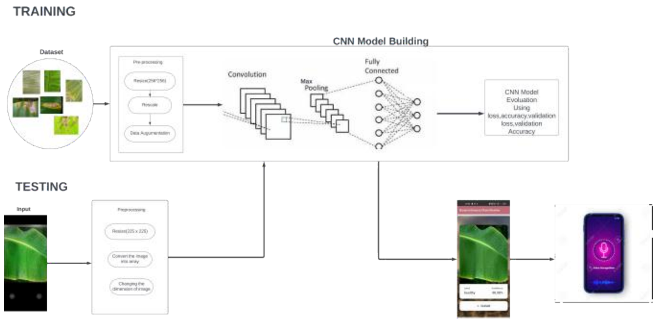

Fig. 2. Banana Leaf Spot Detection and Classification using Convolution Neural Network

The pooling layers sweeps a filter across the entire image used to reduce the number of parameters in the input. The image filter also termed as kernel applies an aggregation function either max pooling or average pooling and generates the output array. The filter moves across the input and selects the maximum pixel value which is shown in Figure 3. The filter moves across the input, and calculates the average value and sends to the output array. Pooling layer is used to drops lot of unwanted information, reduce complexity, improve efficiency, and limit risk of over fitting.

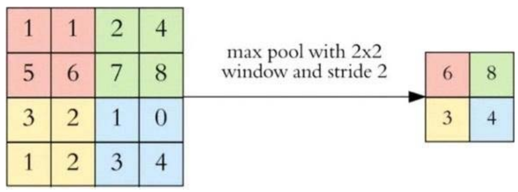

Fig 3. Max Pooling Operations

The proposed model is developed with convolutional and pooling layers with ReLu activation functions. Fully Connected layers use softmax activation function to classify inputs into its corresponding class labels. The proposed system takes the input image of the fixed size 256*256. The first layer is the preprocessing layer which includes resize and rescale. The input image is first resized to 256*256 and the image is rescaled to pixel size of 0 to 1. After the first layer the size of the image is (32, 256, 256, 3). The second layer is the data augmentation where the image is randomly flipped in both horizontal and vertical directly. The image is

DOI: rp-9788770040723.050

randomly rotated to 0.2 degree for better performance. After completing data augmentation process, the size of the image is (32, 256, 256, 3). There are totally 6 convolution layers with kernel size3*3and the activation function used is Reluand the batch size is (32,64). There are 6 max pooling layers with 2*2 kernel size and a softmaxlayer. After each layer the size of the image is reduced. In the flatten layer the images are converted to a single array of size 256. In dense layer, the final image is reduced to the output of 4 classes such as healthy, cordanasigatoka and pestalotiopsis.

…..

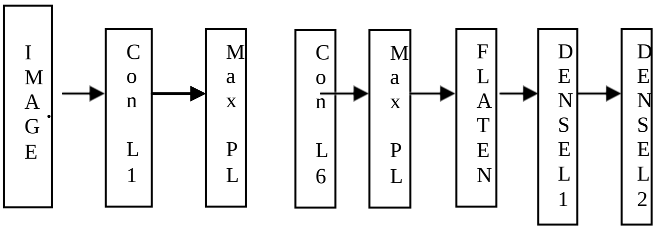

Fig. 4. Proposed Convolution Neural Network Layers

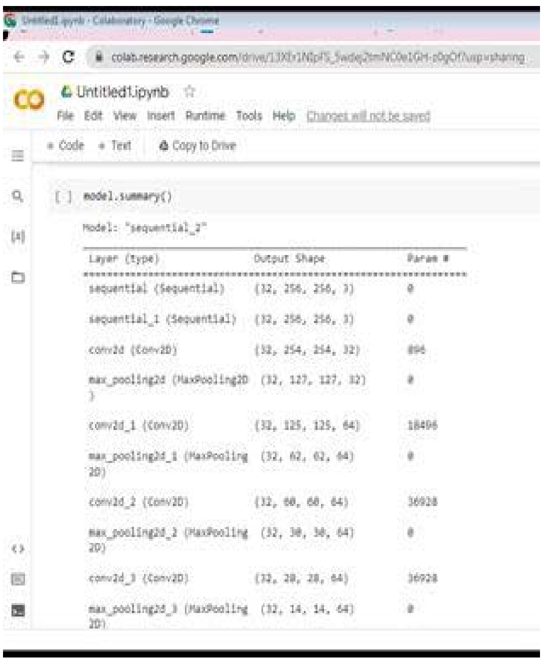
The proposed system takes input of resized image of 256*256*3 into convolution layer. After passing through multiple convolutions flatten and two dense layers, the final output are achieved of image size of 32 with 4 classes. The model is trained for 50 epochs, the training loss and validation loss is decreased. The model produced improved classifier and validation accuracy and finally the trained model is saved.

IV. Results and Discussion

The proposed system captures the image through smart phones and extracts the features from the image using Convolutional Neural Network (CNN). Then with the extracted features, the image is classified into healthy leaf or infected leaf. If the image is an infected leaf then it is classified as either one of the three classes such as cordana, sigatoka, pestalotiopsis.



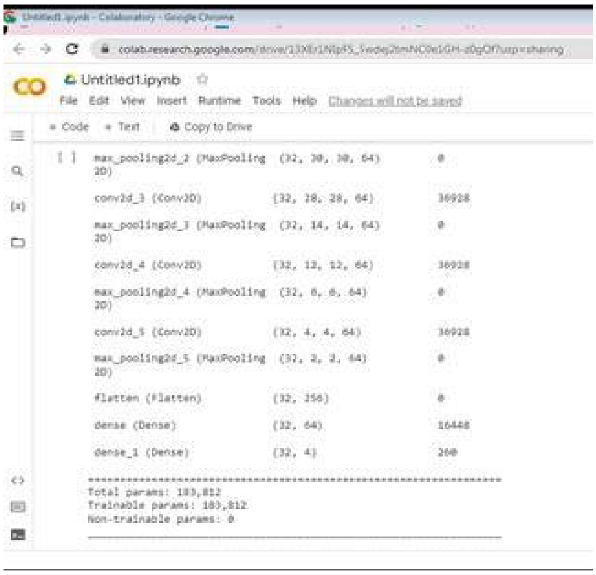


Fig. 5. Proposed Convolution Neural Network Model

The sample test images taken for the study for different banana leaf spot detection and classification are shown in figure 6 – figure 8.

Fig.6. Sigakota Leaf Spot Disease

Fig. 7. Cordana Leaf Spot Disease

Fig. 8. Healthy Banana Leaf

DOI: rp-9788770040723.050

The performance of the system is measured b y accuracy based on confusion matrix. A confusion matrix is a table of rows and columns and diagonal value denotes the correctly classified values for the test input samples.

The 4 elements used in the 2*2 confusion matrix are shown in Figure 9 as true positive (TP), true negative (TN), false positive (FP) and false negative (FN).

TP	FP
FN	TN

Fig. 9. Confusion Matrix

The proposed convolution neural network model confusion matrix for the test data sets is shown in figure 10.

```
Confusion Matrix
[[20 0 0 0]
 [ 0 18 2 0]
 [ 0 0 19 1]
 [ 0 0 0 20]]
```

Fig. 10. Confusion Matrix

The overall correct prediction of the proposed model is measures through accuracy. The recall measure is used to calculate the misclassification of negatives whereas precision is used to measure the misclassification as positives, F1 score is the harmonic mean of precision and recall. The classification accuracy report for the proposed Convolution Neural Network model is shown in figure 11.

Classification Report

```
precision recall f1-score support
cordana 0.19  0.19  0.19  122
healthy 0.11  0.10  0.11  89
pestalotiopsis
         0.14  0.15  0.15  133
sigatoka0.57  0.58  0.57  433
accuracy   0.39  777
macro avg0.25 0.25  0.25  777
weighted
avg  0.38  0.39  0.39  777
```

Fig. 11. Classification Performance Report

For a multi-class classification problem, precision is calculated as the sum of true positives across all classes and recall is calculated as the sum of false positives across allclasses. Both precision and recall numerator value is divided by the sum of true positives and false positives across all classes.

$$Precision\_c = \sum TP\_c / \sum (TP\_c + FP\_c) \quad (1)$$

$$Recall\_c = \sum C\ FP\_c / \sum (TP\_c + FP\_c) \quad (2)$$

F-Measure combines both precision and recall into a single measure and calculated using equation 3.

$$F\text{-}Measure = (2 * P * R) / (P + R) \quad (3)$$

Validation accuracy depicts how the model is able to classify the images with the validation dataset. Loss functions are the important aspects of neural networks which are responsible for fitting the model to the given training data. The accuracy graph for training and validation is shown in Figure 12. The validation loss is measured based on the performance of a deep learning model on the validation set.

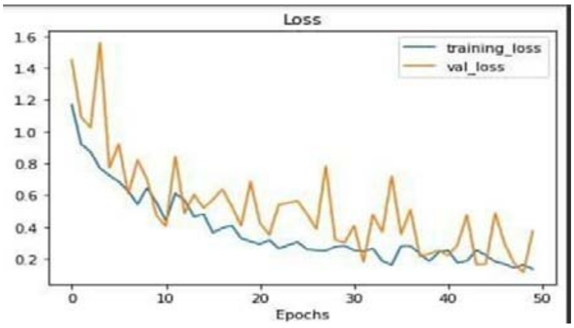

Fig. 12 . Accuracy Graph for training and validation

A loss function is used to compares the target and predicted output values. Loss function shows how well the neural network models fit the training data. Loss value should be minimized between the predicted and target outputs. The Loss graph for training and validation is shown in Figure 13.

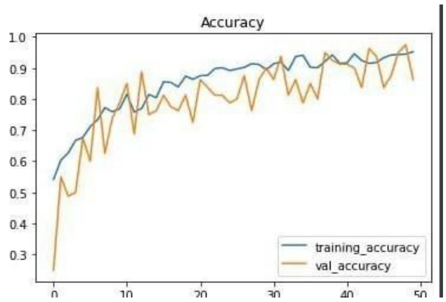

Fig. 13 . Loss Graph for training and validation

V. Conclusion

Farmers should monitor the banana plants to identify for leaf spot disease regularly. If the leaves are affected by fungal disease and not monitored by the farmers reduces the production and quality yield. Hence, the banana leaf spot diseases should be identified at the early stage. So, this paper presented a convolution neural networks model to identifyand classify banana leaf spot fungal diseases. The proposed system helped farmers or any agriculturalist as a decision support tool to identify the disease in the banana plant.

In our future work the model should be enhanced to identify more banana leaf spot diseases. To identify and learn the spatial relationship of the features in an object, a large training data sets are required. To overcome the shortcomings of Convolution Neural Network in learning spatial features, Capsule Neural Network can be trained to identify the spatial and orientation of the object. After detecting the disease we are providing remedies to the disease for the farmers in text format and voice format. The

DOI: rp-9788770040723.050
voice assistance help the layman in agriculture to clearly understand about the banana leaf spot disease.

***Abstract*—Social media as a medium of communication has opened countless possibilities for individuals around the globe to express their opinions on various topics ranging from politics to entertainment, thus reducing the gap in the accessibility of information. However, this has also led to social media becoming a hub for spreading hateful messages. These virulent messages spread online result in the rise of cases of cyberbullying, leaving an enduring impact upon the victims. Manually classifying and reporting these messages is a challenging task and has therefore created an interest in the research community to incorporate machine learning-based techniques to ease up the hand-operated process. The study's goal is to play a small auxiliary role in the prevention and ultimate eradication of cyberbullying. The proposed work in this research primarily focuses on the users from the Indian subcontinent by experimenting with Code-Mixed Hindi-English language. This research achieves this by performing the task of developing a Code-Mixed Hindi-English hate speech dataset containing 4014 tweets, out of which 2000 tweets contain hate, using the publically available tweets from the Twitter platform and classified on the basis of a set of guidelines. These languages are employed in the training of the models to create a more reliable hate speech prediction system for the targeted audience. The use of pre-trained multilingual models are explored by fine-tuning on the collected dataset. This research discovered an accuracy of 80.6 on the fine-tuned BERT Multilingual Base model when trained and tested on the combination of all the three languages and an accuracy of 82.2 on theXLM-RoBERTa model upon the same dataset. The goal of the study is to play a small auxiliary role in the prevention and ultimate eradication of cyberbullying.**

Keywords*—Natural Language Processing, Hate Speech Classification, Virulent Messages, Code-Mixed, Dataset Creation, BERT.

I. Introduction

One of the greatest gifts of modern technology to humankind is social media. This gift has truly unlocked the potential of communication by enabling people to discuss and debate on topics and issues that were once considered off-limits due to a number of reasons, like social stigma or regulations prohibiting free speech. In that way, social media has empowered individuals across the globe with the opportunity to express their opinions, views, criticism and experiences on a wide variety of topics, ranging from politics to entertainment. One such popular social-media platform in today's time is Twitter. In the past few years, Twitter has been extensively used by politicians, media houses, organizations, and individuals to share information such as facts, reports and updates regarding the events taking place in the real world, and correspondingly has been used to debate on the same.

Unfortunately, there is always a flip side to the coin. It cannot be denied that online social media platforms allow users to adopt personas and pseudonyms without providing any accountability for what they say. This lack of restrictions and the faceless nature of the internet have made it easy for people to post content online that can be deemed as hate speech. Generally, Hate speech is conveyed as the depiction of communication that is hateful, demeaning, intolerant, and in some way is degrading and inharmonious. There is no proper definition of the virulent message but in many instances accepted meaning deals with communication in speech, behavior, or writing, remarks which are insulting or abusive concerning an individual or a group of individuals, either directly or indirectly. Rise in spread of hate speech has contributed to a rise in reports of cyberbullying, wherein certain individuals and groups of individuals have emerged with the purpose of spreading misinformation and hate online by attempting to silence dissenting voices and harassing them through repeated threats and abuse. This results in a damaging and usually enduring impact on cyberbullying victims, which may lead to low self-esteem, depression, and other mental health issues. The situation has further deteriorated due to the effects of the Covid-19 pandemic. The Covid-19 pandemic has forced the majority of the globe to shift to online mode of education, work and other interactions, exposing more individuals to the kind of hate speech mentioned earlier, especially children who have moved to the online medium for their educational requirements.

Classifying such hate speech is inherently a challenging task since it is difficult to develop universally accepted guidelines and definitions for hate speech. The precise description of what can be cited as hate speech varies widely based on the language used to convey the message, its context, and the time and location when the message was given, making it an extremely subjective issue. It is hence stated that some may disagree with what others find offensive. Therefore, it has sparked a conversation in the research community, drawing an active interest in the field of hate speech classification, which is considered to be one of the most prominent real-life use-cases of sentiment analysis in Natural Language Processing (NLP). As mentioned earlier, the task of hate speech classification is highly subjective, and one of the factors affecting it is language. Therefore, it is essential to understand the language used to convey a message. When discussing the Indian subcontinent, one of the prominently used languages is Hindi, which is approximately 520 million people speak. It is observed that with respect to the language utilized in social media conversations, the use of a Code-Mixed

DOI: rp-9788770040723.051

language in Roman (Latin) script is favored over the use of native language structure. The same holds valid for the Hindi language, wherein the Code-Mixed Hindi-English is commonly used in online conversations over the conventional Devanagari Hindi structure. Thus, this study focuses on Code-Mixed Hindi-English, and Hindi languages along with the English language.

This research deals with the procedure of gathering publically available tweets from the Twitter platform to create a reliable Code-Mixed Hindi-English dataset. This dataset can then be used to train the state-of-the-art deep-learning model(s) to identify hate text written in the same language.

Over the course of this research, a lot of challenges and limitations were encountered while trying to identify virulent texts from a given set of texts. Some of the identified challenges are as follows:

- First, due to the code-mixed nature of Hindi, there is a lack of pre-existing datasets for Hindi. This required us to create our own dataset from scratch, which was challenging. Our dataset was limited in size and scope, so we had to combine multiple datasets into one. This posed a bit of a challenge because we needed to ensure that the data was not overlapping or conflicting with other sources.
- In addition to this, we also experienced difficulty with the NLP libraries. Although Indic NLP and iNLTK are available for pre-processing Hindi Language, the same doesn't work effectively with Hindi Code-Mix. We were required to do some hand coding and development in order to get it working properly.
- Additionally, strong biases against particular religions like "Islam" and "Hinduism", and particular communities like the LGBTQ community are usually observed and needs to be eliminated, so as to avoid creating a biased model.
- Due to the heavy computation required to train deep neural network models, a lot of computational power was required. It prompted the use of Graphics Processing Unit (GPU) to accelerate the training process by utilizing the principle of parallel computing.
- Also, a few individuals are aware of such techniques, and actively try to evade detection by using slangs or misspelled words. It also needs to be taken into account.

The remainder of the paper is organized as follows. Section 2 describes the related work and section 3 explains about the dataset creation. The proposed work is described in section 4 and results are discussed in section 5. Section 6 explains the conclusions and future work.

II. Related Work

In this section the works done on the hate speech classification in English language and and code mixed language in Indian subcontinent are discussed.

A. *Works Done on the Hate Speech Classification in English Language*

In recent times, with the advancement of computation technologies and the introduction of more advanced machine learning techniques, there has been an increased interest in the field of NLP to classify textual data into various classes. One of the most prominent classes in this is that of hate speech. A considerable amount of research work has been done in the past decade to understand and create highly reliable and sophisticated machine-learning-based models to classify the data as hate speech or not.

A major contributing factor in this task was done by Waseem Z. and Hovy D. [1] in 2016 when they analyzed a publicly available corpus of 16k tweets to classify hate speech based on various criteria for the English language. Furthermore, the authors examined the influence of numerous extra-linguistic features in accordance with the character n-gram. The authors collected tweets over a span of two months and created an annotated corpus of 16.9k tweets containing 1.9k racist and 3.3k sexist comments. The authors further explored the data by analyzing diverse aspects such as the demographic, geographical and lexical distribution. Lastly, the authors derived a list of criteria helpful to identify racist and sexist comments.

In the year 2017, Ji Ho Park, et al. [2] used the same dataset to suggest one-step and two-step classification of hate speech. The authors received an F-measure of 0.827 on the HybridCNN in one- step and an F-measure of 0.824 on Logistic Regression (LR) in two-steps. The authors also implemented Convolutional Neural Network (CNN) models on character, word and hybrid level. Apart from the three CNN models, SVM and FastText were also used to observe the performance for comparative purposes. The same dataset was further used by Pitsilis G.K, et al. [3] in 2018 to experiment on various features related to the user, which includes the past mentions of racist and sexist comments by users on an ensemble of Recurrent Neural Network classifiers. The authors also used word frequency vectors derived from the textual content of tweets. Furthermore, the authors compared performances with single classifiers along with the performances noted by past researchers. The results proved to be comparable and sometimes even better than the state-of-the-art algorithms at the time.

MacAvaney S, et.al. [4] in 2019 in their research discussed the technical and practical challenges when it comes to hate-speech detection. This comprised challenges such as the limited availability of data for training and the discussion about the non-existence of a universal definition for hate speech. The authors proposed a multiview SVM approach that was able to achieve performances similar to the state-of-the-art architecture whilst having a more straightforward, easy to interpret decision-making structure. The authors also used an array of datasets such as the Waseem A [5] and B dataset [6], Stormfront dataset [7], TRAC dataset [8] etc.

Using the HASOC 2019 data, GyörgyKovács, et. al. [9] further explored the challenges involved in identifying hate speech on Social Media and have explored in their study various opportunities, such as leveraging unlabeled data, similarly labelled corpora, as well as the use of novel models. The authors proposed a deep neural network

DOI: rp-9788770040723.051

comprising both the recurrent and the convolutional layers, making the use of CNN - Long-Short Term Memory (LSTM) architecture. The authors also deployed the use of the FastText classifier and the pre-trained RoBERTa model to evaluate its result. Lastly, the authors also experimented with an ensemble of different models to assess and compare the performance with single systems.

Marian-Andrei Rizoiu, et al. [10] in 2019 used the dataset provided by Waseem and Davidson to train a state-of-art model to classify the texts present. It was achieved by using a deep neural network along with transfer learning to create a model that can create word and sentence embedding specific to the task of hate speech classification. The authors further discuss using the models to generate a two-dimensional text visualization process termed Map of Hate. This process can separate different kinds of hate speech and try to illustrate what makes those texts dangerous for the users. The authors aimed to propose models that can reduce the manual work performed by human moderators on chat platforms and automate the same process.

It is clearly evident that a great deal of research has been done for the identification of hate speech in the English language with the use of state-of-art classification techniques. This has further sparked the interest to experiment and extend the same to other languages around the globe. One of the most prominent currently spoken on social media in the Indian Subcontinent is Code-Mixed Hindi-English.

B. *Works Done on the Hate Speech Classification in Code Mixed Language in the Indian Subcontinent*

In the year 2016, Prabhu A., et al. [11] performed sentiment analysis on Code-Mixed Hindi-English and proposed an annotated dataset for the same. Further, the authors introduced sub-word level representations in Subword-LSTM [12] architecture as compared to the traditional approach of character-level or word-level representations. This proved useful even in the case of highly noisy data, i.e. with a lot of misspellings and/or other mistakes. The authors were able to achieve higher accuracy by the margin of 4 % to 5 % as compared to the traditional approaches.

A major contributor in the classification of the code mixed Hindi-English language is the work done by P. Mathur, et al. [13] in 2018 wherein they created a dataset for Code-Mixed Hindi-English language and used transfer learning coupled with multiple feature inputs to identify hate speech. It was successful using the concept of Multi-Input Multi-Channel Transfer Learning Based Model (MIMCT) that was used to detect hate or abusive content. The authors proposed the Hinglish (Hindi-English) Offensive Tweet (HOT) dataset in the study. A comparison was also shown with the baseline supervised classifiers and transfer learning-based CNN - LSTM models. The prescribed MIMCT model by the authors contained two primary components, which included primary and secondary inputs, and CNN - LSTM binary neural network. The author included the Sentiment Score (SS), LIWC Features, and Profanity Vector in the primary and secondary inputs. Here LIWC features included linguistic statistics, current concerns, spoken categories, textual categories, psychological processes, and grammatical structures.

In the same year 2018, AdityaBohra, et al [14] made a significant contribution by presenting a Code-Mixed Hindi-English dataset with word level annotation. The authors examined the difficulties related to recognizing hate speech in code-mixed texts. The authors further presented a supervised classification system that included numerous components such as character level, word level and lexicon-based features. The authors extracted features such as character N-gram, word N-gram, punctuations, negative words, and lexicon. The authors tested the support vector machine-based classifier on each feature separately and on all combined features. The authors achieved an accuracy of 71.7% using the support vector machine-based classifier. The authors also compared the results with the random forest classifier.

In the year 2018, Kamble S., et al. [15] observed that using domain-specific embeddings results in an improved representation of target groups mentioned in the Code-Mixed Hindi-English dataset by Bohra A., [14]. The models proposed by the authors resulted in an F-score that was 12 % higher as compared to the F-score achieved in the past using statistical classifiers. Instead of utilizing the pre-trained word-embeddings, the authors trained word-embeddings on an enormous corpus of pertinent code-mixed texts. The deep learning models proposed by the authors included the CNN-1D,LSTM and BiLSTM models. The authors also used characteristics that included features like number of tweets, number of timelines extracted, number of retweets, the total number of words, size of vocabulary, and percentage of Hindi words per tweet.

Santosh T.Y.S.S, et al. [16] in 2019 further explored various techniques such as attention based on phonemic sub-words on two architectures that are hierarchical LSTM and sub-word level LSTM. This was accomplished with the help of the publicly available code-mixed dataset. The authors also compared the results with a support vector machine-based classifier and random forest classifier. The hierarchical LSTM model with attention based on phonemic sub-words contained the embedding layer, the syllable encoder, and the word encoder, along with word attention and an output layer.

Sreelakshmia K., et al. [17] in 2020 used Facebook’s pre-trained word embedding library, fastText to represent 10000 data samples collected from different sources as hate and non-hate. The authors carried out the experiment for the Code-Mixed Hindi-English language. The authors also compared the results with the word2vec and doc2vec features. With this, the authors achieved an accuracy of 85.81 % by using the proposed methodology with a Support Vector Machine (SVM)-Radial Basis Function (RBF) classifier.

By the end of the same year 2020, Vashistha N., et al. [18] combined multiple datasets available for the English and the Hindi language along with the dataset available for the Code-Mixed Hindi-English to test on a variety of deep neural networks. The author firstly built a baseline model and then used several optimization strategies to increase the

DOI: rp-9788770040723.051

model's performance. The authors developed a tool that detects and rates a given comment with an effective metric in near-real-time and uses the same feedback to further re-train the model, following which the authors achieved a competitive performance score. In two languages, English and Hindi, the authors demonstrated the efficiency of their multilingual model.

The frequency of harsh language on social media motivated Gaikwad S., et al. [19] in the year 2021 to develop techniques that could detect such content automatically. Apart from a few oddities, the majority of research studies have focused on the English language; hence the dataset termed MOLD, which stands for Marathi Offensive Language Dataset, was created to address this issue. It's the first of the kind dataset created for the Marathi language, and it's opened up a whole new field of study for low-resource Indian subcontinental languages. The authors used state-of-the-art cross-lingual transformers to explore machine learning models, including zero-short and other transfer learning experiments, using existing Bengali, English, and Hindi data.

In the year 2021, Sazzed S. [20] proposed the study taking into account the Indian regional languages used in the Indian Subcontinent. The author created a Bengali language corpus of 3000 comments divided into hate and non-hate, having a ratio of 1:1. Furthermore, the author tested the proposed dataset on various machine learning and deep learning classifiers such as support vector machines to detect abusive comments.

In the year 2022, Arushi S., et al. [21] proposed a study that focuses on identifying hate speech in Hindi–English Code-Switched languages. The authors' research entails experimenting with transformation strategies to obtain an accurate text representation. The authors constructed 'MoH', which stands for Map Only Hindi. The term MoH conveys 'love' in the Hindi language. The proposed 'MoH' is a Hindi language pipeline, which consists of language identification that assists with the process of transliteration of Roman formatted Hindi to Devanagari Hindi language using a knowledge base of Roman Hindi terms. Furthermore, the authors fine-tuned Multilingual Bert and, as an extension of that, the [22] Multilingual Representations for Indian Languages (MuRIL) model, as a part of the 'MoH' pipeline.

Based on the research and study performed during the work process for this research, a list of demerits of past implementations was compiled to better understand the requirements and need for this research. In today's time, most of the communications that are happening on social media platforms online are carried in the code-mixed version of the languages. Therefore, it is crucial to develop a system that can process these code-mixed languages. A number of models have been proposed in the past that are created by training on the native alphabet format of the languages. However, these models cannot be applied directly to process code-mixed languages due to their limitations on language modeling and translation. Hate speech classification is a crucial task to be performed in today's era. Therefore, it should not be taken lightly. One of the most noteworthy things to consider when dealing with hate speech is the context in which it was said. There are many resources and publicly available datasets for the English language that contains annotations to classify a sequence as hate or not hate, and which categorize the hate sequences into multiple categories like abusive, offensive, racist, sexist, ethnic, etc. Unfortunately, the same isn't available in abundance in other languages, especially in the code-mixed languages.

A majority of model proposed in the past were monolingual, primarily focusing on the English Language. Whilst, this research mainly concentrates on the vast majority of users from the Indian subcontinent, who speak Hindi and, as an expansion, Code-Mixed Hindi. In this research, various machine learning models are tested alongside with advance d deep learning models on the English, Hindi and Code-Mixed Hindi-English Dataset. This study also includes the process of collecting and creating a new dataset for the Code-Mixed Hindi-English Dataset, by establishing a set of guidelines and rules that can be followed to annotate Code-Mixed Hindi-English texts as hate speech or non-hate speech.

III. Dataset Creation

A wealthy amount of pre-annotated data is available for the task of hate speech classification when it comes to the English language and also the Devanagari Hindi language. The same doesn't hold true for Code-Mixed languages such as Code-Mixed Hindi-English. Hence, this prompts the need to gather and prepare datasets for Code-Mixed languages. This section details the complete strategy followed during the span of the creation of the presented Code-Mixed Hindi-English dataset. This strategy involved scraping publicly available tweets from the Twitter platform, manually classifying the dataset based on a specific set of rules and guidelines set by the annotators before the commencement of the data annotation stage, and lastly, documenting the statistics of the combined dataset.

A. *Data Collection*

As stated earlier, the dataset proposed in this study is created from the publically available tweets on Twitter. The task of scrapping the tweets can be accomplished using Python libraries that access the official Twitter API, for example, the open-source library, Tweepy[18]. Apart from the Tweepy, a few more additional Python libraries are available that provide similar functionality. To build the Twitter dataset for this study, the Snscrape Python library was used. Snscrape is a scraper for social networking services (SNS), providing the feature to scrape data from a plethora of social media platforms, including Facebook, Instagram and Twitter.

A set of keywords and hashtags was chosen, accounting for various current and past events, topics, and discussions occurring on Twitter. The aforementioned set of keywords and hashtags was created with keeping the objective of fetching as many Code-Mixed Hindi-English language tweets as possible in mind. This set was then used with Snscrape to scrape 25,303 tweets from Twitter.

It included the original tweet text, the username of the

DOI: rp-9788770040723.051

person who posted the tweet, the timestamp (date and time) of the tweet, and the tweet's unique tweet ID.

B. *Data Annotation*

The step of classifying the collected data into the hate and the non-hate class was carried out manually by reading and examining all the tweets. This process was performed by bilingual authors who are well versed in both the English and Hindi language. In order to avoid any type of bias from the authors, a set of policies and rules were debated and agreed on before initiating the task of manual classification.

Firstly, apart from the original tweet text, other data values such as the author of the tweet, the tweet ID, and the timestamps were hidden during the course of manual classification. It was done to avoid any bias that may arise based on the tweet's author. Furthermore, the data was shuffled before splitting among the authors to allow each author to get tweets based on diverse keywords and hashtags instead of just a few. As discussed previously in the paper, it is hard to define a standard definition of hate speech, so to acquire a uniform approach to classification by the authors, the following set of guidelines was followed.

1. Any tweet containing severe profanity, abuse, threat, offensive remarks, personal insult, harassment, promotion of violence and harm were classified as hate.
2. Any tweet not following in the above category was classified as non-hate.
3. Tweets containing texts written with some sense of sarcasm were handled on a per tweet basis, where tweets without any malign intent or explicit depiction of hate were marked as non-hate, whilst others were labelled as hate.
4. A tweet containing criticism about any community, group or person was classified as non-hate as long as the tweet didn't include any offensive remark, use of extreme profanity or the intention to denigrate the targeted individual or group of individuals.
5. A maximum threshold was set for the number of words allowed in a tweet belonging to the English and Hindi (Devanagari Format) language with respect to the total number of words in the same tweet. If the use of such words were within the threshold, the tweet was considered for classification; otherwise, the tweet was removed from the data.
6. Tweets not following the above guidelines were considered garbage tweets.
7. Tweets that were challenging to classify were flagged for reexamination and were reviewed later by all the authors.

Once the authors completed the initial data classification stage, the tweets marked as garbage were removed, and the rest of the data was compiled. The authors reviewed and weighed on the classification performed by their peers, which was later used to calculate the inter-rater reliability score. During this step, thorough discussion was conducted on all tweets previously flagged for reexamination.

C. *Dataset Statistics*

The dataset produced from the manual classification task contains 2000 hateful tweets out of a total of 4,014 tweets, resulting in the percentage of hateful tweets being 49.82%. Table 1 shows the hate class distribution. The example data in the dataset are given in Table 2. As stated earlier, the inter-rater reliability (IRR) score was tallied to gauge the consistency of the data classification performed by the authors, using the Cohen’s Kappa coefficient. The resulting value of 0.964 indicated a high level of agreement.

TABLE 1: HATE CLASS DISTRIBUTION

Class	Data Entries
Non - Hate	2014 (50.18%)
Hate	2000 (49.82%)
Total	4014

TABLE 2: Dataset Values (Censored)

@TwitterIndia tum ga*du follower kyuapnega*d me ghusalete ho	Hate

IV. MODEL ARCHITECTURE

This section will discuss the various procedural steps that were followed to evaluate the created dataset by utilizing it to fine-tune an array of pre-trained deep learning models. It involved the process of cleaning the dataset by removing all the not required data, performing a basic exploratory data analysis on the dataset, fine-tuning the hyper parameters during the period of model re-training and evaluation.

A. *Data Pre-Processing*

To process the text data for use in a deep-learning model, first, it was necessary to clean the data and remove all extraneous information. This step was accomplished by removing all nonessential columns from the dataset (tweet ID, tweet author, tweet timestamp). Furthermore, publicly available text processing Python libraries were used to streamline the cleaning and preprocessing of the tweets' textual data. This set of tools includes the Natural Language Toolkit (NLTK) and Ekphrasis library. With these tools, the tweets were processed by removing stopwords (For English Words present in the tweet), unpacking the hashtags and contractions, annotations of URLs, users, emoticons, date, time and hashtags. Table 3 shows the example data before and after cleaning.

TABLE 3: DATA EXAMPLE BEFORE AND AFTER CLEANING

Data Cleaning	Text

After	user khudkegharmeinbijlinahiaurchaledusrokora ahdikhane power grid failure

B. *Pre-trained Deep Learning Models*

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.051

The resulting preprocessed dataset was then fed into a range of pre-

C. trained deep learning models, including the Multilingual Bert and XLM- RoBERTa [19, 20].

i. Multilingual BERT - BERT stands for Bidirectional Encoder Representations from Transformers. It was first introduced by Google AI Language. Bidirectional means that the model can read text from both left-to-right and right-to-left. One of its iterations is Multilingual BERT, a transformers model pre-trained on a large set of multilingual data in a self-supervised manner, enabling comprehension of multiple languages.

ii. XLM - RoBERTa - RoBERTa is a robustly optimised method for pretraining self-supervised NLP systems proposed by Facebook AI. These models can be tuned for various tasks such as document similarity and classification. One variety of this model is XLM - RoBERTa (XLM-R). XLM denotes a Cross-lingual Language Model [21]. XLM-R is a multilingual model pre-trained on 2.5 TB of filtered CommonCrawl data in 100 languages.

Several renditions of XLM-RoBERTa are available, which includes XLM-RoBERTa-base and XLM-RoBERTa-large.

For the purposes of this study, bert-base-multilingual-cased model and xlm-roberta-base model were selected from the Hugging Face platform.

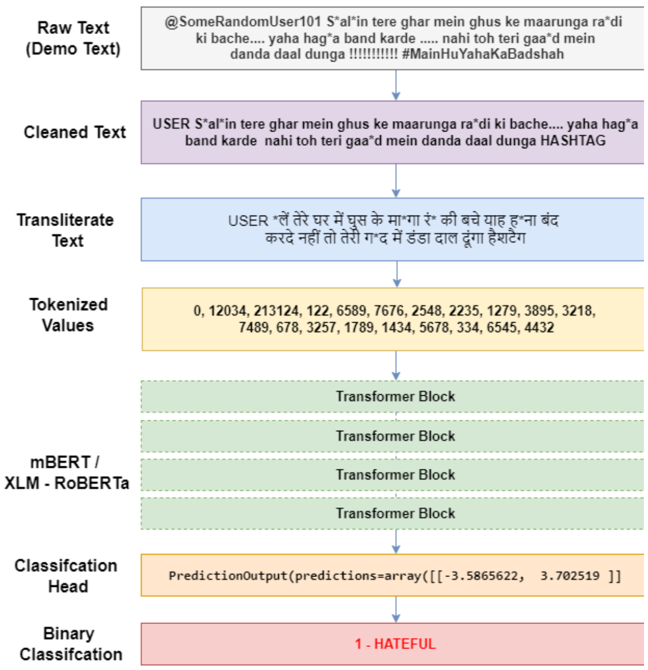

Fig. 1. System Architecture

Fig. 1 shows the system architecture which tells the step by step procedure.

V. Results and Discussion

This section will cover the performance of the machine-learning and deep-learning algorithms used during this study. The results are presented in a tabulated order, and noteworthy observations are drawn from the above-stated results of the research. This section also details the various parameter and hyper-parameters used during the training phase of this study.

A. *Basic Machine Learning Classifiers*

The feature generated from the data for all three languages were individually divided into a train and test set of 70% and 30%, respectively. The extracted features were thenpassed on as an input to an array of machine-learning-based classification techniques. Different parameters such as the number of estimators or the penalty were experimented for the various classifiers.

- Mainly, the models were trained with a K-Folds cross-validator having a value 5 for the number of folds and also, using the method of grid search.
- For the Logistic Regression (LR) classifier, the penalty was chosen as ‘l2’, an inverse of regularization strength of 0.02, and class weight was chosen as ‘balanced’ to give equal weightage to both the classes.
- For the Support Vector Machine (SVM) classifier, the regularization parameter was set to 0.01, and the kernel was chosen as ‘linear’ because of the number of features used in the input.
- For the Random Forest Classifier (RFC), depending on the language, the number of decision trees varied from 120 to 150. Also, the ‘gini’ criterion was used.

Tables 4, 5 and 6 show the machine learning (ML) Classifiers’ accuracy, precision, recall and F1-score for English, Hindi, and Code-mixed Hindi-English languages.

TABLE 4: ML Classifier Results for English Language

Classifier	Accuracy	Precision	Recall	F1-Score
LR Classifier	0.779	0.774	0.775	0.774
SVM Classifier	0.798	0.794	0.790	0.792
RFC Classifier	0.821	0.816	0.819	0.817

TABLE 5: ML Classifier Results for Hindi Language

Classifier	Accuracy	Precision	Recall	F1-Score
LR Classifier	0.785	0.784	0.784	0.784
SVM Classifier	0.814	0.807	0.809	0.808
RFC Classifier	0.834	0.832	0.831	0.831

From the results mentioned above, several observations can be made. Broadly, the Random Forest Classifier (RFC) model appears to yield the best results in all the languages.

TABLE 6: ML Classifier Results for Code-Mixed Hindi-English Language

Classifier	Accuracy	Precision	Recall	F1-Score
LR Classifier	0.712	0.710	0.711	0.710
SVM Classifier	0.735	0.734	0.734	0.734
RFC Classifier	0.753	0.750	0.751	0.750

The reason behind this may be related to the fact that RFC operates on multiple decision trees reducing any bias or over-fitting that may occur when working with only one decision tree or a single procedure classifier. Also, important to note that the results for the English and the Hindi language are considerably better than that for the

DOI: rp-9788770040723.051

Code-Mixed Hindi-English language. This can be substituted to the fact that the more robust techniques and tools for data cleaning and pre-processing are available when it comes to the English and Hindi languages. One other reason that may contribute to this is that the Code-Mixed version of Hindi doesn't have a fixed vocabulary, and due to variation in the method of writing code-mixed language, a single word in Devanagari Hindi may have several spellings in Code-Mixed (Roman) Hindi, resulting in a vast vocabulary and thus, reducing the performance across the board. The results are assumed as the baseline performance achieved on the dataset.

B. *Fine-Tuned Deep Learning Models*

This section presents the results of the experiments performed on the pre-trained deep learning models using the created datasets. Since the dataset was tokenized using the sub-word tokenizer available with the respective models, the dataset was first translated to Hindi (Devanagari) Language using the Google translate library available for Python, and then it was tokenized. The dataset was tokenized with a maxed length of 256 and padding based on the same. It was further encoded using the transformer function available on the above-mentioned platform. The encoded dataset values with corresponding class labels were then transferred as an input to the models.

A set of hyper-parameters was tested during the model fine-tuning period; this includes a learning rate of 2e-5, batch size of 16, weight decay of 0.01, and train-validation-test split of 70-10-20. The models were terminated with a classification head to produce the binary hate speech classification results.

Tables 7, 8 and 9 show the deep learning (DL) Classifiers' accuracy, precision, recall and F1-score for English, Hindi, and Code-mixed Hindi-English languages.

TABLE 7: DL MODEL RESULTS FOR ENGLISH LANGUAGE

Model	Accuracy	Precision	Recall	F1-Score
mBERTModel	0.834	0.830	0.831	0.830
XLM-RoBERTaModel	0.851	0.848	0.849	0.848

TABLE 8: DL MODEL RESULTS FOR HINDI LANGUAGE

Model	Accuracy	Precision	Recall	F1-Score
mBERTModel	0.857	0.856	0.856	0.856
XLM-RoBERTaModel	0.879	0.876	0.878	0.877

TABLE 9: DL MODEL RESULTS FOR CODE-MIXED HINDI-ENGLISH LANGUAGE

Model	Accuracy	Precision	Recall	F1-Score
mBERTModel	0.771	0.770	0.769	0.769
XLM-RoBERTaModel	0.784	0.782	0.783	0.782

A considerable improvement has been observed when compared to the performance delivered by the baseline machine-learning-based classifiers. There have been significant improvements for all the languages separately. But, when observing the results acquired from the models that were fine-tuned on all the datasets combined, the evaluation score appears to be an average of the results of the separate models. This further solidifies the theory that has been proposed regarding one of the drawbacks of the multilingual model approach. Also, it has been observed that the XLM-RoBERTamodel performed better as compared to the mBERTmodel across all the languages. This may be because of the use of Byte-Pair Encoding (BPE) used by XLM-RoBERTa which allows it to have an increased shared vocabulary between languages, which in the case of this research, benefits the Devanagari Hindi and the transliterated Code-Mixed Hindi-English languages.

VI. CONCLUSIONS AND FUTURE WORK

As iterated earlier, this study aimed to play a small auxiliary role in the prevention and ultimate eradication of cyberbullying. The first step towards that direction is the creation of state-of-the-art classifications models that can classify hate messages. The recent interest in this field of research has yielded some promising results, especially in the realm of English language with enormous amounts of data available for training. But, as demonstrated in recent research efforts, this success can be taken further into the domain of other languages. It can thus be applied to a broader audience who speak different languages. The study also emphasizes the fact that the communication that is taking place in today's time on social media forums and platforms usually contain a mix of various languages, some of which are code-mixed versions of English and the native language of the region.

This study delivered a hate speech (virulent text) classification dataset for Code-MixedHindi-English language with 4,014 values, with an even distribution of hate and non-hate entries manually classified from a scraped Twitter corpus of 25,303 tweets. Furthermore, this study also proposed a set of policies and rules that can be followed to classify hate data. The guidelines followed in this study can also be used in future research to create more sophisticated hate-speech datasets. The guidelines can also be employed to further explore the data by dividing the hate speech class into multiple classes, such as abuse, threat, insult, and harassment. This study also attempted to fine-tune two deep-learning models, namely, multilingual BERT and XLM - RoBERTa, on the created dataset, providing models that can effectively identify texts containing hate messages.

More in-depth work is still required to improve the models further and deploy the studied techniques into real-life applications. With issues, such as active avoidance (user trying to evade hate speech detection by using misspelt words or slang) and community bias (race, religion, gender, occupation, etc.) continuing to affect the performance of classical hate speech flagging systems, the need to create more reliable automatic machine learning-based techniques is crucial in the forthcoming times.

***Abstract*— Edge computing bridges the gap between industrial clouds and field devices for the Industrial Internet of Things (IoT). The most difficult aspect of edge computing is gathering data from different devices. The role of Edge is to process client's data at the network's edge, closer to the source. Due to the rapid increase in data traffic exchanged worldwide, there is an increasing need to collect and process data from sensors and devices of the IoT, which are operated in real time from remote locations and hostile operating environments. The proposed system aims to develop an edge-based heart disease prediction. The system was developed using a simple microcontroller that integrates temperature, heart rate and blood pressure. The measured value is tested with machine learning model to understand the patient's condition. Many feature combinations are used to reveal the prediction model and also for large number of well-known machine learning classification algorithms. Prediction model achieved the accuracy measure of 86% for SVM,92.24% for Decision Tree Classifier, 93.01% for Random Forest and 86.91% for K-Nearest Neighbor. So, from these four algorithms, Decision Tree Classifier gives the superior prediction, satisfying all the measures of precision, recall, accuracy and F-Score.**

Keywords—Edge Computing, IoT, Machine Learning, Performance measures, Heart Disease Prediction.

I. INTRODUCTION

Heart attacks and strokes were liable for 80% of people's death. The people who suffer from uncertain heart diseases, can be saved if it is predicated ahead of time. The (IoT) has already been widely used in a range of clinical aspects to capture the sensor values in attempt to diagnose the specific issues and predict cardiac problems through Machine Learning algorithms in real world applications and all healthcare standards. The IoT connects objects within the vicinity, collects the data from the people, and analyses it for early prediction and diagnosis[1]. Multiple inference has examined the capabilities of cloud-based and edge-based computing, concluding that the only system can manage the current scenarios in well-defined manner is Edge-based Machine Learning that can only meet the network delay, bandwidth, speed and all efficiency requirements. A superior execution of edge computing over traditional cloud computing can benefit many sectors, including healthcare[2].This paper's contributes, cardiac patient monitoring system based on the concept of IoT, using various signal sensors and a microcontroller. IoT technology is increasingly being used by sensor networks to capture, interpret, and transmit data from one node to another. IoT is a relatively new and rapidly expanding technology in which multiple sensors can sense, share, and communicate over a local network, public networks and through Internet Protocol. After a specified amount of time, the sensors collect data, analyse it, and use it to initiate the necessary action, resulting in an cloud-based network intelligence foranalysis, planning, and decision making. IoT-enabled products, such as embedded technology, enable data exchange. So here the methodology was tested on only three subjects and predicted their condition. So here the key contribution is to select a machine learning model that which best suits for the prognosis of heart disease.

II. RELATED WORKS

In this literature, various number of sensor-based wearable health monitoring devices in machine learning with edge has been suggested. This section discusses a few related works in detail. Every year, chronic diseases such as cardiovascular disease, respiratory disorders, and brain disorders kill more than 65% of the world's population. Chronic disease patients have a long recovery period and require technology for consistent monitoring of their health condition. Wearable technology is used to monitor vital parameters such as blood pressure, Oxygen saturation, respiratory rate, and Electrocardiograph for the patients.

Ram et al[2022] Machine learning in edge has been investigated for detecting anomalies and improving the accuracy of the data and mobile health monitoring can predict outcomes. Moreover, multi-modal sensor information was pre-processed to cleanse the data and classify the occurrences in the dataset[3].

Md.MahbuburRahman et al[2022] Data that has been pre- processed in order to train and evaluate machine learning algorithms. The first stage divides pre-processed data into two portions. The majority of these are utilised in the training phase (80%), with the remainder (20%) employed in the testing phase. dataset was trained using machine learning techniques such as Decision Tree, XgBoost, KNN, Support Vector Machine[4]

Ayushi Das et al[2022] Four different classification algorithms to forecast certain widely identified diseases are k-Nearest Neighbour, Naive Bayes, Decision Tree, and Random Forest. On a disease prediction data-set, these Supervised Machine Learning classifiers are used to identify 41 prevalent diseases based on any 5 prominent symptoms from the dataset's 132 common symptoms[5].

JameelAhamed et al[2021] To examine the available data on cardiovascular disorders in order to predict and prevent heart disease at an earlier stage. The heart disease patient dataset was collected and stored in the cloud. The information stored is then pre-processed and examined

DOI: rp-9788770040723.052

further using machine learning techniques to forecast cardiac problems[6].

ButchiRaju et al[2021] This model combines Edge-Fog- Cloud computing to deliver accurate and timely results. The hardware components collect information from various patients. To obtain significant features, heart feature extraction from signals is performed. In addition, with, thefeature extraction of other attributes are also combined. All of these characteristics are gathered and fed into the diagnostic system via an Optimized Cascaded Convolution Neural Network[7].

N.Saranya et al[2020] Latency reduction approaches in mobile computing and fog networks, data availability, power computation, and other parameters are analysed and compared to see which gives superior results[8].

R. Latha et al[2019] The blood viscosity is predicted by Partially Observable Markov Decision Process. The decision was made to address two causes of ambiguity. The first is about control, specifically diagnosis. The other is related to the user, namely the decision maker. A hierarchical dynamic effective framework model was chosen to solve this POMDP. Structure-based approximations and approaches are used to reduce complexity[9].

S. Mohan et al [2019] An innovative way for identifying key features by using machine learning techniques, with the goal of increasing accuracy of cardiovascular disease prediction. The prediction model is presented with several combinations of features and various recognised categorization algorithms. We achieve an improved performance level with an accuracy level of 88.7% using the hybrid random forest with a linear model to predict heart disease[10].

ShadmanNasif et al[2018] Cardiac patient monitoring system based on the Internet of Things, with various physiological sensors and an Arduino based microcontroller. Sensor networks are now using IoT technology to collect, analyse, and transmit data from one node to another node[11].

TABLE I.ONGOING HEALTH MONITORING DEVICE

S. No	Motive	Signals	Analysis (edge/cloud)
1	Observing heart illness	ECG, Heart rate, EMG, Accelerometer	Edge with ML
2	Heart Rate Monitor	ECG, EMG, BPV	Edge with ML
3	Tracking sleep	Temperature, Heart Rate	Cloud with ML
4	Cardio vascular disorders	ECG, Blood Pressure, SPO2	Cloud with ML
5	Heart disease Monitoring	ECG, EEG, EMG, Temperature, Oxygen level, Respiratory rate	Edge with ML

III. FINDINGS FROM RELATED WORKS

The majority of the research works analysed cardiovascular disease models using single and two algorithm combinations that are not powerful enough to provide reliable predictions in underdeveloped countries.

The IoT-ML-Edge paradigm is a distinct Information Technology (IT) prototype in which IoT, ML, and edge are three interconnected technologies integrated together to address both existing and future world difficulties associated to the health-care concern.

For cardiovascular disease prediction, we employed three distinct feature choices as well as four classifiers. We have yet to come across any research that has used such classifiers for feature selection and cardiovascular disease prediction. In most occurrences, research scientists employed just three algorithms in their work.

In this system we used various machine learning techniques to forecast cardiac illness because it is one of the best andmost novel tools for prediction work, and it is also used in other subjects such as cancer symptoms and weather prediction system.

IOT- Edge Module

Sensors

The sensor framework incorporates ECG to monitor the blood pressure and sugar, pulse sensor to measure the heartbeat and temperature sensor to monitor the patient’s vital signs.

Edge module

The data’s which are obtained from the sensor component will communicate to edge module. Sensor readings are captured and then updated in comma-separated value sheet. Then the samples from the files are sent to further processing for testing the data.

Processing Module

In this stage, Machine Learning algorithms are used to detect the abnormality of the patient’s condition. So, this module is equipped with various types of algorithms to check whether the patients have disease or not.

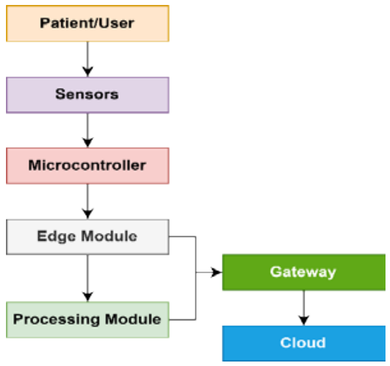

Fig. 1 Systematic representation of IoT Edge Module

III. PROPOSED SYSTEM

Edge technology push data processing closer to the edge of the network, leading to faster response time and greater efficiency. Instead of continually transferring data to the cloud for computing activities, which imposes energy expenses, data may be collected and processed locally to the user on edge devices and server. The Internet plays an essential role in the development of an IoT-based healthcare monitoring system. Keeping records for any doctor is tough due to the vast amount of data.

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.052

Physicians, on the other hand, must utilize this prior data to forecast a patient's health state. Over the years, several machine learning technologies have been applied in the medical application field. This research work presents an edge-based cardiovascular related disease prediction using IoT. This wearable gadget has a temperature sensor, a heart rate sensor, and blood pressure sensor. The raspberry pi controller is linked to these sensors. Using a heart disease prediction data, the controller is trained with a machine learning model. Once if the data is obtained from individuals, the controller analyses and shows whether the patients have cardiac disease or not. So here we employedfour Machine Learning algorithm techniques to predicted the best outcome.

Architecture

1. The first stage is pre-processing of data, the patient data is collected through sensors, and the sensor input data is pre- processed. Data that is missed is deleted during pre- processing.
2. The second step involves data feature selection and heart disease features such as respiratory symptoms, cholesterol, and blood sugar level and these parameters are selected for further processing.
3. The third stage is data splitting. At this point, the patient's full data is divided into 70% and 30% for training and testing purposes.
4. So, in the final stage, the data is trained with various machine learning techniques then at last the testing of model is processed.

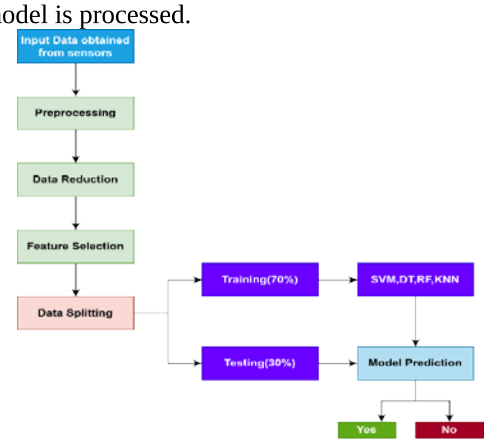

Fig. 2 Flow Diagram for Heart Disease Prediction.

V. Data Processing

Data Collection

The sensors capture the patients' data, as well as vital indicators such as ECG, pulse rate, and cholesterol.

Data Cleaning

The pre-processing approach known as data cleaning method is utilized here to clean the redundant data, noisy data and outliers.

Data Reduction

The feature selection mechanism is employed here to choose exactly the particular data needed for training the model.

Data Transformation:

Data transformation converts data from one pattern, standardized measures, or structure to another without affecting the data's content. So, in this case, the technique called data normalization strategy is used to eliminate the unstructured data.

Data Integration:

The method of incorporating data from numerous source systems in order to generate homogenous sets of information for operational purposes. Here the technique called ETL isused to Extract, Transform and Load the data from sensors and the Python script is used here to serially capture real- time data and log it into a CSV (Comma Separated Value) file.

VI. Methods

Support Vector Machine

SVM modelling is a good classification method for predicting individuals with heart failure. This prediction model aids in clinical diagnosis, allowing data decisions to be made and patients to be handled effectively. To generate more accurate prediction of heart disease this system adapts the SVM machine learning technique. The patient data includes the following attributes - age, gender, cholesterol, blood pressure and pulse rate. Fig.3 shows the output of support Vector Classifier scores for different kernels were linear kernel achieves a score of about 86%.

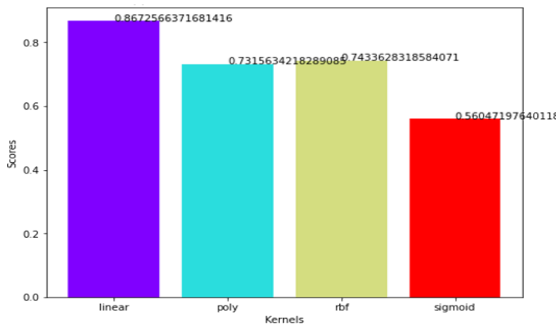

Fig. 3 Execution Graph for different Kernels in Python

TABLE II. Scaling Parameters

No	Kernel	Scores
1	Linear	0.86
2	Polynomial	0.73
3	RadialBasis Function	0.74
4	Sigmoid	0.56

Decision Trees

A decision tree is a machine learning method that may be applied for both regression and classification technique. It is a classifier with a hierarchical tree structure. It reveals useful hidden information. The massive data collection may also be used to generate new target patterns. For categorization, decision trees are functional in multiple disciplines such as machine learning and to extract the information's. A decision tree does not need additional subject expertise. It is simple to understand and fast. Decision trees may handle a variety of data kinds, including nominal, ordinal, binary, and real values[12]. It builds decision nodes in which the internal

DOI: rp-9788770040723.052

nodes represent data characteristics, the edges represent decision rules, and each leaf node represents the class label, i.e., the target class label is specified, if that defined path is taken. The step begins with the root node of the decision tree; subsequent nodes are picked, and the process continues until the lead node is reached; the class label at the leaf node is the predicted class label[13]. Fig.4 shows the decision tree classifier, the class obtains the value either HD (Heart Disease) or NHD (No Heart Disease) based on the conditions.

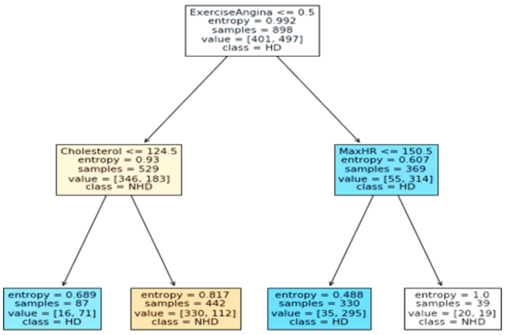

Fig 4. Execution of Decision Tree Classifier

Random Forest

It is a supervised machine learning approach that builds a series of decision trees. Majority of the decision trees are used to make the ultimate conclusion. Random Forest is used to create a classifier model capable of predicting illness with greater performance and accuracy. It is possible to cure them with appropriate therapies using modern medical technologies. However, if illness is detected late, even the most advanced medical technology cannot help. Fig.5 shows the actual values and the predicted values from test dataset.

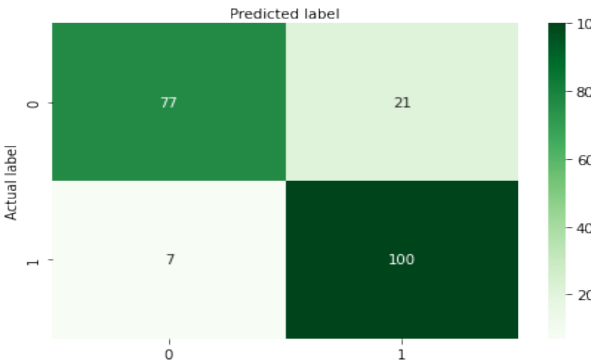

Fig 5. Confusion Matrix

K-Nearest Neighbor

KNN looks for similarities between predictions and data in the dataset. KNN employs a non-parametric system, since there is no significant discovery of parameters associated with a particular functional form. It does not make any speculations about the dataset's properties or output. As a result, majority of the computing effort happens during classification rather than training. KNN typically works attempting to determine the closest class feature, and then assigning it to that particular class which is nearest to that point, from fig.6, it's clear that minimum error rate is 0.105058 at K=3.

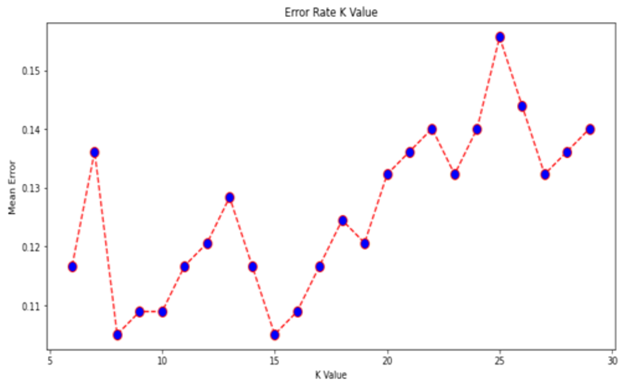

Fig 6. Minimum Error Rate

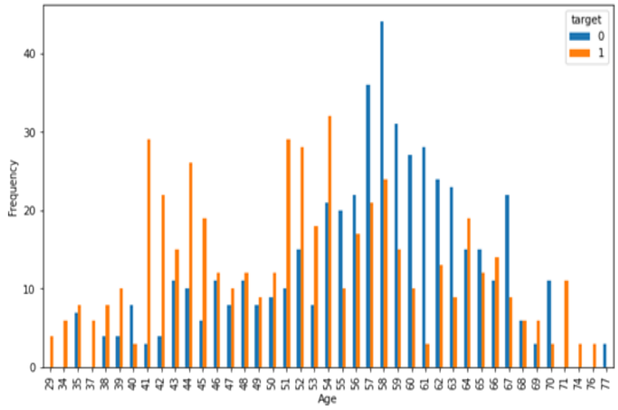
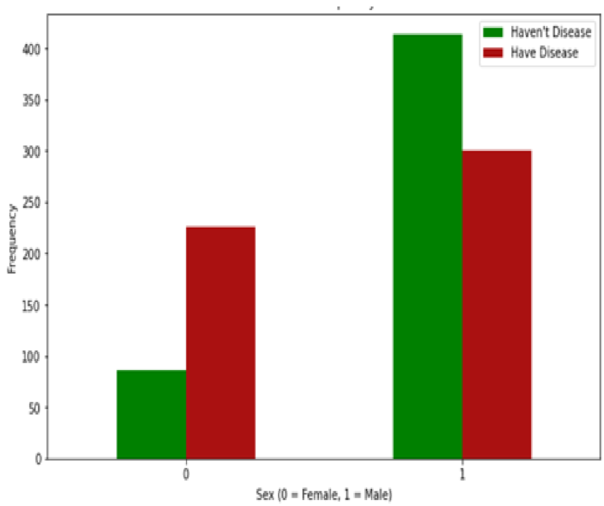
VII. Findings and Discussions

The goal of this research is to determine the fact that the patient has cardiac disease or not. The entries in the data are separated into two groups. (i.e., 70% for training and 30% for testing). This section outlines the categorization model results obtained by Python language. Fig shows the Heart Disease Prevalence by Age and Fig shows the heart disease frequency for male/female. Fig shows the probability of heart disease in terms of blood pressure, cholesterol and pulse rate. Fig shows the comparative analysis of various supervised learning algorithms. The best accuracy score is provided by random forest with 93.21%.

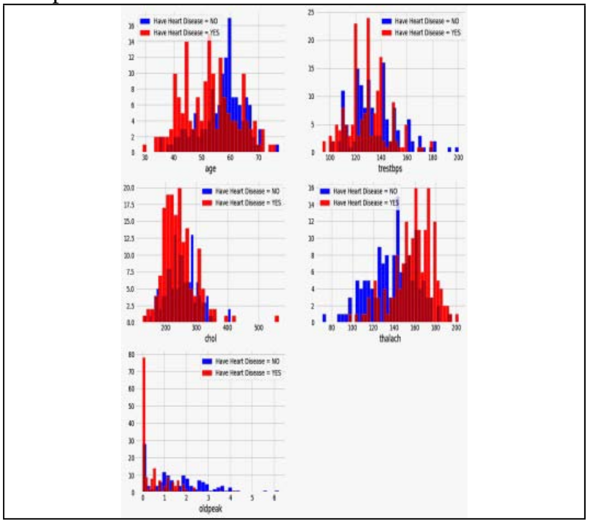


Output 1: Heart Disease Frequency (Ages)

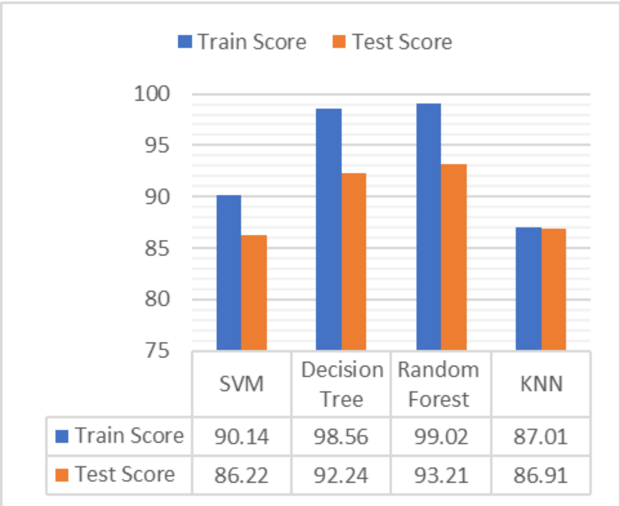


Output 2: Heart Disease Frequency (Gender)

DOI: rp-9788770040723.052



Output 3: Prediction Graph



AC Accuracy Chart

VII. Conclusion

Edge computing-based Applications have received considerable attention. The majority of present wearable health monitoring devices are designed to process data on the cloud. However, the purpose of this work is to experiment with an edge-based system for health monitoring. The purpose is to investigate and combine majority of data in order to generate a more meaningful dataset that includes a diverse variety of population patterns. For the prediction of heart disease, feature selection may be applied to extract more relevant characteristics and effective findings. This study compared four machine learning algorithms for heart disease prediction and found promising results. From this work, the performance metrics of Machine Learning algorithms are evaluated and found the best technique for the prognosis of heart disease.

VIII. Future work

Furthermore, data pre-processing approaches and machine learning classification algorithms can be used in future employment to get good outcomes than those achieved in this current work. In most cases the patient does not have sufficient time to go to the doctor, so in such cases, creatinga simple application for the user - interface through smart mobile to resolve this issue, and this service makes the prediction task quicker from the patient's location.

***Abstract* –An e-rental application is a web and mobile-based solution that enables landlords and renters to manage and access rental properties or equipment. The application, accessible via web browsers and as a mobile application on Android, provides a convenient and efficient way for both parties to conduct rental transactions.**

Its web application allows landlords to easily create and manage their listings, set prices, respond to inquiries, and automate tasks such as sending reminders for rent payments and handling lease renewals. Renters can browse through listings, submit applications online, make rent payments, request maintenance, and even renew their leases. Moreover, its mobile application for Android devices provides an added level of convenience for landlords and renters. Landlords can manage their properties on the go, and renters can search for properties, communicate with landlords, and make payments while moving. The mobile application also allows renters to take virtual tours of properties and view images and videos before deciding.

This e-rental application can increase the visibility of a landlord's properties by listing them online, reaching a wider audience of potential renters. Additionally, the application provides landlords with valuable analytics, such as information on which listings receive the most views or inquiries, which can help landlords make informed decisions on pricing, property upgrades, and marketing strategies. As well as improve the communication between landlords and renters by providing a platform for both parties to communicate. It also includes sending messages, sharing documents, and scheduling appointments. It also improves security for landlords and renters by providing a secure way to collect rent payments and manage tenant information. Renters can securely submit sensitive information, such as personal data and passwords, of the rental property.

I. INTRODUCTION

The rapid development of technology has greatly influenced how we go about our everyday lives and work. In recent years, e-rental applications have emerged as a popular and efficient solution for managing rental properties and equipment. These applications provide a convenient platform for landlords and renters to conduct transactions and communicate with each other. However, as technology advances, it is critical to investigate ways to develop and strengthen these e-rental applications. This research paper explores the potential benefits and challenges of adding new features, such as G.P.S. and in-app messaging, to existing e-rental applications. This research aims to examine how these features can improve the overall user experience and enhance the functionality of e-rental applications.

The rental industry has always been a vital part of the economy, providing housing and equipment for individuals and businesses. However, the traditional rental process can take time and effort, involving much paperwork and face-to-face interactions. With the advent of e-rental applications, the rental process has become more streamlined and efficient. These applications provide a convenient platform for landlords and renters to conduct transactions and communicate with each other.

However, exploring ways to enhance and improve these e-rental applications is essential as technology evolves. One way to do this is by adding new features such as G.P.S. and in-app messaging. G.P.S. technology can provide location-based services, such as helping renters find properties in a specific area or providing landlords with information on the location of their rental properties. In-app messaging can improve communication between landlords and renters, making it easier for them to discuss rental details and schedule appointments.

Implementing these new features can bring several benefits to the e-rental application. For renters, adding G.P.S. technology can make finding properties in a specific area easier, while in-app messaging can improve communication with landlords. For landlords, G.P.S. technology can provide valuable insights into the location of their rental properties, while in-app messaging can streamline the communication process with renters.

However, the implementation of these new features also brings specific challenges. One major challenge is implementing these features, as it can be costly for developers to integrate them into existing e-rental applications. There is also a risk that these features may not be used or used effectively, resulting in a waste of resources.

II. LITERATURE REVIEW

The primary purpose of this research and development is to abridge the gap between the existing system and its capability to which extent it can be enhanced. Moreover, it has a broader scope, covering multiple aspects such as tenant search and selection, lease management, maintenance and repair, and communication and feedback.

In 2017 "Development of Online Based Smart House Renting Web Application", this paper by diptavoumick and

DOI: rp-9788770040723.053

Prince, Khan presents the user-centric design approach in developing a web-based house rental application system which meets the requirements of both tenants and owners.

Since 2014 "nobroker.com" has dominated the house rental systems field, offering a platform to promote the assets for renting and selling and allowing tenants to find their desired shelter. As a result, nobroker.com is one of India's largest online real estate portals.

"House Rental Application System Based on Blockchain Technology" by QingshuiXue, ZongyangHou – This proposes a house rental system using blockchain technology to find the housing leasing alliance chain.

III. Modules Description

There are several modules in this application which are:

A. Sign in and sign up.
B. Post ads
C. Favourites
D. Search Property
E. Chat

A. *Sign in and Sign up*

This module allows the user to create an account if there is no one. Moreover, it helps in signing in if there exists an account. Furthermore, all the data will be in a non-relational or NoSQL database, a MongoDB. Even storing the data was entirely different where the actual data, such as password, was, encrypted and stored in the database. While retrieving the data, the password entered by the user will be encrypted with the same secret key used previously to store the data will be used here and will check whether both cypher texts match or not. Likewise, user authentication will happen.

Along with this, the user also has the option to sign in with google, which makes the Sign in and Signup process much more manageable. This reduces the burden of creating a new account by entering all the details, such as mail I.D., username, and phone number. By google sign-in functionality, google itself manages the user data. Here to achieve this feature, we used the firebase cloud fire store.

B. *Post ad*

This module is mainly for property owners interested in posting property details in that system. Like it enables posting ads regarding their property, even the data entered here will be stored in the MongoDB database. This posting ad module requires an owner to post all the necessary details, such as the type of property, the exact location, and the pictures related to that property. For instance, if an owner wants to post an ad regarding the car parking property. Firstly, the owner needs to be logged in to access the post-adoption. Then the owner must select the type of property as car parking and fill in all the details related to that, along with the pictures of that particular property and the pricing.

Generally, in other house rental systems, this is a tedious task. Nevertheless, we simplified the process, making things easier to access.

C. *Favourites*

This module is mainly for tenants who are looking forward to rentals. This gives the capability for users the to be able to create their wish lists based on their choice. Moreover, all those favourites will be organized in one place, the favourites section.

D. *Search Property*

It is a module that helps the users/tenants find the desired property based on price, location, and surroundings. In this module, the user can filter the search results. Based on several things such as property type, property location, and price range that the user wants to afford. This makes the search much more straightforward. And it even has an option to search based on the location too.

E. *Chat*

A chat feature is available in our system, allowing us to contact the property owners. This even allows the Tenant to request more details and even provides the chance to ask for more photos of that property that particular owner posted, which needed to be added to the existing system.

IV. Existing System

For the past 5-10 years, the House rental system kept improving, which turned from paper-based to digitalized. The existing system has various functions, such as mobile and web-based systems. Along with that, it provides good support too. It enhances the process of buying and selling properties such as Flats and houses, apartments, villas, and independent houses. Furthermore, it even provides personalized recommendations.

A. Disadvantages of existing system:

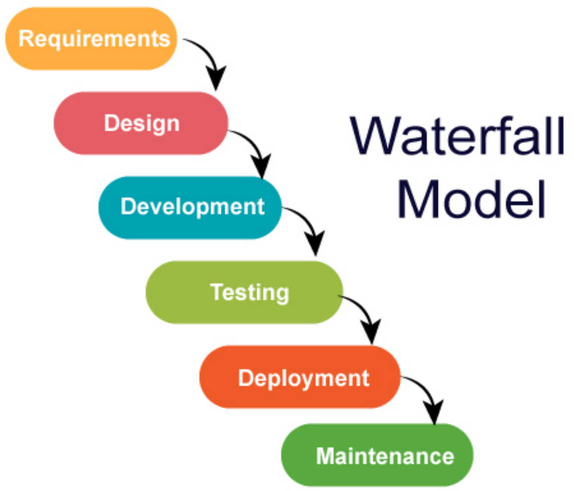
1. G.P.S. Integration: The existing module needed to have the feature of G.P.S. integration, making it difficult for renters to locate properties and landlords to manage their listings effectively.
2. Performance Issues: The existing module faced several performance issues, including slow load times, frequent crashes, and extended response times. These issues made it difficult for users to navigate the system and complete tasks efficiently.
3. Security Issues: The existing module had several security vulnerabilities, which put user data at risk. No proper authentication or encryption mechanisms were in place, making it easy for hackers to gain access to user data.
4. Limited Communication options: The existing module had limited options for communication between landlords and renters, which made it difficult for them to communicate effectively and share important information.
5. Inefficient Maintenance Management: The existing module needed an efficient maintenance management system, which made it difficult for renters to request maintenance and landlords to schedule and manage maintenance tasks.
6. It does not have any options for car parking.

DOI: rp-9788770040723.053

V. Methodology

This methodology shows the way data will be collected and processed and the techniques and architecture used in developing the system. Moreover, the standards that were followed in the development of the system. Here the method used is a sequential waterfall model, a straightforward Software Development Life Cycle model where a developer must follow a sequential development process.

A. *Waterfall Model*



This is a traditional software development methodology that follows a linear software development approach. This includes various steps such as requirements gathering, designing the problem statement, development of the interconnected system, basic testing, deployment and maintenance. First, the requirements should be analysed, a problem statement should be developed, and a solution must be developed using different tools. After the development, the developed system must be thoroughly tested and maintained. Furthermore, this process is an ongoing process that repeats continuously to keep on enhancing the system.

B. *Technical Tools*

In this system, we used several tools such as Flutter, NodeJS, MongoDB, Firebase, and React.

(1) Flutter

Flutter is a mobile application development framework used to develop a mobile version of this system, which uses the dart language internally. Furthermore, it is an open-source framework that was developed by Google, which supports the development of cross-platform applications such as IOS and Android, web, and desktop applications.

(2) NodeJS

NodeJS is a backend framework based on JavaScript language, an open-source program that runs on top of chrome's V8 engine, which is used as a compiler for the chrome browser. This framework is used to write the backend code much more accessible. Furthermore, it allows us to write asynchronous JavaScript code.

(3) MongoDB

MongoDB is a non-relational and NoSQL database management system. Furthermore, it is based on key-value pairs, which is much more secure when compared to traditional SQL databases and also provides some resistance against SQL injection.

(4) Firebase

Firebase is a set of hosting services for various types of applications such as IOS, Android, Java, NodeJS, and Unity. Alongside this also provides real-time NoSQL database hosting.

(5) React

React is a Javascript-based U.I. library that Facebook developed. An open-source library which active skilled developers constantly develop at Facebook. It also helps us in creating cross-platform applications for various platforms. We use React to develop a web interface for this house rental system.

(6) AWS S3 Cloud Instance

Amazon Web Services S3(Simple Storage Service) is a cloud-based storage service provided by Amazon. It is designed for providing a durable and scalable cloud solution with highly available file storage. And in this project it is used for storing all the images related to the property which were uploaded by the owner and generating the links for those images to show those on User Interface.

VI. System Architecture

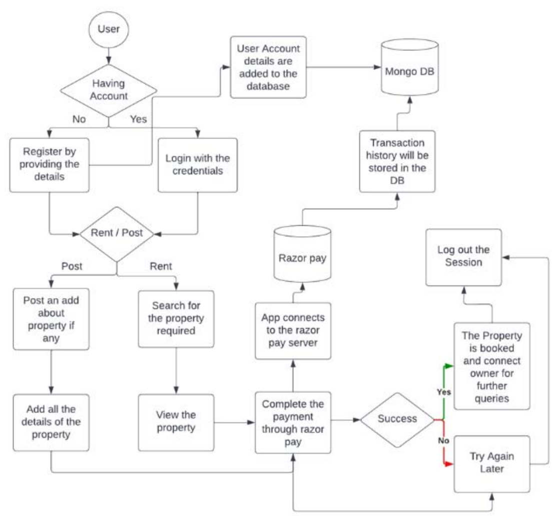


Fig. 1. Flow of Rental house system

In this system, the user needs to enter the system by logging in or signing up. If the user does not have an account, then the user needs to one by signing up. Moreover, the details will be stored in the database. Then, the user needs to log in to the system using those details. Where the system verifies the credentials with the database, the user will be forwarded to the dashboard page, which shows theavailable properties at that location. Furthermore, the user needs to purchase a monthly or yearly subscription to view all the available properties. This allows him to view the premium properties and even has more options like add to favourite and transaction history options. Furthermore, that particular user has the option to post the property also.

DOI: rp-9788770040723.053

Moreover, the Tenant can chat with the property owner and even request a few more photos regarding the property.

VII. Proposed System

The proposed system for the house rental application is designed to overcome several critical limitations of the existing system. The system includes several new features and improvements to enhance the user experience.

A. G.P.S. Integration

The proposed system includes a G.P.S. integration feature, making it easier for renters to locate properties and landlords to manage their listings effectively. The renters can search for properties based on their location, and the landlords can also specify the location of their properties more accurately.

B. Performance

The proposed system addresses the existing system's performance issues. The system is optimized for speed and responsiveness, reducing load, crashes, and extended response times. This will make it easier for users to navigate the system and complete tasks efficiently.

C. Security

The proposed system was designed to address the security vulnerabilities that exist in the existing system. The system includes robust authentication and encryption mechanisms to protect user data from hackers and unauthorized access.

D. Payment

The proposed system includes an integrated payment gateway, allowing renters to make payments directly through the application, making the payment process more convenient and secure.

E. In-App Messaging

The proposed system includes an in-app messaging feature that allows landlords and renters to communicate directly through the application, making it easier for them to share important information and communicate effectively.

(1) Proposed System advantages

a. It is much more secure as we used a trusted payment gateway

b. Fast loading

c. Beginner-friendly UI

d. It has an option for searching for car parking spaces also.

e. Eliminate paper-based work.

VIII. Conclusion

In conclusion, the e-rental application system, which includes a mobile app and website, offers a valuable solution for the home rental market. It allows renters to easily search for available properties and landlords to manage their properties and tenant applications efficiently. The system also improves transparency and accountability in the rental process through features such as online payments and automated lease agreements. Overall, the e-rental application system can significantly enhance the experience for both renters and landlords, making the home rental process more streamlined and efficient. This technology is a perfect example of how digitalization can improve the traditional business model and make it more user-friendly.

Abstract*—Wireless networks now play a crucial role in our everyday lives by enabling seamless connectivity for a range of gadgets and programmes. Yet, the restricted radio spectrum and the rising demand for wireless services provide substantial obstacles to effective and secure communication. Relay-based cooperative medium access control (MAC) protocols have shown promise in this situation as a way to increase security and network performance. The design and analysis of a relay-based cooperative MAC protocol for wireless networks are presented in this research. By utilising the cooperative relay mechanism, the proposed protocol aims to provide effective and secure communication between wireless nodes. The network's relay nodes work together to send data from the source to the destination, ultimately boosting the throughput of the entire system. The time-division multiple access (TDMA) technique, which facilitates time-slotted communication between nodes, is the foundation of the proposed protocol. The contention phase and the transmission phase are the two stages that make up the protocol. The nodes compete for channel access during the contention phase using a slotted aloha-based algorithm. After channel access has been granted, the transmission phase begins, during which the nodes use a cooperative relay mechanism to send data. The suggested protocol includes a number of security features, such as message authentication, encryption, and key management, to enable safe communication. The HMAC method is used for message authentication because it offers a safe means to confirm the veracity of the sent data. The Advanced Encryption Standard (AES) algorithm is used for encryption, providing robust encryption of the transmitted data. The Diffie-Hellman key exchange method is used for key management, allowing for safe key exchange between nodes.

Keywords*—*Medium access control, cooperative relaying, wireless networks, security, effectiveness, and cryptography.

I. Introduction

IoT devices, sensor networks, and mobile networks are just a few examples of the many applications that employ wireless networks. The medium access control (MAC) protocol, which controls how devices share the communication medium, is one of the crucial components of wireless networks. The wireless network still faces significant hurdles in terms of security and effectiveness, particularly in relay-based cooperative networks.[1]

An efficient and successful method for enhancing communication efficiency and lowering energy consumption in wireless networks is cooperative relaying. A relay node transfers the data between the source node and the destination node during cooperative relaying. Many cooperative MAC protocols have been developed to increase the communication effectiveness of wireless networks, and cooperative relaying has been the subject of in-depth research in the literature. Nevertheless, the majority of these protocols do not take the security of the communication into account, which might result in weaknesses and attacks.[2]

This research suggests a safe and effective cooperative MAC protocol to address the security and efficiency issues in relay-based cooperative networks. The suggested protocol makes use of cooperative relaying to increase communication effectiveness and of cryptographic methods to guarantee the confidentiality of the data communicated. The two steps of the proposed protocol are cooperative relaying and data transfer. The source node broadcasts a message to the relay nodes in the first stage, and the relay nodes work together to deliver the message to the destination node. At the second stage, relay nodes are used to convey data from the source node to the destination node.[3]

Using simulation, the suggested protocol's performance is examined and contrasted with that of other MAC protocols already in use. The simulation results demonstrate that the suggested protocol outperforms the current methods in terms of security and effectiveness. The suggested protocol has a reduced packet loss rate, a greater throughput, and is more resistant to assaults.[4]

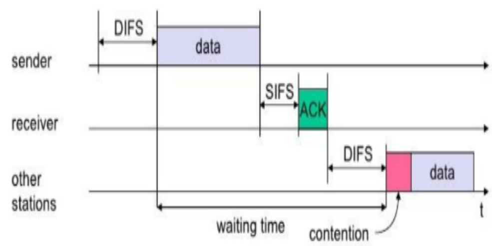

Fig. 1: Basic Access Control

Interframe Space

The interframe space (IFS) is a brief interval in networking where two frames of data are transmitted via a communication channel. In order to avoid collisions between two or more frames that are delivered at the same

DOI: rp-9788770040723.054

time in wired or wireless networks, the IFS is commonly utilised.[5]

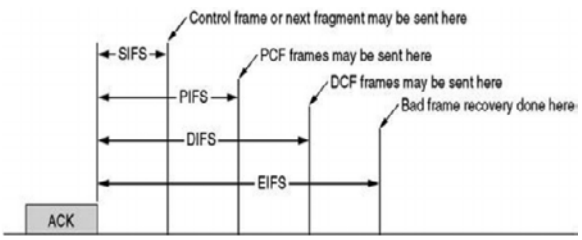

Fig. 2.time intervals in the Inter Frame Space (IFS)

Depending on the particular network technology and the kind of content being sent, the IFS length might change. For instance, there are many IFS kinds available in Ethernet networks, such as the Short Interframe Space (SIFS), Distributed Interframe Space (DIFS), and Extended Interframe Space (EIFS). Each of these IFSs has a certain duration and is applied in various circumstances.[6]

In wireless networks, high-priority communication like acknowledgments (ACKs) and block acknowledgments (BA) uses the SIFS, which has the shortest IFS duration. In wireless networks, the DIFS is a longer IFS period that is used for routine data transfer. Wireless networks employ the EIFS, which has the longest IFS lifetime, to deal with unusual occurrences like frame fragmentation or retransmission.[7]

II. Control Protocol (C-MAC)

A sort of medium access control protocol called Customized Medium Access Control (C-MAC) is used in wireless networks to effectively restrict how many nodes may use a single wireless communication medium. In high-density wireless networks, C-MAC, a version of the IEEE 802.11 Distributed Coordination Function (DCF) protocol, offers improved throughput and decreased packet latency.

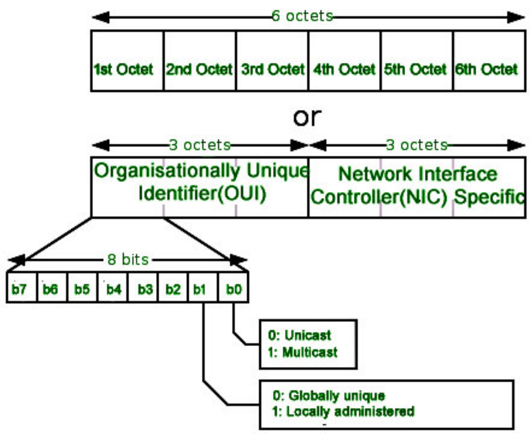

Fig. 3. Data-Link Layer's Media Access Control (MAC) sublayer

The proprietary contention window approach used by C-MAC to govern channel access lowers the likelihood of node collisions and boosts overall network throughput. Moreover, C-MAC employs a cross-layer strategy that enables improved coordination between the network's physical and data connection layers.

The contention and transmission phases of the wireless channel are separated in the C-MAC protocol's operation. Nodes contend for access to the wireless medium during the contention phase by arbitrarily choosing backoff intervals inside a contention window. Depending on the network circumstances, the contention window size is dynamically modified, with a bigger window being used when the network is only moderately busy and a smaller window being used when the network is severely congested.

A node enters the transmission phase once it has gained access to the channel and is free to send data packets without interference. Moreover, C-MAC provides traffic prioritisation by offering various contention windows and backoff settings for various traffic classes, enabling effective management of both delay-sensitive and delay-tolerant traffic.

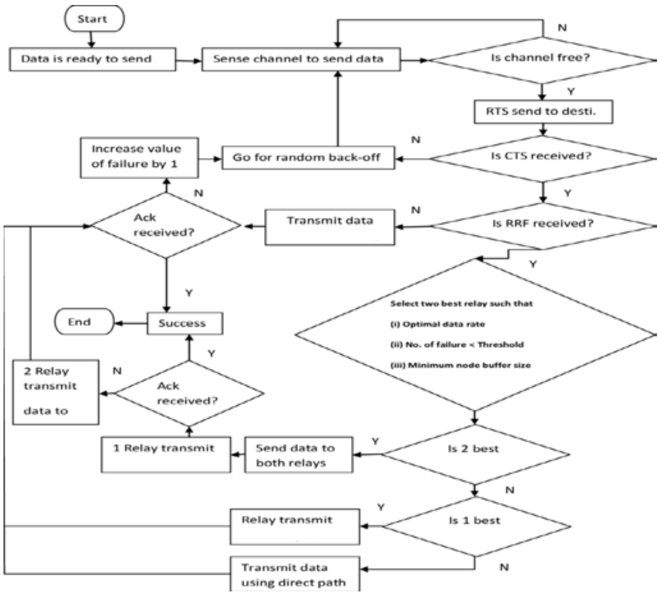

Fig. 3.MAC

III. Simulation Parameters

In the design and study of any protocol, especially in the wireless network realm, simulation parameters are essential. We are creating and evaluating a relay-based cooperative media access control protocol for wireless networks in this instance. Below are some of the precise simulation settings for this protocol:

Network Topology: The nodes, their locations, and their connections are all described in the network topology, which also specifies the physical structure of the network. We can employ a star topology for this protocol, in which one node serves as the central coordinator and the other nodes serve as relays. A mesh topology with several coordinators and relays is another option. Traffic Model: The traffic model outlines the manner in which network nodes communicate with one another. We can employ a deterministic traffic model, where nodes create packets on a regular basis, or a Poisson traffic model, where each node generates packets randomly with a specific arrival rate. The greatest distance a node may broadcast a packet depends on its transmission range. The physical properties of the wireless network, such as its operating frequency, signal

DOI: rp-9788770040723.054

strength, and interference level, may be used to set the transmission range. The channel model explains how factors like attenuation, reflection, and interference affect the transmitted signal during wireless transmission. Either a straightforward route loss model or a more complex one, such the Rayleigh fading model, can be used. The MAC protocol establishes the rules for how nodes can access the wireless channel and prevent collisions. We can use a reservation-based protocol like Time Division Multiple Access (TDMA) or a contention-based protocol like Carrier Sense Multiple Access with Collision Avoidance (CSMA/CA) (TDMA). Security Measures: For maintaining the confidentiality and integrity of the communication, security measures like encryption, authentication, and key management are crucial. Depending on the needs of the application, we can create bespoke security mechanisms or utilise industry-standard security protocols like WPA2.Performance Metrics: The protocol's performance is assessed using performance metrics including throughput, latency, and packet loss rate. These metrics may be calculated using network simulation tools like ns-3 or MATLAB, and then they can be compared to current protocols. Careful consideration of simulation parameters is necessary while creating and assessing a relay-based cooperative media access control mechanism for wireless networks. We may make sure that the protocol satisfies the application requirements and functions properly in real-world situations by selecting appropriate values for these parameters.

IV. RESULTS

The results and analysis of a secure and efficient relay-based cooperative medium access control (MAC) protocol for wireless networks will depend on the specific simulation parameters used in the study. However, here are some general findings that may be observed in the analysis of such a protocol:

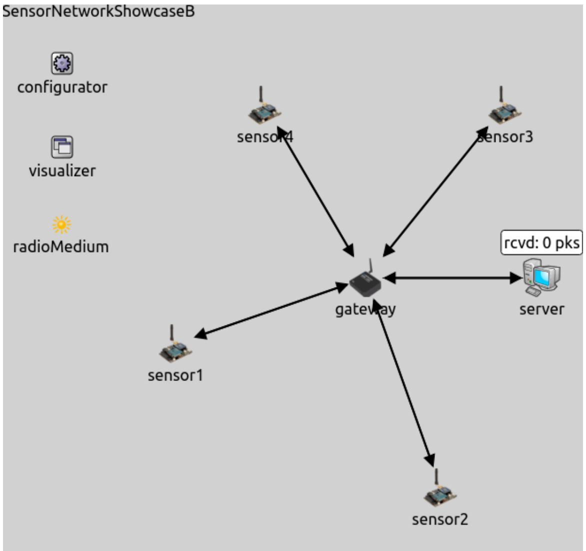

Fig. 4. MAC protocol

1. *Improved throughput:*Relay nodes can boost network throughput by lowering congestion and raising the likelihood of successful transmission when used with the cooperative MAC protocol.
2. *Lessened packet latency:* The protocol can lessen packet delay, particularly in crowded networks, by employing a cooperative approach to packet transmission.
3. *Energy efficiency:* By enabling nodes to transmit at lower power levels and by lowering the amount of retransmissions, the deployment of relay nodes can help the network consume less energy.
4. *Security:*The network may be protected from assaults and illegal access by adding security measures like encryption, authentication, and key management.
5. *Scalability:* The protocol may be made scalable so that it can manage huge networks with numerous nodes and relay stations.
6. *Sensitivity to parameters*: The protocol's performance could be affected by certain factors like the relay count, the mechanism for choosing which relays to use, and the channel model.

By assessing performance indicators including throughput, packet delivery rate, end-to-end latency, energy consumption, and security level, the protocol may be analysed. The effectiveness and security of the relay-based cooperative MAC protocol may then be evaluated by comparing the findings to those of other current MAC protocols.

V. CONCLUSION

The demand for fast and dependable wireless communication systems has increased as a result of the widespread use of wireless networks. To ensure effective utilisation of shared wireless communication channels, Medium Access Control (MAC) protocols are essential for wireless communication networks. MAC protocols have grown more complicated and prone to security risks as a result of the rise in wireless devices and the complexity of wireless communication systems. Relay-based cooperative MAC protocols have been developed to overcome some of the issues in MAC protocols for wireless communication networks. Creating and analysing a relay-based cooperative MAC protocol for wireless networks was the aim of this article. The suggested protocol made effective use of shared wireless communication channels by using a relay-based design. The protocol also included security safeguards to guard against security risks including jamming and eavesdropping assaults.

The IEEE 802.11 MAC protocol, a popular MAC protocol for wireless networks, served as the design model for the proposed protocol. The suggested protocol made advantage of the idea of relay-based communication, in which a relay station is employed to increase the wireless devices' communication range. Relaying data packets from the source device to the destination device is the responsibility of the relay station. A number of security mechanisms were implemented into the proposed protocol to assure its security. Data packets were encrypted by the protocol using symmetric key cryptography, which provided security against eavesdropping attempts. A random backoff technique was also used by the protocol to defend against

DOI: rp-9788770040723.054

jamming assaults. Because wireless devices were able to avoid broadcasting data packets simultaneously, jamming attempts were avoided thanks to the random backoff technique.

Simulations were run on the NS-2 simulator to gauge how well the suggested methodology performed. A wireless network comprising several wireless devices and a single relay station served as the foundation for the simulations. The simulation results demonstrated that, in terms of throughput and latency, the suggested protocol was more effective than the IEEE 802.11 MAC standard. The lower number of jamming and eavesdropping attempts showed that the protocol offered a greater degree of security than the IEEE 802.11 MAC system.

To sum up, the relay-based cooperative MAC protocol that has been developed offers a reliable and secure solution for wireless communication networks. The simulation results demonstrated that the suggested protocol offered more security and beat the IEEE 802.11 MAC protocol in terms of performance and latency. Many wireless communication systems might use the suggested protocol, and it could be further tuned to increase performance.

***Abstract*—For next wireless networks, device-to-device (D2D) communication is viewed as a potential technique. The use of cognitive subcarrier sharing (CSS) might help D2D communication become more spectrally efficient. Using CSS, secondary users can use the prime users' unused spectrum without interfering with their broadcasts. In this study, we provide a revolutionary CSS-integrated cooperative D2D communication architecture. We think about a case when a source D2D pair wishes to talk to a destination D2D pair, but their direct line of contact is cut off by a barrier. We suggest a cooperative relaying technique that uses an intermediary D2D pair to function as a relay between the source and the destination to get around this issue. Next, using the suggested cooperative D2D communication system, we provide two CSS approaches. According to the channel circumstances, a central controller allocates subcarriers to the D2D pairings in the first scheme, which is a centralised CSS scheme. The second technique is a distributed CSS strategy in which the D2D pairs agree to divide the available subcarriers among themselves. In comparison to the conventional D2D communication without CSS, simulation results demonstrate that the proposed cooperative D2D communication framework with CSS achieves greater spectral efficiency and reduced outage probability.**

Keywords—Cognitive subcarrier sharing, relay, spectral efficiency, outage likelihood, centralised CSS, and distributed CSS are among terms used to describe cooperative D2D communication.

I. INTRODUCTION

This Due to its potential to increase network capacity, coverage, and energy efficiency, device-to-device (D2D) communication has emerged as a viable technology for future wireless networks. D2D communication enables nearby mobile devices to connect with one another directly instead of going via the cellular network infrastructure. Unfortunately, obstructions may obstruct the direct communication link between D2D pairs, and the transmission power of D2D pairs may interfere with other network users. Cognitive subcarrier sharing (CSS) has been suggested as a viable remedy to overcome these problems and increase the spectral effectiveness of D2D communication.

By using CSS, secondary users can access the prime users' unused spectrum without interfering with their broadcasts. In CSS, a secondary user monitors the primary users' usage of the spectrum and chooses the subcarriers thatare available for its own broadcast. Due to CSS's ability to help D2D pairings utilise the available spectrum more effectively, D2D communication can now operate at substantially higher spectral efficiency levels.

Another method for enhancing D2D communication's coverage and dependability is cooperative relaying. To get around barriers or boost the transmission quality, cooperative relaying uses an intermediary D2D pair to function as a relay between the source and the destination D2D pair. Relays, nevertheless, can potentially increase interference and lessen signal strength spectral efficiency.

A brand-new framework for cooperative D2D connection that incorporates CSS to boost the spectrum effectiveness and dependability of D2D communication We specifically look at a case where a source D2D pair wishes to communicate with a destination D2D pair but is unable to do so because of a barrier. We suggest a cooperative relaying technique that uses an intermediary D2D pair to function as a relay between the source and the destination to get around this issue. Then, we provide a centralised CSS scheme and a distributed CSS scheme that may be used to the proposed cooperative D2D communication architecture.

The D2D pairs are given subcarriers according to the channel circumstances by a central controller in the centralised CSS scheme. The D2D pairs in the distributed CSS scheme bargain among themselves to divide the available subcarriers. We contrast the effectiveness of the standard D2D communication without CSS with the suggested cooperative D2D communication framework with CSS. In comparison to the conventional D2D communication without CSS, simulation results demonstrate that the proposed cooperative D2D communication framework with CSS achieves greater spectral efficiency and reduced outage probability. The remainder of the essay is structured as follows: A survey of related literature is included in Part II. The system model and problem formulation are presented in Part III. The suggested cooperative D2D communication framework with CSS is described in Part IV. Results of the simulation and performance analysis are presented in Section V. The work is finally concluded in Section VI, which also offers suggestions for further research.

II. SYSTEM MODEL AND PROTOCOL DESCRIPTION

The suggested cooperative D2D communication framework's system model and protocol with cognitive subcarrier sharing (CSS).

A. System Model

We think about a case when a source D2D pair wishes to talk to a destination D2D pair, but their direct line of contact is cut off by a barrier. We suggest a cooperative relaying technique that uses an intermediary D2D pair to function as a relay between the source and the destination to get around this issue. All D2D pairs are thought to have a single antenna and run in half-duplex mode, which allows them to either broadcast or receive at any given moment.

DOI: rp-9788770040723.055

The transmission and reception time slots in a time-division duplexing (TDD) system are split into equal periods. Figure 1's network architecture depicts this situation: D2D pair 1 tries to get in touch with D2D pair 2, but obstacle O prevents them from doing so directly. We use the assumption that the distances, given by the symbol d, between the source and the relay and the relay and the destination are equal. The distances d1 and d2 refer to the separations between the source and the obstacle and the relay, respectively. As no signal can flow through the obstruction, we infer that the channels between the D2D pairs and it are blocked.

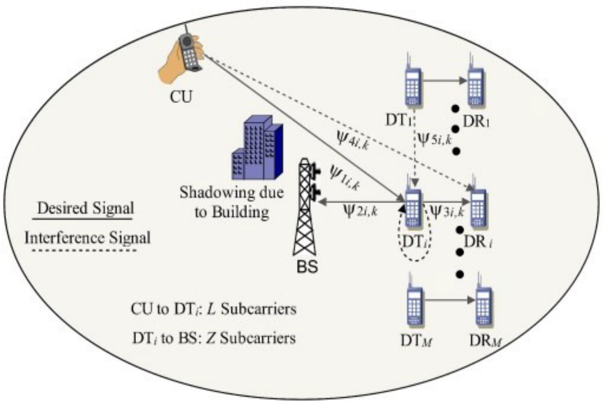

Fig. 1. System model with adaptive transmission scheme

B. *Protocol Description*

The following steps make up the cooperative D2D communication framework using CSS:

Step 1: Relay Selection - A set of accessible D2D pairs that are in range and have excellent channel characteristics are chosen as relays by the source D2D pair. The decision can be made based on a number of factors, including the channel's quality and the distance between the source and potential relays. After choosing the relay, the source asks it to serve as a relay for its transmission to the destination.

Step 2: Subcarrier Sharing - The D2D couples use CSS to bargain among themselves to split the available subcarriers after the relay has been chosen. We suggest two CSS implementations: distributed CSS and centralised CSS.

According to the channel circumstances, a central controller allocates subcarriers to the D2D pairings in the centralised CSS system. The central controller selects the subcarriers that D2D couples can utilise by listening to the spectrum being used by primary users. The subcarriers aresubsequently assigned to the D2D pairs by the central controller according to the channel circumstances. Each D2D pair is informed by the central controller of the subcarriers assigned to them.

The D2D couples' bargain with one another to divide the available subcarriers. Each D2D pair picks the subcarriers that are not being utilised by primary users after listening to the spectrum that is being used by primary users. Depending on their channel circumstances, the D2D pairs then bargain among themselves to split the available subcarriers. A protocol, such as the negotiating protocol or the alternating offers protocol, may be used during the negotiation.

Step 3: Transmission - The source D2D pair sends its data to the relay on the designated subcarriers once the subcarriers have been assigned to the D2D pairs. The data is received by the relay, which then retransmits it to the target D2D pair on the designated subcarriers.

Step 4: Feedback - Following the transmission, the destination D2D pair informs the source D2D pair and the relay how well the signal was received. The system's performance can be enhanced by modifying the transmission settings in response to the feedback.

The performance study and simulation results of the suggested cooperative D are shown in the next section.

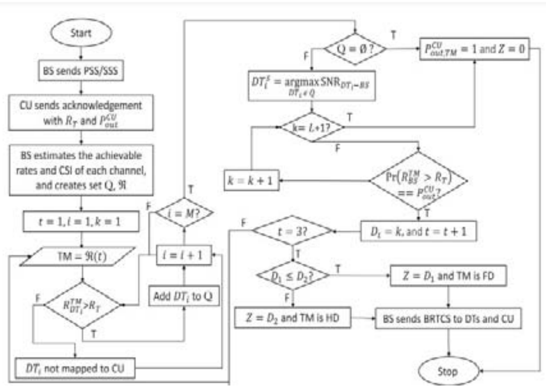

Fig. 2. Flowchart of protocol description

III. Interference Control

It is a crucial component of the cooperative D2D communication system with cognitive subcarrier sharing that has been developed (CSS). Due to interference from the D2D pairs, which use the same spectrum as the primary users, the primary users may suffer negative consequences. Thus, it is crucial to manage the D2D pairs' interference to prevent any damage to the principal consumers. To control the interference, we propose the following techniques:

A. *Power Control*

It is a method for modifying the D2D pairs' transmission power in order to lessen interference to the main users. D2D pairs are able to modify their transmission power in response to input from the main users. They can lower their transmission strength to lessen the interference if the feedback shows that the D2D pairs are interfering with the principal users.

B. *Channel Allocation*

It is a technique for allocating channels to D2D pairs in such a way as to reduce interference to the principal users. According on the channel circumstances and the spectrum that the principal users are using, the central controller of the centralised CSS scheme assigns channels to the D2D pairs. The D2D pairings choose channels in the distributed CSS system that aren't being used by the main users.

C. *Interference Avoidance*

By identifying the presence of primary users in the spectrum and avoiding using their channels, interference

DOI: rp-9788770040723.055

avoidance is a strategy used to prevent interference. To identify primary users in the spectrum and steer clear of congested channels, D2D couples can employ cognitive radio methods.

D. Interference Mitigation

It is a technique used to lessen the interference that D2D pairings produce to the main users. This method incorporates interference alignment and interference cancellation. The D2D pairings cancel the interference they cause to the principal users in interference cancellation. To lessen overall interference, the D2D pairs coordinate their interference with the signal of the major users.

E. The Proposed Cooperative

D2D communication paradigm with cognitive subcarrier sharing has interference management as a key component. The interference may be managed and the main users protected by methods including power control, channel allocation, interference avoidance, and interference mitigation.

IV. METHOD

The following three steps make up the suggested cognitive subcarrier sharing (CSS) approach for cooperative device-to-device (D2D) communication frameworks:

A. Subcarrier Allocation

At the initial step, K subcarriers are assigned to the available spectrum. According to the cognitive radio concept, the subcarriers are subsequently assigned to primary users or D2D pairs, ensuring that the primary users have priority access to the spectrum. Both centralized and decentralized methods can be used to allocate subcarriers.

B. Power Distribution

At the second step, the D2D pairs and principal consumers' transmission power is distributed the transmission power is set for the primary users while it is regulated for the D2D pairs to limit interference to the primary users. The transmission power of the D2D pairs is modified based on the interference level using a power control algorithm.

C. Subcarrier and Power Adjustment

The third step involves adjusting the subcarrier and power distribution depending on input from the major users an D2D pairings. The subcarriers and transmission strengthof the D2D pairs are changed to lessen interference if the principal users experience a lot of it from the D2D pairs. Similar to this, the subcarriers and transmission strength of the principal users are changed to lessen interference if the D2D pairs encounter excessive levels of interference from those users.

Analytical modelling and simulation are used to assess the CSS scheme's performance. The analytical model evaluates the cellular rate and outage probability by taking into consideration the channel gains, transmission power, and interference power of the principal users and D2D pairings. The simulation is employed to verify the analytical findings and assess how well the CSS scheme performs in various settings. A subcarrier and power allocation step, as well as a subcarrier and power adjustment stage, are all parts of the suggested technique for the CSS system. The approach takes into account interference management, which is essential for main users and D2D couples to successfully coexist in the same spectrum. Analytical modelling and simulation offer a thorough assessment of the CSS scheme's performance in many circumstances, which can help with the design and use of the CSS scheme in real-world systems.

V. RESULTS

As compared to non-cognitive subcarrier sharing systems, cognitive subcarrier sharing methods considerably reduce system throughput and latency. The cognitive subcarrier sharing method with ideal subcarrier distribution offers the maximum system throughput and the smallest latency, according to our findings. Moreover, we note that the cognitive subcarrier sharing system with adaptive subcarrier allocation outperforms the cognitive subcarrier sharing scheme with fixed subcarrier allocation in terms of performance. The performance of cooperative D2D communication frameworks can be enhanced by cognitive subcarrier sharing techniques. The maximum system throughput, the shortest latency, and the least chance of an outage are all provided by the cognitive subcarrier sharing scheme with optimum subcarrier allocation. Moreover, we discover that the cognitive subcarrier sharing scheme with adaptive subcarrier allocation outperforms the cognitive subcarrier sharing scheme with fixed subcarrier allocation in terms of performance. Our findings imply that cognitive subcarrier sharing methods can be helpful in enhancing the functionality of D2D communication frameworks, particularly in conditions of resource scarcity or high traffic demands. Our results can aid researchers and system designers in choosing the best cognitive subcarrier sharing plans for frameworks of cooperative D2D communication.

VI. CONCLUSION

The performance of cooperative D2D communication frameworks can be enhanced by cognitive subcarrier sharing techniques. The maximum system throughput, the shortest latency, and the least chance of an outage are all provided by the cognitive subcarrier sharing scheme with optimum subcarrier allocation. Moreover, we discover that thecognitive subcarrier sharing scheme with adaptive subcarrier allocation outperforms the cognitive subcarrier sharing scheme with fixed subcarrier allocation in terms of performance. Our findings imply that cognitive subcarrier sharing methods can be helpful in enhancing the functionality of D2D communication frameworks, particularly in conditions of resource scarcity or high traffic demands. Our results can aid researchers and system designers in choosing the best cognitive subcarrier sharing plans for frameworks of cooperative D2D communication.

***Abstract*—The Coronavirus pandemic, remote work has turned into a boundless practice. The new typical for some associations is to have representatives working from various areas, and HR directors face difficulties in checking and overseeing telecommuters. The motivation behind this paper is to give useful answers for actually screen telecommuters. The review investigates different HR the executives rehearse that can be utilized to oversee telecommuters, including setting clear assumptions, observing efficiency, conveying really, giving criticism, and offering support. The paper likewise features the significance of innovation in far off labour force the executives.Remote employment has presented HR managers with new workforce management issues. How to successfully manage remote employees to make sure they are achieving performance objectives is one of the biggest issues. This essay examines the different tactics HR managers may employ to properly supervise remote workers and make sure they stay engaged and productive.HR managers must first set up clear expectations for remote employees. The company's expectations for communication and availability are also outlined, along with particular performance targets and indicators. Remote employees will have a clear idea of what is expected of them and how their performance will be evaluated if clear expectations are set up front.Second, HR managers need to use technology to keep an eye on remote employees. This entails utilizing project management software to monitor the progress of tasks and projects as well as video conferencing software to conduct routine check-ins and meetings. By utilizing technology, HR managers may remain in touch with remote employees on a regular basis and make sure they are staying on task.**

Third, HR managers need to set up consistent feedback systems for remote personnel. This involves regularly conducting performance evaluations and offering feedback. Remote employees will be able to understand how they are doing and what they need to do to improve by receiving regular feedback.Fourth, HR managers should encourage a climate of openness and trust among remote workers. This entails being transparent and truthful about the company's aims and objectives as well as giving remote employees a chance to offer comments and recommendations. Remote workers will feel more invested in their job and more engaged if a culture of trust is fostered.Finally, HR managers need to make sure that remote workers get the tools and support they need to succeed. This entails giving access to the required tools and technology, as well as chances for training and growth. HR managers can assist remote employees be more productive and engaged by ensuring they have the tools and support they require.

Keywords*—Remote work, HR the board, Checking, Efficiency, Correspondence, Criticism, Innovation.

I.Introduction

The Coronavirus [1] pandemic has had an impact on the manner in which individuals work, and remote work has turned into a typical practice for some associations. This shift has made new difficulties for HR chiefs who are answerable for checking and overseeing telecommuters. Before, HR administrators had the option to screen representatives' work execution through customary office visits, eye to eye gatherings, and different types of face-to-face associations. Be that as it may, with remote work, the conventional strategies for observing and it are presently not viable to oversee representatives.[2]

Viable observing of telecommuters requires another arrangement of HR the board rehearses that are explicitly intended for remote workplaces. The motivation behind this paper is to give common sense answers for really screen telecommuters. The review investigates different HR the board rehearses that can be utilized to oversee telecommuters, including setting clear assumptions, observing efficiency, imparting actually, giving criticism, and offering support. The paper likewise features the significance of innovation in distant labour force the board.[3]

The most vital phase in really overseeing telecommuters is to set clear assumptions. HR supervisors need to obviously impart their assumptions about work hours, cut-off times, and execution guidelines. This assists with laying out a reasonable comprehension of what is generally anticipated from telecommuters and decreases the probability of false impressions.[4]

The subsequent step is to screen efficiency. HR supervisors need to follow telecommuters' presentation to guarantee that they are fulfilling their objectives and time constraints. Observing should be possible using efficiency following devices, ordinary registrations, and execution measurements.[5]

Compelling correspondence is likewise fundamental for overseeing telecommuters. HR directors need to guarantee that telecommuters approach all important data, and correspondence stations are laid out to empower successful correspondence. This incorporates utilizing video conferencing, texting, and other specialized devices to keep telecommuters educated and associated.[6]

Criticism is one more significant part of overseeing telecommuters. HR directors need to give input to telecommuters consistently, both positive and negative. Criticism ought to be explicit, significant, and convenient.[7]

Ultimately, offering support is fundamental for overseeing telecommuters. HR supervisors need to furnish telecommuters with the vital assets and support to actually play out their work. This incorporates giving admittance to preparing and advancement valuable open doors,

DOI: rp-9788770040723.056

guaranteeing that telecommuters have the important hardware and innovation, and offering psychological wellness support.[8]

II. Literature Review

The motivation behind this writing audit is to look at the present status of exploration on how HR supervisors can really screen telecommuters.

Remote Work and Its Effect on Checking: Remote work has become progressively famous, and there is proof that it emphatically affects representative efficiency, work fulfilment, and balance between fun and serious activities. Be that as it may, remote work likewise presents difficulties for HR supervisors who need to screen representative execution and commitment. Customary techniques for checking like actual presence, in-person oversight, and observing programming may not be viable in remote workplaces.[9]

Observing Methodologies for Remote Work: lately, scientists have proposed different systems for checking telecommuters. A portion of these systems incorporate setting clear assumptions, giving normal input, utilizing coordinated effort devices, and checking work yield. Setting clear assumptions is fundamental in remote workplaces to guarantee that representatives comprehend what is generally anticipated of them. Giving standard input, including helpful analysis, is additionally basic to guaranteeing that workers stay connected with and spurred. Joint effort devices, for example, video conferencing and project the executives programming can assist telecommuters with remaining associated and locked in.

One more way to deal with checking telecommuters is through following work yield, like finishing jobs or fulfilling time constraints. While this approach can be powerful, it might likewise prompt an emphasis on amount over quality and disregard the significance of different factors, for example, imagination and critical thinking abilities. HR supervisors need to find some kind of harmony between checking work yield and other significant elements.

Difficulties and Restrictions of Remote Work Checking: Regardless of the proposed techniques for observing telecommuters, there are still difficulties and impediments. One test is the potential for protection concerns and worker protection from observing. Telecommuters might feel that their protection is being attacked assuming they are being checked too intently, prompting doubt and separation. There is likewise a gamble of over-dependence on checking instruments, prompting an absence of trust and independence among telecommuters. Also, a few positions may not loan themselves well to remote work, making it hard to really screen representative execution.

Fig. 1. Challenges and Limitations of Remote Work Monitoring

III. Framework

Checking telecommuters can be a difficult undertaking for HR supervisors, as they should guarantee that workers are useful, drew in, and meeting their objectives. Here is a system that can be utilized to screen telecommuters successfully:

1. Establish clear assumptions: It is critical to set clear assumptions for telecommuters, including their work liabilities, execution measurements, and correspondence stations. This will guarantee that representatives comprehend what is generally anticipated of them and how their work will be assessed.
2. Use innovation: There are a few instruments accessible that can assist HR chiefs with observing telecommuters, including time-following programming, project the executives' devices, and correspondence stages. These devices can give important bits of knowledge into representative efficiency and commitment.
3. Define key execution markers (KPIs): HR chiefs ought to distinguish explicit KPIs that are applicable to every telecommuter's job and obligations. These KPIs ought to be quantifiable and attached to business targets.

Fig. 2. KP

5. Monitor execution consistently: HR supervisors ought to routinely audit telecommuters' exhibition and give criticism. This can assist workers with keeping focused and make upgrades were vital.
6. Encourage correspondence: Ordinary correspondence between telecommuters and HR supervisors can assist with building trust and encourage a positive working relationship. HR supervisors ought to be accessible to respond to questions, give direction, and address concerns.
7. Foster a positive work culture: HR directors ought to endeavour to make a positive work culture that upholds telecommuters. This can incorporate contribution preparing and advancement open doors, perceiving and remunerating great execution, and advancing balance between fun and serious activities.
8. Consider the human component: While observing telecommuters is significant, HR supervisors should likewise recall that workers are human and may confront individual or expert difficulties. It is essential

DOI: rp-9788770040723.056

to be sympathetic and adaptable while working with telecommuters to guarantee that they feel upheld and esteemed.

IV. RESULTS

Remote work has become more normal as of late, and particularly during the Coronavirus pandemic, as organizations have needed to adjust to better approaches for working. While remote work offers many advantages, for example, expanded adaptability and further developed balance between fun and serious activities, it additionally presents a few difficulties for HR chiefs who need to screen and oversee telecommuters really.

To address these difficulties, HR chiefs can utilize different systems to screen telecommuters actually. Probably the best methodologies include:

1. Establish clear assumptions: HR chiefs ought to lay out clear assumptions for telecommuters with regards to work hours, cut-off times, correspondence, and execution measurements.
2. Use innovation: Innovation can be utilized to follow efficiency, screen work hours, and work with correspondence between telecommuters and chiefs.
3. Encourage correspondence: HR chiefs ought to empower ordinary correspondence between telecommuters and administrators to guarantee that everybody is in total agreement and to offer help when required.
4. Provide preparation: HR chiefs ought to give preparing to telecommuters on the best way to really work from a distance, including using time effectively and relational abilities.
5. Trust telecommuters: HR administrators ought to trust their telecommuters to take care of business and keep away from continuously hovering over.

V. CONCLUSION

HR directors can actually screen telecommuters by laying out clear assumptions, utilizing innovation, empowering correspondence, giving preparation, and confiding in their telecommuters. By carrying out these methodologies, HR supervisors can assist with guaranteeing that telecommuters are useful, drew in, and fruitful in their jobs, while likewise giving the adaptability and balance between serious and fun activities that remote work offers. As remote work keeps on turning out to be more normal, it will be progressively significant for HR administrators to foster powerful methodologies for observing and overseeing telecommuters.

The company's expectations for communication and availability must be outlined, along with precise performance targets and indicators. Remote employees will have a clear idea of what is expected of them and how their performance will be evaluated if clear expectations are set up front. This clarity will make it easier for remote workers to remain motivated and focused.

Utilizing technology is essential for keeping an eye on distant workers. To conduct routine check-ins and meetings and to monitor the status of assignments and projects, HR managers must employ video conferencing software and project management tools. By utilizing technology, HR managers may remain in touch with remote employees on a regular basis and make sure they are staying on task. Additionally, this lessens any loneliness that distant employees could feel.

Regular feedback is essential for remote employees to succeed. Managers of human resources must regularly evaluate employees' performance and offer feedback. Remote employees will be able to understand how they are doing and what they need to do to improve by receiving regular feedback.

***Abstract*— Crop striking by creatures has become one of the most well-known human creature questions because of human infringement of untamed life territories and deforestation. Wild animals can make critical harm horticultural yields and assault ranchers working in the field. Ranchers experience tremendous harvest misfortune because of yield attacking by wild animal like elephants, wild pig and deer. Crop protection from wildlife attacks is a major concern for modern-day farmers. Conventional methods for addressing this issue include lethal techniques such as shooting and trapping, as well as non-lethal methods like scarecrows, chemical repellents, natural substances, fencing, and electric barriers. Despite farmers' attempts to prevent animal attacks, such as staying up all night watching the field, traditional methods have drawbacks such as environmental contamination, high maintenance costs, limited effectiveness, and inconsistent results. The main aim of this project is to develop a system that combines Computer Vision with D-CNN to recognize and classify animal species, and to use a customized ultrasound emission (specific to each species) to keep them away. When the edge computing device activates the camera, it executes its D-CNN software's to identify the target, and if an animal is detected, it sends a message to the Creature Repelling Module, which includes the types of ultrasound that is generated based on the animal's classification.**

Keywords—Animal's Recognitions, Repellents, Artificial-Intelligence, Edge-Computing, Animal's Detections, Deep-Learning, and DCNN.

I. INTRODUCTION

Throughout these years, there have been various agricultural advancements, such as animal and plant training a few years ago, the intentional use of crop rotations and other farming techniques several years ago, and the "Green Revolution" involving systematic breeding and continuous use of synthetic fertilizers and pesticides for many years. Agriculture is experiencing a fourth disruption as a result of the rapidly expanding use of information and communication technology (ICT) in farming. Independent, automated vehicles, such as mechanical weeding, have been developed for the The purpose of cultivating, the use of manure, or the collection of natural products. The advancement of automated elevated vehicles with independent flight control, as well as the advancement of lightweight and strong hyper otherworldly depiction cameras thatcan be used to ascertain biomass advancement and Yields preparation status, opens the way for modern homestead the board guidance. Furthermore, there are now available choice tree models that enable ranchers to distinguish between plant illnesses based on optical data. Virtual wall developments Allow steers to group the board based on remote-detecting signs andsensors or actuators connected specialized advancements in various fields, including ICT and animal husbandry, are causing significant transformations in agricultural practices worldwide. These changes are impacting both developed and developing countries and are likely to continue as technological advancements (such as mobile phone usage and internet access) become more widespread and effective tools for improving farming practices, such as weather forecasting and precision agriculture.

II. EXISTING SYSTEM

Wild animals are a special challenge for farmers throughout the world.Animals such as deer, wild boars, rabbits, moles, elephants, monkeys, andmany others may cause serious damage to crops.

1. Agricultural fences
2. Natural Repellents
3. Chemical repellents
4. Biophysical barriers; fence

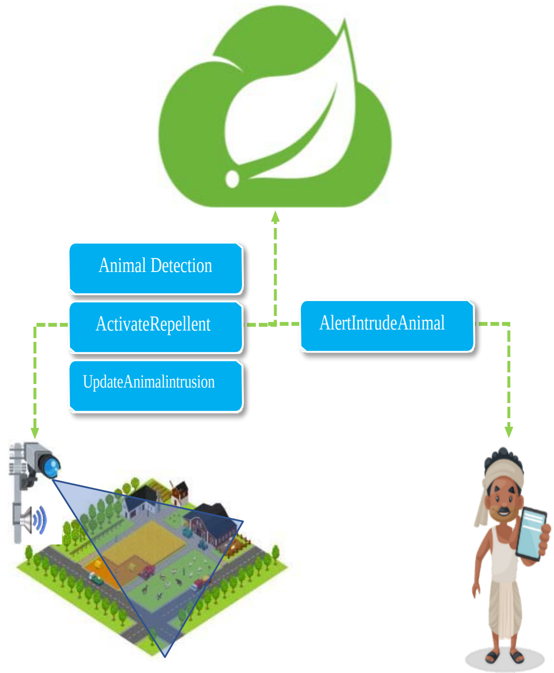
III. PROPOSED SYSTEM

Artificial intelligence PC For distinguishing creature species, vision-based DCNN is used, and explicit ultrasound discharge (different for each species) is used to repel them. plan, sending and this project aims to evaluate an intelligent agricultural monitoring and repelling IoT system based on embedded edge AI, which can detect and identify different types of animals and emit ultrasonic signals tailored to each species. This collaborative technology can assist farmers, agronomists, and managers in their decision-making processes. Convolutional Neural Networks (CNNs) utilize deep learningfor animal recognition. CNNs are a type of neural network that has shown significant success in fields like image recognition and classification.They are feed-forward neural networks with multiple layers, consisting of channels, units, or neurons with adjustable weights, biases, and thresholds. Each channel takes inputs, convolves them, and applies non-linearities alternately. As shown, common CNN's design should be visible. CNN's architecture

DOI: rp-9788770040723.057

includes Convolutional, Pooling, Redressed Direct Unit(ReLU), and Completely Associated, layers.

IV. Architecture of the Proposed System



V. Module Description

A. Animal Repellent Web Dashboard

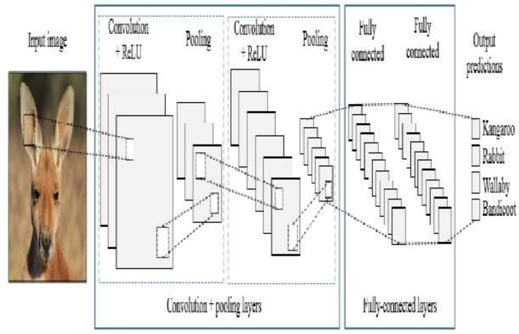
The system allows for real-time detection of animals in the fields and provides the farmer with a live view of their fields from any location through the internet. Additionally, the system includes manual bell controls that can be used if needed, giving the farmer complete control over the system. When compared to many current arrangements, such as electric walls, block facades, and manual field management, this framework is conservative. This framework is extremely effective at driving the creatures from the fields and repelling them. The need for power reduces the dangers of electric shocks.

B. Animal Recognition

This module starts by comment of creature dataset. These layouts then, at that point, become the reference for assessing and enrolling the formats for different stances: shift up to down, draw nearer to further, and turn left to right. Creature10N dataset contains 5 sets of mistaking creatures for a sum of 55,000 pictures. The 5 sets are as following: (feline, lynx), (panther, cheetah), (wolf, coyote), (chimpanzee, orangutan), (hamster, guinea pig). The pictures are crept from a few web-based web crawlers including Bing and Google utilizing the predefined marks as the pursuit watchword.

C. Animal Detection

Hence, in this module, District Proposition Organization (RPN) creates returns for capital invested by sliding windows above the element's maps through secures with various scale and different viewpoint proportions. Creature location and division strategy considering further developed RPN. RPN is utilized to create returns for capital invested and return for money invested.



The specific spatial areas are loyally protected by Adjust. These oversee providing a predefined set of jumping boxes of varying sizes and proportions that will be used as a reference while first anticipating object areas for the RPN.

D. Animal Identification

Once an animal image is captured by the Farm Camera, it is processed by an animal detection module which leverages a Region Proposal Network (RPN) to identify regions within the image that are likely to contain an animal. These regions are then passed to a feature extraction module which extracts key features from the image feature extraction module uses techniques like convolutional neural networks (CNNs) to extract detailed feature representations from the image. The resulting feature vector is typically of sufficient length to accurately represent the animal image.

E. Repellent

A system for safeguarding crops against potential animal threats involves an observation window that detects the presence of creatures, and subsequently triggers a repeller module that uses ultrasound to deter them. Recent research has shown that ultrasound is an alternative and effective method for repelling creatures. This is because animals generally have a much higher sensitivity to sound than humans, with the ability to hear lower frequencies that are beyond the range of human hearing. For example, while the human range of hearing is typically between 64Hz to 23KHz, various animals such as goat, sheeps, pig, dog and cat can hear sounds with frequencies ranging from 78Hz to 37KHz, 10Hz to 30KHz, 42Hz to 40KHz, 37.5Hz to 45.5KHz and 45.5Hz to 64.5KHz.

F. Monitoring And Visualizing

The framework works continuously recognize the animals in the field, moreover the ranchers can get to the perspective on their fields from a distance. The animal recognition module can provide information on the type and number of animals present, which is then transmitted to the cloud via a Wi-Fi connection. The cloud-based system consists of a secure cloud instance running on a machine that analyzes the patterns and behaviors of wild animals using the shared data. The farmer can detect and correct any errors, and thus achieve better results from the system.

G. Notification

DOI: rp-9788770040723.057

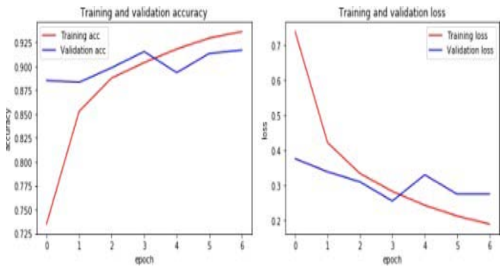
In this phase, when motion is detected, the user receives email and SMS notifications containing a captured image. The email is sent to the registered email ID, and the SMS is sent to the user's registered number on Telegram.

H. *Evaluation of System Performance*

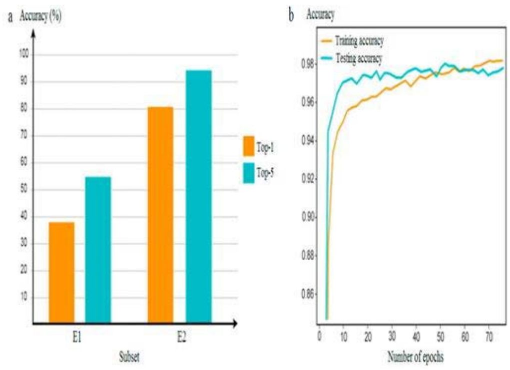
In this section, we assess the effectiveness of our system by measuring its accuracy in correctly categorizing data as either non-animal (negative class) or animal type (positive class) using three key performance indicators: Responsiveness, Specificity, and Precision. The calculations for these metrics are based on the True-Positive (TP), True-Negative (TN), False-Negative (FN), and False-Positive (FP) cases. TP represents the number of correctly identified positive cases, while FP represents the number of falsely identified negative cases. TN represents the number of correctly identified negative cases, and FN represents the number of falsely identified positive cases. The relevance of these performance metrics is analyzed within the scope of this project.

VI. Experimental Results

The generated charts in this module display the accuracy and loss during both the training and validation processes, for each iteration. The loss potential is calculated for each data item within the iteration, providing a quantitative measure of the loss at that specific iteration. The curve displayed during each iteration illustrates the loss of a portion of the complete dataset.



The project aims to create classifiers for endangered animal species by extracting appearance features of animals from the large dataset using the convolutional layers of a pre trained model. The images are then classified at the final layer of the model. Training and validation accuracy and loss graphs aregenerated to evaluate the performance of the classifiers.



The results of experiments conducted on dataset E2 demonstrate higher accuracy compared to the unbalanced dataset E1, achieving a Top-1 accuracy of 80.6% and Top-5 accuracy of 94.1% (as shown in Figure 7.2a). All training and a testing accuracy of plots for joints CNNs (Top 5) are also depicted depending on the numbers of epoch. Two experiments were performed, with the first using a single branch SVM without considering muzzle and shape features, and the second using the proposed joint CNN with decision-making rules. The resulting performance metrics, including Average-Precision (AP), Miss-Rate (MR), and False-Positives (FP), are presented in Tables 1 & 2 for a dataset (E2).

Compared to models trained from scratch, our proposed models demonstrate higher accuracy and require less time to perform tasks. This is particularly true for species with similar appearances because pre-trained models can already extract low-level features of new images. Additionally, using transfer learning eliminates the need for bounding box annotations, reducing the amount of manual work required. Assuming proper calibration, the Tfkeras-based model will be deployed effortlessly on an Android smartphone, and its potential can be broadened. It is anticipated that the precision of the model will maintained.

VI. Conclusion

The increasing demand for agricultural farm security has led to the proposal and implementation of a vision-based system using Python and OpenCV, resulting in the development of a Creature Repellent System to protect crops from animals. A complex intelligent animal repelling mechanism was designed and developed for the system, which incorporates novel software components for real-time animal presence and species recognition to prevent crop damage. The edge computing device employs its DCNN Animal Recognition model to classify the detected animal, and if an animal is detected, it transmits a message to the Animal Repelling Module specifying the type of ultrasound to generate based on the animal's class. In this study, a CNN was tested on a custom animal dataset, with variations in the number of training andtesting images. The results demonstrated that increasing the number of input training images resulted in a higher recognition rate, with the

DOI: rp-9788770040723.057
proposed CNN achieving an accuracy of approximately 98%. The project aimed to address the problem of animal-induced crop damage by introducing a real-time AI monitoring system, which has the potential to assist farmers and agronomists in their management and decision-making processes.

***Abstract*—Identifying a person's identity is deemed essential and can be confirmed through either traditional or biometric methods. The use of biometric technology is expanding due to its implementation in various industries for personal verification. Biometric recognition can be derived from either physical or behavioral traits, such as iris, voice, fingerprint, or face. While biometric recognition has the potential to enhance the process of tracking attendance in educational environments, it is underutilized, thus presenting opportunities for further exploration. Traditional attendance methods, such as calling out names or signing sheets, are often time-consuming and susceptible to fraud. To overcome these issues, there has been progress in using biometric recognition to automate the attendance process. The attendance tracking system employs face biometrics along with Quick Response (QR) codes for authentication. Student information is securely stored in a database in the form of QR codes. During attendance, students scan their QR code and their identity is verified through unique face biometrics. The face recognition is performed through a machine learning algorithm, which helps to prevent false attendance and improve the efficiency of the automated system in real-time college settings. Additionally, the system provides access to view marks and fees information. The system is designed with a .NET framework for the front-end and SQL Server for the back-end, and experimental results indicate the effectiveness of the real-time interface for student information. The student authentication system combines QR codes with face biometrics and uses HAAR Cascade for face detection and face recognition algorithms. The system allows for secure storage of student information in the form of QR codes, and during attendance tracking, students scan their code and their identity is verified through face recognition. The use of HAAR Cascade and face recognition algorithms helps to enhance the accuracy and efficiency of the authentication process.**

Keywords—Student authentication, QR code, HAAR Cascade, Face detection, Face recognition

I. Introduction

The authentication and authorization play a crucial role in maintaining computer system security by verifying users, devices, or systems identities and access privileges. In education, student authentication is essential to confirm their identity and grant credits or qualifications for their coursework. Biometrics is a commonly used authentication method that identifies individuals based on unique physiological or behavioral traits, such as fingerprints, facial recognition, and iris recognition. This field compares biometric data to stored references to confirm an individual's identity. Fingerprints are unique due to ridge patterns, facial recognition uses facial features, and iris recognition uses eye patterns for identification.

Biometrics has become a widely adopted technology for secure authentication in various industries, including law enforcement, border control, and consumer electronics. This is due to advancements in biometric technology and an increased demand for secure authentication methods. However, the widespread use of biometrics also raises privacy concerns related to the collection, storage, and usage of biometric data. These concerns have led to increased scrutiny and debate over the privacy implications of biometrics, and the need to establish guidelines and regulations to ensure the proper use of this technology.

II. Related Works

Mynavathi et al. proposed a framework for a comprehensive student information system that replaces paper records with a secure online platform accessible by college staff and students. The data is stored on SQL servers and protected by user authentication, data validation, and a logging system. The goal is to increase efficiency and reduce time and effort in accessing student records compared to paper records.

Pengtao Yang, et.al, developed a student information management system that utilizes fingerprint recognition for identification purposes. The system is composed of a terminal with a fingerprint recognition module and a microcontroller, and a host computer which can be either a personal computer or a large server, with the student information database managed by SQL Server. The system is designed to be secure, with data encryption based on an improved AES algorithm for secure transmission of sensitive information such as student fingerprints, identity information, and bank card information.The proposed encryption algorithm is optimized to improve encryption time compared to the traditional AES algorithm. The authors recognized the potential risks of data interception during transmission and emphasized the need for secure data transmission to protect students' private information.

DOI: rp-9788770040723.058

Anusha v pai, et.al, The authors in present the design of a simple student attendance management system using Web Services. The system is built around Web browser standards and can be accessed using any browser on any platform. The use of Web Services offers several benefits, such as increased accessibility, platform independence, longer lifespan, and the ability to choose preferred programming languages. The system allows for the recording of attendance in various ways and utilizes a web-based approach to provide worldwide accessibility. The authors aim to deploy a student attendance management system using Web Services to take advantage of these benefits.

DipinBudhrani and team designed and implemented a student information system to replace paper records. The system offers an online platform for students, faculty, and college administration to access student information such as academic progress, attendance, and activities. The data undergoes thorough review and validation for security before any changes are made. The system also has a logging system to track user access and maintain data security. The goal is to improve the efficiency of college record management, reduce time to access and deliver student records, and decrease time spent on non-value added tasks. The focus is on the students who can access information about the college, courses, faculty, exams, and more, as well as ask queries to staff through the system.

Symon C. Lubanga and his colleagues developed an Online Student Information System (OSIS) for academic institutions. The aim was to centralize all student records into one database using internet technology. The advantages of the Online Student Information System (OSIS) are widely acknowledged, but its implementation has proven challenging for African universities due to inadequate Information and Communication Technology (ICT) infrastructure. In Malawi, a study was performed to evaluate the Mzuzu University Student Online Management System (SOMS) from the perspective of the students. The study used both qualitative and quantitative research methods, including questionnaires and follow-up interviews with third-year students and the Director of ICT services. The data was analyzed using Microsoft Excel and the thematic analysis technique. The system has replaced paper-based systems, but with increasing numbers of students, it has become challenging to manage student records effectively. The advent of ICT applications and databases has presented opportunities to manage student records in academic institution.

SudhirBussa and others have implemented a facial recognition system for marking attendance in academic institutions. The system uses computerized biometric software to determine or validate a person based on their facial features. The system is designed to be used in security systems and commercial operations, and is considered a resourceful application of attendance systems. The system uses a webcam to capture images of students or employees and compares their facial features with those stored in a database to mark attendance. The advantages of using facial recognition include its natural, feasible and non-invasive nature. The system aims to automate the attendance process without requiring manual intervention.

ArunaBhat and team developed a face recognition-based attendance system for educational institutions using one-shot learning. This solution offers an efficient and secure way to take attendance by processing a group photo of a class and producing a list of present students. The system is a fully functional Android app and backend architecture, requiring no expensive setup, and has demonstrated an accuracy of 97% on the LFW dataset and 85% on a public student class photo dataset. The authors believe this system is more secure and can prevent fake or proxy attendance.

Sharanya et al. [8] developed a framework for organizations to track and monitor the attendance of staff and students to improve their performance. The traditional method of manually recording attendance is prone to errors and consumes a lot of time, leading to the need for an automated attendance management system. The new system will utilize biometric processes, with face recognition being the most effective, to replace the manual, time-consuming process of taking attendance in the classroom. The advancement of technology and the concept of "smart classrooms" have revolutionized the education system, but the attendance system remains primitive and in need of modernization.

Shamsul J. Elias and team designed a face recognition system to improve the traditional method of taking attendance in universities. The system uses face recognition to record student attendance data in a database. The paper discusses student attendance systems, image processing, face detection, and face recognition, and employs the Viola-Jones algorithm for face detection and the Local Binary Pattern (LBP) method for face recognition. The goal is to make the attendance-taking process faster and more accurate. Historically, attendance has been recorded through a paper-based system, but there are technologies like barcode readers, RFID, and Bluetooth that can automate the process. However, these technologies often require expensive equipment and have limited usage, as the devices can easily be damaged.

Harikrishnan et al. developed a face recognition system that tackles the challenges posed by multiple face recognition algorithms in real-world situations, such as changes in lighting and low image quality. With the improvement of machine learning and AI, computers have become capable of processing vast amounts of data with high efficiency, and deep learning algorithms have enhanced image processing and computer vision, making face recognition more effective and overcoming previous limitations. The system, known as "Vision," runs on a Raspberry Pi and can be managed through network communication with the PI server. The attendance records are kept on the onboard and online attendance server. Artificial neural networks trained on billions of images can now detect and recognize faces with ease and accuracy, and this technology was utilized in the implementation of a real-time attendance and monitoring system. The user-friendly GUI makes it easy to use the powerful face recognition algorithms powered by deep learning, achieving a maximum recognition accuracy of 74% during real-time monitoring.

DOI: rp-9788770040723.058

The system provides a solution to the shortage of robust and user-friendly face recognition attendance systems.

III. EXISTING SYSTEM

The concept of multi-view face recognition refers to using multiple images or videos from different angles to recognize faces. In some cases, the term is used for simultaneous acquisition with multiple cameras, while in others, it refers to recognizing faces across different poses. The recognition process may involve looking up a collection of images to align the appearance of the face, and this method also requires estimation of poses and illumination conditions for both images. The manual approach of taking and maintaining attendance records was challenging, which led to the development of biometric devices like fingerprint scanners for student attendance measurement in institutions and organizations where attendance is important.

IV. PROPOSED SYSTEM

The proposed student attendance system utilizes the concept of multi-view face recognition and leverages the benefits of HAAR cascade algorithm and neural network algorithms to improve accuracy. The system captures the QR code along with the face of each student and stores the information in a database for attendance tracking. The system also provides an SMS and email-based alert system with real-time implementation, and students can view their fee details and overall report. The spherical harmonic representation of the face is a novel approach to face recognition in video scenes, which addresses the challenge of unlimited orientations and positions of human faces. This approach maps the face texture onto a sphere, which allows for the construction of a texture map for the entire face by back-projecting image intensity values from each view onto the surface of the spherical model. The use of this method can lead to improved accuracy and robustness in face recognition systems, making it a promising solution for student attendance systems in educational organizations. The proposed framework for student authentication is shown in Fig 1.

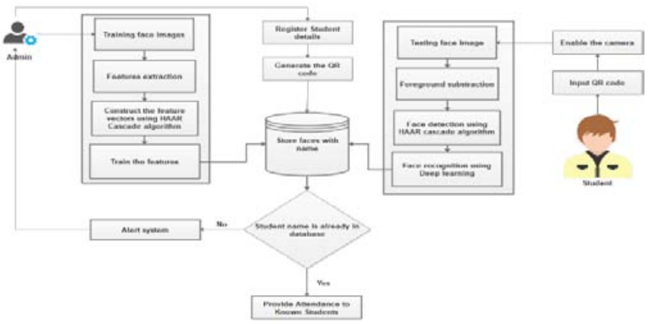

Fig 1: Proposed framework

The process of proposed work shown as follows

Framework construction

In the past 20 years, advances have been made in the field of personal identification. Biometrics, which refers to the identification of an individual through their physical traits that can be both seen and measured, is the term used to describe this. However, traditional biometric methods such as fingerprint and signature recognition have been found to be unreliable when dealing with large amounts of data. In this module, both administrative and student interfaces have been developed, with the administrative interface allowing for the storage of student information for future reference.

QR Code Generation

This QR code-based student information system aims to provide a secure way to store and access student information. By encoding the information in a QR code, the system can reduce the risk of data loss or alteration, and make it easier to access the information by simply scanning the code. The system uses four different encoding modes to ensure efficient storage of the data and to accommodate various types of information, such as names, phone numbers, email addresses, and class information. By using a QR code-based system, the student information can be stored and accessed in a quick, secure, and convenient manner.

Facial Features Extraction

In this module, student faces are captured in real-time for registration and the camera is used to distinguish the face pixels from the background. Preprocessing steps are implemented to identify the foreground pixels, which are then subtracted from the entire image. The HAAR cascade algorithm is used to extract key facial features such as skin tone, eyes, and others, which are then represented as feature vectors.

Label the Details

In this module, feature vectors are created for each student. A feature vector is an array of values that describes an object and multiple feature vectors can form a feature space. The elements in a feature vector can range from representing a single pixel to an entire image, depending on what information is being captured about the student. The granularity of the feature vectors is determined by what is being studied or represented about the student.

Classification

Deep learning is a cutting-edge approach to enhancing face recognition technology. The process involves extracting unique face embeddings from images containing faces. Training a deep neural network is the most effective way to perform this task. In this module, a deep learning algorithm is implemented to classify the feature vectors, which includes a neural network capable of classifying multiple features at once. Convolutional Neural Networks (CNNs) enable the extraction of a broad range of features from images. The algorithm classifies students during attendance and authorized students can also view their fee information.

Alert system

In this module, we can recognize known individuals and provide attendance for students based on recognition. If an unknown face is detected, an alert will be issued. A comprehensive report on attendance details is also generated.

V. EXPERIMENTAL RESULTS

DOI: rp-9788770040723.058

To evaluate the system, a set of faces is necessary. There are various standard face databases available for testing and evaluating face detection algorithms. A standardized database of facial imagery is crucial for supplying consistent imagery to algorithm developers and for providing a sufficient number of images for testing. Without these databases and standards, it is not possible to accurately evaluate or compare facial recognition algorithms. The experiments in this module were primarily conducted using the real-time face database.

Accuracy

The accuracy (ACC) is a common performance metric used in machine learning and artificial intelligence to measure the performance of a model. It represents the ratio of correctly predicted outcomes (true positive and true negative predictions) to the total number of predictions made by the model. The accuracy is usually expressed as a percentage, with 100% accuracy representing a perfect model that makes no errors in its predictions. A lower accuracy score indicates that the model is making more errors in its predictions and may need to be improved or re-evaluated.

The accuracy (ACC) is expressed as a percentage and calculated as the sum of true positive (TP) and true negative (TN) predictions divided by the sum of all true and false predictions (TP, TN, false positive (FP), and false negative (FN)). It is given as:

$$ACC = (TP + TN) / (TP + TN + FP + FN) * 100$$

TP: True positive, the number of cases where the model predicted positive (e.g. presence of a face in an image) and it was actually positive.

TN: True negative, the number of cases where the model predicted negative (e.g. absence of a face in an image) and it was actually negative.

FP: False positive, the number of cases where the model predicted positive but it was actually negative.

FN: False negative, the number of cases where the model predicted negative but it was actually positive.

ALGORITHM	ACCURACY
PRINCIPAL COMPONENT ANALYSIS	65%
LINEAR DISCRIMINATIVE ANALYSIS	85%
HAAR CASCADE ALGORITHM	98%

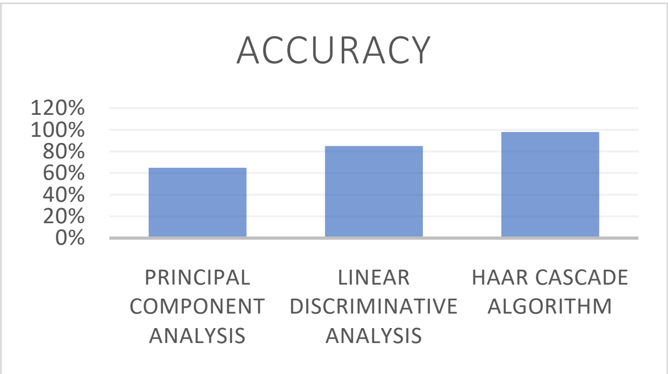

Fig 2: Experimental analysis

From the above graph, proposed system provide improved accuracy rate than the existing PCA and LDA algorithm.

VI. CONCLUSION

This paper presents a comprehensive review of face recognition techniques for still images and video sequences. Conventional methods, which require well-aligned face images and only perform either still image recognition or video-to-video matching, are not appropriate for face recognition under surveillance scenarios. The limitations of these existing techniques include a limited number of face images extracted from each video due to pose and lighting variations, poor video quality, and limited computational resources for real-time processing. Therefore, we propose a local facial feature-based framework for still image and video-based face recognition under surveillance conditions. This framework is capable of video-to-face matching in real-time and is trained using static images but applied to video sequences, resulting in higher recognition rates. Our approach also includes a QR code-based authentication system with fee information and an SMS alert system for evaluation using real-time image datasets.

I. INTRODUCTION

Shadow regions and complicated backdrops can be seen in satellite photos. We suggest using an aircraft identification method on pixel location segmentation as well as reconstructions for remote sensing picture aircraft target recognition to address these issues [1]. In particular, we must use a scatter plot of oriented gradients to infer the aircraft's orientation. The target that needs to be rebuilt must face the same way as the template. Additionally, we offer a better segmentation algorithm. The texture measure in distinguishing the target replaces the color space measuring method again for the difference between the wavelet transform of the target and also the shadow region. The target direction is first estimated using a gradient direction histogram, and the template direction is kept constant with the reconstruction direction [2]. Since the advent of combat aviation in World War I, military troops and civilian auxiliary people have been taught how to recognize aircraft visually. It is crucial for both military intelligence gathering and air defense. It is often a requirement for aircraft recognition to become familiar with the exterior characteristics of the aero plane friendly as well as aggressive are most likely to occur [3]. As teaching aids, people have used replicas, printed contour maps, slide projectors, computer-assisted instruction, and now even specially printed playing cards [4]. Aircraft, and specifically aero planes, are an alternative to the kinds of things that are generally taken into account for fine-grained categorization, such as birds and pets. The recognition of aircraft models is particularly intriguing for several reasons. First off, there have been countless models, manufacturers, and airlines over the past 100 years, totaling thousands of different aircraft designs [5][6].

Second, different aircraft designs are used for different purposes and have different sizes(from home-built to massive carriers)(transporter, carrier, training, sport, fighter, etc.)Technology,propulsion(glider,propeller,jet),andmanymo refactors [7].The fact that the structure of the aircraft changes with their design is one special axis of variation that is not shared with groups like animals (number of wings, undercarriages, wheel per undercarriage, engines, etc.) [8]. Thirdly,different firms may employ the same aircraft model for different purposes, which results in additional visual variances (livery) portrayed in **Figure1.** Depending on the identification task, these maybe viewed as noise or as valuable information that might be gleaned. The constant false alarm rate can be detected using the deep transfer technique [9]. Finally, compared to highly deformable animals like cats, aircraftaremostlyhardobjects,simplifying some aspects of their modeling and enabling one to concentrate on the key elements of the fine-grained recognition challenge [10].

UgurAlganci, et.al,…[11] presented a comparisonofit's still one ofadvancedCNN-basedaircraftmodel-based detectionforidentifyingaircraftfromsatellite pictures .The networks were trained using the DOTA dataset, and their performance was evaluated using both the DOTA dataset and independent Pleiades satellite images. The Faster R-CNN network delivered the best performance, as determined by COCO metrics and F1 ratings. The Yolo-v3 architecture also showed promise with shorter processing time, but SSD was unable to successfully merge the machine learning model with few repetitions. Each of the network tends to learn moreas the number of rounds and parameter valuesincreased.Yolo-v3 can convergemorequicklythanothernetworks,butoptimizationapproaches also performs a big role and in duration. SSD scored higher in terms of object detectionandrecognitionbuthadtheworstdetectionperformance. Results were also impacted by thedisparityinobjectsizesanddiversities.Unbalances should be avoided or the classes like aircraft, gliders, light aircraft, jet aircraft, and bombers,shouldbesplitintosmallergrainswhentrainingdeeplearningnetworks.Forthepurposeofdetectingaero planes from satellite photos, parameter tweaking and deep transfer learning techniques on preconditioned object identificationnetworksproducedencouragingresults.asignificantpartintheprocedure.SSDhadtheweakestdetectionperformance,althoughitperformedbetterintermsofobjectlocalization.Additionally,themethodscouldbeusedwithfull-sized(large-scale)satelliteimagesthankstothesuggestedslide as well as identify as well as non-maximumsuppression-based detection flow.

LimingZhou,et.al,…[12]adoptedthe MSDNnetwork using fewer grids within the input photosto measure subtle aero planes. Then, by enlargingthe show's perceptive reach, we propose to usethe DAWM modules to combat the attraction ofthebackgroundsoundcausedbytheintricatebackdrop.Additionally, To tackle both issues at the same time, we integrated the DAWM module with the MSDN network structure, resulting in a new network structure named MSRDN. The results of the experiment indicate that MSRDN surpasses other high-performance algorithms in identifying airplanes within remote sensing images. While there is a decrease in detection speed, it is accompanied by an improvement in detection effectiveness, this trade-off is to some extent acceptable. In general, our technique can be used to locate different objects and is more effective at finding aircraft in remote-sensing photos. The two-stage approach first uses the predesigned algorithm to produce a ton of regional candidate ideas and then uses the produced regional candidate proposals to find as well as categorize the targeted object through the backbone. Among this group of algorithms, the most prominent ones are R-CNN, SPP-NET, Fast R-CNN, Faster R-CNN, and Mask R-CNN.

YanfengWang,et.al,…[13]basedontheTransformerandEfficientDetmethods,provides the TransEffiDet approach for aircraftobject detection in aerial photos. We enhanced the object detection system in EfficientDet by incorporating the Inverter, which emulates the algorithm's long-term correlation features. ThesuggestedTransEffiDetcanoutperformtheEfficientDet by 5.8% with a +e mAP of 86.6% inaerialphotos.TheexperimentalfindingsdemonstratethatTransEffiDethasstrongrobustnessandissuperiortothecomparativeapproachesforaircraftdetectionandclassification tasks in the military. Along with this work, we will also make available a publicly accessible aerial dataset for the identification and classification of aircraft. In this study, our suggested approach is used to detect aero planes, but it hasn't shown to be particularly effective at distinguishing between fighter jets, bombers, and passenger planes The fact that these aircraft's form features are not readily apparent is one explanation.

Qifan Wu, et.al,…[14] We have suggested an improved approach for detecting and segmenting airplanes in remote sensing images using Mask R-CNN. To enhance the accuracy of aircraft target recognition and high-level feature information, we introduced the WFA-1400 remotely sensed aircraft mask dataset and incorporated modified SC-conv and dilated convolution into the basic Mask R-CNN model. After comparing our model to the basic network, we have attained an accuracy improvement of approximately 2%. We only paid a fair fee in due time and improved aircraft target recognition and instance segmentation significantly. Our research is a crucial practice for the analysis of remote sensing images. Due to the absence of established and easily accessible datasets for remotely sensed airplane masks, we were only able to conduct testing on the WFA-1400 dataset. Traditional object detection methods include drawbacks such as low rotation invariance and poor generalization. Deep learning (DL), which is expanding quickly, offers a better answer to this issue. Convolution neural networks (CNNs) perform exceptionally well in the areas of super-resolution image reconstruction, semantic segmentation, and object detection. Object detection, one of the most crucial DL directions, primarily addresses fundamental vision issues like the classification and localization of different targets in images.

Lifu Chen, et.al,…[15] implemented For the purpose of detecting aero planes from large-scale SAR photos, the geospatial transformer architecture is suggested. We developed a new three-step target detection framework using MGCAN for decomposition and recomposition, depending on the process. This paper's proposed target detection network, called MGCAN, is capable of efficiently extracting multi-scale information from small targets. Moreover, we systematically integrated the suggested EFPCF and PRSA modules into MGCAN to eliminate false alarms caused by complex background information and enable the network to collect important multi-scale contextual and positional data of the targets. To obtain the final detection outcomes, we

DOI: rp-9788770040723.059

applied the CD-NMS filtering method during the recomposition stage. This approach considers the dense distribution of targets in the SAR image by combining the confidence, IOU threshold, and distance between the centroids of bounding boxes. And suggest using the geospatial transformer architecture to address problems unique to SAR in aircraft detection using deep learning. We introduce two modules: the Economical Pyramids Permutation Focus Fusion (EPCAF) and the Parallel Remnant Spatial Attention (PRSA) modules. These modules combine feature pyramid inversion and attention mechanisms as well as geospatial contextual analysis to resolve the influence of speckle noise in SAR data. These geographic contextual attention modules are utilized to extract geospatial contextual information more efficiently, differentiate between different target location data, dynamically concentrate on critical regions, and decrease interference from background noise. When conducting geoscience research, fusing this method can be particularly useful. Deep learning algorithms play a crucial role in analyzing SAR images.

FerhatUcar,et.al,[16] study, A model for detecting aircraftbasedondeeplearninghasbeencreated.Thesuggested model makes advantage of the CNNnetwork'seasy-to-useobjectrecognitionoperator,whichiscreatedwithapplication-specificity as its backbone. The RCNN model,whichexecutestheairplanedetectionprocess,differs from the basic composition by using the"SoftMax"classifierstructureratherthanSVMclassifiers.Alargedatasetwiththeclasses"Plane" and "NPlane" was used for training andtestingthesuggestedCNNmodel.Additionally,adatasetthat wasspeciallydevelopedusingsatellite pictures and Google Earth was employedin the validation process of airplane detection.Theseextensivetestingandtrainingdatasetswere gathered from airports all around TurkeyHigh-performancevalueswereattainedduringsystemtestingusingsatellitephotoscollectedfrom several airports. A table that compares theresults could not be displayed due to an unfaircomparisonbecausethechosendatasetofthisaircraftclassificationalgorithm,whichwasconstructed with a deliberate and plain design,was not used in anyone else studies that havebeenpublished.

ZHI-ZEWU,et.al,…[17]introduced aCNNwiththeconceptofpoorlysupervisedlearningtocreateanaircrafttargetdetectionmethodforRSIs.In the experiments described in Section 4, the proposed AlexNet-WSL algorithm achieves detection results comparable to those of Faster R-CNN and YOLOv3.For their training, these two approaches need information about target location annotations and generate feature maps of multiple forms of information, enhancing the focus on target points while suppressing the focus on clutter points. This is achieved by employing an attention mechanism that assigns weights to different feature maps based on their relevance to the target object. The cascaded transformer block (TRsB) structure used by SFRE-Net is also helpful for the integrity identification of aircraft targets and can be used to model the actual correlation of scattering locations in SAR images. Additionally, the context attention-enhancement module (CAEM) developed by SFRE-Net addresses the problem of complex interference in SAR images by using an expanded convolution pyramid to improve the receptive field, followed by an adaptive fusion approach to combine multiple sources of information. The experimental results on the Gaofen-3 dataset demonstrated the effectiveness of the SFRE-Net algorithm, showing that it outperformed other state-of-the-art object detection systems. feature maps from different layers and scales of the network. The goal is to strengthen the representation of target points while suppressing the representation of clutter points. Numerous experiments on the airspace, especially in low-altitude flights. Therefore, non-cooperative detect-and-avoid modules are being developed, and AirTrack is a recent example of such a module for long-range aircraft detect-and-avoid applications. The module uses a cascaded detection approach with a secondary classifier to improve detection performance. The proposed approach is evaluated on the Amazon AOT dataset and real-world flight tests, showing promising results. Moreover, the module satisfies at least two specification categories of the newly established ASTM standards.

PengZhang, et.al,…[18] propose To solve the issue ofSARaircraftdetection,ascatterfeaturerelationshipenhancementnetwork(SFRENet)wascreated.SFRE-Netinitiallysuggestsafeature-adaptablefusionpyramidal(FAFP)structuretolessensemanticconflictwhilemerging various features. This structure helps toimprovethemodel'scapabilityformulti-scalerepresentationbyenablingthenetworktoindependentlyselectusefulsemanticsthroughan adaptive weighted addition approach. Toacquire feature data from diverse receptive fieldsand enrich the semantic information in featurefusion, we also add the showcase module (FEM)intoFAFP.Second,thecascadedtransformerblock(TRsB)structureusedbySFRE-Netishelpfulagainforthe integrityidentificationofaircraft targets and might be used to model the actualcorrelation of scattering locations. The contextattention-enhancementmoduledevelopedbySFRENetaddressestheproblemofcomplexinterferenceinSARimages(CAEM).TheCAEMfullyaccountsfortheuniquecharacteristics of SAR image targets. The firststep is to use the expanded convolution pyramidtoimprovethereceptivefield.Then,adaptivefusion is utilized to combine and generate featuremapsofmultipleformsofinformation,strengtheningthefocusoftargetpointswhilesuppressing the focus of clutter points. NumerousexperimentsjustonGaofen-3datasethaveproven the viability of our method and revealedthat SFRE-Net outperforms the most advancedobject-detectionsystems.

SourishGhosh,et.al,…[19]present, AirTrack as a state-of-the-art vision-based technology designed to detect and track long-range aircraft in detect-and-avoid situations. The module uses a series of detection modules and a secondary classifier to enhance its performance. Comparative results from the Amazon AOT dataset and real-world flight tests demonstrate the efficacy of AirTrack. The study also evaluates AirTrack against the recently established ASTM standards and confirms that it meets the criteria for at least

DOI: rp-9788770040723.059

two specification categories. While active onboard collision avoidance systems, such as the Traffic Alert and Collision Avoidance System or the Airborne Collision Avoidance System, are typically used for medium to large airborne systems, they rely on transponders installed in cooperative aircraft, which cannot track all airborne threats, such as rogue drones, balloons, light aircraft, and inoperative transponders, that may jeopardize safe operations.

Alshaibani,et.al,…[20]implementedAirporttrafficcontrol hasbeensupportedbyasimpleandaffordablemethod.The suggested method's first phase uses drone-collected aerial photos to train a deep trainingmodel to find aero planes. The following stage forfuture endeavors is to utilize the available data toidentify the type of aero plane first based on itslength and surface area. Given that any nation intheglobecangainfromthisstrategy,thisapproachhasthepotentialtobeauniversalcontribution.Insteadofusingthesatelliteapproach,whichnecessitatesexpensiveandsophisticated gear, drones can feed it system withaerialphotographs.

The existing methods are lagging in proper tracking methods, collision avoidance and component acquisition overcome by the proposed method where the deep neural network is deployed for identifying and recognizing the aircraft and analyzing the matching models.

III. Traditional Aircraft Detection Methods

The principal component analysis is used inthisapproachtoreducedimensionality.Somestepsaretakenhere. Thesatelliteimageisprocessedduringpre-processing. Processingisdoneinthreephases.Theaveragescore,covariance, Eigenvectors,aswellasEigenvectors are generated before anything else.The OTSU segmentation method segments thisimage. Using image segmentation, the satelliteimage is divided into numerous segments afterthefeatures(shape,shape,color,anddimension) are reduced using this technique. Theresemblancebetweentheseimagesisthendetermined by comparing the segmented imagewithseveralsortsoftemplates.Next,anaircraft isfound. It is possible that the aircraft identification area you are referring to is using these parameters to perform shape-based recognition and classification of aircraft. Equivalent diameter is the diameter of a circle with the same area as the aircraft's bounding box, width and height refer to the dimensions of the bounding box, and orientation refers to the angle of rotation required to align the bounding box with the aircraft's major axis. Perimeter is the length of the aircraft's boundary, and eccentricity is a measure of how elliptical the aircraft's shape is. These parameters can be used to distinguish between different types of aircraft based on their shape, which can be useful in aircraft recognition and classification tasks. Utilizing the K-Nearest Neighborclassification approach, aircraft are recognized. Asatellite image is used as the input, and a Gaborfilter is used to process it. For image retrieval, it is employed (shape, size, texture). The magnitude response of the filter outputs is then used to generate the face image, which eases the numerical challenges. After that, the hyperplane between classes is discovered using the K-NN technique.Finally,aircraft is recognized. If it cannot be recognized,it is translated and rotated, with the output thenbeing delivered to a filter. Once the aircraft isidentified,theprocessdescribedaboveisrepeated. Using KNN algorithms, entire shapesarerecognizedanddescribedinthecurrentframework.**Figure 2.**

IV. Proposed Methodology

Object recognition in remote sensing images is essential for both military and civil applications, including airport surveillanceandinshoreshipdetection.Withtheswiftdevelopmentofhigh-resolutionsatellites,thevolume of elevated remote sensing image data has increased significantly. Enabling the creation of a more sophisticated object detection systemforremotesensingphotos.Anexampleofatypicalissuewithsmalltargetrecognitionunderneathawide-rangetargetpositionisairplane detection in remote sensing photos. Theinputimageisasatelliteimage,whichissubsequentlyprocessedtoestimate the direction. To determine the image's roundness and pattern, as well as its histogram, an image's gradient must first be calculated. From there, it is assumed what direction the aircraft is flying with the satellite image. This image is then divided into homogenous sections, and the extracted features are subsequently divided into various sections the highest similarities aremeasuredaftercomparingdifferenttemplatetypesusingthejigsawmatchingpursuitalgorithm.Tolowerthemeansquareerror, this algorithm is utilized. Recently, at leastthree distinct methods for persistent neural netrecognitionhavebeenputforth.Thefirstmethod,calledinvariancethroughtraining,accounts for various targets for various pattern shifts throughout the training phase to adjust for the pattern shift. Such a strategy's primary flaw isthatitcannotbeusedinmanyoperationalcircumstances.Inactuality,thetrainingsetisoverlybigduetotheabundanceofpotentialpattern changes, which also raises the computing cost of the learning program. Invariance through structure, the second method, employs neural networks where outputs are consistently in variant to specific modifications. The drawback of this strategy is the requirement for high-order neural networks. The proposed framework is shown in**Figure3.**

DOI: rp-9788770040723.059

A. Aircraft Image Acquisition

The process of recognizing and identifying a specificobject or element in a digital image or video isknownasimagerecognition.Numerousapplicationsofthismethodexist,suchascomputerizedindustriallineframeworks,tollsectorobservation,aswellassecurityobservation. Regular image recognition methodsinclude facial recognition, license plate matching,opticalcharacterimagerecognition,andscenechangeidentification.identifyingobjects in a picture This stream would likely startwith methods for image processing for example(Low-level) feature extraction is used to discoverlines,regions,andmaybeareaswithspecified surfaces after noise removal. In this module, wecan enter any type and size of satellite image thatwasphotographedbysensors.Aerialvehiclesmaybepartially orfullyformedinsatelliteimagery.

B. Preprocessing

In the context of computer imaging, bi-tonal black-and-white images, or images with only two colors, black and white, differ from grayscale images (also called bi-level or binary images). With grey-scale photographs, there are many different grey tones in between. When only one frequency (or,morecommonly,asmallbandoffrequencyrange)iscaptured, gray-scaleimagescanbeproducedbydeterminingthelightintensityateach pixel under a specific weightedsumoffrequencies(orwavelengths).Insuchcases, the images are monochromatic proper. Theelectromagnetic spectrum is open to theoreticallyany location for the frequencies (for instance, uv, photons, indigo, et.)Thismoduleallows for the conversion of RGB images intograyscaleimages.Afterthat,applyafilteringstrategytoimprovetheimage'squalities.Theimprovedimagemovesontothefollowingmodules.

C. Superpixel Segmentation

Semantic similarity segmentation, visual tracking, pictureclassification,andothercomputervisiontaskshave all benefited from the use of super-pixelsegmentation. This module analyses the aircraftareasfromothersatellitedataandextractsaircraftpropertiesincludingcolor,form,andtexturefeatures.Dividetheaircraftregionsinto the precise shape of the partial orcomplete satellite feature data. Superpixelsareincreasinglybeingusedincomputervisionapplications.Onlyafewsolutionsallowfortheoutputoftherequiredquantityofregular,compressed superpixels with the least amount ofprocessing.WeofferSLIC(SimpleLinearRecursiveClustering),anovelmethodthatefficiently creates small, virtually uniform superpixels by grouping the pixels in coupled fifth aspect color and picture plane space.

SVMCLASSIFICATION	65%
CNNCLASSIFICATION	80%

Accuracy: The percentage of total correct predictions to all test data is known as accuracy (ACC). Additionally, it can be written as 1 - ERR. The maximum accuracy is 1.0, and the minimum accuracy is 0.0. The various classifiers' performance metrics are shown in **Table 2 and Figure 5.**

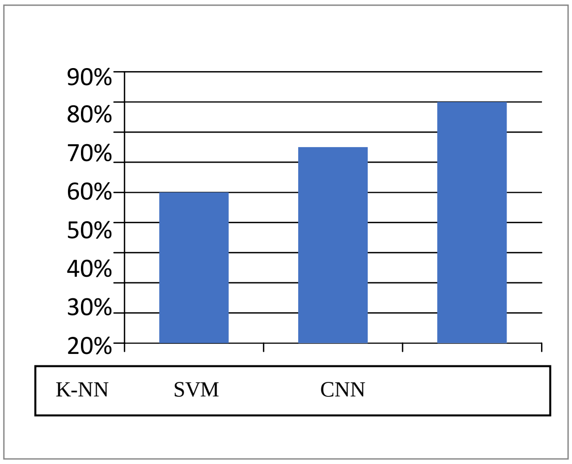

Fig. 5. Accuracy Measure of the ML models

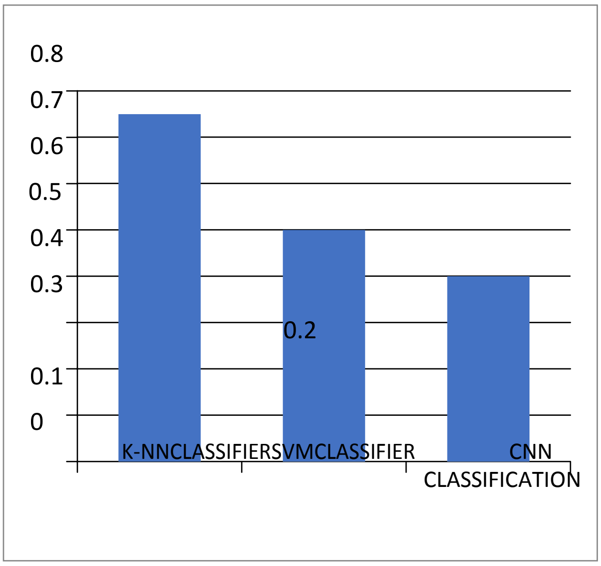
VI. CONCLUSION

In this study, a superpixel classification and templates matching model were used to identify aeroplanes in surveillance applications using satellite photos. Results from the tracking system are more accurate and have less computing complexity. The use of neural network analysis proved successful in improving segmented areas and following target items. Finally, the predicted outcome demonstrated that the strategies and methodologies used led to greater efficiency. An innovative target detection filter using a hybrid neural network system with picture manipulation has been proposed in this work. Two innovative ideas are presented in our work. Before discussing enhanced multimodal processing of MTARSI pictures for automatic object detection, we first presented a novel automatic categorization method. We used a back-propagating artificial neural network-based neural classifier that was built of many neural networks. To identify aircraft targets taken from MTARSI photos, the classifier is employed. To enhance the form and feature extraction procedure, two image processing approaches that were recently added to the literature are combined. Superpixel idiomatic phrases include then computed and employed as features for our combined system's input. Performance analysis is done in contrast to both traditional target



detection recognition systems and conventional multimedia processing methods. The effectiveness of the suggested approach for the use of mechanical airplane sensing elements is demonstrated by numerical results from extensive simulation testing. Future research will focus on enhancing the performance of a single NN by using the right optimization methods during the NNs' learning phase.

Abstract—The proliferation of technology has been credited with making processes that used to take a lot of time more easier to do. Machine learning (ML) enables software products to grow increasingly accurate at predicting outcomes without the need to be explicitly programmed to do so. This is possible because ML allows software to learn from past experiences. Machine learning algorithms make predictions about future output values by using data from the past as input. In the course of this investigation, we are going to investigate an artificial intelligence (AI)-based optimization method with the goal of recognizing the digits that are written by hand. Research in the fields of machine learning, image processing, and computer vision are making significant progress in the area of handwritten digit recognition. The style, shape, orientation, and size of a digit written by one person may be different from those written by another person. An algorithm for optimization is a procedure that repeatedly evaluates a number of potential solutions in order to locate the one that is most suitable. The phase of the design process known as computer-aided design has always included optimization ever since computers were first developed.

Keywords—Hand Written Digit Recognition, Artificial Intelligence (AI), Optimization Algorithm

I. INTRODUCTION

Challenges in research have arisen as a result of the exponential growth in data volume caused by handwritten papers, scientific instruments, and the usage of social media and channels. New areas of study have evolved in response to these problems that have attracted academics from many different disciplines. Users of social media sites often provide material for no cost, thus there is a wealth of information available in both organised and unstructured forms. Image processing, machine learning, and computer vision have all dedicated significant resources to the study of recognising handwritten digits [1]. There are several ways in which one person's numerical representation might diverge from another's for the same letter, including in terms of style, form, orientation, and size. These differences make it difficult for machine learning algorithms to recognize the digits automatically. It is a procedure that detects and recognizes any digit from a given image and then converts the digit into a machine-readable and editable format [2-3].An optimization algorithm is a method that matches various results iteratively till an optimum or acceptable solution is found. Optimization is a part of the computer-aided designing phase since the invention of computers [4].

Handwritten digit recognition is the ability of computers to recognize handwritten digits. Since handwritten numbers aren't always perfect and may come in aextensive range of combinations (in terms of both size and form), this operation is difficult for the computer [5]. A solution to this issue may be found in the handwritten digit recognition system, which proceeds a picture of a digit and determines whether or not that particular digit is present in the image.The capacity of a computer to recognize human handwritten digits from a variety of sources, such as papers, photographs, touch screens, etc., and then organize those digits into one of 10 predetermined categories is known as handwriting digit recognition (HDR) (0-9). Bottomless inquiry in the realm of deep literacy has been the focus of this article. The technique of number recognition is used in a wide variety of applications, including the sorting of postal communications, the processing of bank checks, and the identification of licence plate numbers [6]. In the field of handwritten number identification, we encounter a great deal of difficulty. Due to the fact that various people's handwriting tends to look different and that it is not an optical character recognition system. For the goal of handwritten number recognition, this investigation presents a complete comparison of several machine literacy and deep literacy algorithms [7].

The field of artificial intelligence (AI) considers the recognition of handwritten numbers as evidence that a person's neurons are in good functioning order and have been properly programmed. This particular use of artificial intelligence has been around for quite some time; its watershed moment occurred in 1989, when a dependable machine-enabled parsing of ZIP codes for postal services was finally accomplished.Almost immediately after that, it was shown that multi-layer feed-forward networks are capable of implementing any function. Shortly afterwards, the method for the automated parsing of account numbers that are printed on remittance slips for wire transfers or bank

DOI: rp-9788770040723.060

checks was adopted by the nation's financial institutions [8-9]. The identification of handwritten digits using a variety of AI algorithms is becoming more popular in academic circles nowadays for the purposes of teaching and learning.

II. Literature Review

Patil and Pranit (2020) illustrated the use of various Machine Learning algorithms,some of them to be noted are K-Nearest Neighbor Algorithm, SVM, CNN, Quantum Computing, and Deep Learning, in the Recognition technique for improving the productivity of the technique and reduce its complexity [10]. These algorithms include SVM, CNN, Quantum Computing, and K-Nearest Neighbor Algorithm. Arkiv Digital Sweden is a novel image-based handwritten historical digit dataset that was presented by Kusetogullari, Huseyin, et al. (2020) and Sridaran K et al. (2018). (ARDIS). The findings indicate that ML algorithms that are conditioned on previously collected data may have difficulty recognising digits effectively on our dataset. This demonstrates that the ARDIS dataset has different properties [11]. A novel model for identifying handwritten digits was presented by Haghighi et al. (2021) and Monika M et al. (2022). The model that has been suggested is a stacking ensemble classifier. This classifier's foundations are the Convolutional Neural Network (CNN) and a Bidirectional Long-Short Term Memory (BLSTM). The use of this database helps increase the performance of the recognition of challenging numbers [12]. To increase the accuracy of Farsi handwriting digit recognition, Nanehkaran, YaserAhangari, et al. (2021) and Balan. K (2022) developed a logical CBWME network structure system constructed on convolution bagging weighted common ensemble learning by merging CNN and BWME learning. Both Islam et al. (2019) and Latchoumi. T.P et al. (2022) focused on fine-tuning the algorithms by identifying the optimal values for the KNN, RF, SVM, MLP, and CNN hyper-parameters of the respective algorithms. They have presented Sankhya, which will act as the foundation for an open and verifiable evaluation process that will be repeated every two years from this point forward [13]. This process will also act as a benchmark for verifying newer and more innovative algorithms that will be mentioned in this field in the future.

Schrapel et al. (2018), Sivakumar P. (2015), and Vemuri et al. (2018) unveiled Pentelligence, a pen for handwritten digit identification that works on regular paper and does not need a separate tracking device. Pentelligence was developed by Schrapel et al. (2018). (2021). It picks up on the movements and sound emissions made by the pen tip when you are stroking it. DIGI-Net is a deep convolutional network that was proposed by Madakannu et al. (2020) and Buvana M et al. (2021). This network is able to learn and detect common characteristics from three various formats: natural photos, handwritten, and printed typeface of digits [14]. Experiments were conducted using the MNIST dataset, the CVL is a single-digit dataset, and the digits of the Chars74K dataset is suggested with DIGI-Net performed very well in all of them. A novel approach for the recognition of handwritten digit strings has been developed by Aly et al. (2019). This method does not need any explicit segmentation methods to be used. A unique hybrid principle component analysis network (PCANet) and SVM classifier cascade is used in the suggested technique. This network is referred to as PCA-SVMNet. The suggested approach is capable of achieving recognition accuracy that is equivalentwith the state-of-the-art methods that do not need segmentation [15]. The NN-based configurations for handwritten-based digit recognition that were proposed by Albahli, Saleh, and coauthors in 2020 and evaluated by varying the values of the hyper-parameters are discussed in this article.

III. Proposed Work

Handwritten digit recognition is the term given to the ability of computers to identify handwritten digits created by humans. Because handwritten numerals are not perfect and might vary from one person to the next, the computer has a challenging job. Handwritten digit recognition is the answer to this issue. This technique takes an image of a digit and determines whether or not that particular digit is present in the picture [16].An example of an AI-based optimization method is shown in Fig.1, and its purpose is to detect the handwritten digits of authors. The suggested technique is comprised of a number of diverse operations, the most significant of which are preprocessing, segmentation, feature extraction, and identification. The input picture is preprocessed by applying a Gaussian filter, going through a binarization process, and employing a method that detects skew. After that, the process of segmentation is carried out, which comprises the segmentation of both lines and characters. The split output is used as a source for the feature extraction. After the features have been extracted, the handwritten digits are fed into the most advanced artificial neural network available for recognition [17-18]. In this instance, a typical neural network is modified by the use of an optimization technique. The Optimization Algorithm is used to fine-tune a neural network's weights in order to achieve optimal performance. Metrics such as sensitivity, specificity, and accuracy are used in order to conduct the performance analysis of the suggested approach. The strategy that was suggested is put to the test, and the outcomes are assessed so that the performance can be seen. In order to put the suggested procedure into action, MATLAB will be used.

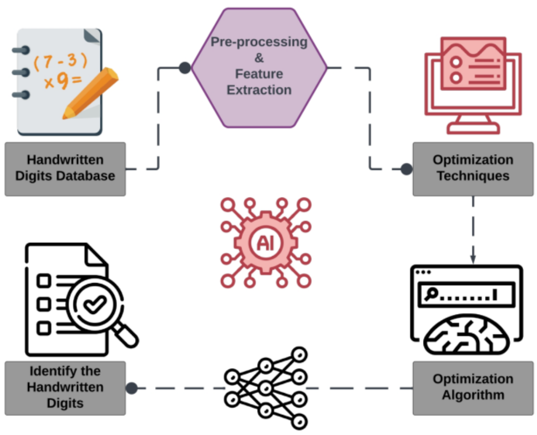

Fig.1 AI-based optimization algorithm for handwritten digits reorganization

Here in the below Equation (1), the average is approximated for ensuring the performance of recognizing the handwritten letters, whereas the equation can be modulated according to the duties that are differentiated in terms of analysis.

$$Y_i^m = \sum_{i=1}^{c} \frac{f_i}{f_i^c} + \sum_{T \to c}^{c} g(t_1 c_1 + t_2 c_2) \quad (1)$$

Wherein f_i^c signifies its terminal f_i knowledge dimensions to coordinate tasks regional basis. As a result, aentire letter is recognized by f_i scientists only at the small level portrayed in Equation (2).

$$f_i^n = \sum_{n \in f} (1 - \alpha_i) f_i^n + \int g(t_1 c_1 + t_2 c_2) \quad (2)$$

If diverse activities, including a t-norm or maybe even a $n_i -$ co norm, are being used to interconnected in trying to reach letter identification, the condition is known as just an optimization input optimization algorithm along with the symbolization in Equation (3).

$$f_i^m = \sum_{i=1}^{m} \frac{n_i}{f_i^m} + \sum_{t \to c}^{c} g(t_1 c_1 + t_2 c_2) \quad (3)$$

These deviations in result along with the enhanced optimization design that is dependent on a novel optimization algorithm for various handwritten letter-identifying concepts is calculated in Equation (4).

$$f_i^m = \sum_{i=0}^{c} \frac{f_i}{a_i^c} + (1 - \alpha_i) f_i^n + \int g(t_1 c_1 + t_2 c_2) \quad (4)$$

For this identification system used in an AI-based managing system, a collection of Enhancing the Efficiency and Performance has been detailed once again. The user's computation time is comparable to an order of magnitude of the stands and the user's processing powers, and such heat has been supported by facts and optimization data.

IV. Experimental Results

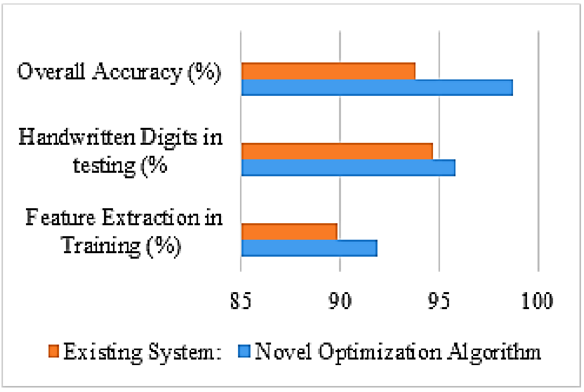

Fig.2 Efficiency and Performance of handwritten letter by the optimization algorithm

Several different NN-based models are used in order to investigate various facets of the same, the most important of which is accuracy dependent on the values of hyper-parameters. As a consequence of this, the broad experimental setup that is detailed in this article ought to result in the solution models that are the most accurate and the most time-efficient. An evaluation of this kind will be helpful in selecting hyper-parameter values that are optimum for jobs that are similar to those. Ramzan, Muhammad, and others (2018) carry out a comprehensive assessment of the many methods currently available for Hand-Written Digit Recognition (HWDR). This study is one of a kind due to the fact that is concentrated on HWDR and only examines the use of Neural Networks (NN) and its modified algorithms. It is examined that a general overview of NN as well as a variety of algorithms that are inspired by NN. Additionally, this research paper presents a comprehensive analysis of the use of NN, as well as its many forms, for the purpose of digit recognition in Table I.

TABLE I. Result Analysis for the Existing Method

Algorithm	Feature Extraction in Training (%)	Handwritten Digits in testing (%	Overall Accuracy (%)
Novel Optimization Algorithm	91.89	95.87	98.76
Existing System: Neural Network Algorithm	89.87	94.66	93.8

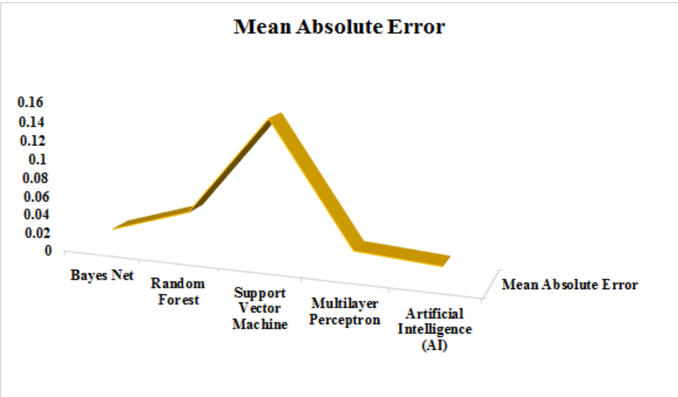

Fig.3 Mean Absolute Error Analysis

Though the model provides higher accuracy rate in identifying the handwritten letters, it is also necessary to find the error rate of any model. In this research, the proposed intelligent system is compared with certain existing algorithms such as Bayes Net, Random Forest, Support Vector Machine, and Multilayer Perceptron. Fig. 3 represents the Mean Absolute Error Analysis of the models which is used

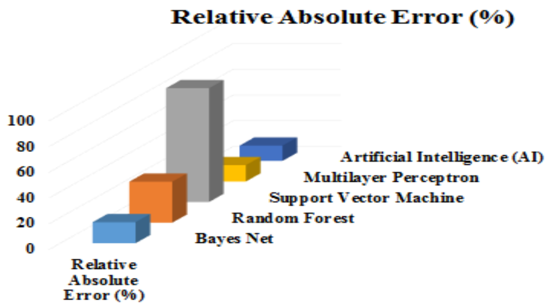

Fig. 4 Relative Absolute Error analysis

to analyze the prediction quality. From the results it is observed that the proposed intelligent system on the identification of the handwritten characters has obtained a very low Mean Absolute Error of 0.0185. The analysis of Mean Absolute Error is followed by the Relative Absolute Error analysis in the Fig.4. This analysis is used to determine the approximation error between the exact error and the resulting error. It is observed from the results that the proposed model maps the exact error rate.

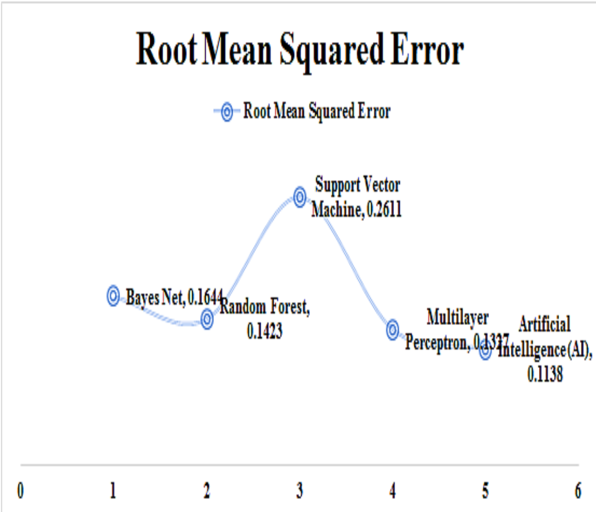

Fig.5. Analysis on Root Mean Squared Error

Analysis on the Root Mean Squared Error is represented in the Fig.5 which is used to represent the measurements for the evaluation metrics of the variables of predictions. The error rate obtained using the proposed model is less with 0.1138 which makes a minimum difference of 3% in comparison with the Random Forest Model.

V. Conclusion

The researchers claim that the proposed method is far superior to traditional handwritten digit recognition methods. The proposed methodology allows for the optimization of handwritten digits. An optimization algorithm is a method that iteratively compares different solutions until an optimum solution is found. Since the invention of computers, optimization has been a part of the computer-aided design phase. It aims to improve optimization by deploying algorithms and has achieved good accuracy.

Abstract—The advancement of technology has shown the use of technology search with some advancement by deep learning models in entire industrial managements.AI is poised to take over tasks that require human intelligence. Computer systems are in charge of these machines. In this model, the main prospect is to examine a Light Weight Deep Learning model for monitoring diabetes patients for continuous risk assessment. DL technology is a kind of subfield of ML where it employs or is inspired by human brain algorithms. DL employs ANN (Artificial Neural Network) as one such network. Diabetes mellitus can be most related to the metabolic disorder which infects the blood sugar level (glucose). A continuous risk assessment is an indirect risk assessment that is carried out regularly. It is a significant and influential form of assessment that should be done regularly as part of day-to-day management.

Keywords—Light Weight Deep Learning Model, Diabetes, Continuous Risk Assessment

I. INTRODUCTION

Artificial intelligence can be remembered as the machine's ability tothe various tasks similar to those performed by humans. Computer systems were in charge of these machines. Human intelligence is required for these jobs. It can also be described as computer systems that simulate human intelligence processes. DL is one of the fields of machine learning ML, which is a subfield connection with AI. Deep learning algorithms continuously analyze data with a predefined logical structure to reach conclusions similar to humans. Deep learning achieves this by employing a multi-layered structure of algorithms known as neural networks [1]. DM is a condition that affects the level of blood sugar in the human body (glucose). In other words, it is a disease that causes an excess of sugar in the blood (high blood glucose). This disease has no age restrictions, so it can affect people of any age. Diabetes has already been diagnosed using artificial intelligence technology [2].

The proposed methodology employs artificial neural networks (ANNs) for diabetes diagnosis. ANNs are computing systems that operate based on biological neural networks. ANN is based on a network of nodes called artificial neurons, which were inspired by the neurons in the human brain. Diabetes data is gathered to make a diagnosis [3]. The main goal of this method is to determine whether or not a person has diabetes. The process of collecting relevant features is known as feature selection. This procedure is critical because it simplifies the model by reducing training time. The data in the given dataset are divided into three categories: training data, testing data, and validation data. The ANN compares the input data to the dataset to determine whether or not the patient has diabetes. Diabetes diagnosis using ANN is a quick and easy process [4].

Deep learning models are essential for automating the process of illness detection. These models must be able to reliably and quickly identify incorrect measures, such as those of tumours, tissue volume, or other kinds of anomalies. A "lightweight" deep learning model can be trained using a small number of pictures, even ones with a high degree of noise. Additionally, this model is resource-efficient, which means it can be deployed on mobile devices [5]. The DL paradigm, which relies on self-monitoring and tele-screening of illnesses, is becoming increasingly commonplace since many societies are becoming older and there is a shortage of medical professionals. Deep learning algorithms, on the other hand, are often designed for a particular goal and may recognise or detect generic things such as people, animals, or traffic signs [6-7].

To diagnose illnesses, on the other hand, requires an accurate assessment of any anomalies that may be present, such as tumours, tissue volume, or any number of other kinds of deviations. In order to accomplish this goal, a model will need to segment the photos by looking at each one separately and marking where the borders lie. However, precise prediction requires a bigger computing output, which makes it challenging to implement such systems on mobile devices [8].

II. LITERATURE REVIEW

Bora, Ashish, et al. (2021) and Monica.M et. al. (2022) set out to develop a DL model that could analyze the

DOI: rp-9788770040723.061

likelihood of managing diabetic retinopathy by developing in an infected person who is affected with diabetes within the next two years. Using color fundus photographs, deep-learning systems predicted the development of diabetic retinopathy, and the processes were self-reliant and more insightful than available risk factors [9]. Ramazi, Ramin, et al. (2019) and Latchoumi T.P. et al (2022) proposed a method for processing time-series datasets collected by wearables based on the long short-term memory (LSTM) structure. Deep learning algorithms were effectively applied by Daniel Sierra-Sosa et al. (2019) to analyze healthcare data in a distributed and parallel manner. They demonstrated the scalability and supercomputing advantages of their method using a case study of over 150 000 type 2 diabetes patients. Large-scale parallel computation, which has become accessible on the new generation of GPUs and cloud-based services, can be used to analyze healthcare data [10]. Khanna, Narendra N., et al. (2019) and Karnan. B et. al. (2022) published a review that outlines the pathophysiology of rheumatoid arthritis and its connection to carotid atherosclerosis as shown in B-mode ultrasound imaging [11]. The function of tissue characterization techniques based on machine learning in assessing cardiovascular risk in RA patients is discussed, as are gaps in traditional risk scores. Saba, Luca, et al. (2019) and Vemuri et al (2021). proposed a DL model following procedure for precise assessment of stenosis in ultrasound images of the common carotid artery utilizing the AtheroEdge system class from AtheroPointUSA.

Theis, Julian, et al. (2021) proposed a process DL architecture to improve existing severity scoring methods by integrating diabetes patients' medical histories [12]. First, past hospital encounters' health records are transformed into event logs appropriate for process mining. Julian Theis et al. (2021) and Sridaran K et. al. (2018) proposed a DL model for predicting MACE that was created and evaluated with the use of administrative claims from over 2 lakh diabetes patients in the Veneto area of North East Italy. He, Tiancheng, et al. (2021) and Sivakumar P (2015) and Buvana M et al (2021) showed that recurrence risk variables, in addition to tumor size and biomarker analyses, may be explored using a deep learning model incorporating clinical, multi-scale histopathologic, and radiomic visual characteristics [13].

III. PROPOSED WORK

Diabetes mellitus isa chronic disorder that is characterized by an average and higher level of blood sugar (glucose). A continuous risk assessment is a type of indirect risk assessment that is performed regularly. It is an important and influential method of evaluation that should be performed regularly as part of day-to-day administration[14]. Fig.1 illustrates the lightweight deep learning model to monitor the diabetes patient for continuous risk assessment. An NN model parameter called weight modifies input data in the network's hidden layers. Nodes commonly referred to as neurons, make up a neural network. A collection of inputs, a weight, and a bias value are included in each node [15-16]. Lightweight CNN architectures are proposed as a solution for making deep neural network deployment on small devices feasible. Within the network's hidden layers, the weight parameter in neural networks changes incoming data [17]. Nodes commonly referred to as neurons, make up a neural network. A collection of inputs, a weight, and a bias value are included in each node.

Scaling Data Each characteristic in the dataset has a wide range of possible values. As a result, characteristics with a larger range of values may dominate the learning algorithm's performance [18].

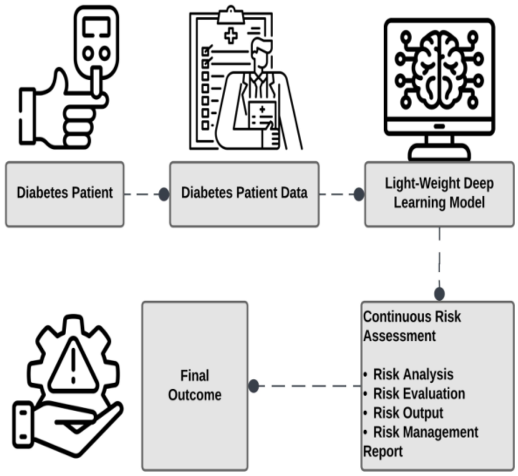

Fig.1 The lightweight deep learning model

The purpose of this stage was to maintain the intrinsic information while scaling the values of each character within a predetermined limit [19-20]. To do this, we employed data scaling based on min-max normalization, where X stands for the feature's initial value, Xmin for its minimum value, Xmax for its highest value, and R stands for the scaled feature's target range.

The data $p(q)$ device is a standard predecessor that receives a unit $n\,[q, q + 1]$. Unit p communicates with the behavior control. The process is completed with a neutralized combination is represented in Equation (1).

$$p(q)_j = \sum_{m+1}^{e} e\left(p(q) + \sum_{h=1}^{m} n[q, q+1]\right) \tag{1}$$

Weightlifting and signs are true values with large data input indications that are unaffected by diabetes. To produce such items, the implementation of the following Equation (2), which is roughly similar to the data to the signal q_j, may work with a truck loaded with t_j.

$$p_j = \sum t_j q_j + \sum_{f=1}^{q} n[q, q+1] \qquad j = 1,2. \tag{2}$$

To implement the massive data, necessary data input G is gathered in diabetes, to represent the Equation (3)

$$G = \sum_{p\to q}^{t} p_1 + p_2 = \sum_{c=1}^{t=1} t_1 q_1 + t_2 q_2, \tag{3}$$

The massive data uses its transfer work $g(o)$ to calculate the F to detect and classify the diabetes production, which could be a massive data function result $g(o) = (1 + e^{-o})^{-1}$, representing the Equation (4)

DOI: rp-9788770040723.061

$$g(o) = \sum g(f) = \int g(t_1 q + t_2 q_2) + \sum_{p \to n}^{t} n_1 + n_2 \qquad (4)$$

This mode command technology employs the point of entry, the available spectrum, and data transmission while doing tasks, but it also conveys the following Equation: (5).

$$t_i^n = \sum_{F=1}^{O} \alpha_i S \log\left(1 + \frac{|n_{i,m}|^2 G_{i,M} N^{-q}}{\sigma^2}\right) + \sum g(n) \qquad (5)$$

As a result, the efficiency of p_i^m data exchange data transfer is defined as Equation (6)

$$n_i^q = \sum_{n=1}^{Y} \beta_i B \log\left(1 + \frac{|N_{q,i}|^2 Y_q p^{-c}}{\sigma^2}\right) + \sum_{i=1}^{t} t_i^p + \sum_{i=1}^{q} |n_{q,i}|^2 X_q n^{-c} \qquad (6)$$

IV. Experimental Results

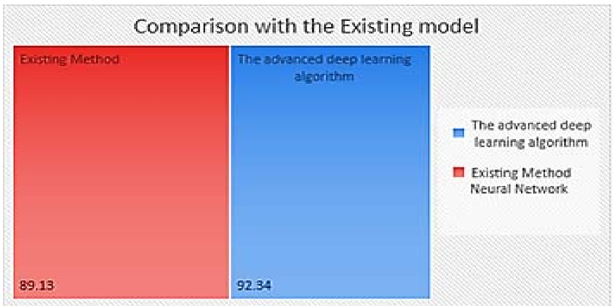

Fig.2Comparison based on accurate identification

Fig.2 represents the comparative analysis on the proposed deep learning model using a cloud-based machine learning system, performance analysis for the detection and classification of diabetes from a large data.

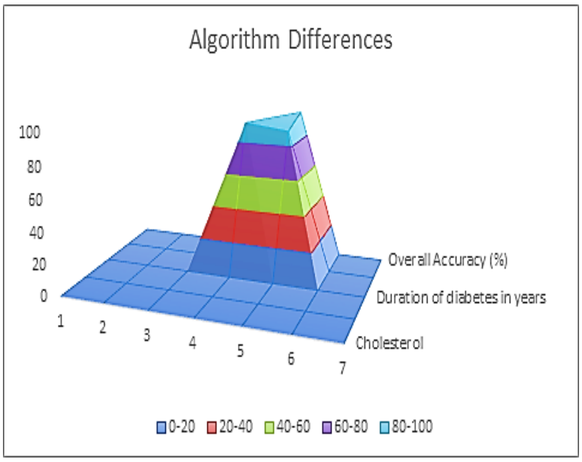

Fig.3 Analysis based on age of the persons

Diabetic analysis based on the age of the persons is presented in the Fig.3. It can be observed from the results that majority of the persons affected with diabetics is between 80 to 100 years of age. It is also to be noted that, in current scenario, the people of very young age of 0 to 20 years is facing the diabetic issues. The corresponding evaluation metrics on the analysis such as cholesterol, triglyceride, and duration of diabetes coefficients are presented in Table I.

TABLE I. Comparison based on Evaluation Metrics

Algorithm	CholesterolCo efficient $p(q)$ and n Value	Triglyceride Coefficient $p(q)$ and n Value	Duration of diabetes in years Coefficient $p(q)$ and p Value
The advanced deep learning algorithm	−0.079 and 0.132	0.020 and 0.694	0.082 and 0.48
Existing Method Neural Network	-0.064 and 0.121	0.012 and 0.534	0.804 and 0.203

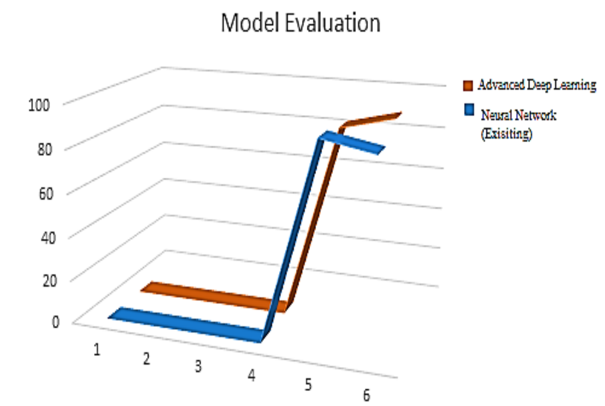

Fig.4 Model Evaluation based on Accuracy

Diabetes is a challenging illness that requires adhering to many restrictive rules, making it challenging to live with. Anyone without a background in medicine may find the instructions given by educators or even doctors to be confusing, which adds to the emotional anguish of receiving a diagnosis and having to make the necessary lifestyle modifications. Using a cloud-based machine learning system, analysis for the detection and classification of diabetes from a large amount of data is being carried out. Many studies on this subject have been conducted on diverse populations using various scales to better understand the mental and behavioral changes caused by diabetes as well as the treatment regimen that it requires. Accuracy evaluation of the models is presented in the Fig. 4 and Table II.

TABLE II.Accuracy Evaluation

Algorithm	Training and Testing (%)	Overall Accuracy (%)
The advanced deep learning algorithm	92.34	87.78
Existing Method Neural Network	89.13	95.21

An analyzing, convergent Artificial Intelligence model of this type can be taken as potential to alter the LT allocation policies for patients, advance the transplantation potential treatment for the infected persons with the most

DOI: rp-9788770040723.061

severe tumor (2021) hypothesized that symptomatic carotid plaques have a reduced grayscale median on ultrasound images due to a histologically higher lipid and comparatively little calcium and collagen type, and elevated chaotic grayscale dissemination because of the composition. Nasser, Ahmed R., et al. (2021) proposed a new technique based on cutting-edge operating systems. An AI and DeepLearning model is proposed to foretell the management of the level of glucose over time horizons of 30 minutes.

IV. Conclusion

This proposed model develops a lightweight DL model. This model is used to assess the continuous risk of diabetes. When compared to many existing machine learning and deep learning models, the developed model outperforms them. This work can be expanded in the future to recognize more complex activities. It can also be used on other edge devices.

***Abstract*—Lung cancer is one of the deadliest chronic diseases in respiratory medicine. This paper aims to talk about how nanotechnology can be used to treat lung cancer. Nanotechnology intervention has revolutionized lung cancer therapy to a large extent by overcoming given circumstances in conventional therapies. The use of nano-based drug formulations in pulmonary delivery has contributed to possibly more advanced and efficient lung cancer therapy.Nanomaterials are used to precisely target tumor tissue to reduce therapeutic side effects and improve bioavailability. It is accomplished primarily through two pathways: passive targeting and active targeting.**

Keywords—*Lung cancer, nanotechnology, respiratory medicine.*

I. Introduction

The cancerous condition known as lung cancer most frequently affects the cells that line the airways in the lung tissues. For both men and women, it is the leading reason for cancer-related death. The two most prevalent types of lung cancer are small cell and non-small cell, as shown in Fig. 1. These two types differ greatly in how they develop and are handled. Lung cancer has become one of the cancer is major causes of death worldwide. Nonetheless, new therapeutic agents for lung cancer have been developed, which may changethemortality rate. Surprisingly, incredible progress in the technology and implementation of nanoscience in the identification, diagnosis, and therapeutic interventions of lung cancer have occurred over the years. Nanoparticles (NPs) can integrate different drugs and targeting agents, resulting in increased bioactivity, sustained delivery, solubility, and digestibility. In addition to early detection of lung cancers, an ideal treatment strategy for optimal care of these cancers is required. Lung cancer is commonly treated with a variety of therapeutic procedures, including surgery, radiotherapy, radiosurgery, chemotherapy, and immunotherapy.

The most adequate intervention for lung cancer is determined by the patient's functional status, stage, and histological type of the disease [1]. Surgery is the best model for treating lung cancers, but it is not appropriate for metastatic or progressed-stage lung cancers. When lung tumors cannot be resected due to spread to nearby tissues or when surgery is not required, the best therapeutic option has traditionally been a combination of radiation and chemotherapy. However, the recent addition of therapeutic strategies and immunotherapy to these modalities has altered the treatment paradigm for these tumors[2].

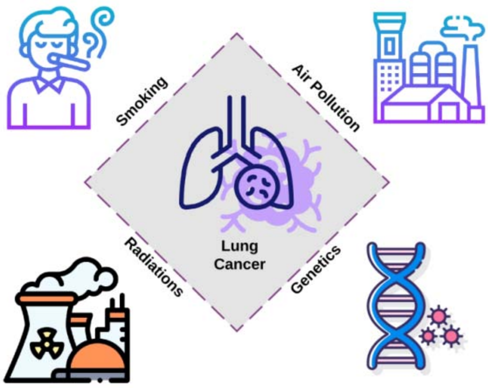

Fig.1. Nanotechnology in various fields

II. Literature Review

In this study, Cryer, Alexander M., et al. and Latchoumi T.P. et al. described the complexity of lung cancer, the current landscape of diagnosis and treatment, and the most recent developments in nanotechnology-based approaches to the management and prognosis of respiratory malignancies. The field's full potential has not yet been realised, so a brief overview of nanomedicine's future directions is given [3]. By learning from and incorporating developments in related fields, nanomedicine can be improved to the point where the current obstacles preventing its full clinical impact are removed [4-5]The pharmacokinetics, pharmacodynamics, and mechanism of action of DTX in the treatment of prostate, non-small cell lung, and breast cancer need to be better understood. Imran and Mohammad, et al. (2020) and Karnan B et al. (2022) conducted studies. It systemsatizes the most recent use of various DTX delivery techniques based on nanotechnology for the treatment of these cancers. The review also discusses the various anti-cancer drug combos that included DTX that were used to find the

DOI: rp-9788770040723.062

aforementioned cancers.Garbuzenko, Olga B., et al. (2019), Sivakumar P (2015), and Monica.M et. al. (2022) proposed a new multi-tier biotechnology diagnosis approach that includes local inhalation therapeutic delivery to the lungs, suppression of all four EGFR-TK types by a pool of siRNAs, induction of cell death by an anticancer drug, and active receptor-mediated targeting of the therapy specifically to cancer cells to reduce side effects [6]. Sharma, Parvarish, et al (2019) and Buvana M et al (2021) discussed various modes of nano drug delivery options such as liposomes, dendrimers, quantum dots, and carbon nanotubes, and metallic nanoparticles. Nano-carrier drug delivery systems appear as a good alternative, with the potential to open up new and more advanced avenues in cancer therapeutics.Zhong, Wenhao, et al. (2021) and Sridaran K et. al. (2018) reviewed the latest events in nanotechnology drug delivery systems strategies in the lungs and investigated the clinical practical significance of nanotechnology in the drug delivery study related to the lung [7].

Sergey G. Klochkov et al. (2021) and Vemuri et al (2021). reviewed the major trends in nano-drug preparations as well as the attributes restricting their use in medical settings. Furthermore, the current situation of authorized nano-drugs for the treatment of cancer is discussed [8]. Doroudian, Mohammad, et al. (2019) examined recent advancements in the clinical translation of nanomedicine for lung diseases, including lung cancer, cystic fibrosis, asthma, bacterial infections, and COPD. Doroudian, Mohammad, et al. (2021) focused on a review that provides both a historical overview of nanomedicine's application to respiratory diseases and latest cutting-edge strategies such as nanoparticle-mediated therapeutic strategies, the novel double-targeted nondrug delivery mechanism for targeting, stimuli-responsive nanoparticles, and theranostic imaging in the management and therapy of pulmonary diseases [9-10].

III. Proposed Work

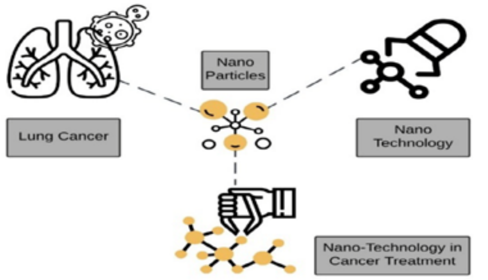

Fig.2. Proposed Architecture

Cancer treatments can be made safer and more accurate with the help of nanotechnology. Specially designed nanomaterials deliver chemotherapy directly to the tumor [11]. They don't give out the prescription medication until they get there in Fig.2. This prevents the drugs from causing harm to the healthy tissues surrounding the tumor. Side effects are caused by the damage [12-13]. Because of their small size, nanoparticles can deliver medicines to parts of the body that would otherwise be difficult to reach. The blood-brain barrier, for example, prevents poisonous substances from entering the brain. It also prevents the absorption of some medications. Nanoparticles are small enough to penetrate through this barrier, making them a promising treatment for brain cancer. Nanotechnology more precisely targets cancer cells while sparing healthy tissues [14-15].

The Carbon nanotubes, which are composed of long, thin cylinders of graphite atoms, are the most significant of today's nanomaterials. These might be the most significant brand-new substance since plastics. They are offered in 8 different structures, allowing for a variety of characteristics. Single-walled (SWNT), which have a single cylindrical wall, and multiwalled (MWNT), which contain cylinders inside of cylinders, are the two categories into which they are commonly separated. Whenever a story in the news mentions the extraordinary properties of nanotubes, SWNT is frequently cited. Weight loss, nausea, and diarrhea are common side effects of current nanotechnology-based therapies such as Abraxane and Doxil. However, these issues could be caused by the chemotherapy drugs they comprise.

$$P_{max} = dig_{s21}^{min} P(S \vdots I_Q; t *; T) \tag{1}$$

In Equation (1), the constants P and Q represent the number of infectious and shielded access points up to time t is calculated using Equation (2).

$$T_{max} = dig_{t22}^{max} \frac{U(I_Q;\ T_R, S, p^*)U(S * t^*)}{T(I_Q; T_R; t^*)} \tag{2}$$

The above results are being assumed to be homogeneous over are used to detect probability.

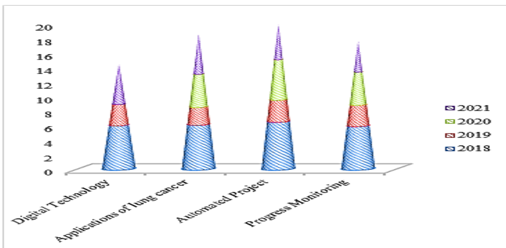
$$T(I_Q; T_R; t) = \sum_{\sigma \in \Omega(S, p^*, I_Q; P_R)} T(\sigma | S, t) \tag{3}$$

Based on the number of possible propagation sequences, the same approach is presented in Equation (3).

$$K(S, t, I_Q, T_R) = |'\Omega(S, t *, I_Q, T_R)| = (R+Q)! \prod_{\mu \in I_Q \cup P_R} |T_\mu^v| - 1, \tag{4}$$

In Equation (4), the feasible propagation sequential nodes provide both information and context around the same time.

IV. Experimental Results



DOI: rp-9788770040723.062

Fig.3.In building a replica for identifying lung cancer for artificial organs with the application of Micro- and Nano Technology

The described the most commonly used nanomaterials in cancer diagnosis and treatment a crucial first step towards a tailored approach to cancer treatment is the capacity to divide patients into groups that are clinically relevant. A growing number of biomarkers have been created over time to identify people who will respond better to particular treatments. By identifying several molecular subtypes of cancer that require various treatments, these biomarkers have also proved useful for prognostic purposes and for understanding the underlying biology of the illness in testing for breast cancer. The main method for analysing samples for diagnostic markers is immunohistochemistry. Lately, the cost and speed of genome sequencing have decreased, making it possible to characterise the DNA and RNA of specific patient samples for clinical use [16]. Based on their physicochemical and biological properties, they have spotlighted the applicability of these nanomaterials for cancer management [17-18]. And discussed the difficulties associated with various nanomaterials Fig.3 and Table I, which limit their use and hinder their translation into the clinical setting in certain types of cancer. Mukherjee et al. (2020) provided a detailed overview of recent advances in theranostics nanoparticles such as liposomes, polymeric, metal, and bio-nano particles [19-20]. Furthermore, they have summarised the benefits and drawbacks of each approach in terms of lung cancer theranostics.

TABLE I. DESCRIPTIVE STATISTICS AND PEARSON CORRELATION ANALYSIS FOR BUILDING A REPLICA OF MICRO- AND NANO TECHNOLOGY (MNT)

Year	**Digital Technology**	**Applications of lung cancer**	**Automated Project**	**Progress Monitoring**
2018	6	6.1	6.5	5.9
2019	2.9	2.4	3	2.9
2020	0	4.5	5.5	4.5
2021	5.5	5.5	4.8	4.2

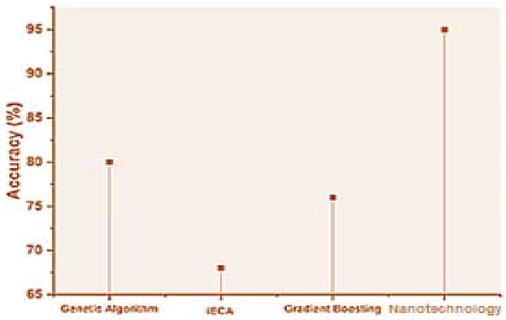


Fig.4. Accuracy Analysis with the Existing models

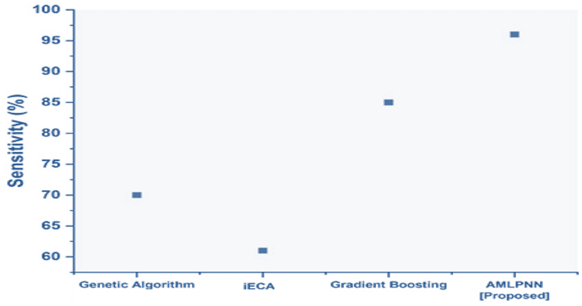

Fig.5a. Sensitivity Analysis of the System using Sensitivity

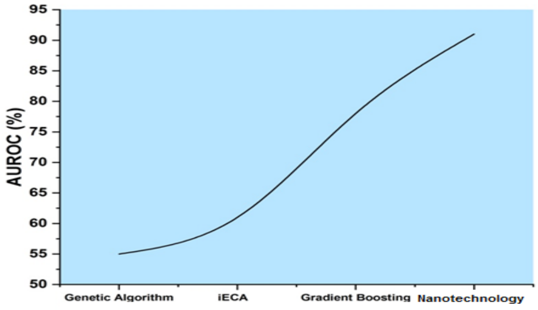

Fig.5b. Sensitivity Analysis of the System AUROC

The analysis of the model based on the Accuracy, sensitivity, and specificity are presented in the Fig.4, Fig.5a &5b respectively.

V. CONCLUSION

The method entails utilizing data from a larger dataset to enhance predictions for a smaller, more constrained dataset. We can more effectively account for variations in patient characteristics and raise the precision of predictions for the smaller dataset by weighting the sample of patients in the larger dataset. The number of experiments required to optimise the deep neural network hyperparameters was significantly reduced as a result of this method, which can expedite and reduce the cost of creating machine learning models. This approach is also applicable to numerous machine learning tasks.A longitudinal mobile health lifestyle dataset of 50 patients who self-monitored their food intake (carbohydrates, fats, and calories), physical activity (exercise time and calories burned), weight, and prior glucose levels over an 8-month period was used to test our model. Since many different factors can affect glucose levels, it can be challenging to predict them in the future.

***Abstract*— The Internet of Things (IoT), which allows common household items to be connected to the internet and communicate with one another, is quickly changing the way we live and work. The healthcare, transportation, and manufacturing sectors could all undergo radical change as a result of this. if a little developing method have led to a number of new developments in the medical and health fields. IoT technologies for wearable health address new problems with state-of-the-art equipment and resources. With the aid of portable medical equipment, the health status of both in- and out-patient patients could be monitored frequently and irregularly. This paper suggests the Patient Health Monitor Framework (PHMF), an IoT application framework that uses Machine Learning (ML) techniques to create a better automation system. Connections, surveillance, and decision-making for precise diagnosis will be made possible by this system.**

***Keywords*—IoT, Healthcare, physical monitoring, Machine Learning techniques**

I. Introduction

The application of a sustainable and environmentally friendly strategy is a crucial component of our project. During the entire project lifecycle, we are dedicated to minimizing waste and reducing our carbon footprint. Health is life. Due to their busy schedules and workloads, people don't pay attention to their health and fitness. Physical inactivity is the biggest problem today's youth are facing [1-2]. People can maintain their physical fitness by continuing their regular physical activities and adopting healthy lifestyle habits, such as eating a balanced diet, getting enough sleep, and lowering their stress levels by practicing relaxation techniques like yoga or meditation. For a fulfilling life, it's critical to priorities our health and carve out time for self-care. When taken as a whole, nutrition and exercise change depending on the users' lifestyles, height, weight, sex, age, & degree of activities [3-4]. Exercise and healthy eating go hand in hand. It's important to manage your calorie consumption if you want to keep your blood sugar levels stable. Therefore, the proposed approach would enable physicians to click a mouse and counsel exercise and diet to their customers who have diabetes, hypertension, or thyroid problems in addition to the medicine they prescribe at every follow-up [5-8].

However, one use is the remote monitoring of clients' healthcare, which enables medical professionals to keep a closer eye on their patients and prevents the progression of medical issues even in regions with limited to distant healthcare facilities [9]. Remote monitoring enables faster diagnosis & prompt, appropriate treatment by giving medical professionals access to timely or past health information in real-time [10]. Even though it reaches regions with limited access to health facilities telemedicine has the potential to improve healthcare delivery and reduce healthcare disparities by providing remote consultations, diagnoses, and treatment options. However, it also requires reliable internet connectivity and trained healthcare professionals to ensure effective implementation. telemedicine has the potential to improve healthcare outcomes by providing remote medical consultations and diagnoses, as well as facilitating the delivery of medications and medical supplies. However, it also requires reliable internet connectivity and adequate training for healthcare providers to effectively utilize the technology. [11–12]. That underscores why such technologies have so far had little impact on rural India's patient and health industries. This essay introduces the idea of AmritaJeevanam, a specific healthcare infrastructure that attempts to serve rural communities' requirements [13].

II. Related Works

By utilising remote sensing capabilities, health monitoring technologies that are combined with IoT/BAN effectively revolutionise the healthcare sector [14]. Detection systems are used in conjunction with such systems to identify crucial parameters and transmit data to an acquiring device via Bluetooth, BLE, and WiFi. Medical and measurement data that has been collected through an intermediary device, like a gateway, is frequently sent to a distant server. For those who live in remote or rural areas, this technology makes it possible for medical professionals to monitor patients' health in real-time, even from a distance. Additionally, by enabling early detection and intervention of potential health issues, the use of IoT/BAN technologies in healthcare can enhance patient outcomes.Using this technology, healthcare professionals can [15]. Data transmission is kept on a distant server, assuring accessibility and accessibility at all times. Cloud-based systems are used to construct popular systems and store the gathered health information [16]. Numerous applications are offered by such healthcare monitoring platforms. However one tool, for instance, uses analytics to

DOI: rp-9788770040723.063

find individuals with serious cardiac issues from the medical information stored on computers.

Based on the acquired data, medical analytics helps uncover distinctive patterns or trends. Big data medical analytics in healthcare platforms offer practitioners insightful information that aids in choosing the best diagnoses [17]. Medical data analysis can help spot changes in medical trends or foretell the likelihood and likelihood of impending peril. It has been investigated in various systems to use a health platform and widely used mobile technology as an alarm system. These systems, which rely on Internet technology, allow for direct medical professionals to intervene [18]. The utilization of this type of healthcare system has, up until now, not been practical in the context of rural and isolated Indian populations which have low literacy levels, a lack of advanced technologies, limited access to medical facilities, and inconsistent or nonexistent broadband internet. These peoples are also digitally cut off from the rest of the world. This development's main goal is to tackle this issue by putting in place a cheap solution for rural healthcare monitoring and education.

III. Proposed Method

The use of IoT health wearables to gather patient data across various settings is a significant advantage in providing continuous monitoring and effective patient care. The ML classification methods used in constructing the training models enable accurate diagnosis and analysis, leading to better decision-making based on the collected patient data. Furthermore, the program's ability to share patient data with doctors, inpatients, outpatients, and caregivers enhances the quality of care that patients receive [19].

The program's focus on high-quality and secure services makes it an ideal platform for healthcare providers to offer healthcare services to their clients, providing them with accurate and prompt care. This feature could also be useful to researchers and healthcare policymakers, as the accurate and precise data gathered by the program could assist in identifying trends in the management of chronic conditions.

Overall, the PHMF program is a significant development in healthcare that can provide healthcare providers with an efficient way of managing chronic conditions and providing high-quality and secure care for their patients. The program's effectiveness could potentially reduce healthcare costs, improve patient outcomes, and enhance the overall quality of healthcare service delivery.

Wearable technology such as temperature sensors, heart rate monitors, eye lance-based diabetes sensors, and blood pressure monitors are suitable for transmitting real-time data from the human body to an e-health care monitoring system. These wearables can capture essential biometric data that doctors and healthcare providers can use to monitor a patient's health status continuously.

For instance, temperature sensors enable remote monitoring of fever or other temperature-related issues, heart rate monitors enable remote monitoring of heart rate patterns, and blood pressure monitors allow remote monitoring of blood pressure, which is critical for patients with hypertension. Eye lance-based diabetes sensors help monitor blood sugar levels and track insulin injections for diabetic patients remotely.Wearable technology is an important aspect of remote health monitoring, as it allows patients to receive care while reducing the number of visits to healthcare facilities. Healthcare professionals can also take advantage of the data gathered by these wearables to make informed decisions, improve diagnosis, and develop personalized treatment plans for their patients.The use of wearable technology in remote health monitoring is a promising development in healthcare. It enables a continuous flow of biometric data to healthcare providers and physicians, which in turn allows them to diagnose medical conditions early and take prompt action to provide the best possible patient outcomes. [20]. Using IoT architecture withML techniques aims to develop a new application model that provides a better solution and considerable improvement for many discrete health services. The PHMF software is linked to devices for data collecting and patient monitoring. Fig.1 depicts the proposed system design.

Each patient must sign up using a special wearable connected to the Global Positioning System. Wearable technology is practical because the patient may simply carry it with them at all times. These gadgets allow for the tracking of a patient's health status andthe location the patient [21-22]. At regular periods, the admin server will get the collected data. These limited gadgets and IoT applications are mostly managing new issues.

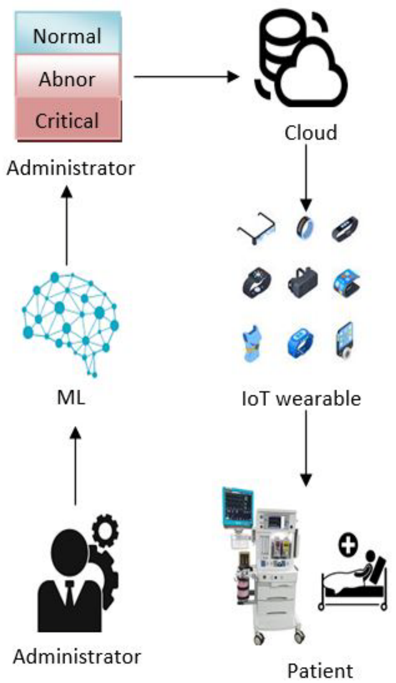

Fig. 1. Proposed Architecture

ML is a computational and statistical methodology that interacts with supervised and unsupervised learning approaches through data mining techniques. Fig. 2 depicts the key ML classification techniques such asK-Nearest

DOI: rp-9788770040723.063

Neighbor (K-NN), Decision tree, Support vector machine (SVM), and Regression algorithms.

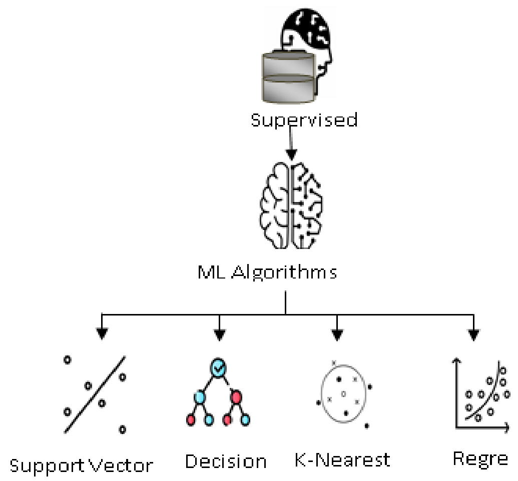

Fig. 2. Proposed ML classification

Currently, one algorithm has been selected by the authors for investigation. SVM recognizes a superior forecast here. The optimal optimization may be achieved by combining regression and classification algorithms. We will use an approach that defines a hyperplane to optimize the separation between the classes using mathematical techniques. plotting the data item in N-dimensional space on the view plane. The representation of data items has a variety of properties when the number "N" is taken into account. Each feature's value is determined by the value of a certain location. Researchers discover the hyperplane that differentiates two classes to be extremely well-equipped and prepared based on the categorization.

TABLE 1.DIABETICS DATASET DESCRIPTION

Items	Normal	Low	Abnormal	Critical
Pregnancies	4<=6	1<+4	7<=9	=>10 above
Glucose	80 mg/dL	120mg/dL<140	140mg/dL<=170	=>170 above
BP	<90mm Hg	70mm Hg<=80	90 mm Hg<=100	=>170mm Hg
Skin Thickness	25<=30	0<=25	40<50	50<=60

A. SVM in data visualization

i). The two classes are the subject of the best discrimination analysis in N-D space.

ii). Increase the space between the data points across all classes.

iii). Finding the margin length and variability of data elements on the hyperplane is its key restriction.

iv). The margin hyperplane may be used to precisely locate neighboring data items and missing values.

v). This could improve class precisely and eliminate certain classification faults.

The hyper lines cannot be used to separate the two classes. Outlier sets can be referred to in situations when the data items belong to a different class that does not control the anomalous sets and the diabetes dataset description is shown in Table 1.

IV. EXPERIMENTAL ANALYSIS

The use of the National Institute of Diabetes dataset on diabetic patients in the PHMF application is a step in the right direction in delivering accurate and personalized care. The use of large datasets such as these is crucial in training machine learning models to enable accurate classification of patients with diabetes. The dataset's inclusion of various age groups, particularly pregnant women, is also important, as gestational diabetes is a common occurrence during pregnancy that can lead to complications if not properly managed. Furthermore, the dataset's class label, which can have values of either 0 or 1 depending on whether the patient has diabetes or not, makes it easy to develop a classification model using supervised learning techniques.

By using the dataset for experimental investigation, the PHMF application can improve the accuracy of its predictive models, thereby enabling more personalized care for diabetic patients. The results obtained from the dataset can enhance the program's decision-making capabilities, leading to more accurate diagnoses, and improved patient management. This can lead to better outcomes for diabetic patients, especially those who may have difficulty accessing medical care due to geographic or socioeconomic factors.

The use of large datasets such as the National Institute of Diabetes dataset within the PHMF application is a significant development in delivering personalized and accurate care for diabetic patients. The dataset's class label and inclusion of pregnant women of different age groups are important features that make it suitable for experimental investigation and classification model development.

TABLE 2.SAMPLE DATA SET

	Pregnancies	Glucose	BP	Skin Thickness	Insulin	BMI	Diabetes	Age	Outcome
0	7	149	73	36	0	33.7	0.629	50	1
1	2	87	67	30	0	26.8	0.355	32	0
2	8	185	65	0	0	23.5	0.677	33	1

To determine if a person has diabetes or not, the SVM algorithm is used on datasets that have been trained on a computer. The likelihood of a specific consequence justifies the age at which a person develops diabetes and any further potential causes. For prediction analysis, the following two primary elements are taken into account: Age and the levels of glucose and insulin in the human body. The report's final result was patterned with two potential hues, such as Blue

DOI: rp-9788770040723.063

and Orange. Fig.3 shows the prediction analysis with age on the x-axis and glucose level on the y-axis. Fig.4 shows the prediction analysis with age on the x-axis and insulin level on the y-axis.

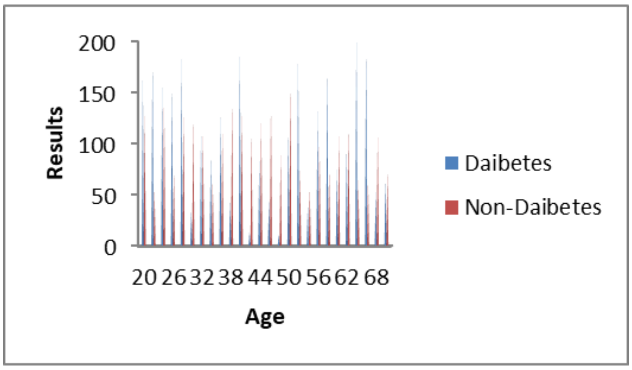

Fig. 3. Prediction analysis with age Vs glucose level

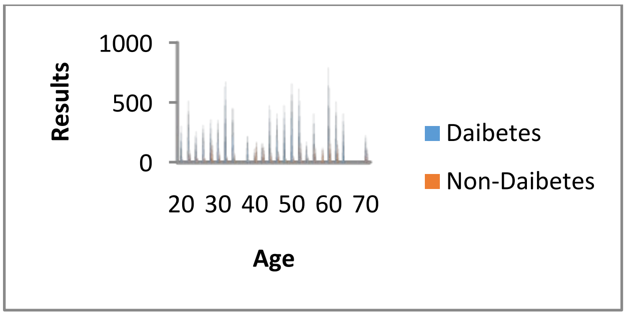

Fig. 4. Prediction analysis with age Vs insulin level

TABLE 3.PERFORMANCE ACCURACY

	Precision	Recall	F1-Score	Support
Diabetes	0.78	0.67	0.72	55
No-Diabetes	0.84	0.91	0.88	100
Micro Avg	0.82	0.80	0.82	155
Macro Avg	0.81	0.78	0.79	155
Weighted Avg	0.82	0.79	0.81	155

According to the performance metrics presented in table 3, the SVM algorithm outperformed other algorithms in the PHMF application in terms of efficiency, with a score of 80.51%. The other algorithms that were tested had the following efficiency scores: Gradient Boosting scored 77.27%, K Neighbour Classifier 71.42%, Decision Tree 70.22%, Random Forest 79.22%, and GNB 76.62%.

It is worth noting that although the SVM algorithm had the highest efficiency score, other algorithms such as Random Forest also performed relatively well, with a difference of only 1.29% compared to SVM.

Overall, the performance metrics presented in table 3 demonstrate the potential of machine learning algorithms such as SVM in delivering personalized and accurate healthcare services. By leveraging large datasets and applying supervised learning techniques, healthcare providers can improve diagnostic accuracy, enhance patient outcomes, and reduce healthcare costs. However, selecting an appropriate algorithm for a particular application requires careful consideration of several factors, including the type of data, the problem domain, and the specific requirements of the system..

V. CONCLUSION

The SMS service-related difficulties faced by PHMF in the provision of health-related services such as daily health alerts, medical appointments, and nutrition recommendations are understandable. However, hospitals can consider modifying PHMF software to provide the best-recommended E-Health services to patients using different communication channels such as emails, phone calls, or social media platforms.By adopting different communication channels, healthcare providers can enhance patient engagement, improve adherence to treatment plans, and achieve better patient outcomes. These channels can also enable remote communication, provide more convenient access to care, and offer personalized treatment options that suit patients' unique needs.

Furthermore, future improvements in the PHMF application can leverage emerging technologies such as artificial intelligence, machine learning, and data analytics to enhance diagnostic accuracy, predictive modeling capabilities, and personalized treatment options. These technologies can also support more effective patient monitoring, early detection of potential health issues, and prompt interventions to improve overall health outcomes. the adoption of different communication channels for the provision of healthcare-related services can potentially enhance patient engagement, improve adherence to treatment plans, and lead to better patient outcomes. Additionally, future improvements in the PHMF application can leverage emerging technologies to enhance diagnostic accuracy and personalized treatment options, leading to better patient outcomes and improved healthcare service delivery. We have gathered a set of diabetes data from web resources for an experimental demonstration of the proposed strategy. The dataset gathered is believed to be the same as the dataset gathered using wearable IoT-based technology. An ML method called SVM was applied to the dataset, and it produced an accurate result. To increase the effectiveness of the proposed approach, we want to collect data from IoT wearable devices and use more ML algorithms in further work.

***Abstract*—In this study, we attempt to identify the emotion levels, such as positive, negative, & neutral feelings, from postings and comments on social networking sites on depression. Social media sites like Facebook and Twitter are becoming effective for helping those in need who require extra care or attention in terms of mental support. They are also utilized for communication and network development among relationships. There are several depressive support groups on Facebook, and they are quite helpful in giving the sufferers mental assistance. In this study, we attempt to formalize the posts and comments on depression into a succinct lexical database and identify the emotion levels from each occurrence. The complete amount of work has been divided into two sections: sentiment analysis and the use of machine learning techniques to examine the capability of extracting sentiment from such a unique category of texts. To determine the sentiment levels, we used the Python textblob module and typical machine learning techniques on the linguistic characteristics. For each of the classifiers, we have calculated the precision, recall, F-measure, accuracy, and ROC values. Random Forest outperformed the other classifiers, successfully classifying 60.54% of the instances. We think that conducting sentiment analysis on a particular class of texts may inspire additional research into how natural language is understood.**

***Keywords*—Sentiment Levels, User Communication, Machine Learning Algorithms. Accuracy Detection Analysis**

I. Introduction

Heterogeneous efficiency for various demographic subgroups is a fundamental barrier to the practical application of mental health surveillance models [1-2]. The training data may not be adequately representative of the population, which may produce this behavior, or some groups may be more difficult to forecast with the same data. In-depth data collection and training regimens can be used to solve the first situation, which has been extensively researched in the machine learning literature [3-6]. The latter situation is frequently more nuanced and challenging to handle. The value of the models is reduced if these performance disparities are not acknowledged and addressed. Particularly, if historically underrepresented people do worse, it can exacerbate disparities already in place, such as the underdiagnosis of depression [7].

Social media refers to websites and applications that have been specifically designed to enable people to distribute little amounts of material quickly, effectively, and in real-time. It has altered the mode we use to travel to and the mode we complete an activity and the ability to exchange photographs, reviews, activities, etc. in real time [8–10]. Shops that employ social media as a crucial component of their advertising strategy typically experience a quantifiable cost. But the key to using social media well is to stop treating it like an extra accessory and instead treat it with the same consideration, appreciation, and interest as the rest ofr advertising and marketing activities [11]. Utilizing various channels to engage with customers and develop r brand, increase revenue, and increase website traffic is what social media marketing entails.

The investigators have spoken about huge data gathered from social media that has been extensively evaluated by research academics and employed as significant to crucial insight into human conduct. [12] discussed how big data, machine learning, and analytics algorithms may be used to monitor social media and identify consumers' perspectives on opulent hotels from beginning to end the new visual data analysis and spin into an enhanced managing brand strategy for comfort hospitality managers. The researchers of [13] gathered data from 8434 startup firms on Twitter and created features based on social media using a machine learning model to predict each firm's level of social media participation [14]. The study's findings indicate that deep learning provides the greatest forecast accuracy for engagement levels. It also indicates that the amount of company-generated tweets, retweets, and likes is what matters most in determining the efficacy of social media marketing practices [15]. Social media users are perceived as contributing to marketing material as a result of the increasing interest in social media and user-generated content on websites like Tube, Facebook, and LinkedIn.Using big data analytics, they examine client perceptions and attitudes towards social media in this article.Related Works

14-year-olds are probably at risk for depression as a strategy to deal with social media or interact with others [16]. This is a widespread fallacy even in developing nations; there are depressed and suicidal persons who for a variety of reasons avoid seeing psychologists [17]. Some people believe they will be laughed at and their standing in

DOI: rp-9788770040723.064

society would decline if they visit a psychologist. They ultimately turned to suicide as a way to deal with their sadness [18]. Numerous deaths due to despair have been reported throughout the globe, and numerous of them posted their final Facebook post. They all shared the same trait, which was that they were all profoundly depressed [19]. If they can recognize their depressive stage before they reach the crucial stage, they may prevent suicide.

It is used to evaluate people's emotions in a variety of circumstances [20-21]. People now utilize social media platforms to express their emotions in their native languages, such as English [22]. The text that individuals publish on social media platforms is what we want to analyze for the sentiment. Many individuals in the world experience depression for a variety of reasons, many people who become drug addicts, many people who are unable to eat, sleep, work, or engage in other activities, etc. Because many of them also commit suicide, many families have lost dear family members [23]. Many individuals can live healthier lives like regular people if it doesn't happen. Language is one way that people may communicate their emotions. Individuals often express their feelings by writing and speaking about how they are feeling daily on social media[24].

It is to identify depression using the brain's volumetric characteristics. There is a chance that characteristics from brain SMRI will multiply [25]. Diagnostic values and volumetric data were looked at. The results show how often it is to spot depression [26]. SMRI volumetric features of diagnosing depression are shown in the output findings. The classification accuracy of the function vector is evaluated using a variety of classifiers, including SVM, Ensemble Learning Encoder, and Components are identified. These are comparable in terms of memory, accuracy, & correctness. In contrast to Naive Bayes' accuracy rate of 89.5%, they achieved a 90% overall accuracy. A motion analysis method for disorganized and grammatically incorrect customer remarks made in Arabic slang was put out in this paper's current Arabic Slang Sentiment Words & Idioms Lexicon, [27-28]. The new language was painstakingly put together from websites for microblogging. Furthermore, to categorize opinions as pleased or dissatisfied, the SVM approach was used with SSWIL.

III. Proposed Methodology

Researchers have a suggested technique that, like any other natural language recognition system, incorporates data gathering, information pre-processing, analysis, extraction, and classification, the use of machine learning algorithms, emotion recognition, and evaluation. Anxiety writings are a specific group of textual data that we have selected for this study. We have explored communities on social media sites like Twitter and Facebook to get this kind of information. Nowadays, individuals use social media as a powerful tool for communication, but they are also using platforms to provide psychological or emotional support via constructive posting. Regarding their efforts, they recently established the "Depression Support Group," "Anxiety Awareness," "Anxiety & Depression Support UK & Ireland," "Cure r Depression," and "Essential Thrombocythemia Support Group" Facebook groups for anxiety. The items and opinions that are related to depression have been carefully divided. To confirm that all of the data we obtained are relevant to depression, we used a psychologist to verify the information we had gathered. Table 1 illustrates the statistical characteristics of our dataset.

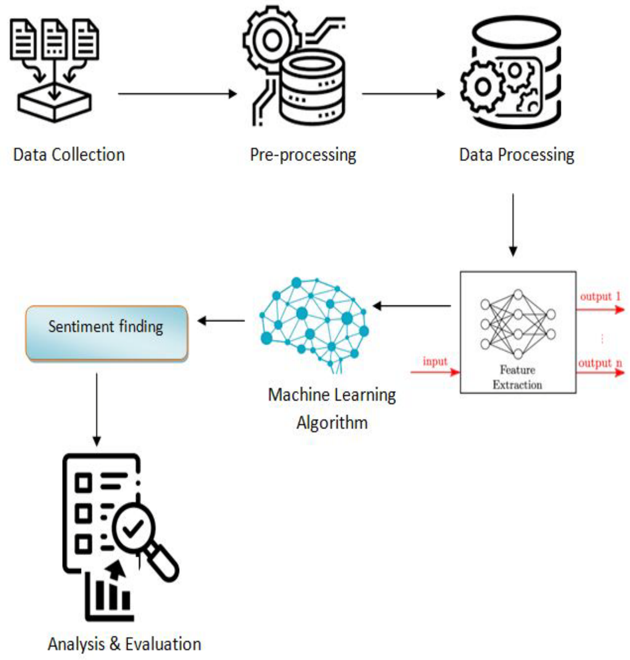

Fig.1. Proposed Methodology

TABLE 1. Overview Of Proposed Approaches

Languages	Wikipedia articles	Training dataset	Evaluation dataset
English	2452	3723	NA
German	2354	NA	3364
Tamil	3562	4785	NA
French	2354	3256	3857
Hindi	2548	NA	3265

TABLE 2. Statistical Properties of the Dataset

Characteristics	Quantity
Data collected size	1021
No. of words	63756
No. of characters	358740
No. of sentences	4407
No. of special characters	2900

Researchers have completed the fundamental pre-processing activities associated with natural reading comprehension, such as data cleansing, as all of the obtained data are in a readable form. Punctuation marks, hashtags, and advertising links have been deleted from the comments and the posts. We have also deleted the HTML entities from promotional postings because they typically contain those elements. As a result, we have left certain marks and special characters in place.

The impartiality and orientation values of each example were extracted using the text blob program after the data had been sanitized. For our dataset, the traditional "V-shape" also appeared. Fig.2 shows that relatively few examples are presented when the polarity values are significantly negative but the subjectivity values are less. It should be noted that

DOI: rp-9788770040723.064

postings with extremely high or extremely low impartiality values do exist. As a result, the scatter plot has a "V shape".

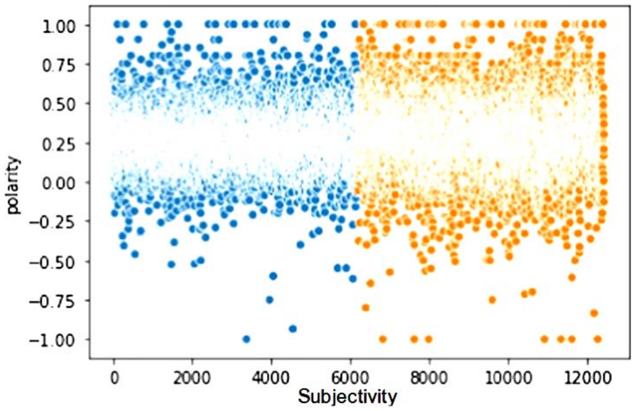

Fig. 2. Subjectivity vs. polarity scatter plot

A. *Feature Extraction*

That process of feature extraction is where this paper makes one of its primary contributions. As opposed to a standard text classification challenge, researchers have retrieved linguistic characteristics at the character, word, and sentence levels. The python NLTK package was used to extract a total of 86 features. They have isolated the special characters and the exclamation point from the 86 linguistic elements. Additionally, we utilized the numbers to determine how these characteristics affected sentiment analysis. These features extracted are immediately input into the training and testing phases of machine learning.10 distinct machine learning models have been used to identify the hierarchical classification issue. The techniques were carefully chosen since they are often utilized in other works of a similar nature. To assess effectiveness, components are identified, and Bayes-based regression and tree-based methods are used.

They have simply relied on the polarization values that were derived throughout the data preprocessing step for sentiment recognition. The inner lexicon collection utilized in the text blob program is quite trustworthy for evaluating the messages from social media or microblogging. Following finishing this phase, the dataset includes cases that are 55.6% positive, 31.2% negative, & 13.2% neutral.

IV. Evaluation and Analysis

Employed the most well-liked measures for performance assessment, including accuracy, ROC, PRC, recall, f-measure, and precision. Efficiency has been regarded as one of the most important measures in the majority of research publications that evaluate classification techniques. We are not presenting the theoretical formula or other characteristics associated with these assessment measures in this study because they are extensively utilized.

A. *Experimental Analysis*

Reliability, ROC, PRC, recall, f-measure, & accuracy were some of the metrics used to gauge success shown in Table 3. In the vast majority of research articles that analyze categorization systems, efficiency has been recognized as one of the most performance metrics. Due to their widespread use, we are not giving the theoretical model or any further features related to these assessment measures in this work.

TABLE 3. Performance Evaluation Metrics

Algorithm Name	Precision	Recall	F-Measure	Accuracy (%)
Naïve Bayes	0.544	0.342	0.333	34.974
Decision Tree	0.509	0.500	0.504	50.035
Random Forest	0.598	0.608	0.548	60.546
Support Vector Machine	0.694	0.577	0.449	56.980
Sequential Minimization Optimization	0.577	0.561	0.718	55.491
Linear Regression	0.522	0.541	0.522	53.83
Proposed System	0.762	0.633	0.713	75.61

Researchers employed a variety of measures to determine the performance, including reliability, ROC, PRC, recall, f-measure, and simplicity shown in Table 4. Productivity has been acknowledged as one of the most important measures in the great majority of research that examines categorization technologies. We are not providing the computational foundation or any more details about these evaluation measures in this study due to their broad use. This sort of outcome demonstrates the data imbalance factors. We employed relatively little data that came from a strong social media environment, the data is unbalanced, which affects the machine learning techniques.

TABLE 4. Statistical Metrics

Models	Kappa	MAE	RMSE	ROC
Naïve Bayes	0.1254	0.4451	0.6598	0.132
Decision Tree	0.1492	0.3470	0.5921	0.143
Random Forest	0.3241	0.3509	0.4192	0.242
Support Vector Machine	0.0677	0.2831	0.5301	0.158
Sequential Minimization Optimization	0.135	0.3446	0.4452	0.112
Linear Regression	0.1242	0.3357	0.4481	0.163
Proposed System	0.0149	0.3856	0.441	0.042

Fig.3 displays the Matthews linear regression data. The Algorithm for Random Forests produces the MCC value with the highest MCC.

DOI: rp-9788770040723.064

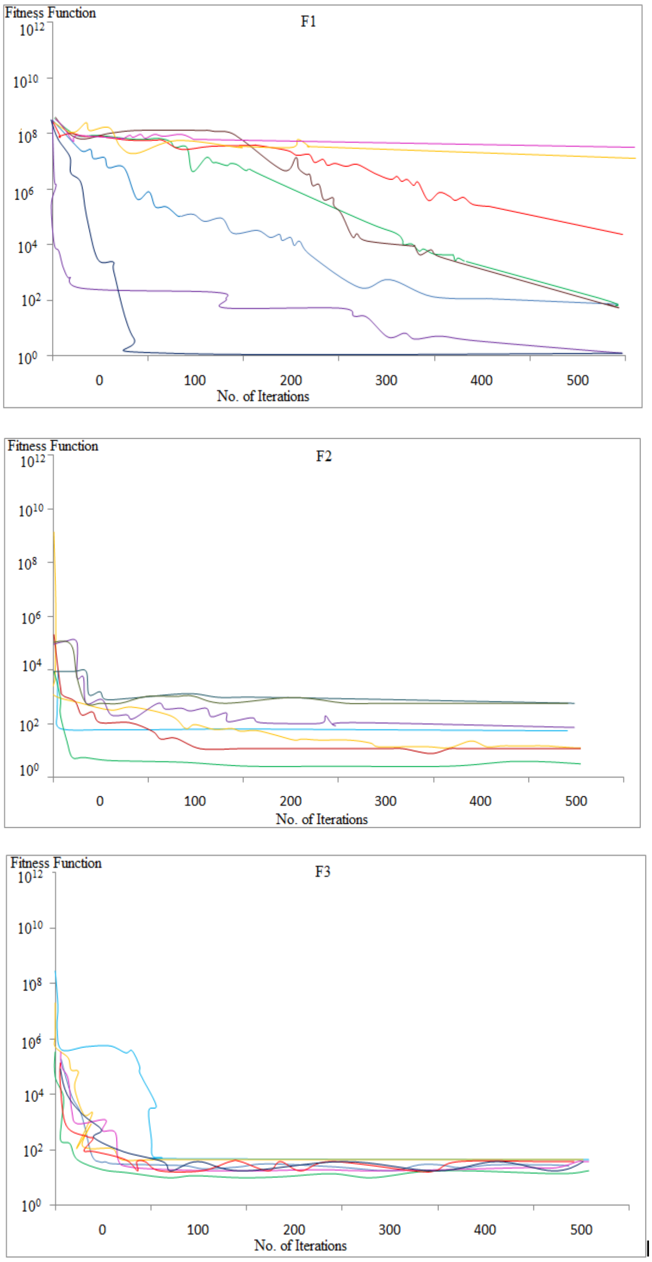

Fig. 4. Comparison of F1-F3 convergence score

The lowest Friedman mean rank across testbed suit programs. As a result, it receives the highest overall score for such functions. Fig.4 depicts the best convergence curves for the implemented methods.

V. Conclusion

Throughout this study, researchers developed an approach for using linguistic elements collected from comments on social media or postings on melancholy. It is exceedingly difficult to develop classifiers that perform better since social networking and microblogging sites use very casual language. We have used 10 classification techniques to investigate the effectiveness of various category classifications. The research methodology part contains the response to the three research problems that were defined. The most effective ML classifier is Random Forest, which has a decent chance of using textual data connected to depression for sentiment analysis.

***Abstract*—The technological transformation has helped to simplify formerly time-consuming tasks. In this study, we will look at neural network-based intrusion detection systems in hospital management systems. This paper presents an intrusion-identifying system based on NN modeling. A hospital managing system (HMS) is a computer-based system that assists in controlling the healthcare data in the way of the effective ending of healthcare providers' jobs. An intrusion detection system (IDS) is software that identifies malicious activity on a network. A neural network (NN) is a set of algorithms that aims to determine interactions in a data set using a process that resembles how the human brain works, and the HMS is functioned in this proposed system using these NNs. In this research, K-Means algorithm is implemented to identify the intrusion in the hospital management System.**

Keywords—***Hospital Management System (HMS), Intrusion Detection System (IDS), Neural Network (NN), K-Means Algorithm***

I. Introduction

A neural network (NN) is a type of algorithmic learning system that employs a network of functions to comprehend and translate a data input in one form into an expected outcome, typically in another form. The neural network concept was inspired by human neuroscience and the way neurons in the human brain work with each other to understand input from human senses. In ML algorithms, NNs are one of many techniques and methodologies. The NN can be used as a component in a variety of machine learning algorithms to convert complex information inputs into a space that the computer understands. An intrusion detection system (IDS) is software that detects malicious network activity [1-2].An HMS is a computerized model which assists in the managing of healthcare data and effective ending of healthcare providers' jobs. They manage data for all departments of healthcare, including clinical, finance, research lab, outpatient care, primary care, operating room, equipment, nursing, pharmacy, radiation oncology, pathology, and so on. HMS entered the hospital management scene in the 60s and has since evolved and synchronized with technology while modernizing healthcare facilities [3]. In today's world, healthcare management begins in the hands of patients via their cell devices and facilitates the patient's needs.

The incorporation of IoT systems into healthcare applications has made it feasible to remotely monitor the information pertaining to patients and to deliver appropriate diagnoses whenever it is required. The provision of high-security features that can ensure the accuracy and confidentiality of patients' data, on the other hand, is a considerable difficulty. Any change to the data might have an effect on the care that the patients get, which could result in human fatalities in an emergency situation [4-5]. When it comes to providing an efficient solution for intrusion detection, machine learning has the potential to live up to its potential as a viable option due to the high dimensionality and conspicuous dynamicity of the data involved in such systems. On the other hand, the majority of the currently available healthcare intrusion detection systems construct their datasets by using either network flow measurements or the biometric data of patients [6-7]. The purpose of this research is to demonstrate that using a combination of network metrics and biometric measurements as features yields superior results than use either one of the two kinds of features alone [8]. A real-time Enhanced Healthcare Monitoring System (EHMS) testbed has been developed by our team. This testbed monitors the biometrics of patients and gathers network traffic measurements. The data that is being watched is then transferred to a remote server so that further diagnostic and treatment choices may be made [9-10].

II. Literature Review

Ashraf, Eman, et al. (2022) and Sivakumar P (2015) proposed FIDChain IDS using lightweight Artificial Neural Network in learning means to guarantee to care of health information secured in managing preservation with the advancements of blockchain platform that enable the ledge that is shared for gathering the weights in local and transmitting the developed weights in global after taking an average, that restricts poisoning attacks and delivers complete transparency at the same time immutability in a distributed system according to the negligibility.Laxminarayana, Nikhil, et al. (2022), Karnan B et al (2022), and Latchoumi TP et al (2022) investigated the IDS is trained using NNs and the concepts of quantum physics. It is suggested to use a hybrid classical-quantum neural architecture with a quantum-aided activation

DOI: rp-9788770040723.065

function, It uses less architectural memory than traditional systems while yet successfully capturing patterns in the dataset [11]. On the well-known KDD99 dataset, the experimental results are shown, and our approach is contrasted with various traditional models. Begli et al. (2022) and Monica.M et. al. (2022) proposed a secure remote medical system architecture. We aim to provide a secure framework for remote healthcare systems that keeps the system's data as safe as possible from common network affection such as the Denial of supplying and User Root attacks [12]. To accomplish this, they have created an IDS based on the ML algorithms, SVM. Following the implementation of the proposed method, the evaluation parameters of IDS' layered architecture demonstrate the efficacy of our proposed framework.Awotunde, et al. (2021), Vemuri et al (2021), and Buvana M et al (2021) presented a study that offers a Deep Learning based detection of intrusion in the form of a framework for the Internet of Things with hybrid regulations based on the feature selection to prepare and analyze the data captured from TCP data packets [13]. The training procedure has been carried out using a deep feedforward NN model and a hybrid rule-based feature selection approach. Two network datasets, NSL-KDD and UNSW-NB15, were used to test the proposed scheme. He, Daojing, et al. (2019) and Sridaran K et. al. (2018) investigated system security flaws and introduced a new intrusion detection system based on a piled autoencoder. They performed the results, and the status demonstrates that the model and its method are effective [14].

He, Daojing, et al. (2019) proposed a stacked autoencoder and a DNN-based intrusion detection system. To reduce feature width, the layered AE learns the features from the input network record unsupervised. The DNN is then trained and supervised to extract DL features according to the classifier [15]. The proposed system has two latent layers in the stacked AE and two or three layers in the DNN, with every layer having an entirely in-touch layer, a batch with normalization, and dropout. Biswas et al. (2019) proposed a cloud service delivery model based on a single window, whereby a smart card acts as a single entry point to several electronic services, including banking, healthcare, employment, and so on.The authors of this paper focused on the IDS of the cloud service model throughout cloud banking transactions to identify and mitigate unauthorized access [16]. Alzahrani et al. (2021) performed research that illustrates the deployment of ML models for traffic analysis to identify the malicious protocol behavior as part of the Software Defined Network controller's NIDS. To demonstrate attack detection, three classical tools that are ML-based tree techniques like Decision Tree classifier, Random Forest Classifier, and Boosting algorithm, are used. The NSL-KDD data info is being used for both the analysis of the dataset; it is a dataset for several options that are laid in the cutting-edge NIDS approaches. Various advanced techniques that are used for preprocessing are applied to the data for obtaining a stable form of data, yielding exceptional results when compared to pre-defined systems. Nandy, Sudarshan, et al. (2021) suggested an Empirical Intelligent Agent based on a cutting-edge Swarm-Neural Network (Swarm-NN) technique to detect attackers in the edge-centric IoMT framework. The major objectives of the suggested technique are to identify assaults during data transmission across a network and to perform a more accurate and efficient analysis of health data at the network edge [17-18].

III. PROPOSED WORK

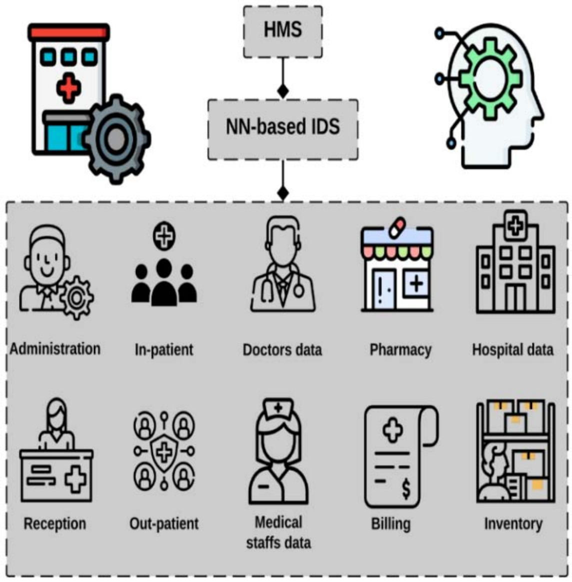

Fig.1. Illustration of NN-based IDS in HMS

Fig.1 Illustrates the Neural Network-based Intrusion Detection System in Hospital Management System. Malicious activity includes the distribution of viruses and other operations that disrupt the ability of others to effectively use networks, systems, services, software, or equipment [19]. A software intrusion detection system (IDS) detects malicious network activity. Because of the services it provides, an IPS is also known as an intrusion detection and prevention system. An IDS monitors network traffic. It works by detecting malicious network activity by analyzing intrusion signatures, generic behavior, and heuristic methods, and then drops the packet and blocks the specific traffic [20]. When such an event happens, the administrator is also notified. The proposed intrusion detection system, which is based on a neural network model, manages healthcare information and ensures that healthcare providers' jobs are completed effectively. The proposed system effectively manages data for all clinical, financial, research lab, outpatient care, primary care, operating room, equipment, nursing, pharmacy, radiation oncology, pathology, and other departments of healthcare [21].

Let ρ_j signify the required to charge up the required stations and can charge those pre-fixed equipment utilization ratio $\rho_j = (\lambda_j / y_j \mu_j)$ According to the conventional slight Equation the waiting period for such $h^{th}\ TC$ and trying to charge point j is represented by Equation (1).

$$g_{ih}^{H} = \sum_{j=1}^{y} \frac{(x_j\rho_j)^{t_j}\rho_j}{\lambda_j y_j!\,(1-\rho_j)^2 \varphi_{E_j}} \left(\sum_{m=0}^{x_i-1} \frac{(y_j\rho_j)^m}{m!} + \frac{(y_j\rho_j)^{y_j}}{t_j!\,(1-\rho_j)} \right)^{-1} H_{jh} \times h^{th}TC \quad (1)$$

DOI: rp-9788770040723.065

The charging k-means method which is always used to detect the intrusion for the h^{th} TC at endpoint j is as shown in Equation (2).

$$g_{jh}^{H} = \sum_{j=1}^{h} \frac{T_{min} - T_{jh}^{h}}{m_g} \tag{2}$$

K-Means Algorithms to enhance **e**nergy consumption is influenced not just by the maintenance of hospitality and various standard servers. Whenever a TC with a charge travels at B_C transportation distance ŋkm/gc on a flat, the ability to run power $E(B_c, c)$ is represented by Equation (3).

$$E(B_c, c) = \frac{\left((x+B_c).h.\int c+\left(S_m.Z_j.c^3/22.56\right)\right)}{3700\,\text{ŋkm}/gc} \tag{3}$$

The *K-Means Algorithms assess and detection of diabetes in healthcare* and h_{ij} the receiver needs to be one of a kind from the alternative whereas at the same time the operator can certainly be connected in the form of neural networks and to the desired tool without dispute. Transition pace is $m_j - \overline{m}$is classed into-the-spot transition and time change. Space-time transformation, inclusive of the preceding NG, takes a while to comply with the series represented within Equation (4).

$$NG = c_{ij}(s) \sum_{i=1}^{y} \frac{y \sum_{i=1}^{y} \sum_{j=1}^{y} + \sum h_{ij}(m_i - \overline{m})(m_j - \overline{m})}{\sum_{i=1}^{y} \sum_{j=1}^{y} + h_{ij}(m - \overline{m})^2} \tag{4}$$

The following Equation (5) represents the detections of intrusion based extrude within the transition time.

$$NG = c_{ij}(s) \sum \frac{y \sum_{i=1}^{y} \sum_{j\neq 1}^{y} + h_{ij}(m_i - \overline{m})(m_j - \overline{m})}{C^2 \sum_{i=1}^{y} \times \sum_{j=1}^{y} h_{ij}} \tag{5}$$

IV. Experimental Results

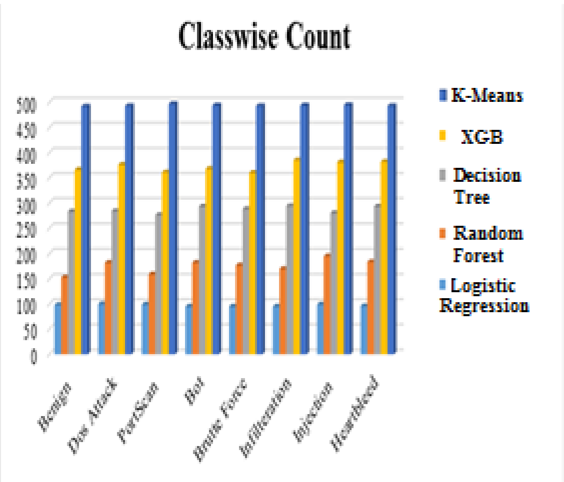

Fig.2. Performance AnalysisK-Means Algorithms to enhance the performance under the Neural Network for Intrusion Detection

The model Swarm-Neural Network strategy is tested using a real-time privacy dataset, the ToN-IoT information, which collects OS, and Telemetry for Internet of Things applications and analyses the performance of normal models that are deployed in classification rule using various parameters. The results show that the model Swarm-Neural Network strategy outperforms the ToN-IoT dataset in terms of accuracy. SGM is a novel class imbalance of technology managing for high-scale datasets proposed by Zhang, Hongpo, et al. (2020), which integrates Based on the Gaussian Mixture Model, the Synthetic Minority Over-Sampling Technique with under is used for clustering. They concluded that SGM-CNN outperforms intrusion detection methods and is a good option for unbalanced intrusion detection. The numerical results are presented in Table 1 as below.

TABLE 1.Comparison Result Analysis for the Existing System

Algorithm	Detection of intrusion in healthcare Training (%)	Detection of intrusion in healthcare Testing (%)	Overall Accuracy (%)
K-means Algorithm	95.63	91.78	97.67
Existing Method: Optimization Algorithm	90.98	89.87	92.98

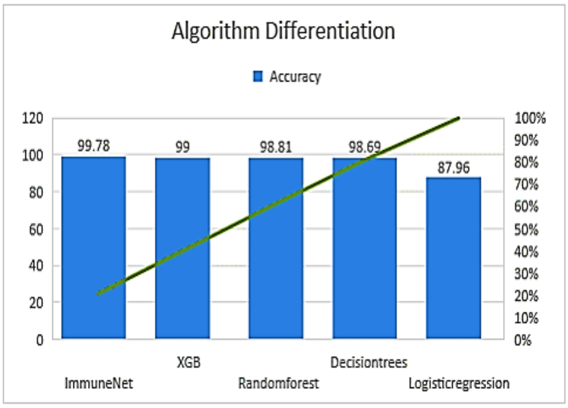

Fig.3. Accuracy Analysis based on different algorithms

Fig.3 represents the accuracy evaluation in detecting the intrusion in hospital environment and the results show that the proposed K-Means algorithm has obtained the highest accuracy in intrusion detection in the hospital data management system.

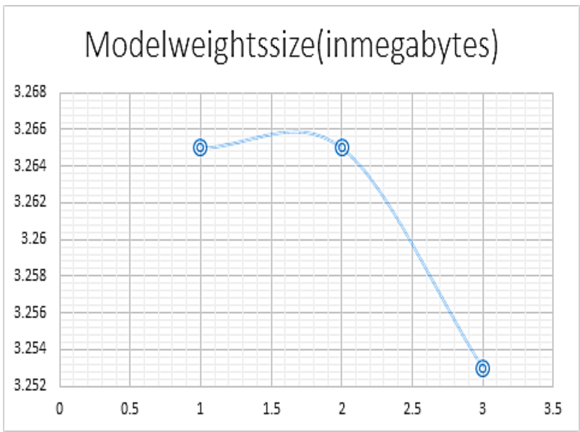

Fig.4. Analysis based on Model Weight

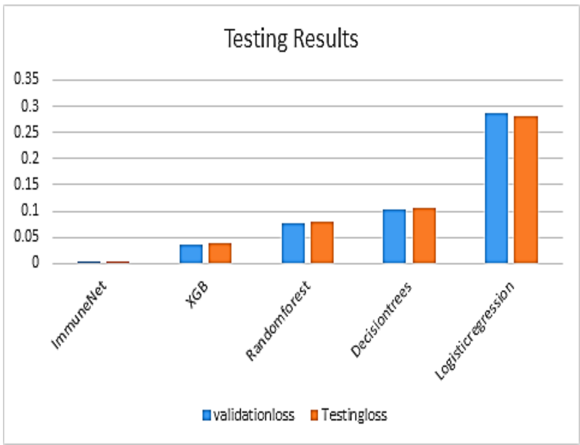

Fig.5. Analysis based on the Testing Results of the model

Fig.4 and Fig. 5 indicates the analysis of the proposed system based on the model weight and testing results evaluation with the existing system respectively. In the research, the existing system considered for analysis are XGB, Random Forest, Decision Tree, and Logistic Regression respectively. In the considered parameters for evaluation, the proposed K-Means have achieved highest performance than the existing models.

V. Conclusion

HMS was developed to address the difficulties associated with managing all of the paperwork associated with each patient associated with various departments of hospitalization while maintaining confidentiality. HMS allows you to manage all of your paperwork in one place, which saves you time organizing and analyzing the patient framework. Hospital Management System performs a differential tasks, which include maintaining patient's medical records, collecting contact info, managing appointment details, tracking bill payments, details of insurance, and so on.

***Abstract*—A comprehensive Supply Chain Management (SCM) solution is designed to improve the inventory management system and lower the material management costs of medical items in the healthcare industry. Hospitals, a wholesaler, and medical supply firms make up the supply chain in this study. First, the system requirements for effective SCM hospitals and their business activities to increase the effectiveness of material handling, Vendor Managed Inventory (VMI) is the key application of SCMembraced and put into practice. For the departments of pharmaceuticals and place orders, an online procurement system has also been built. Additionally, real-time information exchange capabilities are offered to improve the management of medical inventories. This created SCM system helps hospitals to enhance the purchasing procedures including inventory management of medical supplies, which results in a more than 30% reduction in total inventories. By information exchange with clinics, the wholesaler may get more precise and up-to-date data on the inventory levels including drug usage rates of hospitals, allowing it to estimate demand more correctly. This allows for the timely and efficient supply of necessary goods. The proposed method has greatly reduced the overall distribution network cost of medical items.**

Keywords—Healthcare, Supply Chain Management, Material Handling, Medicals, Intelligent Marketing

I. Introduction

Patients are becoming increasingly inquisitive and worried about the availability of healthcare services as a result of the emergence of global competition in the healthcare sector [1-2]. The increase of the senior citizen population and the growing emphasis on health have significantly enhanced general population health requirements and the spread of better lifestyles [3]. The residential industry, particularly healthcare services, has been impacted by the recent expansion in the worldwide competitive service environment. As a result of the rising rivalry between hospitals daily encouraging patients to make the best decision when choosing any hospital, healthcare associations have started to emphasize the better quality of healthcare services [4-6]. Since it is the most important factor for service providers to succeed, service quality needs to be greatly improved and accurately monitored.

Among the few issues in the research on a marketing strategy that has garnered extensive academic attention over the past three decades is the quality of services and its results [7]. It has become increasingly difficult for researchers, hospital administrators, government policymakers, and therapeutic professionals to meet patient needs, which also contributes to satisfaction and retention. Even so, it necessitates higher expenditures to attract new patients rather than to keep hold of current patients [8–10]. As a result, there is increased pressure on the supply side of the healthcare system. One of the key components of a successful business is customer loyalty, which can only be created and maintained by offering higher-quality services that increase customer pleasure. Such enhanced capabilities are all needed for efficient distribution and management practices [11].

Private providers that are not supported by the government are more focused on making a profit than providing high-quality treatment, which causes patients to seek out private care only when they believe it would be more effective and have superior facilities [12]. The current study fills this vacuum by investigating whether variables if any, influence patients to select private healthcare over public ones if they prefer to go to private clinics [13]. Studies have also shown that people only choose private hospitals when they are dissatisfied with the quality of care they receive from public healthcare providers. They force clients to spend more dollars to receive the required level of service [14]. Paying more on treatment options, clients are becoming more inquisitive & expecting supplemental facilities to receive the quality of services above their anticipations, as well as purely any instance of discontentment manages to pressure them to continue moving towards other competing companies, clients now request accurate and complete data before actually utilizing any type of service by a specific healthcare association [15]

As a result, the management of all service organizations places considerable importance on the service quality arrangement, and hospitals should pay particular attention to providing excellent medical care as well as quality support to their customers [16]. From the discussions preceding, it is clear that it has always been essential—and it still is—for

DOI: rp-9788770040723.066

vendors to create and sustain satisfaction among customers by providing high-quality products and extensive medical therapies through a better knowledge of service quality as defined by the consumers [17]. This would only be feasible if service providers learned about and understood the perceptions and views of their clients. The current study thus tends to concentrate on patients' perceptions of the healthcare services provided [18]. The links between quality of service, shopping enjoyment, and commitment in various service industries have been the subject of numerous empirical research. However, the present study focuses on the need to improve the circumstances of the medical quality of services provided by clinics in the private industry.

A supply chain is an organization of producers, transporters, merchants, and users made up of raw material suppliers, as shown in Figure 1.

II. Related Works

Data transmission is a crucial component of SCM. Programmes like JIT, CRP, & QR in retail rely on the supply chain being informed about production, scheduling, and shipments [19–22]. Releasing intelligence enhances supply chain coordination, enables more effective material flow management, and lowers production costs [23]. By enabling the integration of disparate information management, component-based software technologies and XML technologies enhance information sharing. An effective medical SCM system has been created and improved in this study to improve inventory tracking and save material processing expenses [24-25]. Clinics, wholesalers, and leading healthcare firms make up the system in this study. The cooperation between a medical distributor as well as several medical centers of a medical center is the main subject of this study.

First, we looked at the requirement specification for efficient circulation management and inventory monitoring in clinics and examined their internal operations [26-27]. VMI, one of the key SCM systems, has been implemented for managing hospital medication warehouses to satisfy those criteria [28]. Additionally, a CAO system, or electronic procurement framework, is created for the departments that make purchases and utilize pharmaceuticals. Researchers have determined that a vital element in completely attaining the intended aim is information exchange through solid cooperation involving clinics as well as wholesalers [29-30]. Clinics may enhance their pharmaceutical product stock management and purchasing procedures thanks to the established SCM system. To more correctly estimate demand and ensure that necessary items are delivered on time and under budget, the wholesaler can estimate the future by exchanging information with hospitals to obtain precise and up-to-date data regarding inventory conditions and consumption of drug volumes

III. Proposed Method

A. SCM in Healthcare

A supply chain is an organization of producerstransporters, merchants, and users made up of raw materialsuppliers, as shown in Fig.1.

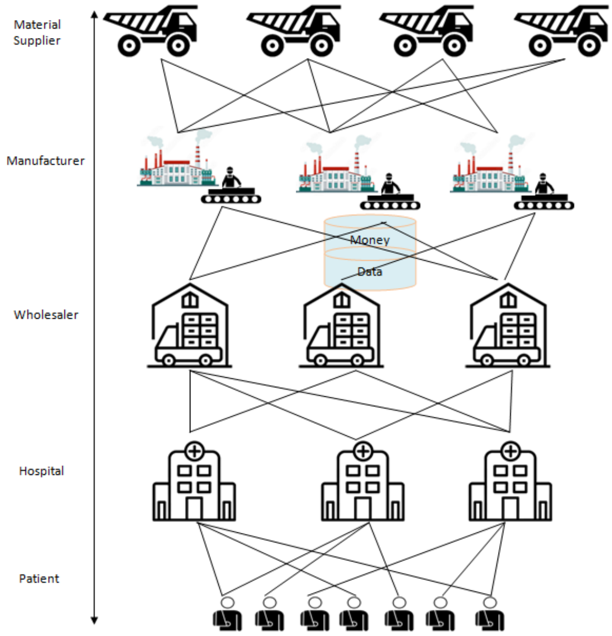

Fig. 1. Composition of healthcare SCM

As seen in Fig.1, a distribution network is a group of manufacturers, carriers, retailers, and consumers made up of raw material suppliers. Commodity management processes may be enhanced by connecting supply chain elements and regulating the movements of commodities, data, and financing in an integrative manner with the use of an SCM system.

B. System requirements

Particularly, medical therapy is crucial to patient care in hospital settings. Following a doctor's precise diagnosis, the patient should receive the best medications at the right time. Based on medical expertise and a fundamental understanding of material management, medicinal items should be maintained well. As circumstances for drug preservation and usage patterns evolved, the legitimacy and safety of medications became increasingly crucial. There are an increasing variety of expensive medicine kinds being employed in medical settings. More specialized physical distribution and effective supply chain connectivity are needed as a consequence of the shifts in the healthcare environments.

Due to hospitals lacking an adequate inventory management system, we had several issues. Before implementing the SCM system, the medical center's ability to share information with the wholesaler was highly limited, which resulted in a high number of emergency orders and average inventory levels. Hospital ordering procedures were also carried out according to general principles. We have examined the following system requirements to design an integrated SCM system that would optimize the material handling of medical items and address these issues.

C. Effective Inventory Control

Hospital inventory control can be enhanced with the use of a suitable classification scheme. Without a categorization system and uniform product control, managing all the

DOI: rp-9788770040723.066

medicinal items in hospitals is exceedingly inefficient. The ABC inventory control system may be used to classify the items according to their attributes and importance. Because there are several product categories and they vary in importance, discriminating inventory control and ordering strategies should be used. The SCM system decreases user involvement and order processing time through intelligent order management. To improve material handling in warehouses, barcode technology should be used. Although RFID technology may be used to identify items, we have not adopted it because of the technology's infancy. To increase the effectiveness of material handling, hospital warehouse layout planning must be optimized, and the FCFS method for distributing medications is also necessary.

D. SCM System Architecture

Fig.2 displays the general design of the created system. Wards, clinical departments, special dispensaries, inpatient pharmacies, and outpatient pharmacies are just a few examples of departments that request the materials they need, which are subsequently transported from the central warehouse to the departments that requested them.Information about orders, shipping document verification, and daily medication consumption is sent from HIS to the wholesaler's ERP system. Documents about invoices, tax statements, and medicine prices are moved in the reverse direction.

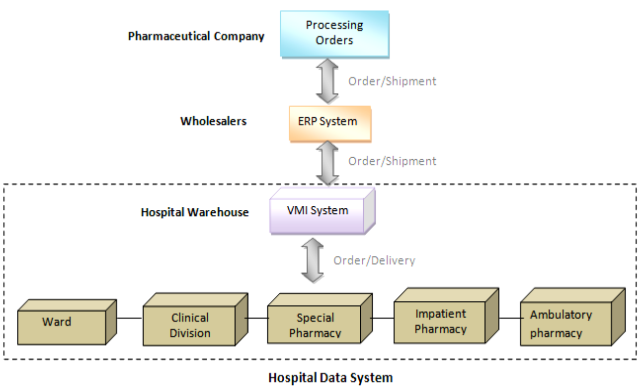

Fig. 2. Architecture SCM system

IV. IMPLEMENTATION

The SCM system had several issues at the time of deployment, including functional and data mistakes, which necessitated ongoing system improvement and modification. Using the Microsoft.NET framework and the C# programming language, we created the SCM applications. C# is a straightforward, contemporary, object-oriented, and type-safe programming language that blends the raw power of C and C++ with the high productivity of rapid application development languages. Two significant application programmes created to integrate the supply chain are described in this section. Each department that uses medications uses the first software, which includes features like "Environment configuration," "Sending document," "Receiving document," and "Receiving delivery order document."With the help of this application, orders may be processed online, and information about hospital warehouse inventory levels and code lists for medical supplies can be shared.

The application displays a list of prepared order papers under the "Sending document" menu. The application offers suggested order quantities for each item when creating an electronic order document, allowing for a quick compilation of the order document. A variety of code lists for medical items, including medication codes, EDI code lists, manufacturer's code lists, barcode lists, and ingredient code lists, are provided under the 'Receiving document' page for hospital users to use. With double the chosen line or using the "Receive" button, one may choose a part of the budget to receive and get the data.

The wholesalers create the delivery document after receiving the hospital's order and completing the delivery. Delivery order papers created by the wholesaler are displayed on the "Receiving delivery order document" page. By double-clicking the chosen line in the data list or depressing the "Receive" button, one can choose a line to receive and obtain the delivery order document. The VMI application software is the second crucial SCM system application programme. Using the VMI application as detailed in Table 1, domain experts delegated from the wholesaler administer the hospital warehouse

TABLE 1.FUNCTIONS OF THE VMI APPLICATION

VMI Function	**Major Roles**
Management of product delivery and receipt	*Every department's control over delivery and reception *Management over the delivery & receipt of goods shipped from the wholesaler
Management of item receipt & delivery information	*Management of item receipt & delivery history information *Inventory management such as physical review of inventory and closing
Management of the delivery request's status	*Tracking the progress of the delivery requests from each department
Base data Management	*Setting up base information needed for warehouse management
Configuration	* Configuring the environmental parameters

A. Benefits of the System

A hospital system made up of eight university institutions has adopted the medical SCM system described in this study. Due to a significant shift in the workers' work processes and a little amount of system instability, there was initially tremendous opposition to the new SCM system. Given that an SCM system comprises several players from numerous companies, collaboration/partnership across organizations is a crucial component of putting the system into place. They have accomplished the intended goals through ongoing system improvement and training. Following the requirement analysis of the SCM system. Following is a summary of some of the main advantages of the SCM system, which come from the effective application of the system criteria. Second, the sharing of information systems built on a solid collaboration has enabled semantic interoperability and improved supply chain monitoring.

DOI: rp-9788770040723.066

Online ordering with electronic documents provide quick order processing and mistake reduction as opposed to exchanging paper papers via mail or fax. Additionally, the wholesaler has access to data on medicine consumption in hospitals, enabling them to maintain the hospital warehouse's stock. Additionally, institutions have access to data supplied by the wholesalers, such as a listing of contractual items, pricing history, details on prescription treatments, and health codes, as needed.

Third, the use of numerous SCM solutions has substantially enhanced the material handling of hospitals. Based on the categories of things, discriminating management strategies are used to control the inventory of the products. Although it frequently happens that the inventory quantity of goods in hospital information systems does not match the actual number of objects, the discrepancy should be kept to a minimum and the information system's dependability should be increased. The SCM is being implemented at the medical facility with much effort, which has greatly increased the information system's dependability. Hospital ordering procedures are made simpler by providing each department using pharmaceuticals with calculated order quantities to restock products. Figure 6 summarizes the output. Consecutive reading, together with writing operations, produces rapid condensed versions of three peaks. Therefore, the storage requires only a few dozen peaks at one time. On cloud storage, spontaneous read/write operations were incredibly intensive. Cloud drivers appear to be the bottleneck as almost all activities have been researched in Fig.3, Fig.4, Fig.5 and Fig.6.

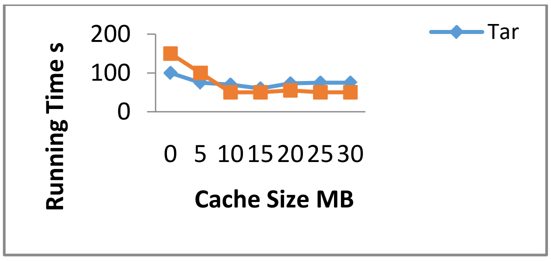

Fig. 3. Target

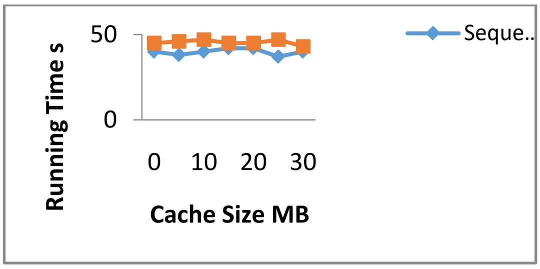

Fig. 4. Sequence

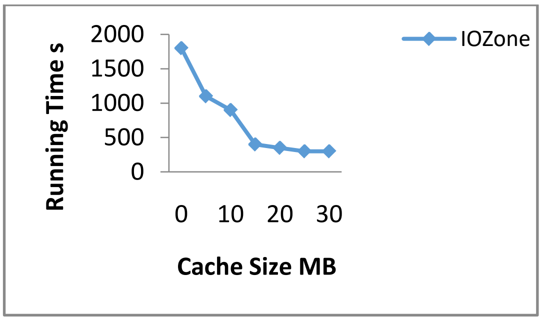

Fig. 5. IOZone

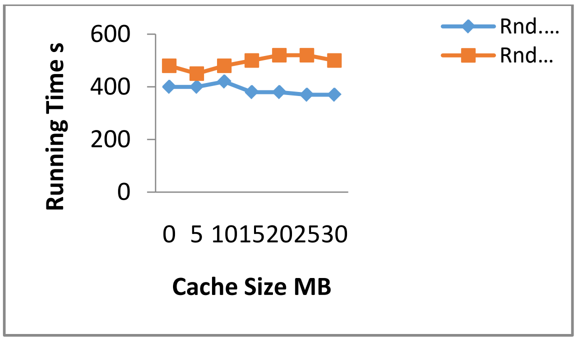

Fig. 6. Cache size workload performance measure

The established system must be regularly evaluated and improved to maintain and optimize the main benefits mentioned above. Collaboration between partners and information exchange in the supply chain are the most important components of a successfully integrated supply chain management system installation. As a result, the wholesaler and the hospitals should promptly submit the information required for supply chain planning. In particular, ongoing information from hospitals, where medical supplies are used and associated data are generated, including drug consumption volume and inventory status, is required.

III. Conclusion

We have created a computer-aided electronic ordering system, effective and efficient information exchange systems, and specialized inventory management, known as VMI. The created SCM system enhances hospital material handling while lowering inventory management expenses and, eventually, raising patient care standards. To increase the overall supply chain's efficiency, several measures are still needed. Medical producers should take part in this sort of cooperative activity to integrate the complete medical supply chain. The manufacturers' assistance was crucial throughout the implementation of the SCM suggested in this study. To fully enjoy the advantages of supply chain integration, all parties in the chain should exchange information. Guidelines for information transmission wirelessly must be defined and approved to expand the advantages discussed in this work.

Abstract—Traditional farming methods are becoming incapable of keeping up with global population growth. As a result, innovative farming ideas are desperately necessary to meet the food needs of a growing population. Intelligent farming systems based on sensor networks with self-organizing algorithms have gained popularity in recent years as a means of increasing agricultural production. In this study, we will use sensor networks with self-organizing algorithms to boost agricultural productivity. Finally, the paper describes the future applications of appropriate technology in agricultural production.

Keywords—Sensor Networks, Self-Organizing Algorithm, Agricultural Productivity.

I. Introduction

The ratio of agricultural outputs to inputs is used to calculate agricultural productivity. While individual products are typically measured by weight, which is referred to as crop yield, the variety of products makes evaluating overall agricultural production difficult. As a result, agricultural productivity is generally measured as the market value of the finished product. This productivity can be compared to a variety of inputs, including labor and land. These types of comparisons are known as partial measures of productivity. Agricultural productivity is the amount of output generated with a given amount of inputs. Long-term productivity growth is a result of improvements in farmer productivity efficiency and technological advancement [1]. A sensor network is a collection of sensors that monitor data in different locations and send it to a centralized location for backups, observation, and analysis. Wireless sensor networks are networks of sensors that are spatial and temporal dispersed and dedicated to monitoring and recording the physical environmental parameters and transmitting the collected information to a data location. Temperature, noise, pollution levels, humidity, and wind can all be measured by WSNs. Fig.1 illustrates the self-organizing map algorithm.

In general, monthly and annual meteorological statistics provide very rough information about respective weather factors. These statistics do not substantially reflect the overall phenomenon of weather features during a certain period, and they do not give any characteristics on the temporal and sequential distribution of repetition and alteration trends. Instead, these statistics provide very general information [2-3].

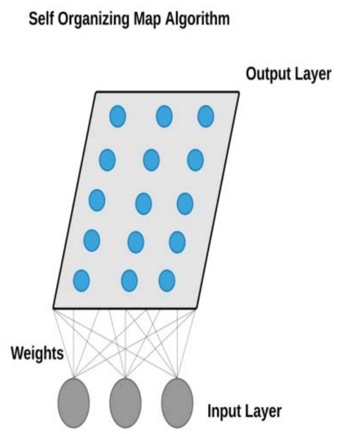

Fig.1 Self-Organizing Map Algorithm

The status of the atmospheric circulation in the surrounding area is used to produce predictions of the weather. Both of these sorts of information are often utilised by farmers as reference guides for crop cultivation; yet, it is difficult for farmers to forecast and comprehend exactly what meteorological phenomena and characteristics may possibly occur within a certain time range. Therefore, the purpose of this research was to use data-mining techniques to discover/induce the annual pattern and distribution of weather types and features of a region based on historical meteorological data, including their occurrence time, frequency, continuity, and intensity, in order to provide agricultural operationists with the ability to anticipate the occurrences and trends of weather types and features during each specified period for the purpose of engaging in appropriate cultivation tasks in advance. SOA makes it easier to provide compound services that encompass the whole of a client's operations; in this context, a customer may be either a citizen or an organisation [4-5]. Existing systems have difficulties integrating the data from the many cloud servers because of these problems. Insufficient

DOI: rp-9788770040723.067

agricultural infrastructure and support facilities, Inadequate ability on the part of institutions to provide services tailored to the needs of farmers due to the farmers' lack of information about appropriate farming procedures, Agricultural content development and its up gradations [6-8].

II. LITERATURE REVIEW

Mohan et al. (2018) proposed a SOM in conjunction with LDA.Self Organizing Map strategy is an excellent dimensionality reduction strategy for emphasizing the self-arranging outline. The dimensionality lowered data is used to predict climate for a reasonable solution after reducing the measurement [9]. The experimental results reveal that the improved approach outperformed existing methods in terms of climate and crop prediction accuracy. Hidalgo et al. (2021) and Sivakumar P (2015) suggested an unsupervised methodology based on Kohonen self-organized maps for reducing the dimensionality of hyperspectral images. This paper's results are based on an RBF classifier. In comparison to other popular algorithms, the results indicate the reduction of dimensionality methodology based on the maps that are always being self-organized in an effective system [10]. This is due to maps' ability to automate the identity relation that creates a set of patterns that are passed as inputand offers to deal with hyperspectral image features with most advancements. Ghadge, Rushika, et al. (2018) Sridaran K et. al. (2018), and Buvana M et al (2021) propose using a data mining approach to assist farmers in determining soil quality. Thus, the system focuses on assessing soil quality to predict which crops are suitable for cultivation based on soil type and to maximize crop yield by recommending appropriate fertilizer. Kumar, Navsal, et al. (2021)Karnan B et al (2022), and Latchoumi TP et al (2022 used microclimatic variables such as air temperature, canopy temperature, and relative humidity to develop a map-based model to analyze CWSI [11]. The canopy temperature was measured on Indian mustard cultivated in a humid climate.Mekonnen, Yemeserach, and colleagues (2019) provided an in-depth examination of the use of various ML algorithms in sensor data analytics within the agroecosystem [12-13]. It goes on to talk about a case study of Internet of Things-based data options that are driven by an intelligent farm prototype of incorporated energy, food, and water(EFW) schemes.Kumar et al. (2018) surveyed the significance of sensors in PA as well as WSN techniques for remote monitoring in various agricultural applications [14].

Sanjeevi, P., et al. (2020) investigated the WSN structure from the perspectives of throughput maximization, latency reductions, high SNR ratio, least mean square error, and enhanced coverage area. The experimental results show that the proposed technique outperforms traditional IoT-based agricultural production and farming. Hamami et al. (2020) researched to examine the use of WSN in irrigation [15]. The use of WSN technology to manage and control irrigation systems is an optimal solution for ensuring efficient and rational water use and thus contributing to the occurrence of the global water crisis.MobasshirMahbub (2020) recommended systems that are used for fields and create livestock in the fields where the controls are supplied from the embedded systems, and wireless network system [16-17]. This system describes systems with electron circuitry, protocols, and intelligent monitoring devices using the remote process for computers and Smartphones. It then includes some propositions before concluding with a description of the prospective scopes of appropriate technology in smart farming[18].

III. PROPOSED WORK

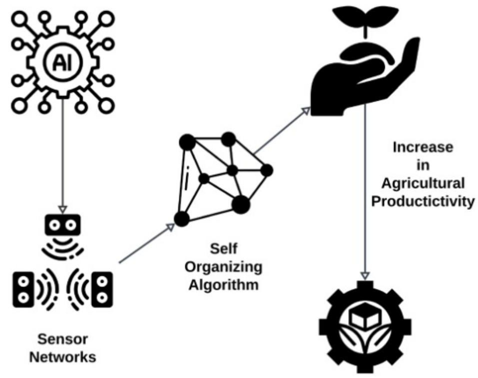

Fig.2 Illustration of Sensor networks with SOM Algorithm in Agriculture

Fig.2 Illustrates the use of Sensor networks with SOM Algorithm in Agriculture productivity increase. Watering, fertilizing, and pesticides are necessary for successful farming and food production. To create an automated type of system that will perform every activity. Systems recommended in this model include agri-field humidity remote motorizationand watering, pest detection and pesticide spraying using automation technique, pH scale tracking and filtering using the copters used for the quad purpose, and agri-field intruder and sometimes it can be an animal alert model, and so on. The agricultural sector has made tremendous progress. These advancements have resulted in a computerized method in which crop growth can be monitored and devices can be controlled using WSN [19]. A WSN's fundamental function is to gather data from a distance and send it across wireless networks that the receiver can monitor. The agri-sector may benefit from the adoption of WSN technology, especially for dispersed data collection from agricultural surroundings and, more crucially, for providing farmers with real-time information from the farming field [20].

Here the suggested model includes an optimization method that can handle time series-based rules to manage a variety of jobs. It is carried out to conserve energy. The only tasks involved are the execution of local data and it’s unloading. More emphasis is placed on queue-based algorithms since queueing is crucial for managing the system's duties is presented in Equation (1).

$$B_{u_m} = P^{*}\left(ru_m \vee \phi_{target}\right) + c(1)$$

DOI: rp-9788770040723.067

The parameters of the neural network are updated using the deterministic policy gradient shown in the following Equation (2).

$$\nabla_{\phi_{target}} g\left(R^*(u_m)\right) = E_{r_{u_m}}\left[\nabla_{\phi_{target}} f\left(p^*(U_{u_m})\right) \nabla_{A_k} p(U_{u_m}, B_c)\right] \quad (2)$$

The device and critic network parameters are provided by the DDPG using the least-squares method. Buffer queue length L(t n), channel matrix$M(u_m)$, SINR, and offloading ratio are the components of state-space s (t n). The action space A (t n) consists of the energy used by the three levels of the devices and the bandwidth distribution between the layers are presented in Equation (3), Equation (4), and Equation (5) respectively.

$$su_m = -F[\psi_1 j_1 \alpha_3 j_2 + (1-\psi_1)\alpha_4 M(u_m) - Q(u)] \quad (3)$$

$$I_1 = \alpha_1 \sum_{i=1}^{c} F_i(u_m) + \alpha_2 \sum_{j=1}^{c} \pi_i C_n(u_m) \quad (4)$$

$$I_2 = \sum_{i=1}^{c}\sum_{j=1}^{m} \pi_m c_m(u_m) \quad (5)$$

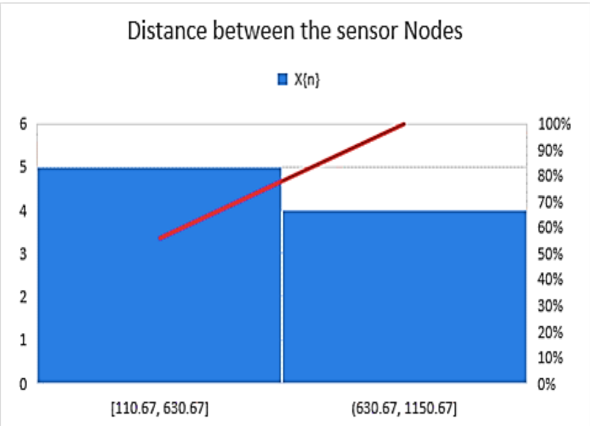

Fig.3. Analysis based on the distance between two sensors

IV. Experimental Results

The distance between two sensors nodes play a vital role in data collection in the agricultural land. The collected data aids in taking necessary action in increasing the productivity of the agriculture is presented in the Fig.3 as shown above.The recommended system also includes a WSN with all the detection systems and some of the sensors that monitor the entire agri-environment. A SOM is an unlabelled dataset that can be processed using an unsupervised learning model in machine ML technique that generates a dimensional representation in the lower range while keeping the data's topological structure, an average-dimensional data set. A SOM is a type of ANN model that, unlike other artificial neural networks, is taught through competitive learning as opposed to error-correction learning

TABLE 1: Algorithm Comparison with the Previous Models

Algorithm	Crop Protection (%)	Crop Yielding (%)	Overall Accuracy (%)
Machine Learning Algorithm	89.78	94.67	95.01
The algorithm used in the existing Model	87.98	91.45	93.60

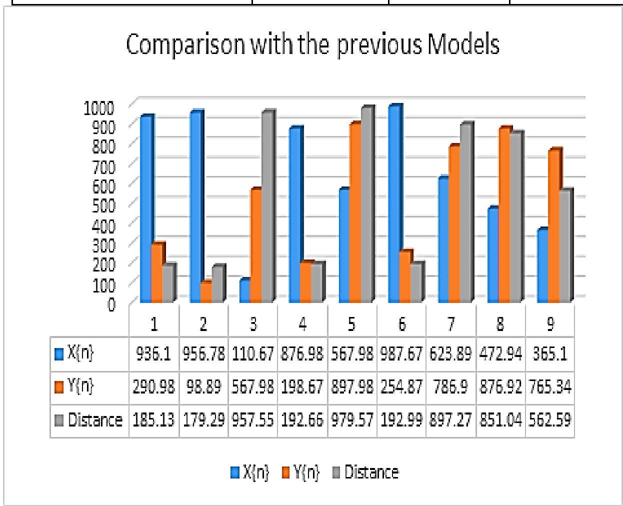

Fig. 4. Comparison on different models on agriculture productivity

Fig.4 and Fig.5 depicts the comparative analysis of the proposed model based on the distance among the different nodes and location of the given area.

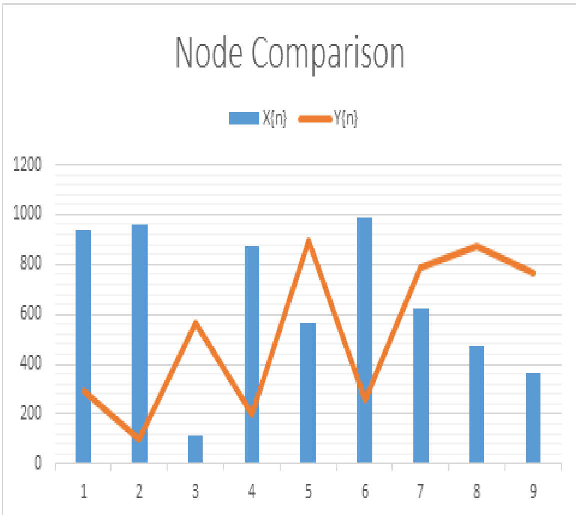

Fig.5. Comparison based on Performance among nodes

V. Conclusion

A mapping is an un-labeled dataset with the ML tool that generates a dimensional representation with a reduced range of increased dimensional data while handling the data's structure. The training process for a SOM differs from that of other artificial neural networks in that it uses competitive learning rather than error-correction learning.

DOI: rp-9788770040723.067

The SOM, also known as a Kohonen map or Kohonen network, was created in the 1980s by the Finnish academic TeuvoKohonen.

Abstract—Knowledge within this same genetic ontology annotating has helped explain the occurrences of biological sciences, hence, being a precious resource for therapeutic development. This same genetic ontology was increasingly changing the way individuals manage, but instead understanding the biological material of systems. Designers turn everything into the amount-based methods founder upper categorization conundrum instead establish a procedure that has used these same connections throughout this same Gene Ontology structural system. It alleviates the quantification inequity of optimistic but rather detrimental coaching specimens to make it easier for genomic component prognostication. This aids in the message extraction approaches but instead establishes infrastructure. Conversely, the proposed technique improves classification discrimination by keeping but instead accentuating these same most important learning examples. Furthermore, our upper edge classifiers predicated around hierarchical branch construction consider overall connection amongst targeted categories, resolving general inconsistency among categorization outcomes and the underlying Genes Morphology framework. Their research's overall F-measure effectiveness using the general Genetic Ontology annotating dataset was 50.7% (precision: 52.7%, recall: 48.9%). These research findings show that even though their trained collection seems minimal, it may substantially increase by propagating linked information across parental and offspring branches throughout that forest architecture using geometrical dispersion. Any group or document within complex ontological architecture with any vertical connection can be classified using this same highest categorization paradigm.

***Keywords: F-value effectiveness; upper categorization method; Genetic Ontology; medicinal domain*.**

I. INTRODUCTION

Exploration of understanding basic physiological activities that human creature was individual amongst this same main goals underlying genetics investigation. Its emergence of an energetic constrained vernacular throughout the Gene Ontology (GO) directory. The intended position of multicellular genetics but molecules inside the compartment and practical bioengineering understanding. But rather prevents genomic device characterizations stable all over a wide range of data sets, has always been an excellent example of the above [1]. This GO annotations collection provides a substantial quantity of all relevant functionality identification information, which is crucial during biotechnology test interpretations. Nonetheless, those annotating datasets remain incomplete. Further more, researchers understand some portion of half every genome across every species, while another much lesser number, even those labeled with functional knowledge [2]. Professional personnel retrieves basic information about GO, annotating carefully using textual information but storing it within systems [3]. Making employment using textual analysis methods that aid improves making collection from functionality annotations knowledge has become an increasingly essential challenge because of given overall increasing development of functionality knowledge throughout increasing scientific publications [4].

II. RELATED WORKS

In addition, researchers may examine this grouping of cable network concentrated areas to see whether molecules containing these similar classifications tend to congregate together typically. Support material approach for inferring enzyme functionalities from proteins interactions information, including the functionalities for their nutrient interactions companions. [5-6]. Researchers generalized serial connections for other surrounding molecules to comprehend each enzyme's overall capabilities, hence single functionality across several [7]. First, analyze this same significance from chromosomal information into protein functionality prediction. Researchers used comprehensive characteristic selecting approaches instead of subsequently studying potential links among chromosomal information and peptide functionalities [8]. Molecular domains, protein-protein interactions, transcriptional expressions, phenotypic ontology, evolutionary profiles, and other illness information resources were among those ten genomics information resources examined with muscles. Researchers calculated the overall quantity from every information collection depending upon this same accuracy in their predictions throughout their investigation [9].These practical data-based approaches could exclusively anticipate overall activities and genetics with biological measures, requiring physical measurements from comprehensive anticipated genomes but rather molecules before preparation, which was unachievable

DOI: rp-9788770040723.068

given several other novel objects within another book [10].

III. Proposed Methods

During classical categorization research, every occurrence is always thought to match precisely a particular classfier. In actuality, every instance seems expected to belong to different software categories [11]. Every article from magazine content, for illustration, can sometimes be classified as belonging within neither this same political business economic categories. Given data results, it must enable every learned classifying algorithm to attribute numerous descriptions to every occurrence (Fig.1). This inter detector includes one amongst several types called classifiers. Every genome that seems anticipated might be associated with many GO principles within that r challenge with predicting genetic expression [12]. In this same vary in severity registry, for illustration, this same chromosome P25686 has been compiled to GO definitions such as 0032436 (good regulatory oversight of mitochondrial pathway these same effectors nutrients, degradative procedure). 0090086 (deleterious requirement of nutrient deubiquitinating), 0030433 (Epithelial nutrient degradative method), 0031398 (optimistic regulatory oversight of nutrient down-regulation). 0090084 (deleterious government oversight of nutrient proteasomes degradation) (negative regulation of the inclusion of the body assembly). Several GO terms explain relevant genetic activities as follows: Favorable regulatory oversight of nutrient de-ubiquitin deleterious modification by endopeptidase casserole dish degradative method, favorable legislation of nutrients ubiquitin by associated nutrients glycogenolysis method, deleterious egulatory oversight of malware endosome arrangement by pathogen endosome legislature by malware endosome legislature by malware endosome legislature by malware endosome legislature by malware endosome legislature by malware endosome legislature by malware endosome arrangement From this result, one might think about genetic functionality predictions from one number commonly known as e founder annotations issue, during which numerous GO topics are used to describe each bacteria's functionality [13]. This work focuses on conceptual identification, meaning detecting whichever GO keywords every detailed scientific description seems connected to, attributable to the excellent analytical quality and unrestricted availability of available scientific explanations.

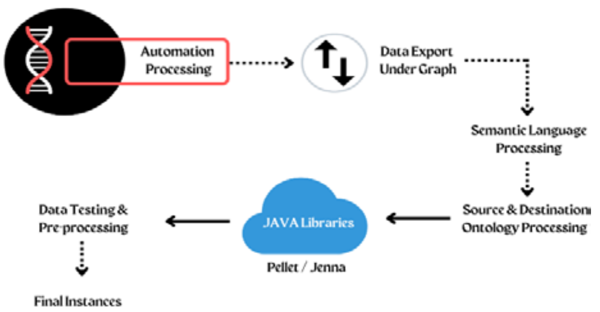

Fig.1.Automatic Identification of Ontology Hierarchy Structure

Those approaches depend upon issue change, but also, these approaches hanging around algorithmic change are those two categories of inter categorization approaches. This same primary principle behind issue transforming techniques was essential to break any inter-classifying challenge down several separate classifiers [14]. Then-current singular category strategies may be employed effectively to solve this challenge. Every student's forecast has been handled simply by any independent singular assessment with its associated predictor. Every category is trained using everything given available learning information, resulting in an overall classification solution that is appropriate for the particular type.Another downside with those techniques was that they ignore underlying connections between categories since they are generally based on actual premises because individual classes remain autonomous. Additionally, every classifying method must be trained using both available relevant learning information that frequently results in an overall unbalance among affirmative among unfavorable learning examples, therefore producing a widespread detrimental influence on broad categorization [15]. Several techniques centered on methodology adaptation work by modifying any established standard categorization system such that they can handle inter-categorization issues.

Humans conduct annotating based upon overall categorization conclusion from that r material within these research provided particular genes and any linked information. These classifications were developed using guided training, having these inputs characteristics were neural keywords within individual documents and original destination classifications being their GO keywords. Researchers use problematic turnaround approaches that educate every individual GO word classifications to establish various genetic classifications. Everyone on relevant classifications was contacted when determining various subclasses for specific genes. Therefore this same labeling for particular mutations were some of these categories, which reviewers provided one favorable result. This horizontal classifications technique is a computer approach that arranges these same subclasses from any branch construction based upon some flat connection. But also allocates individual samples that should identify among individual vertices throughout various branches using said "Keep dividing" principle. Conventional methodologies are less successful than other sorts of segmentation procedures. Horizontal segmentation and upper edge classifications are two prominent approaches to horizontal language categorization. Every vertical interrelationship across this branched architecture becomes "squished" with this same horizontal categorization. Because of building a static categorization framework, each location may not consider neighboring areas. Significant link documentation within every hierarchical architecture between classifications was ignored throughout alternative terms using such a technique. However, researchers feel that several exemplary instances amongst overall computer trained examples that exhibit minor distinctions within individual categories could give crucial classifying teaching.

DOI: rp-9788770040723.068

Specific data become combined amongst many different learning observations buried throughout this same flattened categorization photographer's development phase, preventing computer learners from correctly classifying individual data near their subclass borders. Their identifying capability improves throughout the research study by carefully picking appropriate retraining datasets at every node within the exemplary forest architecture, generating considerably more reliable classified images. This genetic annotation then turned into one categorization depending upon every GO framework throughout this research. Researchers created another GO network by utilizing relevant physiological processes branching knowledge from Genetic Ontological Annotated (GOA) databases. These vertices within this way keep GO phrases, whereas these connections reflect meaningful relationships amongst them. This network architecture follows this GO annotating institutes' description as with active physiological branches.

Furthermore, through integrating relevant Bibliographic publications into GO vertices, this same knowledge inside this same network becomes augmented, making everything just possible can develop a single robust type at every cluster. Every branch correlates approximately 2 Bibliographic identification (PMID) groups within the current methodology. This segmentation model gets built separately for every individual component of this same GO hierarchy during this same learning step. Every predictor with every source vertex was subsequently performed. All content that should be identified during this same forecasting process, commencing with the subsequent parent network, should identify unless network-provided content corresponds to this existing classification. Assuming something succeeds, corresponding assessors from associated daughter networks continue to network to categorize their provided documents. The continuous procedure continues unless their branch endpoints are reached; however, the entire categorization procedure comes to a complete halt. With the above method, every document referring to any specified school should pertain to their mother subclasses. Else because classifying algorithm will fail even reaching such group's nodes. Earlier in this section difficulty of categorization outcomes that are incompatible with the GO framework is efficiently solved by using another upper categorization approach.

III. Methodology

The following was this complete technique involving corpora preprocessing but instead subsequent generation with appropriate categorization models for every individual GO routing:

Step 1: Retrieve is a but instead part of relationships using this same physiological processing branching from information GO for acquiring this same horizontal connection across all pairing data parental and children networks, and calculate individual network component offspring network group and also descendent graph sets. After that, another directional network containing GO phrases gets created.

Step 2: Retrieve that r collection comprising every present node linked PMIDs under any GO word after resolving that r relationship database containing genomes, GO keywords, and PubMed publications (namely CurNodePMIDSet).

Step 3: Geometrical reproduction: ontologically arrange this same entire fucking network using both parent networks collection collected during Phase 1 and this same parent component PMID collection gathered from Part 2. PMID collections connected to networks being transferred between children towards parental networks. Therefore, every network and another descendent component related to PMID collection (called DescNodePMIDSet) was formed.

Step 4: Retrieve summaries using this exact entire fucking Search was performed explanation papers for every PMID referenced in either CurNodePMIDSet or DescNodePMIDSet. Again, search results have been eliminated from these retrieved abstractions. In contrast, another matrix domain modeling per every processing abstraction has been created even though this information may be described using any scalar.

Step 5: Design different categorization methods per every GO node in that r ordered network, one using unlabeled Data and another using SVM. Furthermore, three times the larger bridge is being used: yet another hundredth from that abstracted texts were chosen because they tested batch every session, while this same remainder is being used because their learning group.

IV. Results and Analysis

Its GO hierarchy's sub hierarchical components. Unicellular organism parentage having identification GO: 0048308 but instead cell organelles distributions have separate is a record, indicating, therefore, this keyword contains 2 parental branches. Original description document from MEDLINE (Fig.2).

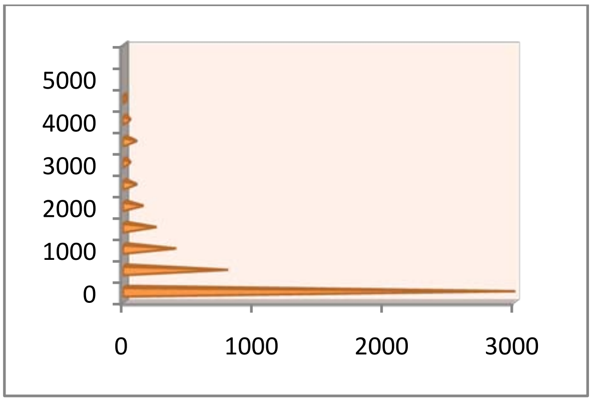

Fig.2.Every GO season's corresponding to distributed content quantities

Quantitative accuracy, remember, but also F-value is used for analyzing individual approaches within this research. Although this same current publication's genetic functional annotating techniques create a unique classification of every component within a GO architecture, specificity and retention are typically calculated manually adding together outcomes from multiple classifications. That assessment parameters were

DOI: rp-9788770040723.068

simply as follows: Yi is these classifier's prediction corresponding to node I in the GO structure, and Zi represents the standard response.

$$precision = \frac{\int_{x=1}^{|O|} \lfloor A_x \cap B_x \rfloor}{\int_{x=1}^{|O|} \lfloor A_x \rfloor} \quad (1)$$

$$recall = \frac{\int_{x=1}^{|O|} \lfloor A_x \cap B_x \rfloor}{\int_{x=1}^{|O|} \lfloor B_x \rfloor} \quad (2)$$

$$V - Value = \frac{2 \times precision \times recall}{precision + recall} \quad (3)$$

Table 1 compares these same proportions on affirmative versus unfavorable conditioning examples obtained through computing estimated median quantities across every GO location using horizontal identification against upper categorization. Average dispersion among documentation identifiers was seen in Table 1.

TABLE 1. OVERALL MEDIAN QUANTITIES

	Average no.of (-ve) training samples	**Average no.of (+ ve) training samples**
Flat Classification	80454	1.845
Top-down Classification	1256	4.486

This confirms that this same inclusion of accompanying publications for GO base stations leads to a broad sense increment throughout this same multitude of optimistic instructional specimens mostly through topographic dissemination among mother but rather that ngster gateways throughout this same forest configuration, because when caregiver base station discrepancies were always accounted to further constrict this same dimensions of this same deleterious professional development test specimen established. Also although mother but also daughter vertices seem often extremely identical, they choose this same strongest differentiating examples amongst these using negativity patterns, that either help with counterbalance overall pessimistic from positives retraining measurements towards a considerable extent (Fig.3).

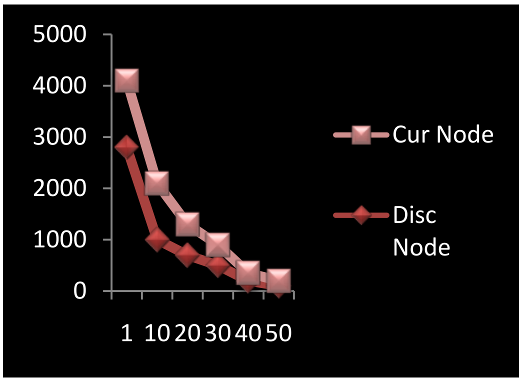

Fig.3. Documentation identifier

Whenever individual examples were under continuous horizontal connection, then the highest categorization strategy outperforms the conventional flattened classifications approach, according to their empirical data. The findings demonstrate shown whenever their learning population seems limited, that r technique may enhance the overall amount more affirmative instances by propagating ontologically amongst mother but also offspring vertices, resulting in yielding higher learning sampling collection exhibiting better variation capacity. Following applying Bayesian adjustment, reliability has improved. Their outcomes have been greatly increased through considering under consideration this same organizational nature underlying operational class. When evaluated against those findings from overall highest outcomes from their technique outperform them, proving overall efficacy using SVM-based leading classifications. This has always been likely due to the same fact that, by getting in and out of account such a same plant configuration of GO base stations, humans can hardly construct a highest level classifying framework, however, and modify its learning measurements but rather broaden the whole same optimistic instructional specimen collections, lowering the said same disparity among supposed to offer favorable but also pessimistic specimen but rather, as a consequence, projecting genomic feature more accurately.

V. CONCLUSIONS

The study aims to improve the accuracy of functional genetic forecasting through the use of language extraction algorithms. These algorithms categorize annotations of underlying genetic functionalities into a sub-hierarchy, creating a more efficient and accurate approach to understanding biological scientific events. The resulting strategy provides a wider learning sampling collection and eliminates statistical mismatches between favorable and unfavorable examples by using the horizontal connection within the Gene Ontology (GO) framework. The GO framework is a useful tool for representing biological concepts associated with genes and proteins, providing a structured and hierarchical representation of biological functions. By leveraging this framework and language extraction algorithms, gene annotations can be efficiently categorized, improving the accuracy of functional genetic forecasting.

By overcoming issues such as statistical mismatches and efficiently categorizing gene annotations, functional genetic forecasting can be enhanced, leading to better patient outcomes and improved healthcare services. The use of language extraction algorithms and the GO framework provides a valuable tool for medical researchers, allowing for more accurate diagnosis, personalized treatment options, and improved healthcare outcomes for patients.

In conclusion, the study demonstrates the potential of language extraction algorithms and the GO framework to improve the accuracy of functional genetic forecasting. The resulting strategy provides a more efficient and accurate approach to understanding biological scientific

Abstract—RNA particles have several varieties of important activities within animals' bodies, involving genetic control, processing, and nutrient production. Because various foldable configurations of molecular RNA are so important for biological functioning, a considerable lot more work has gone into creating precise algorithms that predict RNA supplementary organization using overall basis sequences. The lowest complimentary resource forecasts predicated upon closest neighbour physicochemical characteristics were commonly employed. Techniques that use partitioning functional computations to discover overall organization having maximal anticipated correctness but rather simulated anticipated precision approaches have already been suggested. Considering databases containing established target architectures, advancements throughout predictions algorithms were often appraised employing sensitivities, positively predicting values, especially associated harmonized maximum, specifically F-measure. Because comparable evaluations track development towards increasing environmental quality for computationally forecasting techniques, this seems application have this essential to understanding exactly performance measurements change with changing references collections but also only when enhancements throughout techniques specific environmental characteristics result throughout scientifically meaningful increases. Without regard to this same most recent database but also energetic characteristics, this study extends fundamental knowledge regarding MFE and MEA-based approaches.

Keywords—Secondary RNA sequences; Potential energies; Performance Measures; MFE and MEA approaches

I. INTRODUCTION

RNA proteins were required for a variety of important tasks within every species' body. Certain compounds, such particular, play an important role during genetic translations so well both acting either catalysis but honesty and integrity moderators on genes activation [1]. Considering molecules architecture determines functionality, much has a considerable lot of money is invested in computer approaches that anticipate RNA intermediate architecture, which may then be used to estimate the fundamental framework [2]. The objective was to use theoretically sound methods to evaluate the overall advantages of certain contemporary advancements throughout intermediate structural predictions.

Considering basic foundation sequences, researchers concentrate upon thermochemical inspired techniques towards forecasting pseudoknot complimentary subsequent architectures [3]. This minimal free energy (MFE) organization having regard for the closest neighbouring heat transfer models is found using another commonly employed approach. Both improved maximum expected accuracy (MEA-based) and also greatest pseudo-anticipated reliability were two significant breakthroughs throughout intermediate architecture predictions. Those techniques provide greater averaged correctness over conventional MFE algorithms upon fundamental energies components but also improve (pseudo) anticipated basis pairing correctness being any proportion variable bases pairing possibilities determined utilizing another partitioning functional methodology.

II. RELATED WORKS

Several probability simulations describing architectures are used to anticipate RNA intermediate organization. However, because these statistical techniques were essentially based upon actual macroeconomic framework, designers will not incorporate them throughout any subsequent assessments [4]. Further advancement was that estimate for additional energetic characteristics employing government calculation algorithms from relational isothermal but also architectural information [5]. Inferring parametric settings using energy acquired utilizing optically melted studies is much atomic architectural information. These 2 collections of temperature characteristics were referred to known as BL but also CG, respectively, following this Boltzmann possibility but also constrained generating procedures that were employed to derive these. When compared to conventional Original specifications, those variable groupings resulted in considerable advances in overall MFE methodology predictions efficiency, having both BL characteristics marginally superior to those overall CG variables [6].Here and throughout, the accuracy of a prediction refers to its Measure, which is the harmonic mean of sensitivity and positive predictive value. This research

DOI: rp-9788770040723.069

evaluates algorithmic effectiveness upon individual categories identify RNAs, including genomic regions and transferring RNAs, also much its general median performance across RNAs across various categories. MFE approaches without regard of various variants of original variables, by much as relatively latest BL but also CG specifications using information spanning single RNA classifications on much as huge databases which contain numerous RNA categories to address important concerns [7-8].

Several major conclusions are presented. Firstly, designers demonstrate whether F-measure precision across experimental big databases was expected likely constitute trustworthy estimations of overall demographic precision, particularly this same notion because slightly elevated intervals breadth in F-measure computed employing this same bootstrapping maximum approach were around relatively limited, 2% spread. Over fewer courses, averaged reliability was lower dependable [9]. Given another population comprising 89 Category I introns having recently been employed throughout benchmarks methods, confident estimates with overall MEA but also MFE comprise approximately 8 % variance. Secondly, throughout perspective in total forecasting efficiency, they were an obvious "champion," notably this same pseudo-MEA-based technique [10-11]. This same corresponding exactness of this same MFE but rather Types single sample self-frameworks, moreover, becomes dependent on this same underpinning power generation specifications: that used a factorization experiment, designers encounter that this same correctness of MFE-based estimation on everything with us other humongous databases becomes preferable on 2 of this same 4 electricity input variables which humans regard, at a numerically considerable standard [12]. While MEA-based prediction is better than MFE-based prediction on a third parameter set. Ultimately, while employing this same fourth variable, this same BL* radiation variables, combined Types of self but also MFE approaches obtain overall best reliability. The authors developed Rsample, an algorithm for predicting various RNA structures from experimental data for sequences that populate several forms at equilibrium. They've shown that they can simulate RNA sequences using SHAPE mapping data with high accuracy [13-14].

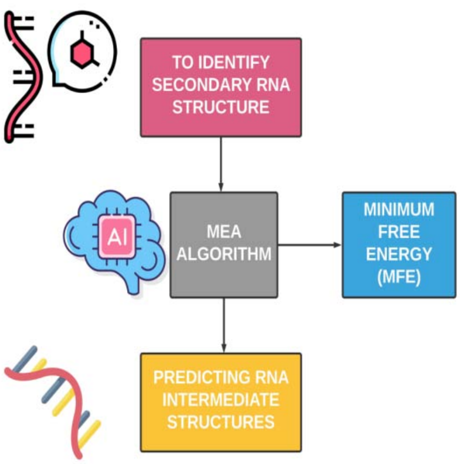

Fig.1. Proposed architecture of RNA secondary prediction using ML

III. Proposed Methods

S-Full includes another collection comprising 3,245 RNA strands with associated supplementary properties culled through several varieties of different credible repositories. Segments within the above but also comparable databases have a maximum limited value of 700 characters; although in certain circumstances, bigger sequencing, including instance 16S Ribosomal RNA segments, be partitioned to achieve compliance. Throughout S-Full, this same overall frequency for every nucleotide was 270nt. 16S Ribosomal RNA, 23S Ribosomal RNA, 5S Ribosomal RNA, Group I organelle, Group II transposon, Ribonuclease P RNA, Signals Identification RNA, but instead Transfers RNA are some of the several types of nucleotide RNA. • MA represents another subgroup for this same S-Full collection, comprising only individual S-Full sequences found within specific RNA categories covered by MT. This MA collection was created such that researchers could investigate different methods around these same categories despite employing that many RNAs representing various categories were feasible. These conclusions were based upon this limited version from this MT collection wherein particular sequencing characters appear written in smaller cases, suggesting indicates its basis was stranded within the original comparison framework. Researchers made projections based upon such fundamental knowledge. Designers, on the other hand, have simply used such knowledge, consequently, overall consistency metrics using actual MT collection remain differently.

This thermodynamics modelling comprises made up of characteristics, which are tiny compositional themes like stacking pairings, and constant temperature transition variables, which are assigned to each characteristic. This same Taylor 99, this same final version humans employ, was the greatest extensively represented energies models in RNA intermediate structural predictions. This framework comprises about 7600 characteristics predicated upon Anderson's closest neighbours constraints, which were to represent this same premise because this durability for any foundation pairing and the circle is determined by their sequencing and structural sequencing surrounding nearby repeats with unattached nucleotides. Another of these architectural patterns, concentric layering, was created using basic characteristics from another later edition of these same Taylor models, Turner2004. This Turner99 designer's characteristics are being used throughout this majority of all these same architectural motifs. Because the majority half these characteristics were Turner99 characteristics because this same concentric layering pattern was never featured within every alternative model humans investigate, humans additionally designate this characteristic collection utilized under this same Turner99. Characteristics that help determine the architecture of RNA. However, researchers need cannot include these characteristics throughout the current study even before they were irrelevant to the overall computation of any partitioning functional however and also, as a result, to the overall probabilities determination needed by using MEA technique.

They look at several different techniques for predicting RNA intermediate structures. This former forecasts

DOI: rp-9788770040723.069

supplementary formations containing this same minimum free energy (MFE) with a certain thermodynamics framework. The following methodology was another maximum expected accuracy (MEA), which improves predicted basis pairing correctness by any proportion on basis pairing probability computed utilizing termed partitioning functional technique. Regarding usage utilizing these MultiRNAFoldmodelling, researchers built using MEA algorithms. For such consequence, scientists experimented simply exclusively using either safe and EMEA techniques, however additionally produced this same UBC MFA MFE program but instead, another unique version for MEA termed UBC MBA. Whenever this same g component of this same rsMEA was adjusted to 1, this delivers the overall highest forecasting performance. As this result, designers adjusted g equal 1 within UBC MBA as well. This extended median estimation technique was this next technique will look examine. One such approach was comparable with previous MEA methodology, however instead infers architectural configuration using base-pairing possibilities using another slightly alternative objectives functional, notably using brightness estimation.

Overall structurally predicting efficiency is determined using 3 initiatives: sensitivities positively predicting values but rather PPV, but also F-measure, whose integrates sensitivities but also PPV together any singular metric. That percentage between accurately forecast basis pairings over this same overall bases pairings within overall standard architecture was the response. This percentage accurately expected bases pairings irrespective of overall forecasted bases pairings were known simply as PPV. This same harmonized average between this sensitivity and PPV termed measures F-measure. Whenever sensitivities and PPV were both identical, one such number equals the overall numerical median. Whenever 1 among these integers approaches 0, meanwhile, these same F-measure increases lower under overall numerical means. Humans chose to use F-measure over traditional Pearson correlations coefficients primarily because makes was easier can compare their conclusions against theirs.

$$\text{Sensitivity} = \frac{No.of\ Correctly\ \ predicted\ \ base\ pairs}{No.of\ base\ pairs\ \ in\ reference\ \ structure} \quad (1)$$

$$\text{PPV} = \frac{No.of\ Correctly\ \ predicted\ \ base\ pairs}{No.of\ predicted\ \ base\ pairs} \quad (2)$$

$$\text{F-score} = \frac{2*Sensitivity\ *PPV}{Sensitivity\ *PPV} \quad (3)$$

Table 1 shows estimated averaged normalizing commonalities, which typically lie amongst 0 but also person, with an overall value approaching something indicating meaning individual segments within this collection were comparable. Whenever si seems to be 0 across every RNA category, the overall weighted average matches this same balanced averages, whereas whenever it reaches across every course, this matches this same overall ordinary approximate. Considering those other circumstances, this same S-weighted average's frequency might be somewhere around either approximate but also balanced averaged.

TABLE 1. RNA INFORMATION SOURCES

RNA class	No. in MT	Mean ± std of length	Average similarity	No. in MA	Mean ≠ std of length	Average similarity
165 Ribosomal RNA	87	367.97±157.13	0.61	671	486.34±112.01	0.60
235 Ribosomal RNA	25	459.6±149.54	0.52	162	443.47±118.88	0.55

IV. RESULTS AND DISCUSSION

This is critical to understanding comprehend because these metrics differ based upon actual comparable information employed. We'll look to examine whether correctness measurements differ based on the energy modelling employed subsequently throughout the following chapter. This background information from Table 2 reveals even between furthermore MA and MT datasets overall must be potentially large disparities regarding algorithmic performance across Nucleotide classifications. By illustrating, while implementing default BL* configuration one DNA polymerase P RNA, UBC MBA obtains an F-measure of 0.471 on the MT collection against 0.643 with matching MA database, total differential equal nearly 17%.

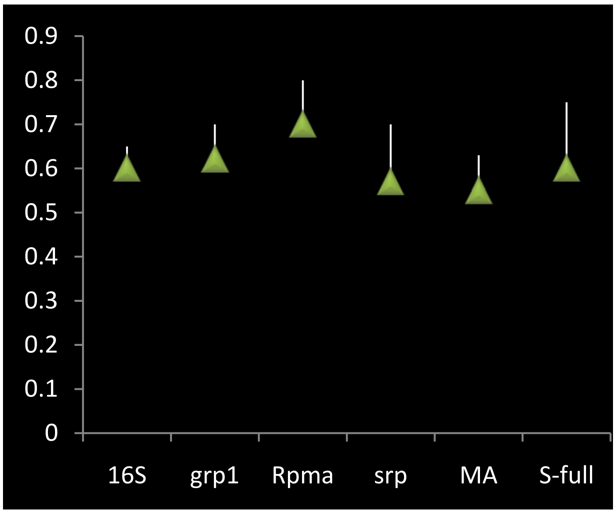

Fig.3. Bootstrap performance over proposed method

Fig.3 displays an estimated 95 % probability of bootstrapping maximum credibility ranges for applying UBC MBA but also UBC MFA methods upon specific RNA subclasses including overall MA but also S-Full databases utilizing this same BL* sensitivity combination. Table 3 shows that BL* characteristic collection's 90 % probability bootstrapping maximum credibility ranges both generating UBC MFA but phase which means flow cytometry procedures. Firstly, both MA and S-Full settings' test statistics possess a maximum mean diameter of around 0.018, demonstrating, therefore, their median reliability assessed using those collections was expected would constitute a very reasonable approximation - around 1% - for overall precision for any community containing Biomolecules reflected under those pairs. Particular classification intermediate thicknesses sometimes are substantially wider, for example, 0.075 using UBC MBA upon any Groups I transposon category, implying, therefore, averaged correctness was a hardly very credible estimate on any product's ultimate efficiency across certain categories. A 0.02 differential overall correctness was deemed substantial within certain relevant studies requiring using application of more sophisticated quantitative approaches. Secondly, overall breadth within RNA subclass probability intervals may always absolutely decline while the overall population in that category grows. Even though its Transporter RNA classification includes around 1.2 twice more numerous RNAs than its Endonuclease P RNA category, this same DNA polymerase P RNA category has maximum probability intervals thickness approximately 0.01 smaller than this same Transport RNA category using this same UBC MBA methodology. Probability intervals thicknesses need thereby be accounted covered by parameters relevant to all individual subclasses additional beyond course number. UbcMEA but instead UBC MFA procedures have 95 percentage bootstrapping probability ranges.

Each hypothesis indicates that categories having more structural similarities maintain lower confident windows because this same probability region approaches 0 breadth towards extreme limiting whenever every sequencing within a given category becomes comparable. Fixtures 1 information, by this same other hand, showed never show exhibit strong link amongst averaged standardized resemblance but also credibility intervals breadth, particularly among categories that were neither very dissimilar overall magnitude. Within this Massachusetts collection, by illustration, individuals Utilizing available 0.001 but also Transporter Deoxyribonucleic acid (DNA classifications possess comparable dimensions, even though identical DNA processor P RNA subcategory has had far lower adjusted weight. Furthermore, the overall breadth of estimated credibility intervals using this same UBC MFA method is generally similar to those from that whole UBC MBA but also GC-pm means algorithms for every particular information, although unless actual intervals locations might seem somewhat dissimilar. Under their DNA polymerase Pg Ribosome category, for illustration, median averaged F-measures from UBC MBA and UBC MFA differed by approximately 0.04, although their credibility intervals thicknesses remain similar. That instance, amongst these three methods, overall least but also maximum confident intervals thicknesses that its 16S Ribosomal RNA classification were 0.026 and 0.030, accordingly, indicating significant differential equal lower about 0.01 % spacing breadth under a particular classification.

DOI: rp-9788770040723.069

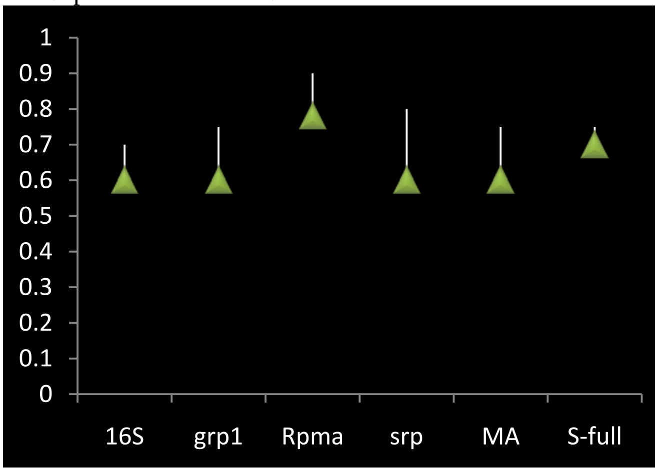

Fig.4. Bootstrapping maximum uncertainty ranges

Using experimental ubcMEA, UBC MFA, and GC-PMFmeas techniques, Fig.4 displays the estimated breadth of the credibility regions vs overall sizes among distinct RNA subclasses. This could be seen, practically the majority set observed locations from those 3 techniques were similar equal height within their respective dimensions, showing either ubcMEA, UBC MFA, but also GC-PMFmeas possess the same breadth. Another key takeaway from this graph was generally, while 1 might anticipate, overall breadth is median probability intervals shrink when total amount individual RNAs having every particular class throughout this same precedent collection is larger, although were noticeable outliers following such a tendency, especially groups smaller than 500.

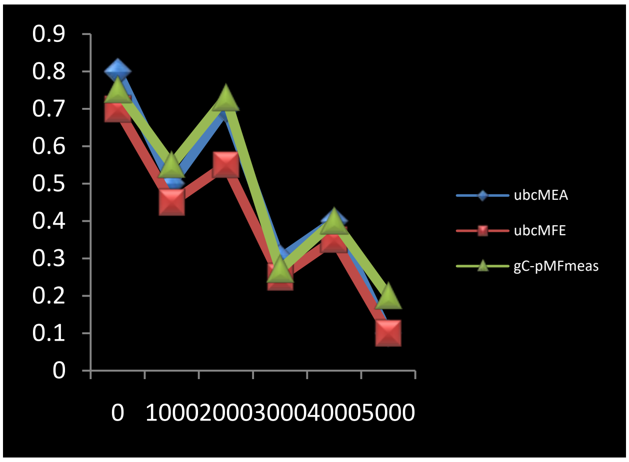

Fig.5. Comparison analysis of performance measures

Furthermore, they see found, dependent upon our power models, MFE occasionally outperforms MEA across any certain category with RNAs but also conversely (shown Start Fig.5). In that instance, MFE beats MEA by about 0.02 while applying standard BL* variable collection with their collection of endonuclease RNAs, but MEA improves Interventions made besides 0.04 because once employing its Complete Newton 98 variables. Furthermore, they find to show this same comparative effectiveness using MEA vs MFE is dependent upon particular physicochemical variable collection employed, particularly, therefore, ubcMBA but instead, UBC MFA using this same BL* information group is much more accurate than rsMEA utilizing standard Turner99 information setting.

V. Conclusions

Scientific advancements using computerized techniques, especially heat transfer computations, have helped intermediary superstructure predictions make substantial advances. Throughout this paper, researchers demonstrate whether GC-pm means without this same BL* variable setting beats most previous MFE and previously unapproached they looked quite considerably. Nevertheless, dependent upon the particular thermodynamics input variable employed, overall comparative effectiveness between Stereotypes with MFE approaches varies. Under this same Turner99 simulation, for instance, Previously un techniques greatly outperform the lowest freed energetic approaches, although this same converse holds applicable for many simulations, while overall differential throughout effectiveness among Stereotype versus MFE approaches using their strongest thermostatic framework, BL*, seems minimal. These observations show suggesting having a varied array of computational approaches would continue will have been useful while thermodynamics simulations advance. Designers additionally demonstrated potential relevance for evaluating overall correctness using certain strategies but abrading thermodynamics simulations utilizing huge information. Humans demonstrated that this same ordinary highest consistency template per cent range test statistics on with us 2 greatest information - frames, MA but rather S-Full, possess constricted dimensions, implying that this same ordinary precision assessed on such pairs possess become probable to be great projections of this same error margins of this same community of RNA particles consumers reflect. Distance lengths remained substantially greater across numerous among those individual RNA subclasses evaluated throughout the research article, without little evident association among probability distance length but also category number but rather a median normalization resemblance.

Abstract—Genomic sequencing is no longer new, the annotation of gene function continues to be a major challenge in biological evolution.From traditional approaches such as affinity precipitation to contemporary broadband approaches such as gene expression microarrays, there are several methods for testing functional genomics.Professional information concerning relative levels of accuracy of data sources is explicitly incorporated into the system for mixing in the normative framework.Multisource Association of Genes by Integration of Clusters (MAGIC) has a level of confidence that enables users to change the rigour of forecasts through Bayesian Model. Researchers used MAGIC to analyze Saccharomyces cerevisiae genetic & physical interactions, micro-array, as well as transcription factor binding site information, but the researchers used Gene Ontology annotations from the Saccharomyces Genome Database to determine a biological value for gene clusters.Compared to microarray analysis, MAGIC simply improves the reliability of functional clustering by building functional clusterings based on a variety of data types.

Keywords*—*Genomics; Genes Integration; Bayesian model; Gene function

I. Introduction

Increasing levels of high throughput biological information have become accessible in recent times. Some of these, including protein to protein interactions research, affinity precipitation, 2 hybrid approaches, synthetic rescues & lethality tests, as well as microarray analysis, evaluate functional interactions b/w gene products on a wide scale[1]. Although many proteins' functions are unknown, in even model organisms, high throughput information might well be crucial for assigning correct functional annotation on a broad scale [2]. Experimental research could benefit from such predictions since they provide particular hypotheses of evaluation. Some high throughput approaches, on the other hand, forgo selectivity in favor of scalability. By examining co-expression associations in a high-throughput manner, micro-array research could yield gene function estimates. Micro-array data alone frequently lacks the level of sensitivity required for good gene function predictions, however, gene co-expression information is a useful tool for hypothesis creation. An improvement in precision is required for such reasons, even if it comes at the expense of certain sensibility [3]. The integration of diverse functional information inside an integrated analysis could achieve such an increased insensitivity.

Another element of GO is GO annotation, which contains the previously available functional data of genetic variants. Every positive annotation connects a gene to a GO term, indicating that the gene's product performs the function specified by phrase [4]. Every negative annotation, on either hand, implies that the gene product doesn't function properly stated by its word. A Go collaboration annotates genes with GO keywords using model organisms of broad interest to biologists, including Homo sapiens, individually or collectively [5]. Although, our understanding of the functional taxonomy of gene products is still very much in infancy. As a result, both GO annotations & hierarchy & were updated on the regular basis with fresh information & saved for future reference [6]. A Go collaboration annotates genes with GO keywords using model organisms of broad interest to biologists, including Homo sapiens, individually or collectively [5]. Although, our understanding of the functional taxonomy of gene products is still very much in infancy. As a result, both GO annotations & hierarchy & were updated on the regular basis with fresh information & saved for future reference [6].In Dec 2019, GO had grown to over 45,000 words, with every gene annotated only with a few / hundreds of them. As a result, accurately inferring the relationships b/w the genes, as well as the various GO keywords, is hard [8].

Every GO term could be described as a semantic label, making the gene function prediction job a classification task to identify if the label is negative/positive for the gene.

Earlier gene function prediction approaches simply took this annotation data & turned it into a simple binary classification task. As a result of ignoring the relationships b/w GO terms as well as the uneven features of terms, these

DOI: rp-9788770040723.070

techniques were inaccurate [9]. Some researchers characterize gene function prediction as just a multiple-label / prediction of structural output problem [10] because a gene is frequently labeled with a group of structurally ordered GO terms at the same time. Some attempted to exploit the inter-relationships between GO keywords & proposed a range of multiple-label learning-based methods.

Various studies that used various sources of data to make functional predictions have demonstrated the utility of merging gene clusters derived from multiple techniques. Other researchers had devised approaches for combining gene expression data including 2 / 2 non-microarray sources of data, resulting in more accurate functional annotation [11]. In gene function predictions, a universal approach of combining diverse high-throughput biological information is required. MAGIC [12] is a probabilistic flexible system fora comprehensive examination of high-throughput biological data information that researchers propose here.

The present aspect of the software is of S. cerevisiae, in which there are numerous interesting data inputs. The technique uses a Bayesian n/w to predict if 2 proteins are functionally connected by combining evidence from various sources of data [13-14]. The n/w effectively conducts a probability "weighting" of sources of data, enabling for structured description of expert knowledge about procedures & avoiding duplicate counting evidence [15]. Each projected functional link is given a posterior belief, which allows users to adjust the prediction's rigor.

In this paper, we introduce MAGIC & show how it may be used to analyze physical & genetic interactions, data on experimentally discovered transcription factor binding locations, as well as a set of data for stress response expression on S. cerevisiae [16-17]. Researchers demonstrate that MAGIC could consistently incorporate non-expression biological information into micro-array analysis, which is impossible to do via simply adding such pairwise complexity information to micro-array grouping systems. Researchers show that, when compared to its input devices, MAGIC improves the accuracy of projected functional connections. Top gene clusters created by MAGIC are described, as well as functional estimates based on it.

II. Materials And Methods

The MAGIC system is designed on a distributed architecture that allows for the addition of new source modalities & sets of data with ease. MAGIC is a general framework that could handle a wide range of data formats & micro-array research techniques. Its n/w incorporates interactions between yeast proteins from the General Repository of Interaction Datasets (GRID)& pairings for the gene from Promoter Dataset for Saccharomyces cerevisiae which had experimentally confirmed binding affinity for the same transcriptional activation. In addition, K means grouping, self-organizing map, & clustering method are all included in MAGIC. A system's inputs were gene clusters based on co-expression or even other empirical studies. A Bayesian network, which is the key part of MAGIC, integrates evidence from input clusters to build a posterior view about whether every gene i to gene j pair does have a functional link. MAGIC effectively poses the subsequent questions for every set of genes: And what's the chance that the product of genes i& j had a functional link, based on the evidence presented.The biological process was defined as a systematic collection of molecular processes aimed at achieving a certain biological goal, such as metabolism. The concept is based on Gene Ontology (GO) Consortium's description for biological mechanisms.

A Bayesian network takes as input gene to gene connection matrix, every reflecting one source of data, with component si,j 0 indicating whether genes I & j were thought to get a relationship of functional &si, j 0 indicating when they're not. Because every matrix is created using a different approach, the criteria of functional relationships for every input sequence are determined by the method utilized to produce the matrix.The intensity of every technique's belief in the relationship that exists b/w genes I & j is represented by the score si,j. This score might be a discrete or binary continuous variable. Because the flexible input format permits genes to belong to several groups/clusters, bi-grouping & fuzzy grouping approaches were not excluded.

An output format was identical to that of the source. MAGIC could accommodate any sort of gene to gene clusters, including protein to protein interactions information, grouping technique outputs, as well as sequence-based information, thanks to the versatility of its I/O formats. MAGIC is written in C++ as well as runs on Linux, with a web-based interface in the works.

III. Network Structure

Researchers engaged specialists in micro-array analysis as well as yeast molecular biology to build a Bayesian network model that effectively depicts links b/w evidence from diverse data sources for purposes of ensemble analysis while avoiding double-counting of data. The structure, as illustrated in Fig.1, integrates sources depending on the type of link found. It makes several independent constraints to enable the much highcorrect populating fordepending upon yeast specialists conditional tables input. These independent assumptions were unlikely to alter the results, considering the sparse environment of non-microarray experimental information. Furthermore, because the techniques represented inside the n/w have diverse underlying concepts, its integration for functional analysis is robust. Specialists of seven in the area of yeast molecular genetics formally examined the previous probability. When the experts were interviewed separately, they showed a high level of concordance in his past beliefs. A PATHFINDER N/W for pathology detection, for eg., had effectively utilized the method of generating Bayesian networks probabilistically offered by specialists in the area.

IV. Measurement Procedures

To assess a gene clustering's integrity, researchers must assess the biological relevance/correctness for gene-gene functional couples which belong to that gene cluster. The key criterion in assessing couples of genes having expected functional links is biological significance, although it is a challenging metric to quantify. Is this a relevant grouping,

DOI: rp-9788770040723.070

an experimental mistake, or a biological finding When genes i& j were anticipated were get the connectionof functional nonetheless, there is no biological information related to their features? Although there was no ideal gold standard of gene clusters, annotations under curator control for an S. cerevisiae genome over GO keywords reflect present biological knowledge and thus serve as a fair biological basis for evaluating functional pairings of S. cerevisiae genes. (i)molecular activity, (ii) biological process, & (iii) cellular element are the 3 types of terminology in GO. Every gene could be annotated with one / much more GO keywords from different regions of the go tree since GO has a hierarchical system with the inheritance of multiple. If genes with the same GO annotation phrase on the biological ontology of procedure were thought to be involved in the same biological procedure, researchers focus here on the biological process portion of GO for such an assessment. This is the most important aspect of the ontology of evaluating genes cluster depending on the existence of a functional relationship, even though genes with the same GO annotation phrase on the biological ontology of procedure were assumed to be involved at the same mechanism of biological.

The major challenge in generating physiologically relevant gene clusters appears to be specificity, not sensitivities, due to the high expense of follow-up experimental inquiry. Unfortunately, estimating specificity and sensitivity in S. cerevisiae necessitates information of the entire amount for true positives (TP) &TN couples forgenes that are connected, which is presently hard to estimate effectively. As a result, a percentage of TP pairings is used to evaluate the accuracy of every approach. In its projections, percentage TP method = number of couples predicted by a technique those have a GO term allocation in common/total number for couples predicted via technique, in which TP pairings were also described as couples of genes i& j which have an over-lapping GO annotation of the term:

Gene to gene connection matrices containing gene clusters provide the anticipated couples for every input function, as stated previously. MAGIC systematically includes multiple gene clusters, producing posterior probability of functional relationships b/w every set of genes in the yeast genome.Researchers may compare MAGIC's performance in various ranges of stringency to its input devices since the stringency for MAGIC's projections could be changed by setting the cutoff of the posterior views needed to deem 2 genes operationally linked. By adjusting the cutoff for a score, a median correlation of 2 genes (A, B) and to group's central point (c) that were each part for researchers may vary the stringency of source clustering algorithms. Whenever these clustering approaches were employed commonly for micro-array analysis, really no process is done. Researchers circumvent the problem of favoring techniques that forecast a lower amount of couples in this assessment by evaluating the efficiency of the source clusteringalgorithm as well as MAGIC at every stringency factor.

Researchers utilize MAGIC will be used to connect protein-protein interactions from S. cerevisiae& transcription factor binding sites information with grouping analyzes of a stress response micro-array set of data to demonstrate the potential of MAGIC for the integrative framework of diverse biological data. Researchers evaluate the accuracy for MAGIC's projected functional couples to that of source clustering techniques, demonstrating the effectiveness of MAGIC in merging heterogeneous data.

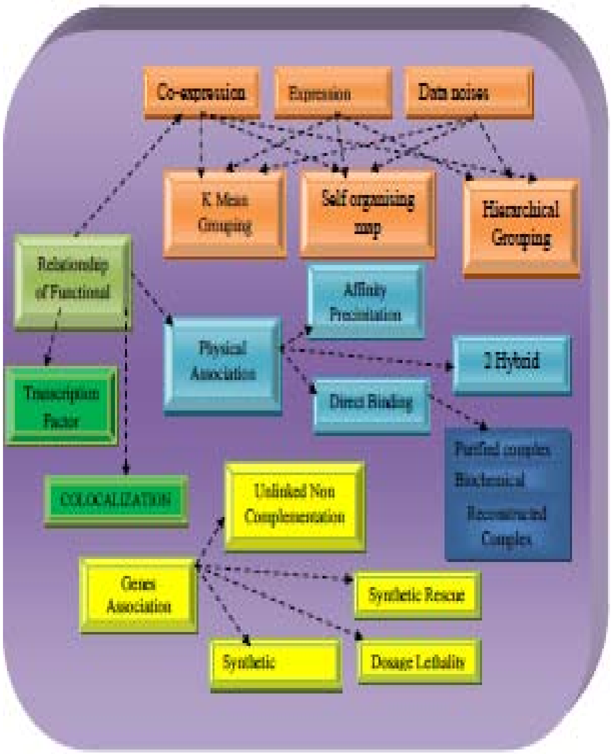

Fig.1.AGIC Bayesian Network

$$S_{A,B} = {}^{x}\!/_{y} \times \int_{k=A,B} \frac{Cov(k,centroid_{\ c})}{\emptyset_k \emptyset_{centroind_{\ \ c}}}$$

V. RESULTS AND DISCUSSION

By utilizing GO with a gold standard, we can assess the biological importance of genes categories. This method of evaluation wasn't without flaws: GO might contain errors in annotation, as well as the activities of several genes inside the yeast genome, were unknown. The false positive (FP) combination of genes might reflect an actual error or a fresh finding, according to the assessment. But certain prejudices may exist inside a subgroup of the gene that was not presently labeled over GO keywords, There's no reason to think otherwise that all those biases might impair grouping techniques in any way. As a result, this strategy provides a sensible & biologically sound foundation for comparing gene categories. Once compared to its input devices, MAGIC continuously increases the proportion of TP couples by incorporating gene clusters depending on micro-array analysis with the already more reliable non-expression based sources of data, as well as MAGIC continuously increases the proportion of TP couples by incorporating gene clusters based on micro-array analysis with the already more accurate non-expression-based sources of data (Fig.2A). High specificity was essential for constructing biologically relevant gene clusters in functional genomic

DOI: rp-9788770040723.070

prediction. As a result, researchers concentrate on the greatest specificity area, in which each technique predicts 1,000 or fewer TP couples (see Fig.2B).

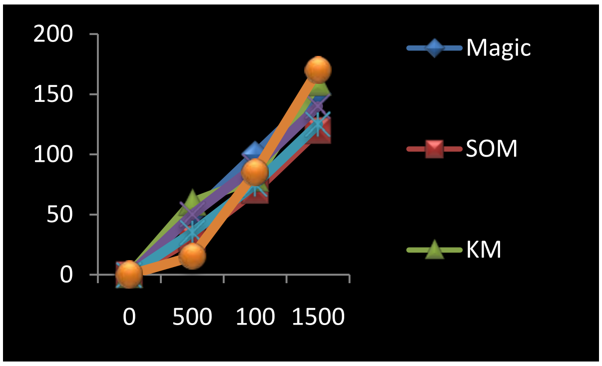

Fig.2A. Non-expression-based sources of data

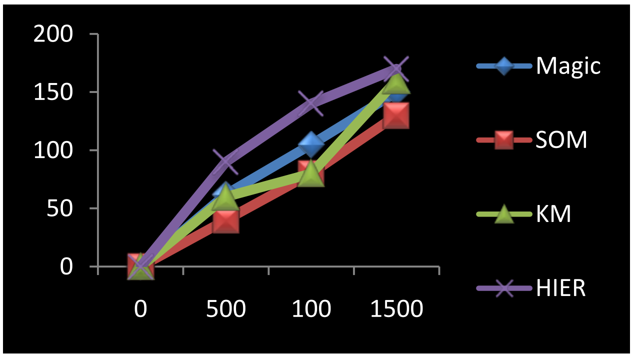

Fig.2B.TP amd FP pairs

When researchers look at the estimates that have the largest percentage of TP couples, MAGIC, which employs non-optimized sources, outperforms the optimized clustering systems, over such a17 percent highlyon the percentage for TP pairings over best forinputssystems but also a most TP couples projected. At very large numbers of projected couples, in which the fraction of TP rates with all approaches are around or below 50percentage, but also at levels unsuitable for precise functional genomic prediction, this variation in efficiency diminishes. As a result, MAGIC generates more physiologically gene that is relevant clusters, over the biggest enhancement inside a highspecificity area.

Micro-array & non-expression information are used by MAGIC. Thus, considering MAGIC's effectiveness based solely on micro-array information / solely on non-expression information is intriguing. MAGIC's accuracy stems partly from the inclusion of non-expression experimental information in the analysis. That's not surprising, then, as MAGIC's efficiency without micro-array information is comparable to the whole system's for a range of over 6,200 projected TP couples (see Fig.2A). A MAGIC application depends on entirely non-expression information that doesn't perform and the complete version as the amount of predictions grows, most likely because it approaches the limit of available information via non-expression sources of data.

Only when micro-array information is considered, however, MAGIC outperforms grouping approaches in the area with such a tiny proportion of couples but has significantly lower TP frequencies than the complete version of MAGIC. When dealing with greater numbers of couples, the micro-array-only system works similarly to the grouping algorithms. As a result, MAGIC utilizes all types of information. It generates extremely precise gene classifications depending on non-microarray experimental information from a multitude of inputs. These clusters were loaded over genes that function in unclear &those functional hypotheses could be generated using micro-array information & other high sensitivity approaches.

Researchers create gene classifications depending on MAGIC's pairwise data by clustering together those genes that have a functional link to the same gene. MAGIC finds groups that reflect the total stress reaction to the surroundings. Such groups are much more specialized for a certain biological mechanism than groups depending on hierarchical grouping which are manually selected. In comparison to a heterogeneous carbohydrate metabolism group depending on hierarchical grouping, MAGIC discovers a group of Snf3, Rgt1, & 5 hexose transporters upregulated in reaction to glucose.A regulation Rgt1, which gets signals via Snf3, a glucose-sensing inside the membranes, induces the transporter in reaction to glucose. With coherent activities involving a multitude of genres, including such protein production (see Fig. 3), MAGIC often detects bigger gene clusters. Protein biosynthesis is ascribed to 49 of 58 identified genes inside the protein biosynthesis group. The research estimates that 10 genes having uncertain annotations inside the group are engaged in protein production.

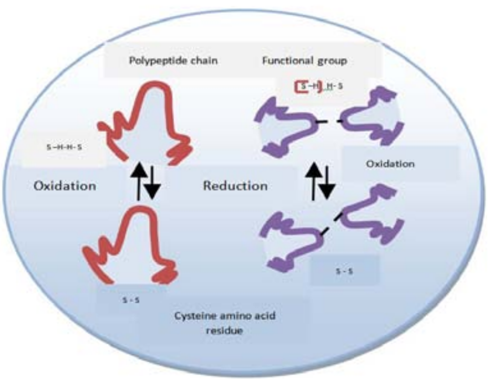

Fig.3. Protein biosynthesis group

As during response to environmental strain, genes responsible for protein breakdown were activated. Refer to Fig.4, MAGIC detects a group of genes associated with ubiquitin-dependent catabolism of protein, gives probable functional annotation of an ORF found in that group, & verifies a previously added annotation of YNL311C. Though Rad23's present GO annotation was "nucleotide-excision repairing, DNA damage detection," it belongs to this cluster. Rad23's role is involved with DNA synthesis probably owing to this prevention for the breakdown repairing protein on DNA damage responding, according to the research. Rad23 connects directly with 26S proteasome & it could play a part in additional degradation of protein processes, according to research. MAGIC categorization indicates Rad23's out-of-date & perhaps deceptive annotation.

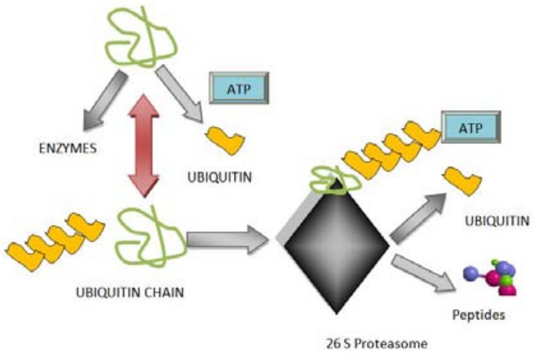

Fig.4.MAGIC detects a group of genes associated with ubiquitin-dependent catabolism of protein

MAGIC thus serves as a durability method of control for current functional classifications for partially characterized genes, in addition to determining the activity of unidentified genes located in clusters well-defined genome. Such examples would be a collection of 3 genes known as PRP8 BUD31& CEF1. PRP8 & CEF1 both are well-splicing enzymes. Depending on a genomic sequence screening of mutations deficient inside the bi-polar budding pattern, BUD31 was currently assigned with bud site location. Although, Snyder & Ni discovered that each number of nuclear proteins, such as those engaged with the processing of RNA, have problems in bud site location, more probably as the result of RNA processing to a gene involved directly with budding. The potential nuclear localization signal had also been discovered in BUD31. Through looking for genes with annotations that don't match some other genes inside a cluster, it's possible to find genes containing erroneous in-complete structural data.

VI. Conclusions

Researchers had demonstrated that MAGIC was another reliable & efficient technique for functional genomic annotation. A method utilizes the probabilistic approach to integrate diverse biological data, resulting in much more physiologically correct gene groups that may be utilized to predict gene function. On combining the outcomes of various algorithms & using the information for biology experts of yeast in the prior probability of a framework of Bayesian, MAGIC avoids the challenge of defining an "ideal" classification approach for microarray data. A system's versatility makes it simple to include different techniques & data sources, and also information from various species.

Abstract—This challenge has been overcome by developing a broad platform based on the K-Nearest-Neighbour (KNN) methodology for functional genomic estimation. KNN was chosen because of its usability or adaptability by incorporating distinct information formats, but also by adapting to unusually extracted features. Conventional KNN algorithms have a flaw in that their efficiency often depends on the random selection of a statistical method, particularly when combined with enormous data sets. We employ estimation techniques to deduce a measure of similarity as a weighted summation of every series various foundation clustering algorithm, which aids in locating the neighbors who are most probably in the same category also as gene product. In addition, they propose a new community consensus to generate insurance ratings to assess projected performance. An approach could be used to resolve difficult interclassification situations. By considering data generated through transcripts or sequence information, they apply this concept to molecular biological estimation based on three well-known categories of Salmonella typhimurium. By extending heterogeneous data sets, they show that our technique outperforms conventional KNN techniques, but is also equivalent to support vector machine (SVM) technologies. We also show if merging separate information providers could significantly improve prediction performance.

Keywords—Support vector machine; K-Means; heterogeneous data; multi-way categorization

I. INTRODUCTION

The rapid advancement of genomic sequence information over the last generation, understanding the biological processes of genes involved substances have become an important approach in article era. On the basis of appropriate biomedical information, computational strategies have been introduced to predict expression profiles [1]. For decades, approaches based on pattern resemblance, like as bloated, were used to annotate determine the sequence chromosomes performance [2]. Since subsequently, a range of new biological financial information, such as gene co-evolution patterns, nutrient fusion processes, transcriptomics information, enzyme production, and nutrient associated issues, were used for operational forecasting [3]. Despite the abundance of whole sequences across hundreds different organisms, either of these methodologies used in combination still creates a bigger number of genes annotated [4].

Combining various data sources for operational forecasting would be a crucial next stage. Various prediction analyses for integrating heterogeneous information have been presented [5]. A supervised classification methodology based on the Markov random field (MRF) concept is employed to describe the enzyme effect in relation of physical processes, biological conversations, and cell proliferation.. When contrasted with using a single quantity of analysis, they determined that using many information sources boosted predictive performance. Investigators attained 87 % affectability or 57 % validity when applying the MIPS classification technique to yeast posttranslational modifications forecasting [6]. Another drawback of their methodology is that it is entirely based on binary coupled linkages. Due to quantization, there could be a loss of data for observed variables such as transcriptomic observations. SVMs have also been improved to handle diverse large datasets [7]. Commonly diagnosed concatenates the relevant features of each data frame, moderate computation provide the associated kernel vectors, while final assimilation includes the different variables from each data document's SVM [8]. More new studies [9] suggest a method for successfully combining numerous units. The challenge of aggregating harmonizing was formulated as a combinatorial optimization problem that may be addressed with moderate computation. Component (nine) departs evidence [9] proposes a way for optimally combining numerous cones.

In this paper, they propose K-nearest-neighbor (KNN) methodologies as a possible solution to this issue. KNN techniques, despite their complexity, are some of the highest performance in a wide range of classification tasks [10].Because KNN configuration contains no assumptions about nature information, they are particularly effective when the classification algorithm was asymmetric or a class included several implementations [11].For biomedical research classification methods, where substantial academic are intrinsically ambiguous and several categories cannot be classed by a simplified example, KNN's adaptability is extremely useful.

DOI: rp-9788770040723.071

This same original KNN's primary concept is as follows: Create a set of quantitative attributes to characterize each piece of information, and then choose a measure to quantify the similarity of pieces of information predicated on all characteristics, such as Euclidean distance [12]. Furthermore, balanced measure, selects the KNN elements in training instances for a destination address, or allocated to the democratic congress of its peers in a group. This technique's performance is impeded by the arbitrary adoption of a statistical technique, especially for large datasets with related created attributes of various kinds and scales [13]. Moreover, the computational burden issue afflicts conventional KNN methods. In a high-dimensional structure, the neighborhood of a fixed location becomes pretty limited, resulting in massive variability. Our methodology alters a usual structure. They develop numerous "foundation" statistical features, among couples of sample points, one estimate from each data provider, rather than creating a separate "universal" matching score among the new providers [14]. Then, based on the fundamental characteristics, they try to maximize the probability of a couple belonging to the different category. The probability calculation could be handled as a typical prediction model in this style.

As previously, the predicted conditional probability should be used as a universal statistical method to select the KNN neighbors. Another of the framework's significant benefits is that even the standardized data system was normalized and their connection is managed instantly through stalling, enabling one to design one clustering algorithm at a moment from a particular dataset while disregarding related link [15-16]. In some ways, our method is analogous to the fractionation process kernels. Each KNN statistical method is equivalent to an SVM kernel, with the exception that the earlier does not have to be moderated, allowing for more formability. Lanckriet's technique incorporates kernel grading with the objectives of increasing SVM classification accuracy. The base similarity metrics are evaluated in our methodology to find the "greatest" k nearest neighbors', who is most inclined to share the different category of the target destination, and so provide the most accurate forecast [17-18]. By decreasing the uninteresting dimensionality of the input space and pushing more essential neighbors' closer to the target location, this method also helps to ease the computational burden.

II. Materials and Methods

The summary is a short summary of our methodology: During the training stage, they estimate the foundation statistical features for all genes in the training dataset and use a regression technique to integrate them into a universal mutual information. In the classification process, they identify k nearest neighbors in the training dataset based on the learned mutual information for a gene with uncertain operational categories, and then apply a customized election system to provide a list of recommendations using posterior probability. Two important aspects are the intricacies of its calculations.

In other aspects, they try to calculate the probability of a set of genes belonging to the same category as a consequence of a set of structural clustering algorithm, which operate as the universal statistical method for determining the closest neighbors. This measurement, in a perfect world, would award a value of 1 to all pairings in the same category and a value of 0 to couples in other categories. Depending on this assessment, the nearest neighbors are in the same class as the template strand, resulting in a prediction. Furthermore, due to the limitations of both collecting data and knowledge on correlating the parameter h, the learning, inference likelihood is only an estimate in practice. Nonetheless, it is an inexpensive KNN framework that incorporates the essential, necessary insights. The matching constant h belongs to the category of traditional regression and classification. (1) To counter this issue, we used two prediction techniques: linear regression or regional prediction.

Let $T_x = \langle l_x^1, l_x^2, \dots . l_p^n \rangle$ be the feature vector

$$log\left[\frac{xr\{D_x=1|Z_x\}}{xr\{D_x=0|Z_x\}}\right] = \int \partial^v Z_x + \rho \quad (1)$$

This varies and is the scale parameter. Because the log posterior probability is asymmetric, supervised classification predictions and could be determined quickly. The probability method is utilized as the statistical method, and the acquired training algorithm reflects the perceived importance of each characteristic. To capture the connections between features, the statistical method might be expanded to complex numbers, presumably including interaction components.

Another way for resolving this issue is to use native instability. In essence, this method calculates the correction factor to matching a different, yet basic predictor (such as a quadratic equation) to each target position simultaneously. Only measurements that are close to the desired location should be used to validate the data, and their ranges for the target position are evaluated accordingly. The local extrapolation model provides more versatility than regression analysis since the prediction curve could mimic any smooth variable. By comparing each simulation in a limited region determined collectively by all the features, this technique could easily incorporate the connection between the characteristics. Regional extrapolation, on either extreme, is more computationally intensive but less extensible. At each random value, a somewhat compact neighborhood is designed to satisfy local algorithms. With discrete features and perimeter data sets, local extrapolation could have problems.

III. Proposed Work

We constructed a basic KNN technique using Euclidean distance, adjusted so that separation relating to an individual source data has a maximum value of 1, assess the performance to the logistic regression both component weighting and the polling mechanism. The basic KNN approach finds this same operational category that receives to most votes from the KNN neighbors provided the k similarity measure. To share power across sections having fair elections, the one of the quickest distance across all sympathetic friends is chosen. We also evaluated the RB-

DOI: rp-9788770040723.071

KNN approaches against the naive Knn algorithm, which is based on all permutations of datasets.

On the different database, we evaluated the SVM algorithm to evaluate RB-KNN to other approaches for merging massive datasets. They found that combining the kernels delivered the best results out of three ways of combining several data sources: concatenate relevant features, integrate the kernels, and combined the differentiator scores. This approach is an unadjusted variation of the methodology, which determines the strengths of each kernel using a moderately computing technique. Even though the latter option appears to be superior, the necessary technology is temporarily unavailable. Interestingly, in many circumstances, the approximate methodology is almost as good as the weighted method, particularly when all picked kernels have similar estimates of future (William Stafford Noble, personal communication), which seems to be the case in our scenario.

The prologue parameter is a kernel, just as the block signal, because it could be expressed to the embedding of the prologue metricizing bring the three particles together, divide the expressive kernel by 8 and put them together so that all three kernels have comparable proportions. For a variety of purposes, we did not employ the chromosomal separation in SVM. First, because the proximity has been calculated on a single chromosome, an acceptable kernel is not immediately evident. They used the partial derivative of either the Euclidean distance row columns as a kernel in the experimental kernel map approach. This same generated SVM, unfortunately, performs poorly (ROC score =. 581). Furthermore, provided another three datasets, the experimental findings for such RBKNN techniques in Table I show suggesting chromosomal separation are repetitive. As a consequence, the SVM is not penalized over neglecting this data.

TABLE I. VALIDITY OF PERFORMANCE

Combination	Navie km	Glm	loss
1111	0.48	0.59	0.65
1011	0.56	0.52	0.65
1010	0.48	0.49	0.51
1000	0.41	0.42	0.48
0100	0.45	0.47	0.54
0010	0.39	0.65	NA
0001	0.39	0.65	NA

IV. RESULTS AND DISCUSSION

To highlight the capability of proposed strategies regarding component grading and casting, they will first evaluate the results of RB-KNN and that of conventional KNN techniques in this chapter. Furthermore, we'll contrast our methodologies with an SVM-based strategy for combining large datasets. Eventually, we'll look at effectiveness based on the structural categories. A short description of the relationship among posterior probability and forecasting models has been included, as well as aggregate information based on all three classification systems. Furthermore, the chapter discusses the findings of erroneous assumptions, they would examine several of the difficulties with this issue. All of KNN techniques they examined were titled that after techniques, which could be keen (deluded KNN methodology), glm (logistics extrapolation predicated KNN), or less (regional stagnation predicated KNN), but then the information sources. In the sequence of interpretation association, chromosomal separation, block signal, and paralog signifier, this requirement usually expressed in sequence in that each value denotes whether a collected information was included. For instance, Laos. 0001 denotes a KNN approach depending on local extrapolation that only uses the prologue signal, while knn. 1111 denotes a naive KNN method that uses two, four data collections. They used "svm. Comb" to test SVMs on a group of statistics that included the statement, restrict, and paralog statistics. They also tried SVMs in this scenario, termed "svm. Exp," because expression data independently is often employed during operational categorization. They did the 5-fold classification algorithm across each experiment or presented overall results.

4.1 Comparative approach

We evaluated various RB-KNN approaches toward the naive KNN methodology in order to see how effective they are in integrating different data sources using appropriate feature grading and casting algorithms. We investigated the predictive ability of each additional source of information or whether integrating more data sources significantly improve by testing each approach with varying configurations of different databases. By standard, the KEGG classification methodology has been used except otherwise stated. They only looked at the 1603 genes that were allocated to operational classifications. Each gene could be classified into numerous functional categories, with a maximum of 2144 operational categories. Because the naive KNN strategy allows only one forecast for each transcript, they choose the greatest single estimate for each genotype for RB-KNN methodologies the ensure an equal assessment. We discovered also that naive KNN's effectiveness appears highly dependent to k, this same neighborhood radius, but that lower k is typically preferred.

They also discovered that throughout the RB-KNN techniques, using more sources of information seems usually invariably advantageous. Considering some other three data sources, the dataset includes "1011" delivering exceptional results throughout our studies, implying that chromosomal separation is really a superfluous source of data for operational forecasting. The effectiveness of RB-KNN algorithms for information source "1111" is nearly always different downweighting unnecessary features. In glm. 1111, Table 2 provides algorithm values to every source data. Introducing chromosomal proximity to some other three sources of data, on either extreme, leads of considerable fall in effectiveness using naive KNN. Even though only one or two information systems are utilized, loss performed better than film, fore more the variation in performance in different approaches approaches trivial when more information sources were employed. Weights to every data provider are listed in Table II.

TABLE II. DATA WEIGHTS

Sources of Data	Expr Correlation	Chromosomal distance	Block indicator	Paralog indicator

DOI: rp-9788770040723.071

Weights(w)	1.96 ± 0.15	0	71 ± 0.06	4.61 ± 0.10

The reliability of the RB-KNN and Svm classifiers was evaluated. We employed transmitter operational conditions (ROC). A ROC curve shows the relationship between the likelihood of detection and responsiveness as a function of a weighting factor. Because this is an inter classification task, the overall amount of forecasts typically computed as the sum of the group of genes or the number of subjects, although in the case of KEGG is 1603 * 18 = 28854. Each forecast has a grade assigned to it, such as RBKNN probability value or the SVM differentiate quality. The positive result frequency and sensitivity for one spot also on ROC curve have been computed using forecasts beyond a specified tolerance, which are sorted depending the overall ratings. (One downside of using differentiator ratings to grade forecasts is that they're not equivalent across categories because each group has its own SVM.). Fitting a deterministic sigmoid activation function depending on characteristic ratings for each class separately would be a reasonable solution. They anticipated the instrument for assessing to become more consistent across categories therefore generate higher standing, although the associated ROC rating seems to be definitely lower, just 0.81 as opposed that 0.91 throughout the existing approaches, therefore they didn't use it.

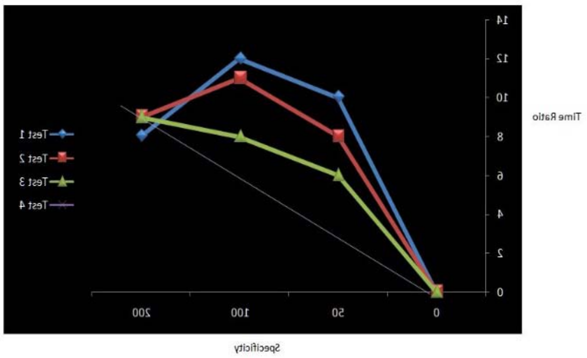

Fig.1. ROC curve assessment

In Fig.1. represents the ROC curves of a few of the techniques they investigated are shown in Table 1. It's worth noting that the overall amount of erroneous categories in this challenge is approximately an astronomical amount more than the proportion of actual categories. Although the techniques' ROC scores seem to be relatively similar, they are only concerned inside this portion of ROC curves where the prediction error relatively minimal in practice. The techniques perform very differently in this area. The ROC curves reveal that the predictive capacities of all the information sources are relatively close, including prologue signal, chromosomal separation, block signifier, and transcriptional relationship listed from greatest to worst. Glm.1000 is a swimmer. The efficiency of methods depends on differential expression is fairly similar, maybe less so. 1000 is a significant improvement. Furthermore, due to increased model adaptability, Laos. 0100 outperforms glum. 0100 (data not shown).

4.2 Performance measurement

Fig.2 demonstrates the vulnerability of four strategies (Exp, Laos 1000, SVM, glum 1111, classifier. Comb) at 50% right for all functional domains. They categorized all estimates based on the genuine operational multiple genes for each technique. Then, to every class, we chose the estimates that were above a 50% confidence criterion and determined the proportion of genes that were successfully predicted. Except for class 15, we found that loss. 1000 significantly beats SVM, Explain in class. This is particularly true in class 17, where swim. Explain has a susceptibility of 8.7% and less. 1000 has a sensitivity of 71.7 percent so at boundary limit. SVMs employing quadratic or circular kernels also perform badly (0 percent, 10.9 percent conversely, susceptibility). That demonstrates that classification methods for class 17 has a unique feature that cannot be captured using SVM modules, but could be detected using RB-KNN techniques in Fig.2.

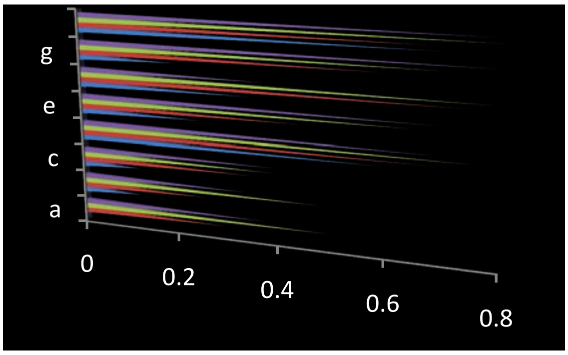

Fig.2. Sensitivity, accuracy in organizational procedures

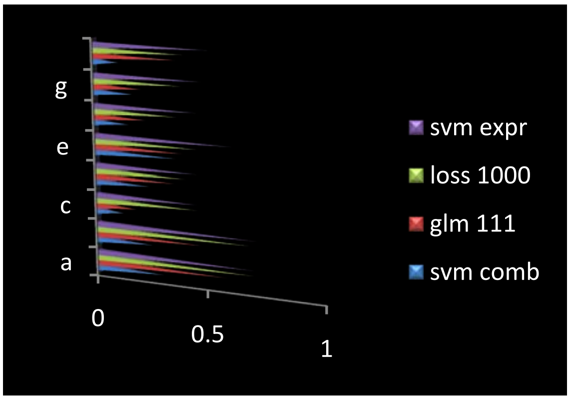

Fig.3. Proposed with existing algorithm comparison

Through all operational categories, glum, 1111 and swam. Comb has reasonably similar effects; both are preferable to technologies based solely on microarray datasets in Fig.3.. Both classes 20 (Cell Digestibility) and category 13 (Interpretation) have excellent prediction performance when all four techniques are used. In darkness, the ROC values for such 2 categories, 1111 are 0.97 and 0.96, correspondingly. Most genes in these 2 categories are recognized to be co-regulated, and most are expressed in integrons, which explains the excellent categorization findings for such 2 categories. Because many representatives of Class 17 (Signal Effector) and Class 16 (Membrane Mobility) have comparing specific protein structures, the prologue signal is useful in both categories .It

DOI: rp-9788770040723.071

seemed gloomy. 0001 has a responsiveness of 80 percent for another 2 categories, but 76 percent in the other.

They looked at a set of erroneous forecasts with a great deal of confidence. Many of them would be caused by the fact that genes can correspond to different functional groups. Various classification approaches for such genes could focus on the importance of their functional activities, and comments may be lacking. Furthermore, because all genes connect with one another in some way, the beforehand such are hazy. It's hard to see the difference across class 1 "Complex Carbohydrate Respiration"Glucose Metabolism" are two categories. Several genes engaged in signalling pathways (class 17) processes, for instance, are also participating in membrane integrity (class 16). False negatives, or correct forecasts with low levels of confidence, were also examined.

Heterogeneous or small method categories cause a lot of false negatives. Class 10 (Metabolites of Bioactive Molecules), in an instance, has just 24 genes in their database but can be divided into nine classifications. Such classes are notoriously hard to characterize. False negatives are further exacerbated by deserting neighborhoods caused by the lack of knowledge. Approximately 20% of genes in KEGG have no operationally evaluated paralogs, co-expressed genes, or chromosome neighbors with identified measures larger than 5, implying they had professionally foundered genes, evaluated paralegals, or chromosome relations. The only way to overcome this problem is to provide additional training examples.

This research makes a major addition by proposing a new methodology to merging heterogeneous data in the KNN paradigm, which comprises two essential elements: a regression-based grading methodology and a deterministic election process. The prediction model, which takes into account their exceptional acceleration factor affecting, encompassing their interconnections, affects the intensity of each data provider. An election technique made inferential analysis easier by combining component category suggestions from the KNN neighbors, but also producing a sorted list of recommendations having posterior probability. This method also permits a gene to be classified into numerous performance categories. The local estimation technique performs better via one of two information sources, likely to increase model variability, while linear model is more resilient or adaptable, according to our findings. We've shown that merging four datasets produces good outcomes. We produced incredibly competitive performances in comparison towards the Neural Network Based technique, which mixes large datasets. Their ROC curves are extremely similar in accuracy was obtained larger than 50%. SVM performs better for genes located near to class boundary, but at the expense of a significant false alarm rate. RB-KNN algorithms have the excellent potential at same degrees of effectiveness: SVM requires tractor trailer support vectors, whereas RBKNN supports unlimited interpersonal correlations. Furthermore, RBKNN generates supplemental data (e.g., nearest neighbors along corresponding resemblance ratings) to aid throughout the discussion of the data during post-processing.

V. Conclusions

There are several ways in which we might enhance our techniques. We created a single prediction model for all data in the testing phase in this investigation. The prediction accuracy of each source of data, on either extreme, may range from grade to grade, and they may be evaluated accordingly. An amount of training data is such benefit of our current strategy; one disadvantage is the clear lack of performing this task. A one-class-one-model strategy, on either extreme, is the absolute antithesis. For categories with massive populations, an alternative approach is to construct class-specific models. The regression analysis can be very problematic when parameters are highly correlated. To construct more predictive results, you can use principal deconstruction or controlled extrapolation approaches like regression. Another possibility is to employ improvement complex predictive model. For example, from 106 types of experiments, we only derived one fundamental similarity measures, transcriptional association. Nonetheless, some palettes are more useful than some others, or the relationship between them might vary greatly depending on the number of studies used. By employing Correlation analysis depending on all 106 trials, such evidence is omitted. One method would be to divide the operations across different subgroups and calculate a baseline semantic similarity for each group. They could be immediately combined with other sources of data, such as chromosomal similarity, or they can be blended using regression techniques, which could then be correlated with other information. A pyramidal techniques have advantages to use only a few terms for each extrapolation, making it more durable than a conventional framework that incorporates all characteristics. They found overall optimism ratings are directly correlated with forecast performance, however, the association is not continuous, and the values expand as the size of such neighborhood grows. We would want a scoring system which is the more regular overall reliability of standardized methods.

Abstract—Gene Ontology (GO) is a systematic taxonomy that employs organize languages to explain the biochemical activities, functional activities, including tissue placements underlying transcription factors. Gene Ontology (GO) markers link proteins to GO concepts as well as show which genetic variants perform the physiological activity specified by the words. Forecasting proper GO descriptors for individuals from a large number of GO words specified by GO, on the other hand, would be a challenging task.To address these issues, researchers present a conceptual approach for functional genomics predictions involved in Gene Ontology Hierarchical Preserving Hashing (Phish). Phish begins by comparing the taxonomy homology of GO keywords. It all then optimizes a succession of hashed algorithms to store huge GO concepts via a small binary format, using a hierarchal structure scrambling method to maintain the hierarchical system between GO words. Following that, Phish uses those scrambling techniques to transfer the gene-term connection matrices into a cheaper region, where it conducts lexical resemblance gene function estimation. Phish outperforms existing similar methods as well as being resistant to the number of encryption schemes, according to experimental observations on 3 model organisms for intercultural gene function forecasting. In particular, researchers use Phish as a BLAST-based gene function forecast component. According to the findings of the experiments, Phish greatly enhances forecasting accuracy.

Keywords: Gene Ontology; Hierarchy Preserving Hashing; gene function; Phish Technology

I. INTRODUCTION

Most biological activities, including those of metabolic, hormone control, including cell signaling, rely on genetic variants, including such enzymes including RNAs [1]. Medication research, illness research, gene collection expression values, as well as other disciplines, could benefit from detailed information on all these genetic variants. Moreover, because detecting the gene functions using wet-lab approaches was labor-intensive, costly, as well as limited bandwidth, operational classifications of genetic variants lagged substantially while behind the speed of acquired genetic information [2-4].Moreover, the operational classifications of genomes were influenced by biologists' research goals, including experimentation morals including people and animals. As a result, developing mathematical algorithms to effectively as well as accurately identify genetic activities was highly necessary.GO was created as a collaborative attempt to enable computerized gene function forecasting as well as to organize biological material of genes as well as their metabolites in a formalized as well as uniform manner among genomic information [5]. The Gene Ontology (GO) would be a collection of concepts as well as a foundation for describing the activities of genetic variants across all species. The GO research was made up of two parts: the Ontology, which uses a directed acyclic graph to organize GO words, hierarchical structures, and goes markers, which link proteins but rather gene products to GO concepts [6].

A GO word in the DAG denotes higher specific operational information than its progenitor words. If a GO word was associated with a gene, its ancestor phrases also were associated with that gene, but not another way around. On the other side, if a word must not be attributed to a gene, then neither would its descendent words [7]. In the field of gene function, structural similarity-based techniques have been intensively researched. Those approaches were predicated on the fact that semantic relatedness produced from gene GO classifications correlates with familiarity estimated from a variety of biological information, including such sequencing, gene expression patterns, as well as posttranslational modifications [8]. These primarily aim to fill up gaps in GO classifications imperfectly identified genes [9].The structures of GO descriptors could be designed to estimate gene function using a tree structure or perhaps a Bays classifier coupled to the data. However, to effectively estimate the likelihood function between GO words, such a template method requires enough annotations [10].

II. RELATED WORKS

As a result, it is incompatible with sparse words assigned to less than 30 genes. In practice, the majority of GO words were sparse words; with various GO words having varying amounts of associated genes, as well as the amounts are quite unbalanced. Because sparse words convey

DOI: rp-9788770040723.072

a higher precise basic understanding than their parent phrases, which have been linked to many more genes, it's preferable to forecast the future relationship among sparse words as well as genetic mutations. To consider explicitly, researchers employed the GO structure to calculate the relationship between GO words as well as put the results into a gene function predictions algorithm [11]. Their research shows that integrating the relationship would increase forecasting accuracy greatly, particularly for sparse GO keywords. Many gene GO classifications were imperfect, and fresh GO classifications were added to those same proteins on a constant schedule. To predict empty gene GO annotations, a randomized walking systematic model has been used [12]. It must be motivated by the finding that the GO words refilled to a gene usually match the grandchildren of the words previously ascribed to the genes. That approach also generates additional labels for a gene depending on the characteristics of its conceptual surrounding genes as well as the predicted identifiers [13] to take the benefit of annotation from other genes.Just GO evaluations of genes from the very same genus have been used to evaluate those linguistic resemblance alternatives. Because God would be the genus and therefore can tag genetic variation, species with the same GO concepts, the semantic relationship among genes across various organisms may also be assessed [14].

These investigations reveal that GO comments from separate species were complementing to be together, but also that the forecast performance improvement was clear for two varieties with strong homology; however, the increase was insignificant for two varieties having poor homologous recombination.The abovementioned conceptual techniques can't effectively quantify the semantic relatedness among genes having regard to huge GO keywords based on partial as well as sparse GO classifications [15]. Large GO keywords also are a problem for gene function forecasting models that combine heterogeneous biological information.The GO hierarchy could be utilized to make reliable forecasts as well as increase forecasting accuracy dramatically. These GO words reduction approaches essentially use the GO hierarchy largely represented by the gene-term interaction matrices explicitly as well as convert the GO DAG into an undirected one to make management sets. As a result, those who do not follow the GO structure well enough, negatively affected [16]. Humans present a computer methodology based on GO Phish for functional genomics estimation to overcome the difficulties with existing GO words pressure methods. The fundamental goal of Phish would be to solve the problem of accurately guessing gene-to-massive-GO-term correlations. Phish could not only retain the hierarchy system areas And provide words in a cheap environment but rather the taxonomic homology between GO words, increasing the accuracy of gene function forecasting in that storage.

III. Proposed Methods

To evaluate taxonomic resemblance among words as well as preserve the GO hierarchy, Phish initially utilizes a meaningful biological matching score. Then it uses a ranked team scrambling method to optimize a set of scrambling algorithms that could keep GO words' similarities as well as their structures of power. The gene-term correlation matrices were subsequently compressed into a low-dimensional one using these cryptographic techniques.Following that, Phish uses the compressing gene-term interaction matrix to quantify semantic relatedness among genes as well as guesses activities of a gene depending on descriptions of its semantical neighbors. Those forecasts then were projected return to the initial GO words universe, resulting in the formation of gene-to-massive GO term relationships.

The goal of scrambling would be to learn information as well as task-specific hashing algorithm that produce compressed digital signals while maintaining the original information's comparable associations. Phish, on the other hand, seeks to represent huge GO keywords using compressed binary digits that maintain both the taxonomic identity and the structures of power among those. Researchers employ Lin's resemblance throughout this research, which would be a sample taxonomic measurement extensively used during hierarchical Ontology. To accomplish a purpose, researchers utilize a well-known metric called Standardized Discount Cumulative Benefit to assess the integrity of the hierarchical ordering leaderboard:

$$NDCG = \frac{1}{L_x}\int_{y=1}^{n} + \frac{2^{k_{xy}} - 1}{log_2(1+y)} = \frac{1}{L_y}\int_{y=1}^{n} + \frac{2^{k_{xy}} - 1}{log_2(1+s_x^y)} \qquad (1)$$

$$s_x^y = 1 + \int_{v=1}^{n} + sgn(Ham(t_x, t_y) > Ham(t_x, t_v)) = 1 + \int_{v=1}^{n} + sgn(t_x^M(t_v, t_y) > 0) \qquad (2)$$

Humans could see from the approximations in Equations (1) & (2) That NDCG favors phrases having smaller ranking commands over words with big rating values. As a result, rather than include all my words, NDCG was frequently cut at a specific order of popularity. Because the deepest point of branch words in the GO structure was currently 15, q could essentially be set to 15. The bigger the NDCG number, the further the scrambling algorithms coincide with the priority order, according to the specification of NDCG.Whenever the Distance measure between GO words generated respective individual hashes was entirely consistent with hierarchy structure as well as mutual information among tea as well as other words, the maximum NDCG score was reached.By maximizing the NDCG measurement, the desired scrambling algorithms could guarantee that the scrambling algorithms were compatible with the taxonomy resemblance of GO words, as well as preserving the relative ranking of GO aspects. The NDCG across m GO periods was maximized as follows, depending on the above order to prepare:

$$B(T) = \int_{x=1}^{n} + \frac{1}{L_x}\int_{y=1}^{n} + \frac{2^{k_{xy}} - 1}{log_2\left(1+s_x^y\right)} \qquad (3)$$

$$s_x^y = 1 + \int_{v=1}^{n} + sgn(t_x^T(t_v, t_y) > 0) \qquad (4)$$

DOI: rp-9788770040723.072

IV. Results and Discussions

To assess the effectiveness of Phish-based cross-species gene function forecasting, researchers performance management process in a medieval to current manner. The previous comments seem to be the GO annotations of 3 model organisms completed on 2020-05-07, while the latest comments seem to be the GO evaluations completed on 2021-09-01. Researchers use previous identifiers to educate Phish as well as create gene function predictions, as well as then we could use contemporary identifiers to confirm the predictions. Humans obtained the historical and current GO classifications from Gene Ontology simultaneously, as well as the current ontology documents. 2 GO adheres to the standard of annotating genetic instructions at every genus database to some of the most relevant and comprehensive levels in the ontologism that accurately reflects the biology of the gene product; straight comments were interpretations that have been available immediately in the reference documents.Humans additionally annotation all the parent words of direct connections of a gene to the very same gene using the True Path Rule. Humans exclusively utilize words accessible, including both preserved Ontology data during trials to minimize the influence of GO modification, as performed in CAFA.

V. Comparative Examinations

Baseline as well as Baseline explicitly calculates the semantic relatedness among genes in the same GO words field using the Based feature selection as well as a Cosine measurement approach, and afterward, utilize a comparable KNN classifier as Hash GO as well as InterGFP for functional genomics estimation. ClusDCA seems to be a variation of Cloudscape that employs SVD to condense the Gene Ontology mapping function into a cheap environment before doing gene function estimation in the reduced area, similar to HPHash as well as Hash GO.hash seems to be a variation of Phish that seeks cryptographic techniques immediately using a clustering algorithm of GO instead of using Lin's resemblance. Because the correlation between a nongenetic as well as other genes was 0, those approaches cannot identify activities for genes which annotation was wholly unexplained.

As a result, researchers confirm Plash’s efficacy in sequencing information functional genomic forecasting, which may also generate predictions for genes that seem to be essentially annotated. Researchers use Phish to condense the wide gene-term correlation matrices into a cheap version, as well as BLAST to calculate sequence identity across genes, before estimating the model depending on the collapsed relationship matrices as well as pattern similarities. Humans utilize Rank Loss rather than RankingLoss to keep these things comparable to the rest of the assessment criteria. Throughout this approach, the greater the efficiency, the greater the value of all of the other evaluation criteria. Humans select the most suitable q conditions with the biggest probabilities as the appropriate words of a gene, as well as q has been equivalent to the expected amount of captions of a gene, as completed in an earlier study, as well as humans recognize the top q conditions with the biggest probabilities as the appropriate words of a gene, as completed in a past analysis.

Some measures appear to be related simply to the projected numerical connection matrices. Because all these measures assess gene function predictive performance from either a variety of perspectives, it's challenging for one technique to regularly beat others throughout all measures. To compare as well as quantify the efficacy of refilling GO descriptions of largely characterized genes, researchers perform research on GO classifications of 3 model organisms stored in various decades.

The revised GO classifications of every species stored in 2021 have been used to verify the predictions, and go classifications of these creatures stored in 2020 were utilized to build gene function, forecasting models.

The neighborhood size k is set to 300; the password bits duration d was adjusted to 60, the parameters were set to 0.1, as well as the variable was adjusted to 0.01. Those settings have been set as indicated by the researchers in the primary documents. The neighborhood, as well as dimension parameters for the methods based, are much like before. Table 1 of the Support and contribution contains the documented experimental data among those contrasting approaches.The boldface information within every column among those figures seems to be the best possible result from multiple methodologies of comparative. Across all 3 species, including across practically all assessment methods,

DOI: rp-9788770040723.072

Phish beats alternative comparative approaches in identifying gene function, as shown in the following figure. Hash GO, similar to Phish, utilizes network cryptographic algorithms to compress the gene-term connection matrices into a low-dimensional another before doing semantically resemblance gene function forecasting; however, it often falls short of Phish.

These findings demonstrate that the selected GO hierarchal structure scrambling method outperforms Hash GO as well as cloudscape in respect of research including using hierarchical structural linkages among huge GO words. Another intriguing discovery would be that Phish usually fails to Phish, even though they might equally preserve the GO words' hierarchical structures.The reason seems to be that Phish employs the GO dense mapping function, which really only stores the family link areas and provides words and does not properly store additional genetic heritage connections. S, on the other hand, has been used by Phish to store not just too genetic heritage links areas and providing words, as well as other types of associations. Although those who utilize a comparable KNN classifier like Phish to forecast genes involved, two control techniques yield similar outcomes with everyone, plus those who frequently maintain similar findings using InterGFP. This seems to be because those same three techniques employ the high dimension dense GO words universe to quantify the semantic relatedness of genes as well as forecast genes involved. This finding implies that the strength of semantic interaction calculated using huge GO words suffers from superficial as well as inadequate annotating, but the semantic relatedness generated from condensed Y suffers less. The findings for Fax, Smin, and MCC on Early humans were seen in Fig.1 (a), (b), (c) of the Resulted. Phish was extremely resistant to hashing bits sized, or perhaps the complexity of a compacted gene-term correlation matrix. Such consists of results, on the other hand, were susceptible to do and then have oscillations inside the examined d ranges. Furthermore, researchers find that Phish facilitates movement, steady sometimes at d = 5 as well as d = 10, and that this is untouched by password mismatch. These findings show that high numbers of GO words could be represented using simple binary frequent patterns, and that certain GO word seems semantically related enough to be combined. In reality, researchers investigated the responsiveness of d in two additional organisms; the experimental findings reveal identical interpretations of the results, and they've been deleted from this paper to conserve content. Humans could deduce from either of these results that specifying an important performance value of d using HPHash was simple.

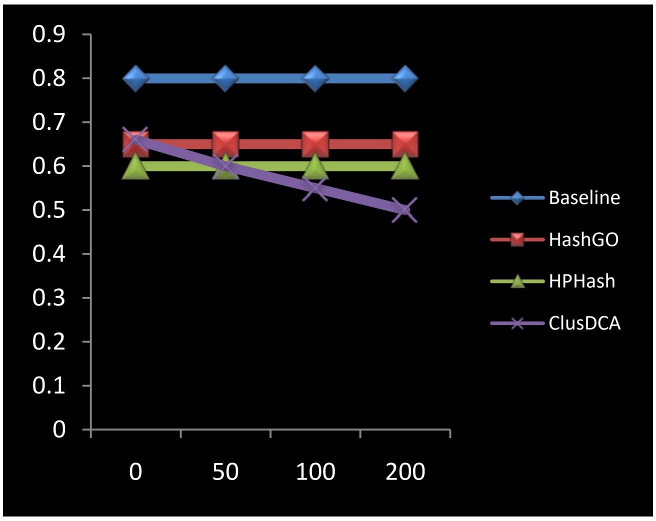

Fig.1(a). Sensitivity analysis of hash codes length

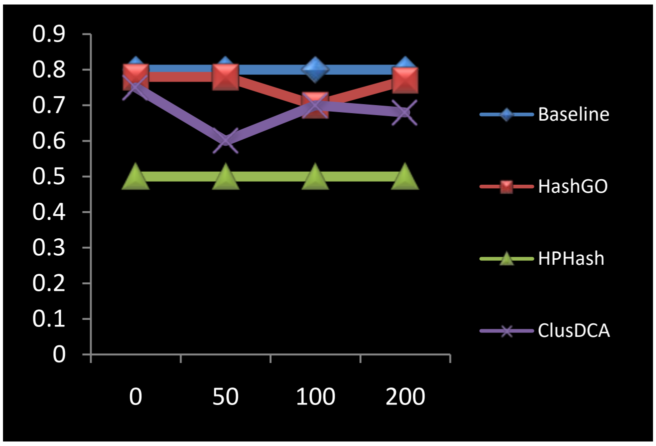

Fig.1(b). Sensitivity analysis of hash codes length

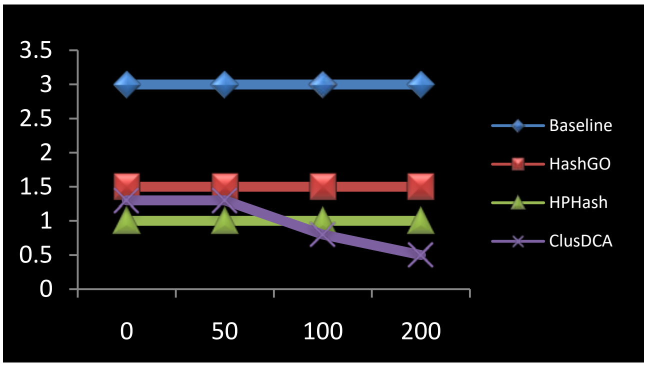

Fig.1(c). Sensitivity analysis of hash codes length

The outcomes on Homo sapiens for various k input parameters were seen in Fig.2 of the Supplemental Material. Humans could see that the initial value of k seems to have little effect on Phish. Many comparative approaches, from the other side, were susceptible to k. Moreover, selecting an efficient k for most of these comparison techniques was difficult since there is no definite trend for selecting an appropriate k that produces superior Fax, Sin, and MCC. Phish, on the other hand, was essentially unaffected by k.The excellence of Phish could be credited to the GO power structure conserving hash functions, which could also effectively start exploring as well as implement the relationship existing between GO aspects, allowing for a more precise measurement of similarity measures among genes, including the replenishment of GO captions as well as the reduction of the influence of imperfect captions. Humans could deduce from all these findings that choosing an efficient k for Phish was simple.

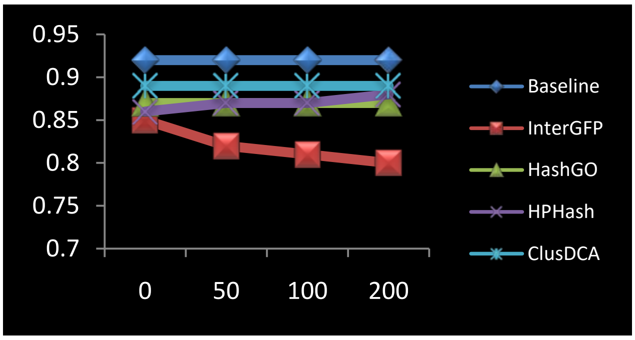

Fig.2(a) . Sensitivity analysis of neighbor size k.

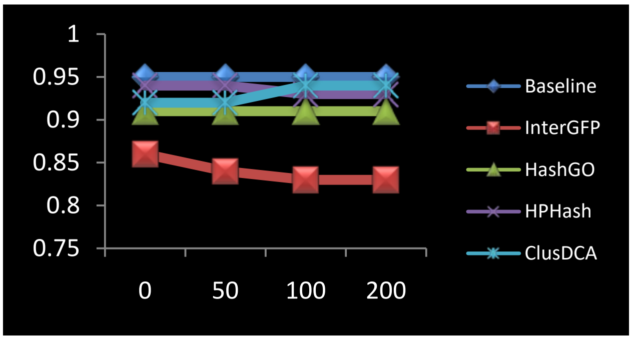

Fig.2(b) . Sensitivity analysis of neighbor size k.

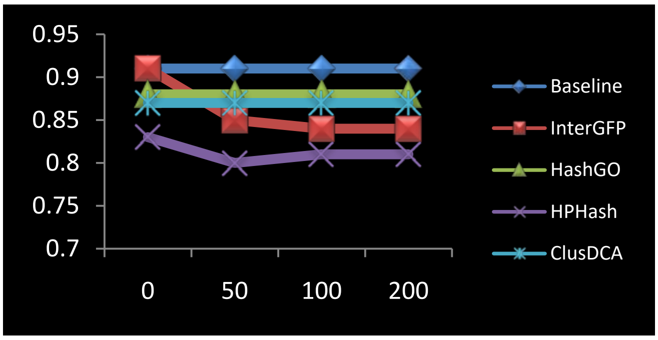

Fig.2(c). Sensitivity analysis of neighbor size k.

Fig.2 (a), (b), (c) displays that BLAST + Phish outperforms BLAST regularly. Since the previous gene-term affiliation structure would be a sparse matrix as well as the compact somebody may not be as sparse, the BLAST predicted gene-term affiliation structure seems to be sparse as well, while the affiliation framework of BLAST + Phish has been retained by cryptographic hash features H and therefore also contains the most nonzero records.Because all these nonzero values affect Aargau, BLAST + Phish occasionally do have a smaller Aargau than BLAST. BLAST + Phish, on the other hand, consistently outperforms BLAST in terms of Fax as well as Sin. The variance among BLAST as well as BLAST + Phish across one of these 3 species as well as assessment criteria also was assessed using signed-rank testing, with a p-value of less below 0.001. Based on this approach, researchers could infer that Phish may be utilized as a component for sequencing information gene function forecast, and it can increase forecasting accuracy greatly.

VI. Conclusions

Among the most important responsibilities in the specific biological age was predicting genetic mutations. Lexical similarity-based techniques were also used to deal with the challenge that has shown considerable success, however, the majority of methods struggle from scant as well as inadequate genes GO classifications. To enhance the assessment of semantic relatedness among genes as well as for functional genomics forecasting, various GO keyword condensing methodologies have been developed. Even during the process of compression, though, individuals might not always obey the Gene Ontology structure, which may impact forecasting accuracy.Researchers offer a Phish based on Gene Ontology Hierarchy Preserving Pattern matching to resolve this challenge as well as quickly predict the relationships among genes as well as huge GO keywords. During the optimization of hashes, Phish may preserve the taxonomic resemblance of GO words as well as the structures of power among those. The hashes reduce strong gene-term connection matrices to a cheap version, making it easier to accurately measure semantic relatedness among families as well as predict gene function.

Abstract—Linear non-coding RNA (lncRNA) has recently attracted a variety of research, critical attention to some intriguing new knowledge about its essential functions. Thousands of lncRNAs were discovered in absurdly short durations because of tools like RNA-Seq. Only a handful of them should be intrinsically depicted, although, due to lesser citation incidence. Wet lab tests to elucidate the roles of lncRNA are complex, laborious, and sometimes ridiculously expensive. This research explores the critical topic of generating molecular docking toward determining the essential functions of lncRNAs. The model provided here uses a measure based on a systematic review known as AvgSim on a heterogeneous network infrastructure to predict various lncRNA (HIN) RNA activities. The same framework is designed with proposed statistics on the lncRNA enzyme or activity relationships and information on the lncRNA co-expression and linkage proteins. The proposed methodology forecasts probable capabilities for 2,695 lncRNAs with a reliability of 73.68% out of 2,758 lncRNAs evaluated for investigation and was performed remarkably better than other methodologies like a random forest for an impartial training dataset. These same linked roles of two well-known lncRNAs are investigated inside as an example. The findings were confirmed by research observations identified in this review.

Keywords—Heterogeneous Intelligence Network; noncoding RNA; statistical approaches; Random forest approach

I. Introduction

They possess essential features like enzyme translating capability and structural conservation, which are also required for biological functions. Until a generation later, many quasi segments of RNA were thought to be 'garbage,' having no specific genes [1]. Recent evidence suggests that lncRNAs play a part in developing cellular mechanisms, including cell-type-specific expression, intracellular element distribution, and sickness correlation [2]. The activity of lncRNAs is engaged by these physiological and morphological attributes because it is no longer considered. Even though many lncRNAs have been discovered to date, the amount of adequately annotated lncRNAs is meager [3]. The asymmetry in lncRNA identification or categorization frequencies is responsible for the lack of functional awareness concerning lncRNAs. Wet labs' investigation to characterize lncRNA operations is costly, consequential, and exhausting. As a result, the computational intelligence approaches anticipating lncRNA activities are an urgent requirement in lncRNA exploration [4]. Consequently, a distinct field of study has evolved in which computer architecture is employed for lncRNA investigation. The web techniques rely more on the channel's implicit information than on the biological features of lncRNAs [5]. Consequently, such attempts gained popularity in a short amount of time. The cornerstone of infrastructure approaches is built on two assumptions. First is the "remorse by association" theory, which holds that genes that regulate biochemical reactions might co-express proteins involved in the same activity [6]. The second is that while executing a function, compounds communicate with others. As an outcome, while developing a model for predicting lncRNA activities, the relationships of lncRNAs, especially their co-expression, should be emphasized [7].

II. Related Works

The interacting links among lncRNA and enzyme are used as the primary component to create a channel in the number of existing methodologies for a statistical sense of lncRNA functions. Approximately 340 lncRNAs were designated categories based on the functionalities of nearby molecules in an encoding non-coding genetic co-expression system. This was among the first experiments at predicting lncRNA function. Molecular interactions were not examined in this study. Interacting protein data from the international lncRNA function and performance tool (link-GFP) into the co-expression system [8]. It identified 1,625 lncRNAs that had biological functions. However, none of the other approaches processed data from Next Generation Technology (NGS).In the available research, all internet techniques rely on the lncRNA - protein association as a critical criterion for developing a predictive model the capabilities of lncRNAs [9].As a consequence, these approaches could be used to forecast the activities of lncRNAs with known protein complexes. The lncRNA-

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.073

lncRNA linkages should be considered in order to employ this same benefit of an infrastructure paradigm. Even with the lack of protein sequence relationships, the proposed study analyses lncRNA-lncRNA interactions and forecasts overall activities of lncRNAs.After the HIN is built, a coefficient of determination is used to determine relevant promoter regions meta-paths [10]. Along certain results were compared, the connectedness metric AvgSim is determined. The features for a Classification Algorithm that predicts lncRNA processes were formed by combining the AvgSim scores along multiple metapaths. In comparison to existing approaches that rely solely on lncRNA-protein interactions for forecasting, the proposed study makes advantage of HIN's meta-path based knowledge. The technique assigns available features to a maximum of 2,695 lncRNAs.The precision is proved statistically using involves attempting through a recent review research [11]. The outcomes of a research study of two well-studied lncRNAs are indeed confirmed.

III. Proposed Methods

The Heterogeneous LncRNA-Protein-Function Connection (HLPFN) is a network which connects five separate binding interactions: proteins connections, lncRNA co-expression, lncRNA operational connections, or lncRNA-protein interrelations and protein function connections [12]. To preserve the heterogeneity of vertices and edges, all connections are retained as independent pairwise models. Fig.1 depicts the multiple transitive vectors required to generate HIN. This same transitive index of subnetworks is constructed as follows.

NPInter is used to gather information on LncRNA-protein interactions. It discusses the interactions of ncRNAs with various macromolecules [13]. To extract enzymes, the lncRNAs are separated from the ncRNAs using NONCODE ID and the particular intervention is limited to 'RNA-protein.' Only 'Human Ancestors' can converse with others. The lncRNA-protein association system is managed as a data structure, with lncRNAs in the rows and enzymes in the columns. The borders are generated based on the obtained contextual information. The analysis of the structure MLP is employed in this work. This method is impossible because of the amount of potential conceptual grows exponentially as the duration of the conceptual expands, rendering the issue unsolvable. One option is to follow the regular patterns identified in HIN research [14].

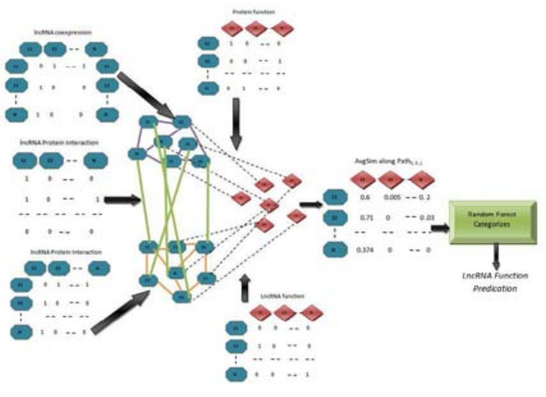

Fig.1. Determining lncRNA expression

$$K_{lp}(x,y) = \begin{cases} 1, if\ LncRNA_x, interacts\ \ with\ Proteins_y \\ 0, otherwise \end{cases}$$

In most cases, increasing overall conceptual duration endlessly in an HIN is pointless. Consequently, the chain of relationships between of expected completion elements might be very extensive in prolonged metapaths. As a consequence, inadvertently increasing conceptual duration is generally unproductive and produces outcomes that are far less accurate. As a consequence of this understanding, most HIN-based approaches specify a conceptual duration maximum limit in preparation. It only examine the meta-paths that are smaller than the criterion. It's critical to ensure that the findings aren't harmed by the removal of longer paths when setting such a threshold.If the findings are impacted, the threshold value should be reviewed, and this technique attempts to justify the maximum permissible setting process. A criterion limit can be established arbitrarily, statistically, or heuristically in most cases.

An observational technique is used in this study. The connection of all life conceptual with real existing life linkages is repeatedly evaluated beginning at duration three. The repetition ends when the number of adversities linked metapaths equals half of the number of favorably connected metapaths. The duration criterion is determined by path length at this point. The next eight lines go into this technique in great depth. The prospective meta-paths to be included in the investigation are discovered in the first stage, which is an incremental method also on conceptual duration. Because of mission is to find a link among lncRNA to service, only meta-paths that begin with lncRNA or conclude with feature are taken into account. The repetition must begin with shortest conceptual conceivable: lf, with a duration of two. In reality, this route correlates to actual function in the HIN and illustrates the actual functional association of lncRNAs. In practice, the iteration begins with a three-length meta-path. Every repetition leads to formation of a vector containing an overall maximum count of the concept of that type among each combination of lncRNAs or processes.The next challenge is to decide the appropriate meta-paths. If the concept question is significant, connectivity features suggest that its number across l or f should be higher. This suggests that the lncRNA is quite likely to fulfil that role. In contrast, if the amount alternative conceptual is low, this same likelihood of such lncRNA performing that purpose is low. A comparison study of the conceptual column is done against the known relationship pattern in order to function this tendency.All conceptual in the meta-path vector that have a significant correlation to established of connections are thought necessary, while the rest are considered invalid. This same terminate requirement is written so that the repetition comes to a halt so when the amount of negatively correlated meta-paths exceeds half of number of positively associated meta-paths. As previously indicated, the repetition begins with a three-length meta-path and continues until the termination point is achieved. A termination condition is satisfied in this study at a conceptual duration of four, that is used as duration criterion.

DOI: rp-9788770040723.073

IV. Performance Evaluations

K-fold cross-validation idea to evaluate overall forecasting accuracy. The specimens TP or TN have accurately predicted advantages and disadvantages correspondingly. FP and FN reflect the amount of incorrectly anticipated positive and negative samples, respectively. It can be produced in the following manner: An indicator value for each connection is calculated using the possibilities supplied by the algorithm. This same forecast value is used to order related couples. True Positives are known relationships with a more excellent predictive value than a certain criterion value point. In contrast, True Negatives are unknown correlations with a lower predictive value than the threshold. False Positives are recognized relationships with a value just below the criterion, while False Negatives are undiscovered connections with a value above the criterion.

V. Results and Discussions

Assuming 73.68% for the model can predict novel capabilities for 2,695 lncRNAs. Different functions were expected for some of the lncRNAs. The factor influencing outcomes suggests that lncRNAs are directly implicated in physiological systems rather than cellular and molecular level capabilities. Many previously unknown lncRNA functions were predicted using this strategy. The functions come from the GO collaboration. The GO ontology tracks parent-child connections using GOBasic, GOSlim, and other operational groups. To comprehend any such activities provided by lncRNAs, various operational GO Terms are grouped according to their GOSlim category. Table 1 shows this category-by-category list. The figure displays a list of functional domains and the number of GO keywords within each classification. It demonstrates that lncRNAs have key roles in cellular mechanisms, growth, cellular component, and metabolism, molecular function. The CateGOrizer program was used to generate these outcomes.

To use a different experimental dataset, lncRNA2GO-55, accessible for downloadable in NeuraNetL2GO, we compare our estimate to two state-of-the-art algorithms, LncRNA2Function and NeuraNetL2GO. The result is evaluated the using F-score, accuracy, and recall measures, and our approach is shown to be the greatest. The benefits of performance assessment are shown in Fig.2. In terms of availability, the proposed methodology has also demonstrated satisfying performance (see Table 2).

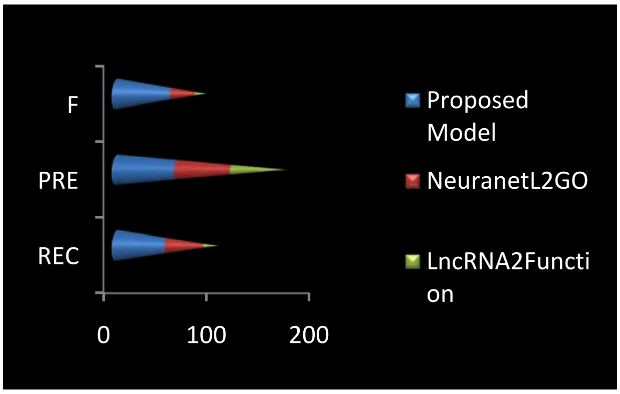

Fig.2. Performance measures

TABLE 2. Comparison of Proposed and Existing Systems

Model	Annotated	Coverage percentage
Proposed Model	52	88.03
NeuranetL2GO	47	94.10
LncRNA2Function	15	29.55

A consideration of the perceived significance of the meta-paths as RF classifier characteristics is offered here. Statistical assurance is also provided that paths proposed by the appropriate path selection procedure are significant. The final section demonstrates the validity by using four as the maximum criterion for the conceptual duration. Furthermore, the appropriate meta-paths chosen are relevant in terms of biological scraps of evidence. The meaning of the unnecessary abstract, lplf, is that one lncRNA connects with an enzyme, which binds with another lncRNA to execute a purpose. According to existing research, enzymes perform operations immediately, while lncRNAs are used relatively infrequently to generate functionalities. Therefore, the conceptual interpretations of all essential meta paths identified either by automated selection procedure or on either extreme are closely related to scientifically confirming lncRNA-function pathways.

This designer's large variety of differences is O, where n is the highest amount of lncRNAs/proteins/functions in the investigation, m or g are the amount and duration of meta-paths, and one or fare the number lncRNAs and activities in the study, correspondingly. It's worth noting that the amount and duration of concepts used in the research significantly impact the total intricacy. Furthermore, these are the variables that we can control by accepting or dismissing conceptual based on predetermined duration criteria.

According to a ROC curve analysis, the gain in outcome for more extensive conceptual was inappropriate to the processing effort required to analyze a more significant number of abstracts of more extensive durations. Fig.3 illustrates the ROC curves for tests with three, four, or five distances. The meta-path experimental with duration four

DOI: rp-9788770040723.073

performs much superior to one with three. The duration of five conceptual research, on the other hand, does not enhance the outcome to the extent that the increased processing complexity necessary to analyze individual concepts could be accounted for compensated. Furthermore, setting the upper boundary of conceptual duration to four for the particular data set seems to be the best option.

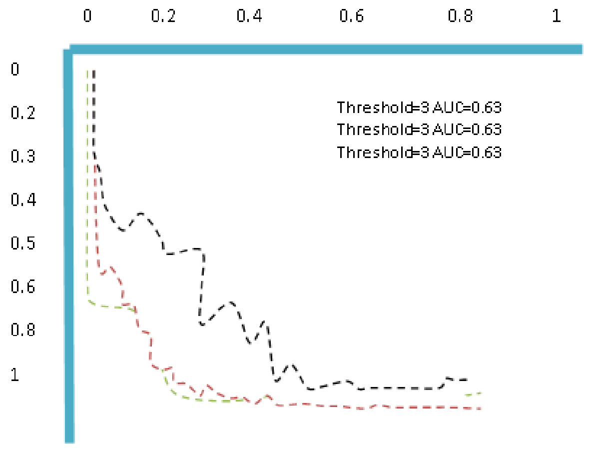

Fig.3.ROC curve for proposed system

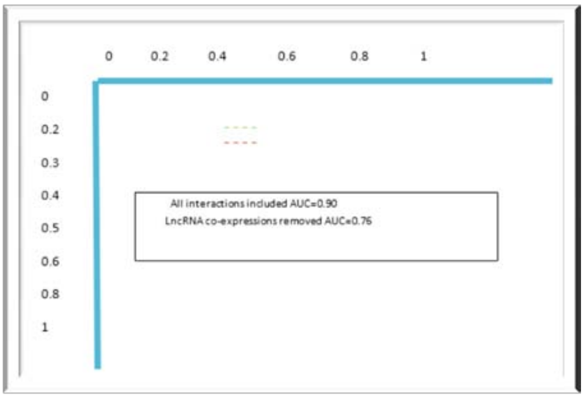

Fig.4.Impact of lncRNA co-expression information

The inclusion of lncRNA co-expression data into the network is among the innovative features of this article. This knowledge aids in the identification of lncRNAs that are structurally comparable. The relationship among lncRNAs was assessed using the co-expression patterns of lncRNAs in 24 organs. Experimental evidence indicates that lncRNAs have tissue-specific production, but that their position has a significant impact on their activity. As a consequence, tissue-specific co-expression features of lncRNAs could help determine important biological lncRNAs.In light of this, it is reasonable to assume that incorporating lncRNA co-expression information has aided in improving predictive performance. An ROC curve examination of the factor influencing outcome in a network with and without lncRNA co-expression data supports this hypothesis. Fig.4 depicts overall results of the analysis. It reveals that when the lncRNA co-expression system was removed from HIN, the AUC dropped consistently.

VI. CONCLUSIONS

The current research topic of fast and effective protein identification of lncRNAs was inspired by the mounting evidence for operational characters played by lncRNAs in biological and cellular processes. Because the wet-lab technique for operationally annotating lncRNAs is costly and complex, algorithmic approaches have become very interesting lately. The research presented here forecasts the roles of lncRNAs analysis of protein behavior data and co-expression information. While previous techniques for identifying lncRNAs primarily focus on protein contact, this method considers lncRNA co-expression patterns and correlation to established benefits and associated proteins. More importantly, the technique can effectively examine the importance of lncRNA-function pairs in a HIN by associating functions with lncRNAs even if there is no protein connection. The model has a predictive performance of 74 percent altogether.

***Abstract*—During the human thread age, classifying genetic functionality remained among one of both greatest essential as well as difficult challenges. The overall majority that contemporary computer-based prediction approaches compare characteristics that are generally basically proportional against overall polypeptide sequences. Non-sequence attributes from particular proteins, on the same hand, might prove indicative of biological action. Computer training approaches, including Support Vector Machines (SVMs), appear especially well suited towards leveraging similar characteristics. They propose SVM but also empirical masquerading chemical makeup within that paper.Towards this same realm for molecular functionality predictions, comprehensive compilation comprising nonlinear features extracted using polypeptide sequencing. Experimental SVMs enabling classification involving rRNA -, RNA-, but also Mitochondria enzymes were been constructed. Every among these SVMs forecasts when given molecule corresponds into either among those 3 categories based upon its protein acids sequence with the specific restricted ranging association between surfaces charge and also solvents permeable exterior region. Intergenic SVM has continuously obtained >95 percent correctness both personality but also bridge experiments, where quantify both effectiveness algorithm training but instead predictions, accordingly. Overall effectiveness that overall RNA- but rather Genetic material SVMs is considerably varied, spanning between f 76 percent through f 97 percent. These outcomes from overall tests go towards this manner towards upgrading using SVMs.**

Keywords*—Computer teaching techniques; Reinforcement Dynamical Networks; rRNA; RNA- dependent Genetic material proteins

I. Introduction

Genetic transcripts are currently being produced with an extraordinary frequency by sizable genomic decoding studies. Approximately 60 biological chromosomes have been transcribed entirely and otherwise almost entirely throughout just a very couple of months [1]. Hundreds of millions nucleotides can be found within early cretaceous even bacterium genome, whereas hundreds many hundreds can be found throughout mammals but also vegetable genetic material sequences[2]. This massive influx of fresh genetic information puts a lot more strain upon this challenge for determining genetic functioning. Hardly very few prediction computing approaches could maintain current with that speed right now [3]. Almost majority of those approaches use rapid techniques that can explore annotation datasets seeking sequencing, theme, feature, but rather concealed Markov modeling similarities [4].Each request gets expected may have a comparable functionality if there exists enough commonality across each request sequence that another of that repository where functionality seems recognized. Investigators were managed that identify functionalities approximately 69 percent among approximately 4524 hypothetical enzymes contained within this same previously completed chromosome from another archean, M. acetivorans species C2A, using a similar method [5].Though this same former has impressive penetration, they were nevertheless 1500 molecules remaining identified meaningfully given such comparatively short chromosome. That was hardly surprising when just a relatively small percentage among those molecules turned out having to exhibit any new activity [6].

Antibody structure but also functionality, on the one contrary hand, might cannot necessarily be linked within any straightforward sense. That example, development might maintain intrinsic connection amongst fragments composing particular interaction region, although typically small but also fragmented, instead of maintaining complete entirely consistent stretches enclosing everyone those sections amongst enzymes with overall shared interaction functionality [7].Another dynamic mapping if this sequence involves simply measurement for correlations amongst places throughout another range [8]. Such insight invites us to think about properties that aren't proportional towards proteins sequences, as well as ways when comparing complex patterns. Although those double components constitute novel peptide functionality predicting, they were previously employed for previous contexts [9. Researchers used SVM can estimate peptide structure classifications,

DOI: rp-9788770040723.074

cytoplasmic placements, including digestive domains, such example [10].

II. Related Works

Every among those SVMs functions using unique curvilinear collection the properties of the proteins known called pseudo-amino acids breakdown. Researchers have obtained results that are equivalent to but rather better than those of various modern approaches [11]. Researchers were inclined should expand their applicability toward enzyme functionality forecasting as a direct result of recent positive discoveries. The following is a relatively brief description of SVM. The contribution generating any SVM is one weight matrix, which is simply a combination of properties. [12] That generates another categorization. Provided another trained collection given characteristic matrices with established predicted outcomes, computer SVM knows where correctly discriminate [13]. From some metaphorical sense, those incoming matrices were transferred onto any characteristic region. This binaries classification SVM can use previous learning to construct another plane within the neural characteristic field that best differentiates overall learning variables from 2 classifications [14-15].Whenever each freshly extracted feature was entered, this category that every characteristic vector gets anticipated based upon whichever edge is aircraft everything just translates onto. SVM, computer categorization along with prediction machine that was subsequently established, primarily founded upon strong statistics modeling concepts but also have successfully had to use to the very broad spectrum of tasks, spanning picture detection, word categorization, including medication creation. SVM is increasingly being used extensively to solve proteins categorization challenges, such example folding identification and transcriptional transcription information [16].

This was built through supplementing standard protein chemical compositions using another set of molecular parameters to link all thermodynamic qualities for protein groups dispersed over specified intervals within a given string [17-18]. Those connection equations provide describe their impacts that localized sequential ordering regarding certain thermodynamic qualities, but typically are unaffected by the overall sequence's length, adjacency, even world order. SVM has a very steep subset of features thanks to the sort of anti-hydrochloric content. Any particular pseudo amino protein makeup could be created with just that given Classficatio n use through determining essential thermodynamic features. They constructed 3 prototypic SVM because of an early study with a computer training technique incorporating those key aspects towards enzyme functionality predictions [19].Those SVMs determine when a given question string corresponds to rRNA, RNA-binding enzyme, as well as Genetic information nutrient categories. We have gotten some findings that show how feasible such a strategy is. They may anticipate better results from this technique throughout this same coming through perfectly alright their SVMs while testing using different features matrix methods [20].

III. Proposed Methods

SVMlight, one free open-source program, was employed to make 3 SVMs for predicting amplicon, RNA-binding, and Genetic material enzymes, accordingly. These SVMs used dichotomous classifiers, which means they predicted when either given incoming molecule had any specific functionality. Basic basics underlying SVM are explained within basic subsequent sections. SVM was another statistics information theory-based training system.This core concept could be expressed like the following. These contributions were initially expressed into characteristic matrices, every one of them being assigned into either among 2 classifications. Every category for each weight matrix was determined from every beginning during learning. That category represents this outcome for SVM during predictions. Finally, a convolution operation maps these information matrices onto one subspace, whether smoothly but rather earlier this month.Finally, within neural subspace, another divide was calculated to effectively divide these 2 categories with learning variables. SVM retraining pursues the worldwide ideal but instead prevents too much during most times. Because having those properties, this then was well suited towards dealing handle huge amounts more properties. All whole textbooks about this same use using SVM with patterns recognition. This simplest fundamental principle underlying SVM is informally illustrated in Figure. 1.

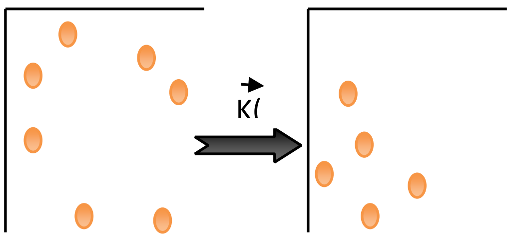

Fig.1. SVM based learning linear translation

Apart from initial breadth between model determined basis values, which has been determined towards reducing any estimation in variable Private equity investment, plus software variable C, which regulates model uncertainty tradeoffs, which been adjusted near 1000 throughout the particular study, most other settings remained fixed near-standard SVMlight setting. SVMlight's specifications and Vapnik's publications are recommended reading for anyone concerned about both nomenclatures and various intricacies. The 40-dimensional incoming features vectors using SVM comprised the pseudo-amino acids content on the human polypeptide. This pseudo amino party makeup involves linking equations used for these charges, pore-volume, but also visible size distribution individual repeats, as well as actual physicochemical characteristics within the actual molecule.

IV. Results and Discussions

This relevant information was used to educate both target genes, Oligonucleotide, and genetic material SVMs. There was one favorable selection but also another deleterious population within a particular database. This affirmative subset's molecules proved recognized that have

DOI: rp-9788770040723.074

this functionality that exactly SVM had been taught for predict. This functional previously discovered would be absent from that positive subgroup. Irrespective matter whether biological functionality has been confirmed physically versus projected, every phrase annotations within this same SWISS-PROT database being treated sufficient preexisting understanding about that enzyme functionality. Those SMVs' testing findings were presented below. Every SVM was subjected to 2 exams: either self-consistency check with another merge check. Using this soul experiment, using SVM educated using this entire information were applied to estimate overall functionality for each molecule during the given identical database and compare this against recognized functions. Using rRNA binding SVM was tested was found that have relatively close accurate predictions prices: 100% with just using affirmative subgroup, 99.98% overall protein negativity relatively small group, overall, 99.98% for the overall entire dataset. SVM that binds to RNA, their findings were unstable: f 76% with this same positive subset, f 97% with this same unfavorable subgroup, with f 92 percent altogether. Our Genetic material SVM yielded lopsided findings as well, although along with our other manner: 93 percent with exactly affirmative subgroup, 77 percent with this same negatively relatively small group, with 87 percent altogether, as shown throughout Tables 1.

TABLE 1.OUTCOMES OF A PERSONALITY EXAM

SVM	Correct Predication		
	(+ve) subset	(-ve) subset	Overall
rRNA binding	1167/1031= 100%	4698/4891= 99.68%	5795/5936= 98.27%
RNA binding	1069/1364= 73.61%	4557/4691= 96.82%	5783/6399= 93.91%
DNA binding	7912/8356= 89.23%	3512/4690= 76.07%	10619/13651= 84.36%

When this jackknife testing has been used instead of using cross-validation testing, then anticipate their accurate forecast percentages to become considerably greater but instead greater constant. This Jackknifing testing seems less neutral as well as efficient when evaluating highly learned SVM's forecast capabilities since that just removes one input sample again from the learning group during projection. Unfortunately, the terminator of each of the hundreds of sequences might need to be demanded far more CPU effort than could afford. As a result, chose that lesser stringent option whilst nevertheless demonstrating their left-10 percent -out merge approach. Overall CPU durations spent when retraining individual rRNA, RNA, and genetic material SVMs using individual computers averaged 5 minutes, 28 minutes, but also 18 hours, correspondingly, as shown from Table 2. Their median CPU latency during forecast is approximately 2 minutes for each request, based on 10 907 tries. These various retraining timeframes represent what challenging this then was for these SVMs and convergence onto any good separation vector space. Generally speaking, the higher larger learning collection, the usually increasingly challenging it becomes could achieve confluence, resulting in generally incurring a penalty that increases proportionally with its database length.

This research was one of those first to use SVM, using machines intelligence approach, towards creating gene functional predictors. Several SVMs for categorical identification and rRNA-, RNA-, but also genetic material enzymes had been constructed. Every among these guesses which among those 3 types given question molecule corresponds into. Those SVMs were concepts that will be used to assess economic viability with my methodology. Because with these varying amounts overall sequencing but also physiological variety, this same various types human enzymes provide various amounts significant difficulty. By combining the overall learning dataset using SWISS-PROT annotating, they were able could generate an artificial level of distortion that seems nearly identical to those found with actual understanding. Identity but instead bridge testing were used to evaluate overall effectiveness for these various SVMs. We rate their effectiveness as average through excellent.

From their understanding, methods relying upon nonlinear sequence homology had previously identified encoding genes enzymes into any specific course. Those 1056 Crispr molecules within this successfully trained sample, under our PROSITE dataset, belonged into hundreds more distinct translational polypeptide families, everyone with their unique hallmark pattern. Those couples have quite a lot in common. In speaking, oriented" remains minimal. Protein nucleotide commonality, for instance, equals roughly 10% among individuals from either ribosome lineages 30S S4 but also subunit L20, each species which are widely represented within this learning collection. As a protein result, this intergenic SVM's outstanding efficiency throughout this same board unit was largely owing to having been educated using just a single, comparable optimistic subgroup.

Instead, it demonstrates how SVM may locate the component that is similar to a broad group of good coaching information but absent from the negative collection and employ it to acquire optimum categorization. It's intriguing to figure out what this common component is for rRNA-binding proteins. This would assist us to learn much about ribosomal proteins and develop more logical prediction algorithms. Unfortunately, translating the sophisticated SVM internal architecture to biological concepts is also challenging, as it is for various nonlinear learned systems.

The cross-validation testing predicts for such remaining of the coaching collection using SVMs educated on a subset of it. The objective was divided into 2 parts. For starters, it makes a realistic estimate with demonstrable Secondly, precision. This also tests the reliability of prediction ability by switching the section available to projection. The rRNA-binding SVM obtained 95–99 percent accuracy on that sample (see Table 3). The precision is great and constant. The less-than-ideal outcomes are consistent with the coaching set's sequence variability. Utilizing considerably larger negativity selection (f 26 percent overall amount if it's affirmative subgroup) for train model SVM instead of just original f five rounds decreases overall efficiency into 85–93% that seems consistent given their viewpoint.

DOI: rp-9788770040723.074

The decline is mostly due to a reduced identification rate. The randomly selected, bigger alternative negatives subgroup is likely to have a higher amount of incorrect negatives which have perplexed the SVM. As a result, the SVMs that have been properly educated are expected to produce have stronger predictive greater than that partly educated counterparts when using the original, better balance database. Nevertheless, the fluctuation inaccuracy, although little, brings to think a feature that uses SVM presumably generally pertains towards computational understanding. Specifically, the statistical principles it extracts from the training data restrict its prediction potential. Any "deterministic" regulation which remains aspirational grasps consequently substance in early facts, on the other hand, may have a higher potential for extrapolation. Once that learning information is complete, as appropriate in addition to a low large lot of disturbance, because that SVM isn't very good at it. Used, these 2 types of algorithms can agree.

TABLE 2. Cross Validation Tests Outcomes

SVM	Correct Predication		
	High	Low	Overall
rRNA binding	642/675= 99.01%	601/634= 94.3%	5694/5907= 95.28%
	2761/2618= 91.69%	2773/2851 83.91%	25862/26850= 88.10%
RNA binding	549/638= 91.34%	624/713= 80.61%	5481/6384= 86.94%
DNA binding	1138/1435= 86.09%	816/1352= 78.24%	11317/13607= 80.34%

Both Transcriptome and genetic material are two different types of interaction. Proteins are large divisions with a wide range of sequences and nucleic acid binding modes. The pairwise sequences are typically under 20% in one of these groups, but also there was one overall commonality of 8%. The functions of Antibodies that connect to Genetic material were known as RNA and Genetic material enzymes quite varied. There are nucleic acid-processing enzymes that identify particular monoclonal locations. The correctness of contains SVMs that attach to Ran's, as well as Chromatin within the cross-validation experiment, was 82–91 percent and 78–86 percent, accordingly. We believe that, at the present level on corrections rates, such prototypic SVMs may be employed as an initial pass of functionality predictions, in addition to existing approaches.

Both SVMs demonstrated uneven accuracy in separated findings for the positive & negative subgroups on the self-consistency test: 93 percent vs 77 percent, and 76 percent vs 97 percent, accordingly (see Table 2). Its SVMs' sensitivities are strong for such a better score group, but their selectivity is low. Sensitive & selection swap places for the lower scoring subset. With this information, we can put SVMs to actual usage in the right situation. Moreover, the imbalance might provide us with insight into how to develop. The phenomenon means that the ideal separation hyperplane is fundamentally capable of isolating the vector 1 among them subgroups However, within that characteristics region, they were unable cannot prohibit elements from any alternative group from entering. The characteristics that are connected embedded with fundamental characteristics can be tweaked to provide more acceptable vectors dispersion. If the penetrating is not randomly diffusive, on either hand, using an alternative kernel function of SVM might "bend" the space toward a greater separating.

Our technique is meant to be used in conjunction with others often employed in operational genomics. To transmit its operational annotations between hits into question, a majority of these employ databases searches for similarities on sequencing, motif, profiles, or hidden Markov models. Recently, its complete genomic for its bacteria P. putida KT2440 included 3571 with 5420 accessible sequencing elements given the potential purpose using BLAST & embedded Markov models searches. If assignments were confined on the same approaches, just over one hundredth completed chromosomes from these 3 primary categories all exist to have about 60 percent identification frequency, which seems expected to increase when well chromosomes are transcribed all across that world. Several of the thousands of genes that aren't allocated by this method may have known activities but aren't equivalent matches every molecule that has been characterized. With a particular case, light, it seems to be important to mention because if 're looking for another unique way to express, newly created simulated neuronal network networks technique proteases were allocated with another substantially bigger proportion beyond that for typical person chromosome initial human genome draught publication indicated.

Despite the fact because ANN researchers considered that it hard can evaluate the changes in prediction due to technique differences, the work does demonstrate the potential benefits of using complementary approaches. It's additionally hard to compare the ANN method's effectiveness to ours because various there were several types of proteins investigated. However, they found this fascinating because using the neural approach has some compromise as well inaccuracy when estimating positives and negatives. For identifying Twelve SWISS-PROT groups, as an example, 90% accuracy for estimating positive is followed by the comparable 20–90% efficiency in estimating negatives. When comparing accuracy levels, the proposed technique has proven to be competitive even at this early stage. We hope that combining this with other approaches, will help to improve the protease functionality breadth but instead precision predictions.

V. CONCLUSION

This has shown proven that combining SVM using quasi acids makeup towards any revolutionary enzyme functionality predictions method was viable. These 3 SVMs that developed functioned wonderfully especially simply one prototype. We discovered insights to enhance SVM using assessment testing. SVM achievement depends on features vectors & kernel functional choices, as well as an acceptable and low-noise learning dataset. For greater precise any formula could forecast, that better accurate it is precise any workout setting May been made, therefore greater than group, stronger forecasting capability of the accompanying SVM. However, as the SVMs have demonstrated, being particular in purpose would not

DOI: rp-9788770040723.074

necessitate sequence similarity. Some of our greatest popular appealing features when it comes to protein functioning, SVM is a great way to go. predictions would be the separation of sequence or operational similarities. SVM requires a lot of computer time to train, test, and tune. Predicting is a pretty quick process. We see another collection of more supervised learning taught may foresee particular functionalities in interpreting information on genetic sequences sequence in the future, supplementing present approaches to provide more accurate, and high-throughput gene function predictions.

Abstract—Obtaining RNA secondary image data seems to have been increasingly significant in RNA and genetic analysis interest in recent decades. Even though some RNA secondary structures may be discovering approaches, many RNA secondary structure predictions require adequate and reliable analytical modeling. Present RNA robust estimation algorithms were typically focused on the minimal free power approach, which uses an ongoing method to identify the optimum RNA packing condition in vivo while meeting the lowest power and other such limitations. Due to the ecological atmosphere's intricacy, a real RNA architecture constantly provides a good balance of living potential power position instead of the ideal retractable prestige that fulfills the lowest power requirements. Because the RNA compact individual's responsibility for maintaining order position was similar to the minimal free power position for simple sequence RNA, the lowest free power method for forecasting RNA secondary structure does have greater precision. Continuous packing, however, leads the total bioelectrical energy of a lengthier chain RNA to stray significantly from either the simple or cost level of energy. These discrepancies were due to its complicated design, which caused a significant drop in the secondary structure's demand forecasting Convolutional Neural Network (CNN). Researchers present a unique RNA secondary structure prediction approach that combines a deep learning algorithm with a stochastic optimization approach to conformity with huge RNA sequence and an example based throughout this research. We build an extensive convolutionary neural network using present investigation variants plus knowledge construction. We would then derive implied characteristics of accurate processing from huge forecasting of the coupling likelihood of every character in an RNA sequence. An upgraded stochastic optimization analysis is used to identify the best RNA secondary structure based on RNA sequence foundation matching probability. Their multiple access outperforms standard RNA standard biochemical methods in identifying three reference RNA groups, according to the findings.

Keywords—RNA, Convolutional Neural Network, RNA sequence, structure prediction algorithms

I. Introduction

In biological systems, RNA would be a critical component. It is involved in genes coding, processing, and regulation, including expression [1]. The conformational change of RNA determines its activity in a creature. The conformational change of RNA molecules, on the other hand, was complicated and lacked an accurate description to explain it, making it difficult to guess the three-dimensional structure simply from either the primary sequence of RNA molecules. As a result, the basic approach to investigating RNA architecture involves estimating the conformational changes of RNA given the direct line of RNA [2]. Medicinal tests like X-ray absorption and NMR determined the discovered RNA secondary organization. While assessing extended-sized components, natural, controlled experiments were ineffective, costly, and time-consuming. These also aren't appropriate, including all RNA molecules [3]. Howard and Eran introduced the PARS method to anticipate the RNA secondary organization. It uses protein sequences to break the human always double portions of the RNA, resulting in a collection of two RNA pieces that then segment independently to produce an RNA secondary framework [4-5]. On the other hand, Restriction enzymes cannot enter the cell barrier. Therefore RNA must be removed from the organisms. An RNA's original framework would be destroyed, resulting in potential alterations. DMS system wasn't without flaws. It could only identify sets of two sequences in an RNA molecule; the remainder must be simulated using software methods [6]. Furthermore, without using DMS chemicals, which could also articulate the 2' hydroxy team of four positions in an unmatched condition, researchers utilized SHAPE chemicals to examine the different elasticity of the RNA framework at any point and speculate whether the characters were coupled. The partnering item, on the other hand, is unknown. Recently, neither biology RNA approach seems to have been possible to forecast an actual RNA secondary organization in huge volumes, necessitating the use of computer forecasting models to predict RNA secondary constructions [7] accurately.

II. Related Works

While analyzing and commenting, the first methodology employs a posterior probability of RNA molecules containing human evolution. The influence of a given sequence significantly impacts the findings obtained by such a technique. The second strategy does top with a framed plus sequencing matching

DOI: rp-9788770040723.075

simultaneously, although it uses a lot of computing power. The third approach of comparative sequence data forecasts first rather than analyzes. That technique could produce many potential buildings, but it cannot ensure that they are all true constructions. Machine learning techniques were used in a variety of areas. Some artificially intelligent supervised learning, including the evolutionary algorithms, human brain method, fully convolutional network method, and other approaches, has indeed been developed to anticipate the secondary structure of RNA. All of the studies yielded positive outcomes [8]. However, every one of these algorithms was characterized by small sets, and the accuracy of the model for individual data specimens was poor. Deep neural networks have arisen in the area of artificial intelligence due to advancements in digital technologies, and then they can dramatically enhance predictive performance. Deep learning approaches could leverage underground systems to identify explicit and intuitive characteristics from big data using these characteristics to create a successful forecasting model. Learning techniques have recently achieved significant advancement in developing protein sequence structural characterization [9].

Regrettably, RNA secondary initial design seems more challenging and complex than nutrient supplementary structural characterization. Because every couple of foundations on the RNA must correlate to some other foundation in the sequence. However, every aspartic acid chemical in nutrients isn't linked to certain other peptide acids that make up through structural characterization [10-11]. These works provide a unique computing technique for predicting RNA secondary comprehensive solutions, mixing supervised learning and combinatorial optimization, and recommending specifications for the previously mentioned challenges. Its approach outperforms the modern mainstream methods in terms of accuracy [12].

III. Proposed Methods

A branch structure created by the complementary coupling of consecutive letters and looping sequence analysis of quasi of letters makes up most of the RNA secondary organization. The spinal cord and brain architecture would be another name for this RNA secondary organization. Once every one of the linked characters of an RNA sequence has been established, the sequence information of the whole RNA can be calculated. This research provides a more effective process for RNA secondary structure characterization depending on the Secondary structural forecast problems raised in the literature survey thus far. CDPfold would be a homology modeling approach incorporating a deep neural network, evolutionary computation, and a dangerous sequencing approach. Researchers built a deep neural network to identify the components of successful indirect elements of widescale information and forecast the agreement possibility of every character in the RNA sequence in comparison to protein sequences.

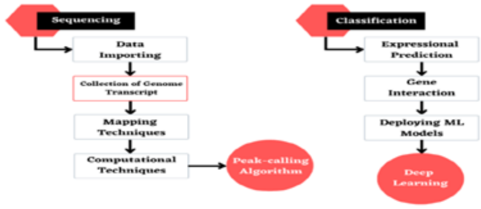

Fig.1.Proposed Neural Model for RNA Structure Prediction

Deep neural networks could use recently gathered RNA sequences as training images, removing the comparable frequency restriction on comparative sequence data. Researchers employed the systematic approach of evolutionary algorithms and the description of the RNA secondary architecture to achieve the base perfectly matched likelihood and the maximal RNA secondary organization for the stochastic findings acquired by the deep neural network. Owing to the employment of the free power approach, this process could reduce the erosion of lengthy sequences prediction performance. Integrating both viewpoints, these works present the method described in Fig.1 for calculating the particular values of every location of the programming grid Wii. Calculations could be used to determine establishments based on the RNA sequencing translating grid. The location of the stem region in the actual building of the RNA was indicated by a sub-diagonal line in the programming matrices with a big approximate solution and a lesser number on both ends. Deep neural networks benefit recurrent neural networks by efficiently extracting the aspects of the units in the grid. As a result, researchers utilized deep neural networks without using computational intelligence techniques to estimate the matching of elements in RNA sequences.

Researchers needed to separate the RNA pattern imprinting matrices from anticipating the coupling of every letter on an RNA sequence. A phrase of fixed length was converted into a vector of size n n using the RNA simulation model. Humans utilize the template matching approach to partition the column into n columns of length d n. The letter d denoted the width of the moving window. As either a result, a vector of dimension d n could be used to describe the characters on every RNA sequence. When employing the template matching approach, the width of the moving window does significantly impact the study. The selected features would be incorrect if the reference image were adjusted excessively. A significant parameter causes additional redundant data in the matrices, resulting in a lengthier learning algorithm and possibly affecting the quality of the resulting forecast prediction models. The duration related to the provision in the RNA must be connected to the result of the moving window following processing. To estimate the size of the given image, researchers would have to collect the root area information about the sample item. The information supplied into the deep neural network must be consistent in quantity, and the magnitude of the RNA sequence matching every RNA sequence varies owing to the duration of the RNA sequence (Fig.2).

As a result, researchers must compute the average scores of the RNA sampling frequency in the experimental results collection and use the figure-to-data

DOI: rp-9788770040723.075

augmentation techniques during the study. The template matching approach plus normalization of the RNA programming matrices may transform an n-dimensional RNA sequencing into the n-dimensional matrix, that meets the deepest convolution cable network intermediate data specifications.

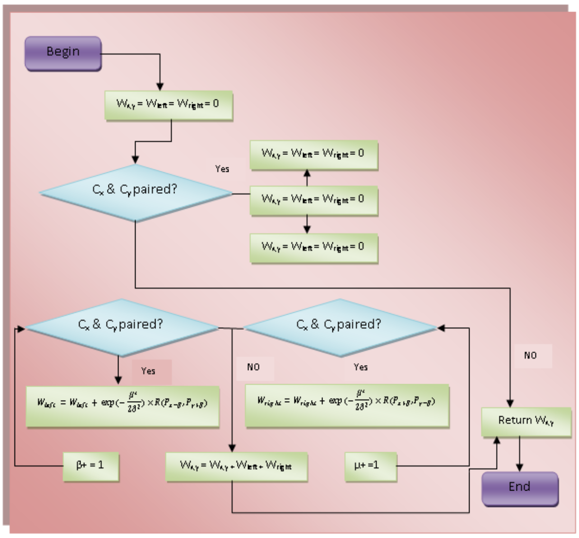

Fig.2. Matrix representation of RNA

IV. Results and Discussions

The researchers chose the 5sRNA with the biggest number and the most homogeneous dispersion without the need for a pseudoknot from among the numerous RNA categories shown in the information. Sequence alignment of the 5sRNA information shows that perhaps the RNA dataset includes certain genomic information that would be the same or comparable to the 5sRNA information. It must be required to normalize the data in the collection in place to evade the impact of the tests by the very same and comparative sequence information. That seems to be, the 5sRNA data set would be designed to filter out essentially equivalent patterns. The overall amount of 5s RNAs employed in the study following redundancy elimination was 1,059. Researchers determine the total of eliminating 5sRNA records into training images, which includes a classification algorithm and a test dataset, in required to practice and correctly assess the appropriate framework. The training examples, verification needs to be set, and a testing set has a 7:2:1 RNA proportion. Table 1 displays the information in the data collection.

TABLE 1. RNA TYPES DATASETS DISTRIBUTION

RNA Type	Number
TelomeraseRNA	35
tRNA	655
tmRNA	419
srpRNA	987
RNasePRNA	504
grp2RNA	9
grp1RNA	96
25sRNA	32
16sRNA	107
5sRNA	1192

The learning training data set the routing protocol and established the set of parameters, followed by the confirmation collection for system identification. As a result, the concluding training dataset was utilized to examine the generalization capability of the entire classification algorithm during the final refinement and the conclusion of the models. Numerous variables in the CDPfold may influence the study's findings, thus the issue variables should be changed first before the experiment started. The width of the moving window seems to be the problem identification variable. From the 5sRNA collected data utilized in the research, researchers estimated the height of the longest stemmed section of all RNAs. Fig.3 illustrates the findings achieved. The template matching product's breadth was determined by the size of the largest stemmed area in the 5sRNA information. This can be seen in Fig.4, researchers additionally estimated that the average duration of the 5sRNA pattern in the sample group.

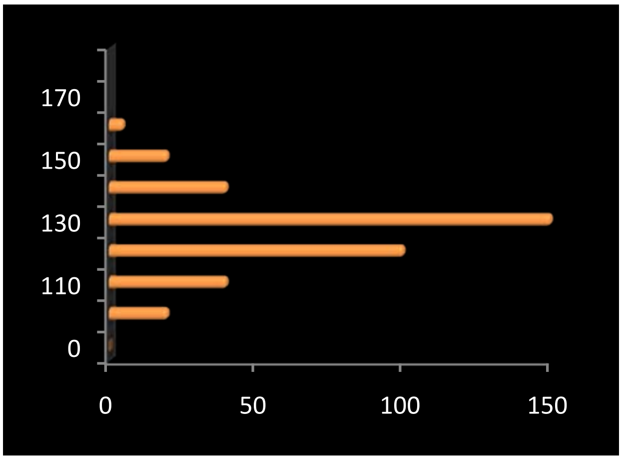

Fig.4. RNA length distribution

Fig.4 reveals that perhaps the 5sRNA pattern has the greatest enhances the overall of 11 contiguous base pairs and the average duration of 120 nights. The concept of picture scalability has been used in the article because the deep neural network does have decent reliability for tilted and sized pictures. That implies that the term referring to the components produced from the moving window may

DOI: rp-9788770040723.075

be evenly converted into a matrix size of 11 120. Data processing had been used to build the deep learning algorithm presented in this study. An input image, 3 CNN , 3 max-pooling, three fully connected layers, and a final feature overlay make up the learning algorithm. The production gradient. The top k algorithm was eliminated during the testing stage to determine the likelihood that every foundation corresponds to 3 labels. Fig.5 represents the proposed CNN model.

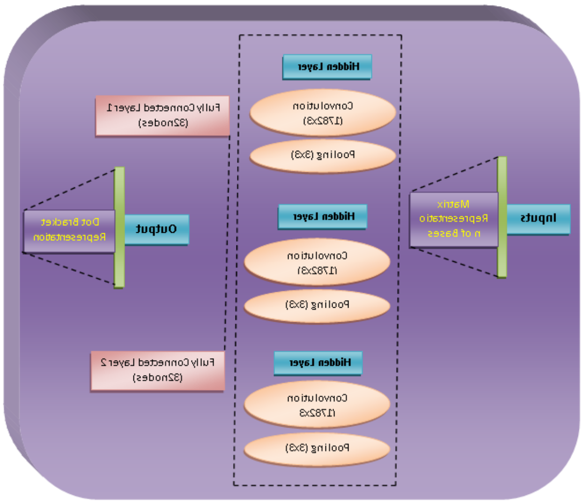

Fig.5. Proposed CNN model for prediction

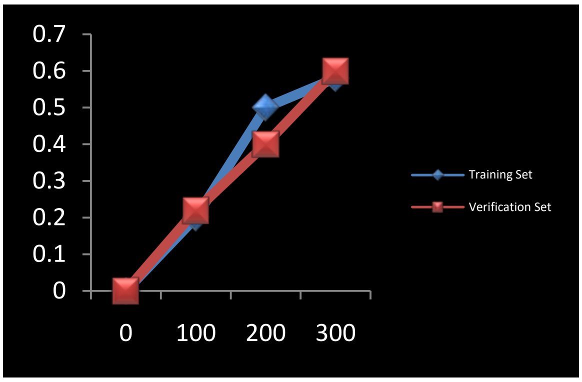

Fig.6. Accuracy of proposed model

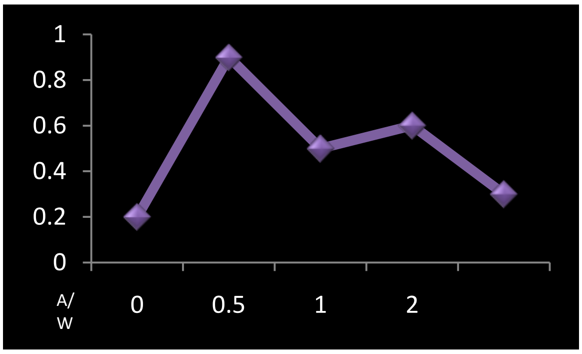

Fig.7. Error accuracy of proposed model

A vector expression matching every compound in the 5s RNA sequence in the training dataset could be constructed using normalization and feature extraction approaches. Every basis has a matching structure labeling. The research findings indicate that the number of single characters within every 5s RNA sequence was more significant than the number of coupled nucleotide sequences. The three types of information sampling in the data set would be imbalanced, requiring the information to be analyzed with high dimensionality. The average pooling information processing approach would be used to rebalance the various sample information in the information source since the number of experimental results was adequate. The deep neural network classifier is constructed using the processed data. The figure illustrates the effectiveness of the artificial machine learning algorithm humans created in the training and testing sets. The system maintains an identical accuracy percentage on the training and testing sets, as shown in Fig.6, and the experimental data wouldn't be over. This picture shows that the system exhibits an identical accuracy rate on the training and testing sets, and the extensive experiments are not entirely. Researchers must choose a suitable number for the weighting x of G-U coupling following identifying the model employed in the research. The swinging couple's length should never be excessively huge or less.

The accuracy of the model would suffer the consequences of negative weighting. Humans ran a lot of investigations to determine the suitable weights. Fig.7 presents the outcomes. Experiments showed that the entire photographer's variance of correctness was optimum whenever the pairing value of G-U coupling equals 0.8. The training and testing information was sent into the learned CDPfold, and the deep convolution show's matching likelihood for every character on every RNA was employed as an intermediary outcome. The likelihood, and maximal adjustment approach, uses those preliminary findings. The ideal sequence information that meets the description of RNA secondary structure was found and matched to the foundation, in reality, confirming their entire simulation study.

Researchers calculated the projected impacts of the developed method framework on the 5sRNA information using the given measures. Humans utilized this very same method to prove other existing methods with the same results. Table 2 contrasts the outcomes of these studies, which were included in the proposed form, with the effects of those other successful shows available today. On the 5sRNA information, Table 2 compares the efficiency of their proposed approach to those of different methods. Their presented individual's detection accuracy was far greater than any of those discovered in those other methods.

TABLE 2. ALGORITHMS COMPARISON

Software	Correct Predication		
	Sensitivity	Specificity	F-score
Sfold	0.634	0.826	0.936
CDPfold	0.895	0.953	0.691
mfold	0.727	0.690	0.680

The researchers of that kind of research incorporated community and provided optimization methods like the evolutionary algorithms in their technology methodology.

DOI: rp-9788770040723.075

Those machine learning applications could handle complicated nonlinear issues by modeling evolutionary biology. Furthermore, because the goal is to identify non-mismatching conformational changes of RNA, and the quantity of this kind of outcome, was considerable, the development of every optimization was unclear; therefore, the community and provides method cannot be employed as the optimization technique throughout this research. As a result, the nonlinear control strategy was selected as the optimal approach, and the Nussinov technique was being used to suggest the probabilistic and more excellent correction methods.

V. CONCLUSIONS

Predicting pseudoknots in the present RNA secondary structural characterization would still be a challenge. In this research, pseudoknots were absent in 5sRNA, SRP RNA, and even Tirana, whereas pseudoknots were discovered in most RNasePRNA and marine. Although the number of pseudoknots in every one of those RNAs carrying pseudoknots was tiny, their presence cannot be overlooked. Should not only pseudoknots play a crucial role in RNA functioning, but if the pseudoknot impact forecast were incorrect, this would result in a miscalculation in the tissue-specific stem region. The dots bracket format was employed in this research to illustrate the RNA architecture. On the other hand, the dots parenthesis depiction doesn't depict the incorrect knots found in the RNA structure. As a result, the information, including pseudoknots, was removed from the study. If a protein sequence description of RNA that could describe a pseudoknot was discovered, the CDPfold presented throughout this research could be adjusted to forecast the secondary structure of RNA containing a pseudoknot.

Abstract—The challenge of predicting RNA construction with pseudoknots is NP-complete, and the objective is to achieve the best RNA configuration with the least quantity of electricity. Numerous approaches for predicting RNA frameworks, including pseudoknots have been developed throughout the years. Metaheuristic techniques are influential in determining lengthy RNA frameworks in a small amount of time. For a forecasting RNA secondary structure with pseudoknots, we employed two optimization methods: Optimization Algorithm (GA) and Simulations Annealing (SA). We've also employed a hybrid of these different techniques called GA-SA, in which GA is used for universal searches, but SA was employed to searches, as well as GA-SA, in which SA would be employed of universal searches or GA was employed to organic investigation. The efficiency of such RNA structure was calculated using four main computational methods. Methods were built using five databases derived from the RNA STRAND or Pseudobase++ databases. The algorithms' values are compared to that of various other optimization techniques. On all databases, the conjunction of GA and SA (GA-SA) techniques, as well as the other four state-of-the-art techniques.

Keywords—Simulated Annealing; RNA framework; metaheuristic methods; Genetic Approach

I. INTRODUCTION

All living cells contain ribonucleic acid (RNA), which is an important biomaterial. Transcription and translation are the fundamental features of RNA [1]. RNA polymers play a variety of additional important roles in biological activities, including transporting genetic data, regulating gene transcription, and acting as catalysts [2-4]. It is vital to determine the configurations of RNA to comprehend its operations. Physical technologies of estimating RNA architecture, such as X-ray crystallographic NMR, is costly and time [5]. pseudoknot was the RNA secondary structure in which is stem's unmatched leading nucleotides are coupled with the stem's unbalanced inward region.

Two optimization and famous metaheuristic algorithms are Genetic algorithms and Evolutionary Computation [6]. To benefit the local search heuristic, the simulated annealing algorithm was introduced [7]. It could be used as a metaheuristic for both local and global searches. In most cases, evolutionary algorithms are employed in the search strategy. Numerous studies have employed simulated annealing or evolutionary computation to forecast RNA pseudoknotted structure. The knot method depends on the Genetic Algorithm [8]. Itcreate an x n matrix to represent an RNA secondary framework of duration n. Several rows or columns as in incoming RNA sequence were used to designate essential nucleotide [9]. An I nucleotide and j nucleotide, for instance, is represented by row I and column j, respectively. This same value matrix[i, j] = 1 if a member in the matrix is a conventional Watson-Crick base couple or Wobble base couple (GU); otherwise, matrix[i, j] = 0. After the matrix has been filled, a list of the greatest stems, known as the stems list, is generated [10]. The structure and composition of RNA are then built using various combinations of the maximum stems. An optimization algorithm was then used to determine the best solution with the least amount of free power.

For the adaptation calculations, two alternative thermodynamics, power systems were used. Itemployed the same power spectral density in the alternative stem strongly indicates [11]. Itused the updated (D&P) electronic model to updated attributed as an optimization process to evaluate the fitness for individuals in the genetic method. For confirmation of GAknot, itused two databases. The PK168 database, which was acquired from, features 168 RNA pseudoknotted molecules. Another is HK41, which contains 41 elements and is made up of a subgroup of the frequencies used in HotKnots [12]. The main benefits of their technique are that ithave removed the constraint on single development or have made certain changes to the contractors and chromosome structure to boost reliability.

II. RELATED WORKS

Another methodology that enhanced RNA secondary structure prediction employing pseudoknots used a customized version of the free energy function. The DP09 estimation algorithm is used to develop a new proposed scheme. Itbegin by selecting 1057 RNA investment framework pseudoknots from the RNA STRAND database [13] as the training sample. The branches of each chain are then extracted from the learning algorithm and scanned to produce lists of 1-meters, 2-meters, or 3-meters, correspondingly. K-meter was subsequence of such RNA classification which is k segments long. Following that, itcalculate the counts of each k-mere sequence. The optimization algorithm or the GRASP approach is used to create an approach for predicting RNA secondary framework. The GRASP technique's biggest benefit is that it incorporates the benefits of the search algorithm, neighborhood approaches, and excessive heuristics. Itcalculated the free electricity of the RNA secondary configuration using the Turner framework since 2004. The findings demonstrate that the technique outperforms the other approaches [14]. The biggest drawback is that they've only performed with smaller patterns, and the best option isn't always confirmed.

An approach to forecasting RNA secondaryconfiguration of pseudoknots predicated on evolutionary algorithms. Initially, the largest number of consecutive complimentary base couples is determined. K consecutive base pairs are complementary sequence couples of the form (i, j, k), when i or j were the component locations and k was the amount of consecutive basic couples. The requirement [15] should be met by the base pairs. New nearby nations are created at random using subsequent nucleotide sequences. The annealing system's scheduling attributes are created to gradually reduce the temperature until the RNA structure was solved with the least amount of available electricity. The methodology does not use a thermodynamic framework; instead, it uses sequential basepair stacks to estimate the free electricity of the RNA structure [16-17]. Employed 10 RNA pseudoknotted transcripts from the PseudoBase collection to test the method's capability. The computation median Responsiveness and PPV are 92.6 and 84.3, correspondingly, according to the outcomes.

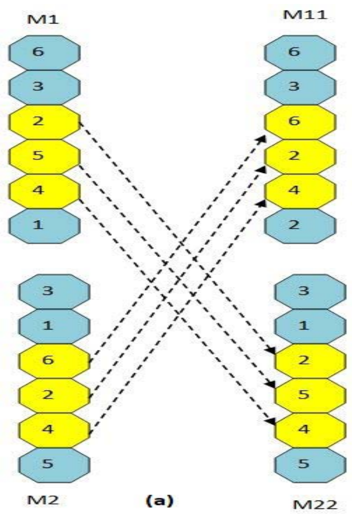
III. Proposed Methods

We used the Simulated Annealing and Genetic Algorithm to estimate RNA secondary system, pseudoknots, in this study. Italso employed the Evolutionary Algorithms but also Simulated Annealing to create two hybrid technologies. GA-SA or SA-GA were the names to the techniques. GA is employed for worldwide searches, whereas SA should be used for local searches in GA-SA. In the SA-GA system, on either extreme, GA was employed for global search, and SA was employed of exploration strategy. There are three basic stages in the methodologies: initiation and population development, iteration, and termination or assessment are all steps in the process.

An RNA pseudoknotted sequence of length n is fed into the population process. Then an unfilled collection named a board of size n n is created. Both the column or row is classified, with the denoted containing the sequence's is a nucleotide. The panel is then covered with the numbers of the set, v = 0 and 1. A stem integer is selected at random from the original population. For each index in the branch quantity, a stem could be taken from the stemmed list. Assume that a stem is expressed (p, q, l). While p denotes to stem's beginning location and q denotes the stem's ending location. In the matrix, p corresponds to I and q corresponds to j. A person is selected at random from the community. The input signal is 21 characters long. As a result, a list is formed, with all integers filled with a dot. From index 19 backward, five opening parenthesis is provided for the stem. The stems of stems 1, 5, and 2 are overlapping. As a result, the architecture is unaffected by these stems. Several alternative possibilities are available for branch 3. First, because the stems are overlapping, branch 3 cannot be inserted. Second, for stem optimization, we can substitute stem 4 with stem 3. Finally, compute the power of both intersecting stems and keep the one with lower power. This method might also be used with the other branches. A helix with fewer seems, on the other hand, generally has more favorable free electricity.

The Genetic Algorithm (GA) is a search-based improvement approach that focuses on biological and ecological choice concepts. It's a well-known approach for finding perfect and nearly-optimal responses to NP-hard temporal making this change. To find the best responses, itused three GA technicians: overlap, evolution, and survivor's choice.

Biological confluence is comparable to the mutation operation. More than one parent is chosen in this function, and one or more offspring are generated. We chose two parents in our method and have them cross to generate two new offspring. Crossover can be carried out in a single location, multiple points, or uniformly. The consistent overlap could undermine the favorable solutions if a single mutation occurs produces a practically identical solution. Itchose a two-point crossover predicated on our retraining research. Two chromosomic, m1 to m2, were randomly selected for community, as seen in



DOI: rp-9788770040723.076

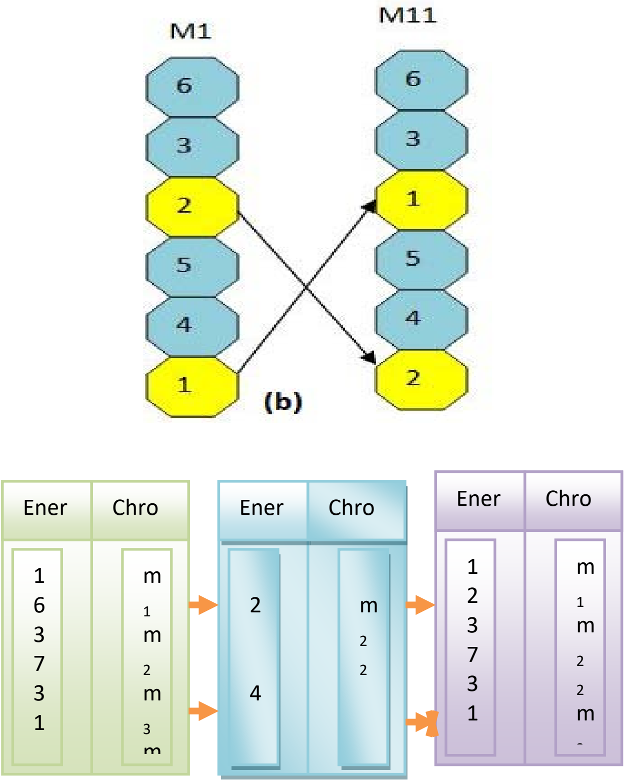


Fig.1.GA 3 Techniques (a) Crossover, (b) Mutation and (c) Selection

Figure. 1(a). To determine the crossovers locations that break each chromosome's three segments, two random digits x and y in the range m1 or m12 were created.For this study, an alternative database called DCC06 to 20 RNA pseudoknotted sequences isselected. The coefficient of Determination improved from repetition 80 to 200. There was no discernible improvement in outcomes after 200 (up to 1000) repetitions. As a result, iteration = 200 is chosen as the optimum number. According to the findings of the experiments, PopSize = 70 is the best fit for achieving improvement. A tiny population may lack all branches, whereas a huge population may have double chromosomesMutation Rate set between 0.05 and 0.4, and the value Mutation Rate = 0.1 yielded the best results. CrossoverRate was also tested from 1.0 to 0.65 before being set at 0.85. A final assessment was conducted using all of these attribute values. It obtains the following result: F-measure = 87.34.

IV. Implementations

The configuration phase utilizes information to Primarily consist or generate the first community. The optimal solutions of the chromosomes are determined at the start of the repetition, and the fittest chromosomes are chosen. The identified community is then subjected to evolutionary algorithms. If no crossover occurs, the offspring is a carbon duplicate of the parent. If it is a crossover, the kids are required up of both fathers' chromosomes. During the crossing, there is no transformation, the progeny is collected without alteration. When a mutation is executed, a portion of the chromosome is altered. CrossoverRate and Mutation Rate are two variables that specify how frequently crossover and mutation will occur. The performance index of the new demographic is computed after each repetition, and the best members are chosen. Variants continue until the halting criteria are satisfied.

The technique of heating systems, copper to modify its internal structure is known as tempering. The metal's new framework is gripped when it cools, and the alloy preserves its newly acquired qualities. Simulated Annealing is a software method that imitates this natural event (SA). The temperature is maintained varied during the crystallization process. The heat is set very high at first, then gradually decreased as the process progressed.

Characteristics employed in SA are listed in Table 1. A variable particular method is summarized in Table 2. The same database that was employed in GA is being used in the procedure as well. This same effectiveness was F-measure = 74.7 when the weather (T), short (T 200). A coefficient of Determination is increasing for temperatures between 200 and 500 degrees Fahrenheit. There was no notable improvement in outcomes after 500 repetitions, and the F-measure was set to 91.3. As a result, T = 500 has been chosen as the ideal temperature range. According to the findings of such tests, PopSize = 70 is an optimal value for maximizing performance. Figure 2 depicts the parameter estimation curve for SA.

TABLE 1.RNA STRUCTURE SA CHARACTERISTICS

Symbols	Description
T	**Intital temperature of the sytem that is decreased over time**
PopSize	**The population size or the no.of individules in the population space**

TABLE 2. PREDICTING THE RNA FRAMEWORK

IV	1000	90.8

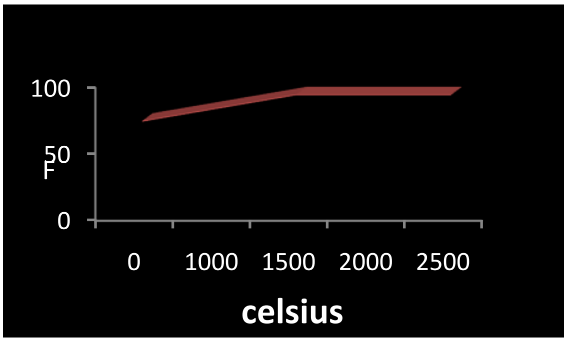

Fig.2.SA parameter modification

Figure 2: SA variable modification The values are defined numbers at the start, but the first community is created. The majority's initial energy is determined, and the person with the lowest energy is chosen. Each cycle generates a set of that individual's neighbors. The person with the minimum energy is chosen from the group of neighbors. For RNA secondary structural characterization to pseudoknots, designers merged to create GA-SA, a hybrid

DOI: rp-9788770040723.076

approach. On the result of GA, we employed SA of exploration, strategy or SA of explorationengine in this methodology. The GA-SA algorithm was run using the same variables as the GA and SA methodologies separately. GA and SA techniques have some drawbacks in this strategy.

As a consequence, we're considering integrating SA-GA to re-search the optimum outcome to shorter stem portions. Another drawback of GA is that it is prone to become caught in a local optimum. Due to the negative influences of its employees, GA occasionally loses better alternatives. An alternate careful evaluation, such as the Gaussian distribution, could be used to compute the likelihood of refusing or adopting a new construction. A minimum guaranteed position could also be found by searching in varying configurations of a person. This could be accomplished by hybridization techniques such as GA GA or SA SA. The analysis revealed that a hybrid GA-SA system outperforms a single GA and SA system.

V. Results and Discussions

To test our methods, we selected five different data sources. The variable sample was chosen with D-CC06, and the test was conducted with another four. The datasets employed in CC06, Evolutionary Computation, and Simulated Annealing are denoted in the chart as D-CC06, D-SA, and D-GA, correspondingly. IPknot yielded the PK168 database, which comprises 168 pseudoknotted RNA sequences, and the HK41 set of data, which includes 41 sequences. On Windows, the techniques were written in Python. For each sequence of the suggested technique, itaveraged the results often runs. Awareness, Positive Predictive Value (PPV), F-measure, and Protein Interaction Integrity are all measures of prediction accuracy (INF). Reflectivity is characterized as the measure of positive examples of the overall amount of positives in the actual course. In a prediction category, the PPV is roughly proportional positives to total positives. The F-measure, which is a proportional evaluation of excitability and PPV, is the weighted harmonic estimate of resonance or PPV. Matthews' coefficient of determination of connection prediction, often known as INF, is a measure of how accurate a prediction is. The following are the numerical expressions for exposed, PPV, F-measure, or INF:

Basepairs are considered positive in RNA structure, while free bases are considered negative. As a consequence, anticipating a correct base pair is TP, whereas failing to forecast a base pair is FN. TN denotes omitting away free bases as such, whereas FP denotes transferring them as a specific gene. Designers did not use TN in RNA-PSPP because it is not specified formulae.

TABLE 3. Comparison performance measures

Dataset	**GA**	**SA**	**GASA**	**SA GA**	**Result of the algorithm mentioned in references**
PK168	90.54	80.12	83.47	81.76	74.10,73.4,71.5
HK41	75.65	77.55	88.52	98.22	76.1,76.23,56.75,67.01
DGA	88.66	88.55	40.58	95.25	80.87

TABLE 4. Comparison of proposed with existing system

Dataset	**GA**	**SA**	**GASA**	**SA GA**	**Result of the algorithm mentioned in references**
PK168	100.54	82.12	83.47	86.6	76.88,76.5,74.6
HK41	77.55	70.145	84.51	97.44	75.6,7.30,54.50,76.51
DGA	93.47	87.50	77.80	98.60	85.87

Table 3 related that GA-SA would be the greatest PPV in the D-SAor PK168 databases solely, and the HK41 database includes the SA-GA method. On the D-GA database, the technique has the greatest PPV. Furthermore, the PPV of all four of our methods is greater than the PPV of the methodology database. The GA-SA method has a great outcome on all databases, as shown in Tables 4. In addition, SA-GA, along with GA-SA, has a high score on the DGA database. In comparison to previously created algorithms, four of methodologies would be a greater F value or INF. In respect of F value as well as INF, GA-SA method outperforms the database technique.

These optimization methods, SA-GA or GA-SA, exceeded both pure GA but also SA techniques as well as connected comparative methodologies. Designers talked about the drawbacks of using GA or SA to establish our technique, as well as the reasons for and benefits of convergence. For the choice of stems, we employed a variable called u. It aids in the reduction of huge sequence processing time. Itsplit larger RNA architecture branches into numerous smaller stems during hybridization. As a result, the low-energy branches are more thoroughly investigated. The performance of the two methods was significantly improved as a result. We've also used a large data set to refine the methods. That was extremely useful in determining the optimal number of criteria for the algorithms. As an outcome, the technique gives better outcomes when such deserve the right are used. For its smart optimization method, decomposition of huge branches, and full energy estimates, GA-proposed SA's hybrid metaheuristic methodology attained the highest results.

VI. Conclusions

This paper describes an implementation of the Evolutionary methodologies or Simulated Annealing to RNA secondary configuration determination including pseudoknots. The construction to SA-GA or GA-SA optimization methods of tackle the issues is our vital contributor to this research. One of the most difficult jobs was implementing GA to the persons established by SA and implementing SA to GA persons. To determine the optimum RNA structure, four energy estimates were used. The energy calculations for pseudoknotted and pseudoknot fewer structures have been established. In the hybrid version, the local search algorithm looks for all feasible structures based on the results of the universal query optimizer. Almost every type of pseudoknot may be found in our database. It can anticipate pseudoknots of the second element. It cannot, nevertheless, anticipate exceedingly complicated pseudoknots. The findings show that GASA and SA-GA perform significantly better than solo GA or SA outcomes. The GA-SA and SA-GA techniques outperform established methods. The GA-SA algorithm predicts RNA structures

DOI: rp-9788770040723.076

with both short and long sequences quite well. On all databases, GA-SA outperforms three techniques and all four state-of-the-art technologies. In the future, these techniques could be extended to evaluate performance using alternative energy assumptions.

Abstract—In post-transcriptional control, protein-RNA interactions are crucial. Estimating the relationships from a protein sequence, on the other hand, is challenging.We demonstrate that localized physical properties of proteins sequence surfaces may be used to estimate qualities like RNA backbone component bonding preferences and various bases employing a deeper learning method called Nucleic Net.Nucleic Net could reliably reconstruct association forms identified through structural science investigations on a wide range of problematic RNA-binding enzymes, including Fem-3-binding-factor 2, Argonaute 2, and Nuclease III.Additionally, we demonstrate that Nucleic Net could obtain agreement with tests like RNA compete, Immunohistochemistry Test, &siRNA Takedown Benchmarking even without witnessing either through Vitro and in vivo analyte results.Nucleic Net may therefore be used to anticipate probable binding slots & binding RNAs for earlier discovered RNA interacting protein, and it offers statistical efficiency for RNA patterns in specified interaction sites.

Keywords—Protein-RNA; Fem-3-bind; NucleicNet; binding RNAs

I. INTRODUCTION

mRNAs experience several interweaving events following transcribed before becoming converted into functioning proteins [1].Contacts among RNAs and RNA-binding proteins were often used to regulate such post-transcriptional controls, that offer cells more options for fine-tuning their proteomes. RNAs were substantially controlled in organisms with 2 modalities of particular encounters: straight identification of RNA motifs on the RBP surfaces or an indirectly RNA-guided method [2-5].In the first scenario, the RBP comes into immediate touch with the RNA strands.The Pumilio FBF family, for example, can govern translating by direct base-protein interaction, such as UGUR patterns on RNA transcripts1.The RBP interactions with the core or non-Watson-Crick sides of the base in its later situation, allowing WC-edges for targeted identification [6].Specific insertion of a guide-RNA onto its RBP is required for engaging essential enzyme of RNA interfering and gene-editing complex, for illustration.The WC margins of gRNA are subsequently used to identify its targeted D/RNA, whereas other sections of the gRNA stay in interaction with the RBP [7].Knowing the roles of RBPs, discovering RBPs, and creating RNAs for RBP identification and control all hinge on knowing the selectivity and processes of RNA-protein connections.

The emblem image for every RBP or analytic ratings on specific RNA sequences may be used to depict specific trends acquired using these approaches is generally [8].Interacting processes for several of these described RBPs, including hnRNP, Nova, and PAZ, have also been elucidated using structural deconstruction approaches. Despite these accomplishments, experimental tests are limited by reaction, detecting, and scaling constraints [9].Although pyrimidines were higher photo activatable than purines, Ultraviolet crosslinking tests preferred uridine-rich patterns. However, ribonucleoprotein co-crystals could plausibly confirm the biochemical basis of the tested particularities, one and a several like these co-crystals would barely describe the confusing patterns on emblem diagrams [10].Computational techniques can help improve experimental outcomes in that regard. The body of sampling research findings, assays, and frameworks can be improved in this genre to find previously misunderstood/unacknowledged specific features. Exemplary test-based computer techniques, such as Deep Bind and variations, may combine and educate over RBP assay information to predict a specific pattern that is compatible with widescale experiments [11]. Other structures haven't been thoroughly investigated.

II. RELATED WORKS

Provided a three-dimensional protein shape and its amino acid sequence, these last techniques often, with the unit of residue, regional protein sequences contexts, and additional structure data may be retrieved, and RNA-RBP sequences from the Protein Data Bank [12] were employed to build algorithms. As a result, assay-based approaches are less reliant on experiment information, to begin with [13].Nevertheless, because of the minimal number of characteristics accessible, their prediction value is restricted to distinguishing RNA-binding regions from non-binding sites, i.e., Binary prediction based on protein residues positions and scores lacking the favored base/sequence and other revealing contact modes [14].Computation procedures, on the other hand, are scaled and cost-effective, making them useful complementary to experiment methods.

DOI: rp-9788770040723.077

Nucleic Net is evaluated using information from three main references, structure, in vitro, and in vivo investigations, 2 tests were performed on structure information, one in comparison to an exterior reference, and the other in the absence of an exterior standard [15]. We demonstrate that Nucleic Net could successfully distinguish RNA-binding regions from non-sites on protein interfaces, outperforming all current sequence-based techniques and When comparing to our non-redundant 7-class database, which we properly built, Nucleic Net has a class-averaged AUROC of 0.77 for all 6 RNA components and non-sites, and 0.66 for its 4 bases, demonstrating how it could identify RNA components. To test the correctness of our Nucleic Net PWMs in working with RBPs that effectively identify RNA patterns at the interfaces through vitro, we used an RNA competes for assay. In all eight cases, we demonstrate that Nucleic Net PWMs are similar to RNAC PWMs in selecting optimal interaction 7-mers from all conceivable 7-mer sequences without further coaching just on test results [16-17].Ultimately, we also looked into downstream possibilities that may be useful in vivo RNAi research. We demonstrate that the Nucleic Net scores may describe in vivo asymmetries in humans Argonaute 2 guiding string loads as well as the varying knockdown rates in differential siRNA configurations [18].

III. Proposed Methods

In this paper, we offer Nucleic Net, a structure-based computing system that tackles the following issues: We devised methods of effectively learning from the PDB, allowing us to anticipate contact types for various RNA components – phosphate, ribose, adenine, guanine, cytosine, uracil, and non-site – and display these on any protein surfaces. Its logo diagrams and placement weight matrices (PWMs) acquired to Nucleic Net could also be used to grab a codified possibility in personal RNA segments; an emblem drawings and placement weight matrices (PWMs) acquired to Nucleic Net could be used to rate the binding possibility of individual RNA segments; Nucleic Net demands no outer assay insight to extract logographs constant to assay information, which include RNA compete, Immuno precipitation Test, &siRNA.Nucleic Net could be employed to discover unique RBPs and their interaction pockets/preferences by explaining over diverse RBP families. Our workflow is based on the FEATURE vectors architecture, which uses high-dimensional features vectors that represent physical information on proteins interfaces. Because of the discontinuous radically dispersion design, this rich vector field not only covers most characteristics produced in previous applications but can also compensate for small changes in local topology. Because training from such a high-dimensional input field is difficult, deep residual networks are developed and developed for this task.

IV. Results and Discussions

Our objective in Nucleic Net is to forecast whether the physicochemical atmosphere offered on-site is appropriate to interact with an RNA and if so, the binding preferences to every sort of RNA component on every position of a protein's interface. We recast the issue as a guided seven-class categorization issue in terms of computing. As a result, we develop a Nucleic Net end-to-end teaching as shown in Fig.1. In begin, surfaces positions of ribonucleo protein complex were obtained from the PDB & classified into seven groups, each of which corresponds to coupled RNA components and non-RNA-binding sites. The FEATURE software is subsequently used to describe the physical atmosphere at every site. Then, in such a hierarchical way, deep residue networks were groomed to correlate every physical atmosphere to any of the seven categories (see Fig. 2). Lastly, the network's variables are tuned using typical category crossing entropy losses back propagation. Notice that all teaching information came from three-dimensional components in the PDB; we didn't employ any information from outside experiments. After Nucleic Net has been trained, raw surfaces feature retrieved with FEATURE on the question protein's surfaces site may be used to infer binding preferences for every category on a location-by-location premise.

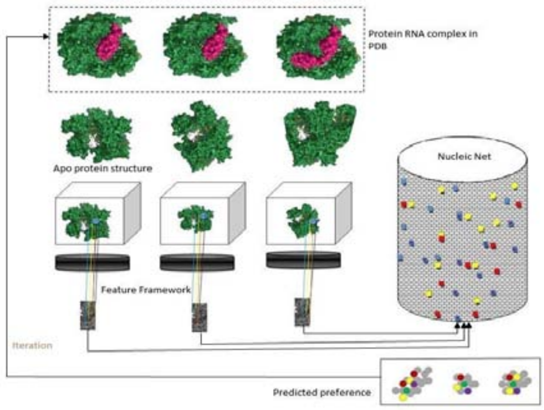

Fig.1. Proposed System

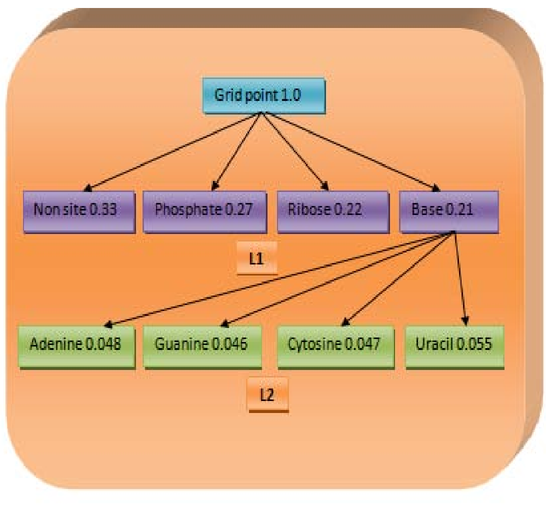

Fig.2. Performance of data statistics

On a location-by-location level, a connection to every category. Not only were binding locations of all 6 types of RNA components anticipated and displayed on the surfaces of protein, but such precise data may also be integrated into logo drawings or score interfaces for RNA sequence, which separates our technique from preceding studies.As a result, a feed-forward module's output would be bundled into 3

DOI: rp-9788770040723.077

power components: a Visualization subsystem which displays top expected RNA components as a ground storyline (see Fig. 3a–c), a Logo Diagram subsystem that creates the logo diagram, and a Logo Diagram subsystem which creates the emblem diagram. The hidden Markov system, which encompasses both the positions of the base and the geometrical restrictions for possible RNA patterns, may be described as the latter two components (see Fig.4).Our estimates are compared to structural biology studies using the Visual component. To evaluate our estimates to in vivo or in vitro test information, we employ its Logo Diagram & Score module.

Validation scheme

From established ribonucleoprotein structure from the PDB, a variety of verifiable basic truths may be retrieved. Firstly, we use a binary categorization to separate RNA-binding proteins from non-RNA-binding residues. Many computerized predictions on protein -RNA interaction handle this basic challenge. In general, a protein residue in a co-crystal is deemed RNA-binding if at minimum one of its elements is at a specific range from RNA molecules. Both 3.5 Å and 5.0 Å cutoffs were evaluated in the last few research. The benchmark RNAT database, which includes 175 RNA-binding protein chains, was created by grouping protein chains based on their sequencing and structure similarity and then transferring annotating of RNA-binding residues between comparable chains to mitigate the impact of strands error types.We compared Nucleic Net against a wide variety of state-of-the-art classifiers based on sequencing data using this grounding reality (see Fig. 2).Employing our Nucleic Net prediction, which operates on grid cells across its protein surfaces, we assigned the binary tag to every protein residue, The voting for two coarse classifications, RNA binding site, and non-site was based upon scoring matrices around 30 grids neurons nearest near a proteinresidue.'RNA-binding site' refers to the six finer classifications. Reference proteins are not tested throughout learning. Nucleic Net surpasses all other approaches in each of the abovementioned length cutoff values (see Fig. 2). As the result, Nucleic Net's fundamental applicability as a method for predicting universal RNA-binding locations is demonstrated.

Its capacity of Nucleic Net to extract interaction locations for the six specific RNA components presented is next assessed, this comprises Phosphate, Ribose (R), & other sugars. Cross-validation was done using a properly chosen and vetted non-redundant database comprising all protein-RNA complex architectures from a PDB, that has 158 complex architectures & around 280,000 grid cells. The 158 proteins were sorted into 3 folds. Two folds are employed for teaching and one-fold for assessment every session. BLASTClust structural homology of less than 90% was prohibited across folds. Individual proteins, rather than grid cells, are a resolution of the pass, that reduces bias for protein length. Every class's achievement in terms of AUROC, F1-score, Accuracy, and Recall. On the mean, an AUROC of 0.66 may be obtained for the base. Surprisingly, an AUROC of 0.97 recapitulates its ability to distinguish between site and non-sites. The reliability of each protein's category classification is also evaluated.

Structure-based approaches have the advantage of being able to uncover and identify binding sites on proteins interfaces. Although earlier structure-based approaches could only show binary categories, our approach can show all six typical RNA components in more detail. Three sample RBPs are used to highlight the specific ability of their technique: Refer to Fig. 3a for Fem-3-binding-factor 2, Human Argonaute for Fig. 3b, and AquifexaeolicusRibonuclease III for Fig. 3c.RBPs that bind directly with single-stranded RNA motifs via base interactions, such as FBF2, are an illustration, hAgo2, on the other hand, is an RBP that works in an RNA-guided way via backbone or non-WC edge interactions. AaRNase III, the 3rd instance, has a double-stranded RNA-binding domain. Employing the displayed tool, we show the top anticipated binding locations on such proteins in every interaction category in Fig.3. Following extracting RNAs from the ribonucleoprotein combination, projections are generated on

DOI: rp-9788770040723.077

the protein architecture in all instances. Many of these proteins, as well as their homologs, was left out of the instruction. Whenever nucleotides engage specifically to protein residues while superposed on a ribonucleoprotein architecture, we see a substantial predilection for nucleobases, as seen in the central panels of Fig. 3.Sequencing logo diagrams were created by average the Nucleic Net rating at nucleobase sites on the lengthy natural RNA thread in the bottom panel of Fig. 3.Nucleic Net has successfully recreated the exact binding selectivity acquired by structure biology investigations in all situations.

Duplexes with such a guiding strand rotational speed with less than 25 RPM are often removed, leaving 222 duplexes for testing. A histogram of Nucleic Net score differential QguideQpassenger among the guiding and guest threads of each duplex is generated for every dataset (see Fig. 4).As per Nucleic Net research, the favorable differential suggests that the guiding was anticipated greater positively than the passengers when binding, that is the intended consequence. In conclusion, advantageous changes may be seen in 76% of the examined duplexes. A paired T test and a Wilcoxon indicated rank test was used to determine the statistical importance of such variations. In all samples, both analyses passed the p-value 0.005 criteria, demonstrating Nucleic Net's capacity to estimate short RNA asymmetries determined by a vivo scenario. Varied guide sequences having various loading effectiveness can impact RISC construction in siRNA reduction studies, resulting in varying silence effectiveness. We examine how effectively Nucleic Net's projected guide-hAgo2 connections may describe such disparities. In this case, we gathered knockdown standards for shRNA licensed by the National Institute RNAi Consortium through a company's webpage and compared them to the Nucleic Net value.Econometric analysis was performed independently on every item to account for the variation of cell cultures and targeted proteins and was limited to objects with greater than an information value. Trends are removed from entities having a knockdown frequency variation of less than 0.1.

To study RNA-binding characteristics of proteins, experimental tests and assay-based computational techniques are critical beginning points. Nevertheless, because atomic and topological features of RBPs were removed from research, little could be deduced regarding the overall chemistry of base-protein interactions, i.e., the source of specificity, except for detecting RNA structural patterns. This knowledge gap might be bridged by clarifying additional ribonucleoprotein co-crystals, according to some. Even as structure deconstruction methods become more conventional and libraries of co-crystals grow, effective strategies to harness this huge abstraction structure information remain elusive. We demonstrate that in a purely structure-based computer paradigm, relevant predictions regarding RNA-binding locations & interactions modalities for RNA components may be inferred simply by sensing the immediate physicochemical surroundings through a large residual network. Most crucially, our findings reveal that these structural lessons may be used to correlate with state-of-the-art in vitro and in vivo behavioral test information, implying that actual RNA-binding relationships with verified biological consequences can be captured. Structure-based paradigms, on the other hand, are subject to several restrictions. For starters, the specialization that is additionally maintained by RNA–RNA interactions were not taken into account, in ribosomes, for instance, the RNA contents outnumber the amount of the protein by many folds, allowing mistakes in RNA–protein connections to be balanced by RNA–RNA interactions33.Those proteins were not included in our study since they are not found in our database. Furthermore, base stacking, base-pairing, and bulges can aid RNA-protein interactions mechanisms in some circumstances, such as in FBF2 and RNase III.

V. Conclusions

Despite their distance from the protein surfaces, those portions can influence enthalpic/entropic cost during the interaction process and so should not be overlooked. Structure-based approaches of ribonucleoprotein complexes could be expanded in the coming to include retraining using RNA-structure annotation & RNA-relevant physical characteristics; This might be useful in figuring out how target-D/RNA binding works in RNA-guided machines like Argonautes and CRISPR/Cas. Lastly, protein movements in RNA-binding processes are ignored by structure-based techniques. For integrate RNAs, Argonaute and RNase III, for example, might need substantial structural modifications. Furthermore, when a protein binds to distinct RNA strands, it might experience structural alterations. Nevertheless, the overall advantages of structure-based approaches for retrieving chemical binding specificity sequences are significant, and this genre might soon become widespread.

***Abstract*—Operative RNAs, including non-coding RNAs (ncRNAs) and cis-acting RNA elements involved in posttranscriptional genome regulation, are found based on two distinct computerized examinations of Trypanosoma genomes. Based on compliance with comparable trypanosomatidLeishmaniabraziliensis, the expected possible ncRNAs are discovered in the first analysis. Several of the expected ncRNAs are novel categories having undetermined characteristics, such that predictions have a low estimated incorrect fraud threat. This research uncovered several mechanism regulatory motifs in the subsequent research we used to develop a classification that can distinguish between actions that aren't identical. The first genomic sequence analysis of trypanosomatidfRNAs helps focus the research on practical approaches and accelerates the discovery of those elements. These functionality predictions classifiers built upon cis-acting regulation regions may potentially be used to offer homology-independent annotating for the trypanosomatid genome when combined with existing approaches.**

Keywords*—*RNA elements, gene regulation, trypanosomatid genomes, ncRNA, trypanosomatidfRNA

I. INTRODUCTION

Functionality RNAs (fRNAs), and RNA components functioning on the RNA levels, were being extra acknowledged as their extensive architectural, regulation, and catalysis activities are disclosed [1]. Another type of fRNAs is the cis-regulatory factors found inside the 5' and 3' non - translated sections (UTRs) of mRNAs, primarily engaged in post-transcriptional control of gene activity [2-4]. Current advances in computational approaches for fRNA predictions have revealed a large number of RNA components that are engaged in post-transcriptional regulation mechanisms. While important in numerous organisms, post-transcriptional control is particularly important in the class with multicellular worms known as trypanosomatids. It is the primary method for regulating gene translation.Trypanosomatids, including Trypanosomabrucei, Trypanosomacruzi, and many Leishmania species, cause significant human & animal infections with a higher frequency and fatality rate if left uncontrolled [5]. For trypanosomatids, genomes are translated as polycistronic mRNAs, then trans-spliced [6]. Numerous cis-acting fRNA factors, including in U-rich components (UREs), shorter intervening degeneration retroposons (SIDERs), and others, are involved in genes translation control, which happens mainly around or following spliced [7]. Those features primarily control mRNA integrity or translational rates by interacting with various trans-acting proteins, several of which are unidentified [8]. While little empirical evidence has been discovered, this has lately been suggested that miRNAs may function in post-transcriptional genome expression.

II. RELATED WORKS

Comprehensive functionality experiments with numerous organisms bearing expulsion mutations of the putative regulatory region are required to identify cis-acting fRNA components experimentally [9]. The scenario of ncRNAs isn't much clearer since it's unclear where in the genomes there must be looked for & how that screened research must be conducted. Because of the absence of significant conservation markers within their sequencing, automatic recognition of fRNAs using genomic patterns was not as reliable as recognition of protein-coding RNAs. Which were exceptionally trustworthy based on analytical and technological evaluations, it provided a computerized analysis of the genomes for T. brucei and L. braziliensis in the hopes of discovering a group of preserved ncRNAs.We showed that this technique could identify a significant variety of possible ncRNAs, both identified and unknown [10-11].We look at possible Premi RNAs within prospective ncRNAs and find that the occurrence of miRNA sequences maintained across T. brucei and L. braziliensis was very improbable. We also employ a new strategy for identifying shorter regulation RNA motifs in T.brucei genomes' 5' & 3' UTRs, which are homology-independent [12-13].

Those motifs list the more operationally relevant sections of possible cis-regulatory fRNA components to go along with our projected ncRNAs. Such regulation patterns could be employed for predicted genetic activity and provide fresh suggestions into the regulatory processes for protein production in T. brucei.

III. PROPOSED METHODS

DOI: rp-9788770040723.078

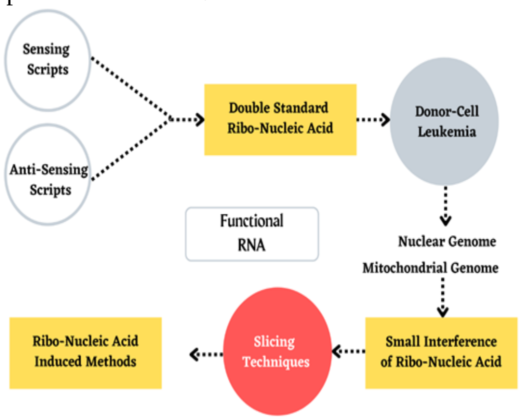

Fig.1.Proposed Model for Identifying Functional RNA

Fig.1 represents the sample model for identifying the functional RNA using computational techniques. The binomial-based method was used to find preserved genome areas. Shortly, after disguising LCRs with mreps, the 2 sequences of T. brucei and L. braziliensis were matched for so every screen of 25 nucleobases. N, the quantity of preserved nucleic acids, has been ascertained. This same likelihood of noticing N kept nucleotides out of 25 nucleotides has been estimated under the assumptions of impartial replacement and predicated on binomial dispersion of mutants. Territories demonstrating proof of Lastly, similar areas separated by less than 25 nucleotides are linked together to form a unique area.

QRNA was employed to find sections of the same genome areas that retained structure RNA component sequences. Long sections were broken down into 80-nucleotide overlapped chunks, one of them overlapped by 40 nucleotides alongside the neighbor segments. Intersecting regions having RNA values greater than 0 were consolidated, QRNA values were reassessed, and probable f RNAs containing final positive RNA values were chosen. The proportion of preserved encoding regions identified as fRNA was used to compute the ratio of the erroneous positive. LCRs were calculated using TIGR's 'mreps' and 'must,' which are denoted in lowercase characters as Supplementary Files 1. This same importance of every applicant has been determined by correlating its QRNA rating to a dispersion acquired by irregularly flipped T. brucei-L. brazilensis pairings: so, every ncRNA person's connectivity was regarded individually, and sections to similar preservation trends have been moved arbitrarily. Sections with gaps were exchanged with just too many gap-containing sections, mismatched with the discrepancy, and compared with the game.

FIRE, a newly created method, can detect DNA and RNA motifs that are redistributed throughout distinct sequencing groups, i.e., were highly represented within specific groupings but deficient in another. We employed FIRE to find themes that are spread disproportionately across various activities. First, T. brucei functionality classifications were obtained from the KEGG pathway dataset. It divided these genomes into 2 categories, with each route depending on whether or not people are engaged with this pathway. Then we employed FIRE to look for 5' and 3' Unique registration motifs which were significantly overrepresented and underrepresented within one of the 2 groups. Based on newly reported splicing position estimations, the genome of matured 5' and 3' UTRs were recovered in T. brucei genomes. The motifs generated by the various algorithms were gathered, and duplicated motifs were deleted.

Because KEGG employs an automatic workflow to allocate genomes into templates routes depending on overall similarity with existing proteins, KEGG annotations might never correlate to the specific activity of elements. Nevertheless, we assume that the genome connections will be preserved due to this method. For example, if two genomes were allocated to the identical pathway in KEGG, they are highly likely to have similar activities, especially if the KEGG allocated features were incorrect.We used a naive Bayesian network to predict gene-function connections based on expected regulatory mechanisms in the 5' and 3' UTRs.With a naive Bayes network, the qualities required to classify items are presumed to be unconnected. Considering any collection with identified motifs, the chance for genetic g corresponding to clusters is determined as:

$$A(h \cup \partial | G^N) = \cap_{g_x \partial G^N} A(h \cup \partial | g_x)$$

IV. Results and Discussion

That anticipated false-positive percentages employing coded areas will never apply to noncoding areas. This should be indicated if it has used values other than the RNA grade from QRNA, such as the COD & OTH ratings. However, because translating sequences develop in a particular fashion, QRNA activity might change across coded and non-RNA, noncoding genetic areas. Moreover, RNA architecture in the encoding gene might be targeted for selection. In conclusion, as explained in the section "Identification of Highly Important Candidates," it used a different, exceedingly careful approach to quantify the false positives frequencies of the ncRNA estimations. Addition Item 1 contains the comprehensive listing of every discovered ncRNA variant and its accompanying data. As illustrated in Fig.2, most of these contenders may be classified under multiple homologous groups. This prediction could be deemed highly credible when numerous homologous sequences are separately estimated to be ncRNAs. Cluster 10 is particularly significant because of its size, implying that the members of this class are found throughout genomes at a great rate.It was just postulated that trypanosomatids might employ miRNAs to control the amounts of specific mRNAs depending on a computer examination of the T. brucei genome. This research, however, contradicts our present understanding of miRNA genesis management. Mirna appears to have evolved in a distinct branching of living, albeit convergence development in numerous lineages was not feasible. As this result, we chose to look at probable miRNA precursor amongst our projected ncRNAs using a basic but particular technique that considers a few architectural and thermodynamics parameters for identifying pre-miRNA structures. Employing 250 pre-miRNAs chosen at randomized from 24

DOI: rp-9788770040723.078

various species for reference sequencing, the accuracy of pre-miRNA predictions utilizing our parameters is predicted to be about 32.4 percent ± 2.1 percent.According to research findings, there are very few retained miRNA genetics in T. brucei. However, it's worth noting that several of the previously anticipated T. brucei miRNAs might be addressing mutant surfaces polypeptides that aren't seen in L. braziliensis. In addition, some miRNAs expected are likely to bind preserved components like the 20S proteasome likely & should thus be anticipated to discover in our analysis if they are preserved. While this would not rule out the existence of miRNAs in its T. brucei genomes, it may imply that its genes should be reexamined for these components.

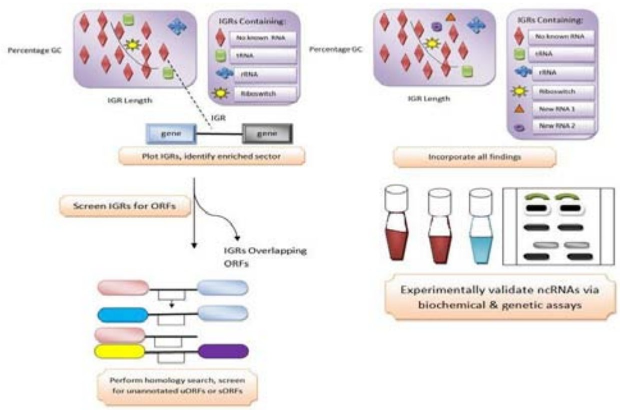

Fig.2. Proposed Architecture of ncRNAs

This was dismissed when a potential ncRNA is exceeded with greater than three randomization variations. This screening process yielded 117 very important unique potential ncRNAs, 53 of that did neither intersect nor were comparable to any documented characteristics of the T. brucei genomes, suggesting that it may be wholly unique ncRNAs (see Table 1). The RNA model, not the COD or OTH modeling, had the most significant rating across the 117 contenders who could never intersect within a decoding sequence, even though it was initially chosen solely based on the RNA score and neither COD nor OTH values. The determined p-value gives an additional, more cautious metric for measuring our program's accuracy. If the majority of the non-coding genomes are made up of non-RNA randomized elements, a p-value of 0.001 corresponds to around 0.887 kbp of false positives.This is more than 5.7 kbp of our contenders are meaningful at this level, showing an accuracy of around 85 percent at this level.

TABLE 1. PREDICTED CLASSIFICATION OF NCRNAS

	With in 100 bp of a non overlapping coding	ncRNA cluster	With in a stand switch region	elsewhere	Total
Overlap psaidogene	1	1	1	30	33
Overlap unlikelyproteins	1	2	2	1	6
HomoloeoustorRNA	1	2	2	1	6
Homologous to rRNA	5	5	3	1	14
Total	8	10	8	33	59

Nevertheless, depending upon its placements, a rough assumption may be made about the ecological role of distinct possibilities. For instance, there are eight unidentified potential components in the surroundings of code sequences. Such components might regulate structures found with between 5' or 3' UTRs of coding segments that regulate post-transcription genes. In addition, the string switching area is also discovered that includes one unidentified potential fRNA. Because polycistronic mRNA production begins at strand flip sites, this fRNA might be a component of the resulting transcript's 5' end. It could be implicated in its localization, post-transcriptional treatment, or control.

We evaluated the occurrence of mechanism motifs in the 5' and 3' UTRs of T. brucei genomes using a homology-independent technique using FIRE, a newly constructed approach. FIRE was found to detect several recognized, and new regulating components in upstream and downstream domains grouped similar on its activity patterns having such a near-zero false positives discovery rate. We employed FIRE to look for 'function-specific regulation components in T.brucei genes' 5' and 3' UTRs: genes with similar activities are frequently co-regulated, implying that they must have identical cis-regulatory components. As a result, grouping genes based on their actions could be employed as a stand-in for grouping transcripts based on the activity trends. This method is especially beneficial in species whose gene regulatory happens mainly at a post-transcriptional stage, like trypanosomatids, where transcripts profile techniques cannot discern the fluctuations of protein production.

It discovered Sixteen mechanism motifs in T.brucei 5' UTRs and 21 mechanism motifs in T.brucei 3' UTRs.Based on the results of running FIRE across ten subgroup pairs with gene-function combinations, we should expect a reliability of 75.3 % for finding mechanism 5' UTR themes & 84.8 % for 3' UTR themes. Most motifs discovered through FIRE had an orientations bias, meaning it primarily appears in a specific direction relative to the coding sequences. RNA patterns are known to have this characteristic. Furthermore, two of the common themes of 3' UTRs have placement biases, which means it likes to be located within a certain distance from the forward decode sequence's final codon. This feature has been seen in various regulating patterns in other species, increasing the likelihood of whether the anticipated pattern can have a biological function.

RNA motifs

It developed a naive Bayesian network that can determine if a genome belongs to a definite pathway based on the presence or absence of patterns within 5' and 3' UTRs. For example, this naive Bayesian network can be used to detect T. brucei proteins for various pathways consistently; see Fig.3, just as fewer themes were required to provide the most significant feasible predicting ability, as illustrated in Fig.3. Introducing more motifs to this classifier, on the other hand, does not influence its predictive strength, making the building of successful nave Bayesian networks easier. It might be possible to significantly increase the functional annotations of T. brucei genomes by integrating our technique with additional functional prediction techniques. Extra Item six contains a

DOI: rp-9788770040723.078

detailed analysis of functional predictions in T. brucei employing our technique.

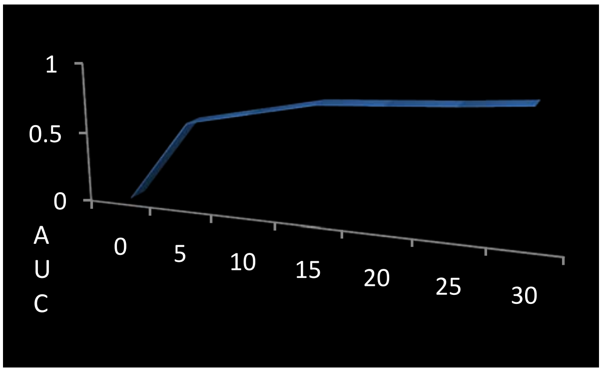

Fig.3. Proposed system prediction using regulatory motifs

V. Conclusion

The ncRNAs identified in this work might be employed in investigations to understand trypanosomatids' operational RNA repertoire better. In addition, the options with no existing homologs are expected to be unique ncRNA classes in T. brucei, making them even more fascinating. Discovering the function of these ncRNAs would help us better comprehend the infections' biology. Nevertheless, because we only looked at two chromosomes for this work, our list of anticipated ncRNAs was much but comprehensive. Analyzing a wider number of trypanosomatid genotypes could uncover additional ncRNAs and offer a more comprehensive picture of those species' non-coding functioning transcriptomic.

Abstract—RNA can no longer be regarded as a single component of the transfer. Conversely, a series of RNA molecules are identified, which revolutionizes our understanding of how cells were controlled. Inside neurons, huge and short ARNs, now make a vast repertoire of biochemical properties. RNA plays an important role in the basic management of vital biologic functions. NRAs, like enzymes, require three-dimensional models to produce them. Despite advances in our understanding of RNA folding and deployment, we still have a limited comprehension of such atomic processes through which RNA molecules become biologically important. Furthermore, because of volatile RNA molecules, it is difficult to quantitatively check RNA structures using X-ray crystallographic or NMR. As a result, numerical techniques to predict ARNs' 3D structure have become increasingly important in the research of RNA performance spectroscopy pathways. The basic principles of the RNA structure are first described, along with descriptions of data sets and methodologies to evaluate individual RNA sub-frameworks, as well as 3D frameworks.

Keywords—genomic DNA; biological RNA; structure elements; Computational techniques

I. Introduction

Enzyme elements, intracellular genetic placement, food production legislation, and development, especially instability, were assumed to alter RNA particles. The structural properties of such a huge category of actions are determined by the (3D) structure of RNA molecules, but also their connection with other nuclei in the cell [1-2]. The figure of actual RNA configurations has increased exponentially, but since the 1960s, when the first architecture was demonstrated, only recently has the rate of new configurations been predictable [3]. In addition, in the late 1970s and early 1980s, the first statistical techniques to predict the linkage of RNA sequence were established. It took another ten years for the Western team to plan the first 3D RNA structure.

Only certain computer-based forecasts of 3D structures of the biggest RNA particles have een made to date [4]. Despite the limited quantity and variety of observed RNA configurations, computer techniques for RNA configurations determination have become one of the primary instruments for assessing phenotypic variation in RNA molecules and its connection to performance [5]. The majority of the available methods are predicated on the idea that RNA folding is a hierarchical mechanism, and that understanding its conformational changes could better determine its 3D configuration better. As a result, computational intelligence methodologies have been implemented in recent decades, which try to anticipate the potential associations of nucleotide sequences in RNA based on its composition.

II. Related Works

Furthermore, the expanding quantity of structure determination of RNA molecules, as well as early seeks to name their patterns, opens the possibility of using comparable methodologies similar to those applied to the forecast structure of proteins. It is, of course, more difficult to estimate large 3-D RNA structures using comparable techniques than to estimate protein complexes. This claim is based on two characteristics of RNA: its bending is especially notable by its specific genetic or frequent themes, yet RNA sequence durability is primarily limited to tiny single-nucleotide segments while maintaining strong crystalline materials sustainability initiatives [6]. Both criteria demand that an RNA particle's two bands be determined while predicting its 3D structure, but that's acceptable comparing methodology be limited to RNA configurations that match an accurate complementary sequence with more than 60% close similarity in shown in.

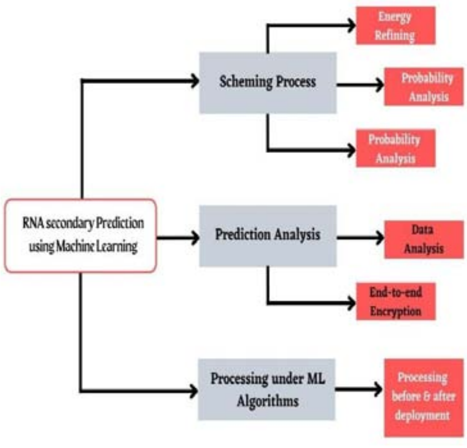

Fig.1. Proposed architecture of RNA secondary prediction using ML

Indifference the deoxyribonucleic, a multitude of possibilities In terms of structure, RNA consists of waste

DOI: rp-9788770040723.079

materials, phosphates, and aromatic groups. The phosphodistrics bond links waste and phosphates, providing a framework from which aromatic bases are regularly bound through the C1 atom of the venous fraction. Hydrogen bonds and assembly connections at bases cause RNA molecules to bend as they are generated. However, the WC genetic material retains the canonical helices intact. In addition, nucleotide groups can engage in ribose or phosphatase molecules, as well as in non-anionic base-base connections, resulting in unique RNA morphologies. RNA supports complex 3D structures due to pair interactions between nucleotides. A lot of three hydrogen bonds between coupled nucleotide bases are expected to hold a radical pair in RNA. The swells, stem connects, stem-loops and pseudo nodes that make up the genomic sequences of an RNA molecule are generated either by the configuration of the base couple in the framework. Stem-loop takes, coaxial layering, Loop-loop contacts, and triple or quadruple propellers are examples of tertiary relationships that keep that entire [14] 3D RNA frame together. The authors conducted a thorough examination of numerous methods for predicting N1-methyladenosine and N6-methyladenosine sites. They've addressed a wide range of key topics, including dataset quality, operational algorithms, sequence and genomic characteristics, model performance, feature selection, and software utility, all of which are critical for the construction of successful predictors. [9-10]. The scientists examined computational approaches for quantifying RNA levels in single cells using the Single-cell RNA-sequencing (scRNA-seq) technology. They then analysed eight imputation methods, assessed their power in recovering original genuine data, and ran a variety of analyses to see how they affected cell type clustering, discovering differentially expressed genes. [11-12]

III. Proposed Methods

The NDB section contains information on all compounds that include nucleic acids, including categorization and interactions of nucleic acids using enzymes, frame configuration aspects, and baseline pair identification [7]. The SCOR database, as well as the SCOP database for functional areas, organizes the RNA patterns into a hierarchical classification scheme.The RNA structural category distributed each entrance by the physiological functions of their particle, motif, and research framework; the RNA operational study divided each entry into the natural process of particle, themes but also study framework; and the RNA tertiary conversation cluster separates RNA frameworks by intramolecular connections that diverge of WC or non-WC base couple.

The AFM provides another form of data that could be of great value in RNA modelling. RNA molecules can now be seen to highlight properties such as dual or nanomaterial domains, as well as their connections, through various improvements in this method. The AFM is especially useful for determining the structure of RNA molecules of reasonable size with several secondary building components that could be positioned on a substrate while maintaining local geometries. In addition, A FM may reveal other patterns because it is a one-molecule approach. AFM images, like the 2D level courses of cryo-EM research, could theoretically be used to code structure restrictions shown in Fig.2 .

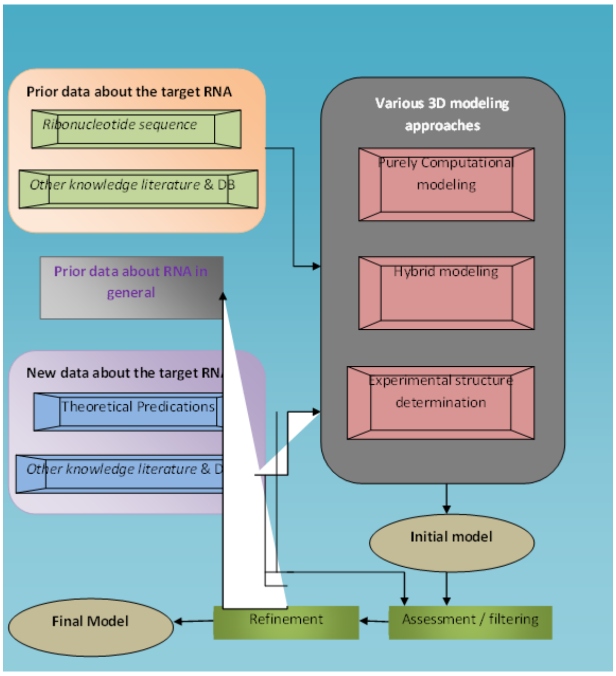

Fig.2. 3D structure architecture of RNA.

IV. Results and Discussions

Prediction of conformational changes in an RNA sequence can help researchers learn more about its final shape and composition. Regional contacts occur first and are significantly larger than tertiary connections in the NRA simulation procedure, which is architectural. Consequently, the secondary structure of RNA serves as a frame for the 3D structure of RNA. This feature implies that the sequential RNA information could be estimated even without tertiary relationship information. The first approaches for forecasting the conformational changes of RNA molecules were built along with the concept that the optimization approach and Nussinov's methodology could be used to detect the lowest free-energy configuration for such a native state. The institutions were established particularly for such approaches employing actual calorimeter investigation or confirmed RNA configurations published in the PDB and were predicated on physics' free electricity estimates. Nevertheless, the minimal free energy methodology does not check whether the final product chosen or projected is the native configuration or often corresponds to a quasi-native configuration. The employment of a hybrid algorithm for substandard structural components, the computing of all unsatisfactory sequences towards the effective bending interior, or the identification of unsatisfactory strategies predicts on RNA texture analysis are all examples of MFE concept applications.

The horizontal developmental forces on genetic variants of RNA are seemingly ignored when predicting changes in conformation from a short sequence. Accordingly, the several variants of forecasting the secondary framework for RNA facilitate the implementation of limitations on the sharing of common sequence characteristics. The secondary structure [15] of RNA is more likely to be preserved through development than the sequence. A second alteration to an RNA molecule is said to repair a mistake by restoring the baseline couple relationship. This approach is used in several protein structure forecasting methods which attempt to discover such a correlation between different locations in a multiple sequence alignment. The concept of mutual information was used to gather correlations between bases in the initial deployment of such a method.

4.1 RNA Structure Analysis

Predicting the three-dimensional configuration of an RNA molecule is simple, but generally requires human involvement. A completely automated methodology, unlike the current state of protein structure prediction, is incapable of the presence of a large 3D RNA structure from its sequence. Nevertheless, in recent years a series of different innovations for the manual or automated characterization of the RNA structure has been created. ERNA-3D, for example, builds a 3D structure of RNA independently, starting with its QA: Should it be 'from'? Secondary [16] configuration..v MANIP assembles complete RNA structural models using either RNA patterns or segments from a library of choice. The final refinement protocol incorporates basic canonical and noncanonical coupling requirements, as well as covalent morphology, stereochemistry, and van der Waals contact requirements. By utilizing the dimensions or relationships between the bases on known RNA structures, the MC-Sym software creates 3D RNA structures. During the construction process, reasonable limits could be placed on the framework for the preservation of specific structural components. To reduce the stability of the anticipated framework, MC-Sym employs numerical simulations modelling.

Integer programming is used in RNAmoIP infrastructure to modify expected or known structural properties that allow such integration of 3D RNA patterns. Assumptions are then used as models in the MC-Sym program for building entire 3D structures. Researchers give government approaches to the prediction of a secondary RNA structure, including pseudo nodes, mathematical optimization approaches have received a lot of attention recently [8]. The RNABuilder program for the software application creates a template RNA configuration by processing mechanics and pressures to various levels of detail. Caution connections, certain sequence lengths, and certain whole molecules are kinematically hard, while other bonds are malleable. The rigid base concentrating on specific atoms is subjected to forces.

4.2 Comparison of Experimental Methods

The different approaches mentioned above generate different kinds of structural features, and their implementation presents unique obstacles. Different methods used to determine the architecture of many NRAs, especially those designed to capture the internal system with extreme accuracy, have proven their resistance. A hybrid strategy, which combines several experimental and analytical methodologies, has turned out to be an efficient means of determining structures for even the most "challenging" RNA targets, going by the shortcomings of the methods used independently. The methods of selection for determining 3D structures of RNA at the atomic level are MX and NMR. Patterns derived from crystallographic information are frequently snapshots of a compound that assumes several configurations in its native state, whereas structures derived from NMR provide an ensemble to coincide with the structure of the compound under investigation. Other methodologies such as cryo-EM, SAS, and AFM, which provide the accessible entire shape of such examined targets in environmental circumstances, can be used to compensate for MX and NMR inadequacies, which include the design to regulate the monomer or complex under research.SAS methodologies provide low-resolution tertiary shape information of an enzyme under physiological circumstances, extending disturbed or adaptable areas, as well as facilitating the assessment of intramolecular' dynamics, such as transcriptional activation, complex formation, folding, adaptable domain circulation, and aspect in the process occurring in reaction to foreign circumstances.

Only coarse grain structural components that capture the average arrangement of atoms in a molecule could be constructed using SAXS and WITHOUT data only. SAS approaches may also be used in a variety of methodologies. A current example is the use of SAXS in conjunction with microfluidics technologies and overall modelling with MD to generate a consistent RNA environment.Chemical probes and impression approaches paired with MS, EPR, or FRET can be applied to value restrictions in medium or long-range connections, or binding affinity sites, which greatly improves collected information. Additionally, dispersion measurements are not determined by the size of the target compounds, and so complement methods like maximum level NMR or cryo-EM, which are typically confined to larger and smaller items, respectively. Cryo-EM, NMR, and MD were used to solve the framework of 30 kDs HIV-1 RNA Dimerization Signal, demonstrating that merging methodologies that expose the general structure with methodologies that focus on local structural properties allow for structural [13] characterization of molecules that exceed the limitations of the conventional methodology.

4.3 RNA 3D structure modeling approach

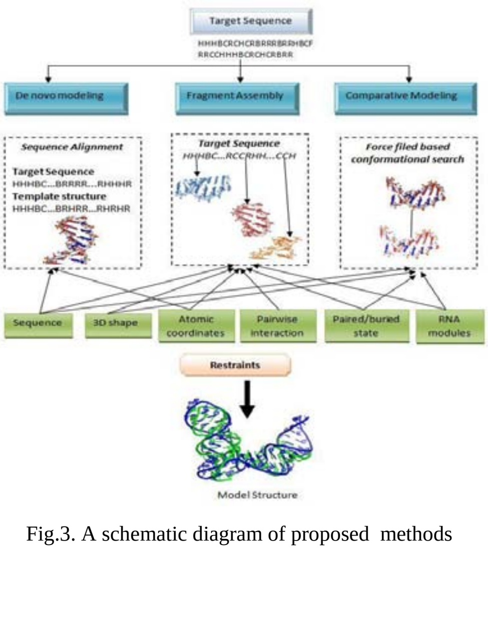

Fig.3. A schematic diagram of proposed methods

DOI: rp-9788770040723.079

The first and most important step of this type of modelling is to identify a formed structure and link the sequences of goals and models. Therefore, the particular availability of empirically resolved RNA 3D structures that can operate as substrate threshold the overall efficacy of comparison modelling, and this scheme is strongly reliant on macromolecular structure datasets in Fig.3.

Comparative modelling can typically generate incredibly accurate designs for target molecules with high sequence identity, such models, indicating a narrow phylogenetic relationship. Like proteins, evolutionarily similar RNAs with different sequences often maintain the original tertiary creases. Due to configuration differences and increasing difficulties in generating precise sequence alignments, the likelihood of creating an appropriate model reduces as the evolutionary distance between the target and the prototype increases. In practice, comparisons can be modelled using models that are not biologically related to the target, but this requires the unconnected model to be structurally highly comparable to the objective. Comparative analyses based on erroneous frameworks or appropriate frameworks with erroneous guidance are almost always erroneous.

In two ways, the atomic coordinates of experimental measuring structures are frequently used in contrasting modelling techniques. One set of approaches transfers the structural core's atomic coordinates from the template straight, keeping the backbone in areas of continuous conformance, and 'patches up' backbone incompatibilities produced by insertions or deletions by patching the template with short segments from other constructions. Geometrical comparison is used to replace bases when the motif architecture or subsequent segments are out of phase with the destination.

These approaches require no energy calculations, and classification is mainly used to reduce vertebral column deviations and severe conflicts between implanted segments and the centre. Another class of comparable modelling approaches, such as Modular or MacroMolecular Builder, uses target-template congruence to assign correlations between residue and then apply spatial constraints to the template strand depending on the principles for comparable positions in the pattern. After that, the target gene is bent to respond to those constraints. A force field is also used to perform an optimization technique, ensuring that the final product is nearly exact. Geometrical restrictions based on generic statistics from 3D RNA structures can also be implemented to ensure adequate stereochemistry. Protein structure data could be used in both types of techniques to control segment selection or restrict propellers to create optimum connections and shape.

V. CONCLUSIONS

Finally, we submit that approaches to modelling the 3D structure of RNA that permits the use of experimental values as restrictions should be greatly improved. For starters, there are a variety of experimental procedures that are not able to determine the architecture unambiguously but produce data that can be used as restrictions in computer models. Since much of this information is low-resolution and uncertain, process models must be modified to accept them appropriately, and suitable analytical structures must be used to allow choice among numerous options and to accept a fairly high level of constraints that could be inaccurate. Second, modelling techniques often rely on experimental data produced by an industry that can be misleading. MX and EM data, for instance, are typically used in 3D statistical approaches rather than dispersion structures or 2D images. Similarly, slope information is used indirectly to generate projections of the secondary structure rather than immediately. As a consequence, we consider that substantial progress in 3D structure determination could be achieved by modifying existing techniques to use experimental results at an early stage in the procedure, in parliamentary procedure to prevent distortions. This may require the development of new approaches to address experimental results in the prediction phase, bringing methodological concepts closer to the type of real information collected in studies. This trend towards progress can also encourage theoreticians to work in close collaboration with experimenters. Computational methods that treat raw data may be able to get more details of cellular mechanisms that have been explored in the research laboratory, and may yet contribute to the emergence of novel physiological functions.

***Abstract*—The longest non-coding RNAs have been extensively explored as well as published in current history for their participation in transcriptional copying, immunological reaction, developmentally induced pluripotent stem cells, tumorogenesis, including hereditary control, among other cellular activities. Many theoretical and simulation techniques for genome-wide searches as well as showings of ncRNAs have been developed, each with its own set of constraints, based on sequence properties such as size, frequency, as well as a backbone structure. In comparison to other classification methods, the suggested Deep Neural Network (DNN) seems to be a rapid and precise substitute for identifying lncRNAs. Utilizing annotated image learning algorithm from LNCipedia as well as RefSeq file, the data preserved ink-mere patterns would be used as an exclusive characteristic for the DNN classification model, yielding a precision of 98.07 percent, responsiveness of 98.98 percent, as well a clarity of 97.19 percent, including both, on the validation set. The enhanced classification performance was due to the k-mere data benefits created using the Shannon entropy algorithm. Such implementation of an appropriate has also been evaluated on a published human DNA collection, and it is 99 percent accurate in identifying recognized lncRNAs.**

Keywords—non-coding RNAs; Deep Neural Network;ClassificationModel; Shannon entropy algorithm

I. Introduction

Ribonucleic acid (RNA) would be a large molecule that encodes specific genes in a series of DNA nucleotides across a nucleic acid string, allowing it to be transmitted from one generation to the next with great accuracy as well as adaptability [1]. Different forms of RNA could be distinguished by a variety of characteristics such as stimulation, transcription, movement, as well as meandering characteristics, all of these are important in core dogma. RNA was already divided into 3 types based on its functions: messenger RNA (mRNA), transfer RNA (tRNA), plus ribosomal RNA (rRNA), which perform as data stages in the polypeptide manufacturing equipment [2]. Furthermore, because most of these products need not translate for polypeptide and rather operate as ncRNA, the genetic information was categorized as interpreting RNAs as well as non-coding RNAs. Furthermore, with the improvement of greater RNA generation sequencing, snRNAs may now be approximately categorized. Moreover, the PLncDB provides data on botanical lncRNAs, whereas the income website provides similar results for humans [3]. The ncFANs web application may be used to functionally annotate lncRNAs, while DIANA-LncBase contains extensive data across both suggested as well as practically proven miRNA–lncRNA relationships. In rapidly discovering ncRNAs in novel genomes, computer detection systems supplement different techniques. Several regulations as well as guided having to learn algorithmic techniques for predicting ncRNA have indeed been presented in the previous, based on a combination of characteristics significant sequence characteristics. To evaluate the transcript levels of lncRNA, the 1 regulation technology utilizes preconFig.d probing spanning shared entrance as well as inhering regions to help identify ncRNA strings [4]. Some other methodology employs the lncRNA genomic following are the examples in the tumour as well as non-tumour cells to determine possible lncRNAs implicated in oncogenesis.

II. Related Works

Multicolour information has previously been utilized to determine ectopic as well as atopic endometrium lncRNA as well as an mRNA transcript treatment in people, as well as to anticipate lncRNA activities using founder mRNA classifications. Including both lncRNA as well as mRNA, the ArraystarLncRNA Production as well as Transcription genotyping permits monitoring of complex formation or methylation locations at transcription factors. Furthermore, some resources, such as fans as well as NRED expressions Database, leverage which was before microarray information to functionally annotate lncRNAs, making use of such a coding-noncoding transcription founder system [5].

RNA-seek information can also be used to detect the existence as well as the architecture of lncRNAs using a range of information. LncRNA2Function, as well as NONCODE, were consumer online interface services for investigating the functioning of the body lncRNAs using RNA-seek information. RNA-immunoprecipitation seems to be a modern approach for identifying lncRNA that connects to associate with a particular enzyme. That method has been used to uncover Xist, which reacts with PRCII. The RNA-IP approach is used in several Registered Motif as well as

DOI: rp-9788770040723.080

Millipore products to purify peptides as well as recognize associated lncRNAs with ribonucleic transcription factors. TaqMan quantitative PCR tests are included in Digital Equipment products to calculate the transcription of specific lncRNAs. To produce genomic sequence assessments of chromosome patterns, a chromosome handwriting technique is most commonly utilized. The genome's transcriptional areas were identified, as well as the sites of lncRNAs were identified as well as investigated. Genome sequencing allows for maximum identification of RNAbound proteins and DNA in subsequent tests utilizing chromosome separation by RNA filtration [6-7]. Those regulation techniques, on the other hand, are getting more and more complex. Genotyping has limitations in that this was not sufficient to identify RNA components having lower expression levels, and tagged information was needed to research lncRNA activities [8]. Because SAGE seems to be more costly than sequencing, it must be rarely used in huge investigations. To forecast the types of ncRNA, the authors constructed a computational predictor. Deep learning was employed straightforwardly and effectively. When compared to existing methodologies, the proposed tool has produced the best results.

RNA-sick does have several benefits over typical microarray technology for investigating the expression of genes. It's better at recognizing rare transcriptomes plus finding novel therapeutic processing variants including noncoding RNA components [9-10]. Additional signature properties that might also aid in the condition based on lncRNAs should be included in present approaches and strategies. Even though the approaches outlined above were proved to be instrumental in detecting lncRNAs, rare examples have been documented. The transcription factor RNA stimulator had long been described as ncRNA, but somehow the decoding product was discovered later [11]. While further information regarding lncRNA becomes available, this ambiguity would be resolved. Traditional methods rely on the width of the open reading frame (ORF), and ORF preservation, but rather on architectural protein structures. Because of the lncRNAs' complicated characteristics, a great number of computer training approaches have recently been created. To distinguish lncRNAs from mRNAs, for example, a variety of structural characteristics like protein content, secondary structure, and peptide size were employed to build SVM models. SVM is used by the Coding-Potential Calculator (CPC) to train as well as category component information [12].

These approaches show how to construct as well as retrieve sequencing characteristics as well as genetic testing characteristics to evaluate the programming ability of genes using lengthy, greater ORFs having resemblance (BLASTX) to associated genes. Combining every one of these elements altogether and then using the information from the server as inputs would be a basic as well as straightforward first stage. Therefore, to fully use the information's possibilities for physiologically meaningful interpretations, technologies that really can extract features recurring patterns from the information are required [13-14]. Technologies based on machine learning were very well to solve various Bioinformatics challenges using greater precision. These could cope with massive datasets with high dimensionality, as well as versatility in modelling a variety of data collection techniques.

III. Methods and Discussions

The goal of the research would be to create DeepLNC, a generalized deep neural network (DNN) classification for distinguishing lncRNAs from programming RNAs (mRNAs). To easily categorize the lengthy component of the ncRNA family, researchers used the k-mere probability contents to estimate the k-moire patterns as the only descriptor of lncRNA. Using a forward selection-backwards elimination (FSBE) feature extraction technique, many consistencies on varied permutations of k-mere characteristics have been used to choose the end selection of characteristics. The word k-Meir refers to the mixture of potential subsequences of fixed size in a prospective learning as well as the assessment sequence's complete phrase. The fundamental idea underlying k-mere additional comprehensive selection would be to take advantage of the complexity of the k-more regular recurrence vs. the total available data of the entire program, which would be critical for the genomic enhancement of any given pattern. To discover as well as understand the likely k-mer configurations with several more goal mappings, we use DNN, a probability deep learning method. (1) The Shannon entropy approach had been used to minimize the information's intricacy as well as obtain tallies, including all non-unique k-meres. Shannon entropy, indicated by H as well as written as, was among the most critical indicators used in statistical mechanics.

$$H = -\sum_i^N (p_i log_b \text{i}) \quad (1)$$

Wherein pi seems to be the likelihood of finding the k-meres in a transcript. Including its shared execution of the multi-thread H2O system, the DeepLNC technique lowered the deeper connection for collecting k-Mars when compared to those other classic data mining algorithms. The new method was already verified to show that it outperforms prior techniques like CONC, CPC, lncRNA, as well as PLEK. To use our custom-built classification model, researchers matched DeepLNC to PLEK. PLEK identified mRNAs with a 75 percent average accuracy, while DeepLNC successfully identified 82 percent of mRNAs. PLEK was used to identify 98 percent of lncRNAs, however, our suggested technique recognized 99.8 percent of lncRNAs. As indicated in Fig. 1, information sources have been considered: preparing for the exam. Patterns, as well as descriptions, were collected from the LNCipedia collection, the most recent edition of the lncRNA data set, including contains 111,685 humans identified lncRNAs as well as includes complete descriptions of eukaryotic lncRNAs. mRNA transcribed from the RefSeq database was used in the testing dataset. Wikipedia provided 80,214 people with lengthy transcribed affirmative training data. RefSeq provided 99,395 nutrient transcriptomes for the pessimistic training dataset.

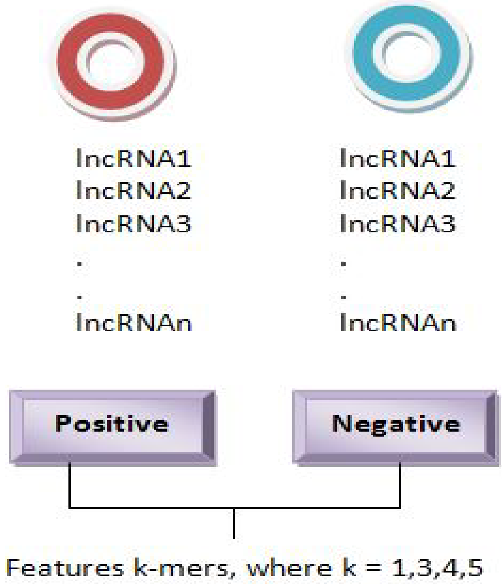

Fig.1. Combimations of K-mers range

Researchers discovered that k-more pairings of 2, 3, as well as 5, produced better results in lncRNA identifying when tested against information delivered that used a simulation model across all possibilities of k-mer utilizing FSBE. Furthermore, the DeepLNC seems to have a restriction in verifying the greater of k-Meir, which would result in substantial growth in the training dataset, which is above our computer's processing capacity.In Fig. 2, the achieved diagnosis based can be seen in the kind of correctness against any k-more pairings, whereas TABLEI displays the combination of multiple pairings for every value of k.

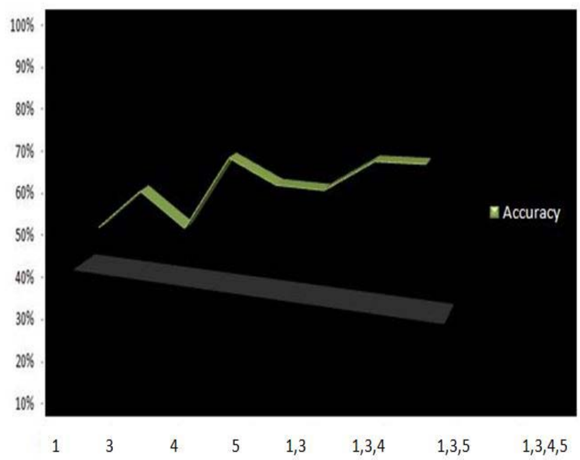

Fig.2. Performance Analysis

TABLE I. CLASSIFICATIONS OF FEATURES

Value k	No of possible Comination	Total
1	4^1	4
3	4^3	64
4	4^4	256
5	4^5	1024
Total Feature = 1128		

IV. ML &DEEP NEURAL NETWORK

Designers used DNN as the major predictor to learn their sample. DNN would be a collection of machine learning techniques that have been significantly reliant on the collected data used to develop several multilayer models of non-linear operational insight. Classification technique, analytical classification, multilayer deep learning methods, including multi-layer perception are among the technologies that could demonstrate to be multipurpose since they use a combination of human comments, experimental investigation, as well as various Bioinformatics techniques. Several important traits, researchers predicted, might aid in the characterization of heterogeneous lacunas. DNN was validated k-mar rates of lacunas as well as programming transcripts segments.To distinguish lacunas from mRNAs, a binary class model was developed using the k-mar segmentation method as well as the implications of the DNN technique. Using tenfold cross-validation, the recognition system acquired a good performance on the training sample. With lower dimensionality as well as superior hierarchy surface feature reduction, the suggested DNN optimization technique tackles non-linearity in information. Using an advanced gradient supervised learning; allows for worldwide error detection and correction of numerous fully connected layers. Through the stages of DNN, the incorporation of advanced optimization techniques like Dynamic Teaching Dropouts as well as Nesterov's Accelerated Gradients allowed the least amount of classifier, the fastest growth of mistake reduction, as well as the highest predicted performance. Ox data H2O has been used to build the DNN. This is free software advanced analytical system that does statistical modelling using Hardtop.

The REST API has been used to link Ox data H2O to R for information processing. Machine learning algorithms were described as a multi graze artificial neural network (ANN) that is learned utilizing a backpropagation algorithm and learning algorithm. Researchers utilized the tan h learning algorithm because their information was queasy. Excellent predicted reliability was achieved because of innovative features. Our encoder DNN's forecast evaluation was done utilizing a conventional matrix that included various conventional performance indicators, as shown in Esq. (2), (3), as well as (4). The performance of the predictor has been further assessed utilizing just a few statistical parameters obtained from the test results: true positive (TP), true negative (TN), false positive (FP), as well as false negative (FN). TP denotes accurately guessed lacunas, TN denotes properly identified programming RNAs from negatives collection, FP denotes negatives objects that have been wrongly categorized as lacunas, and FN denotes instances wherein genuine lacunas were mistakenly classified as non-lacunas.

$$Accuracy\ (ACC) = \frac{TP+TN}{TP+TN+FP+FN} \qquad (2)$$

$$Sensitivity\ (SN) or\ true\ positive\ rate = \frac{TP}{TP+FN} \qquad (3)$$

$$Precision\ or\ positive\ prediction\ value\ (PPV) = \frac{TP}{TP+FP}$$

(4)

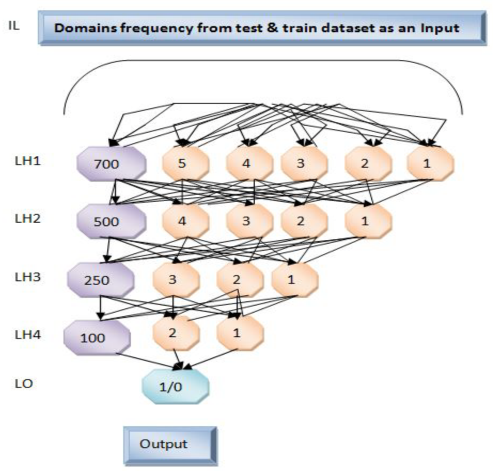

Fig.3. Training phase of DNN

The number of hidden neurons employed, the representation of the input classification model, as well as the set of independent vertices all influence the system performance of DNN. Even though the suggested DNN structure has a larger number of information vertices, the sparse structure of the data frame meant that the load optimization algorithm required lesser model parameters. In addition, as shown in Fig. 3, the number of hidden nodes was set to '4'. On an i7, 2.6 GHz AMD system with 14 GB RAM, every folding cross-validation for the learning algorithm takes about 20 minutes. Various researchers have been used thousands of high approaches to identify lacunas. Furthermore, the characteristics of lacuna were yet to be adequately depicted. As a result, developing a method that would be, independently of previously forecasted traits and could be equally adapted to large datasets has become much more important. The concept of cognitive characteristics was critical for categorization, thus humans sought to use the traditional k-more value in their research. Lastly, the suggested k-mere utilization patterns combined with complexity computation were found to be superior characteristics for identifying lacuna. K-mere strands with greater lengths give important information than those with small distances. DNN consistence on ten methods learned on positively and negatively databases, as well as a combination of processes utilizing tenfold pass on training examples with only an intake dropout's proportion of 0.2 as well as a concealed washout proportion of 0.5 for every surface, were examined. In the very same training sample, every learning variable was repeated five times.

The maximum accuracy (ACC) was 98.07 percent, and the Matthews coefficient of correlation (MCC) was 0.968104, indicating a strong efficiency because the outcome had been very nearly 1. The You den's Index (J) was determined to be 0.968208, indicating that the examination has a low false-positive rate (FP) as well as false negatives (FN) when compared with other methods. DNN, as demonstrated in Fig. 2, is much more effective than some other machines attempting to learn classifications from their information showing a myriad of benefits. TABLEII summarizes the effectiveness as well as the assessment of their algorithm. TABLE IIPerformance and analysis of DeepLNC in detecting lacunas At various decision ranges, researchers investigated the effectiveness using the receiver operating characteristics (ROC) curves, where insensitivities (TPR) are shown against a factor of the false alarm rate (1 - specific).

TABLEII. DETECTING LNCRNAS PERFORMANCE ANALYSIS

Performance	Ranges
TN	15.315
TP	14.675
FP	140
FN	454
Accuracy	0.977134
Precision	0.968974
Sensitivity	0.979481
Specification TPR	0.979481 0.034897
NPV	0.97

The area under the ROC curve shows the product's actual quality as the approaches suggest. Deepen was able to get a ROC score of 0.9930, indicating provides a positive performance of the classifier. Fig. 4 shows the efficiency, clarity, susceptibility, as well as particular characteristics of their DNN classification during the 10-fold pass on the training images [15]. E-mail information is usually accessible. When there is so little knowledge regarding Lacuna, it is a difficult category of the crane to study. Deepen, the technique that can be implemented throughout this work has a high degree of precision as well as forecast frequency, and that can be suitable for determining novel lacunas.

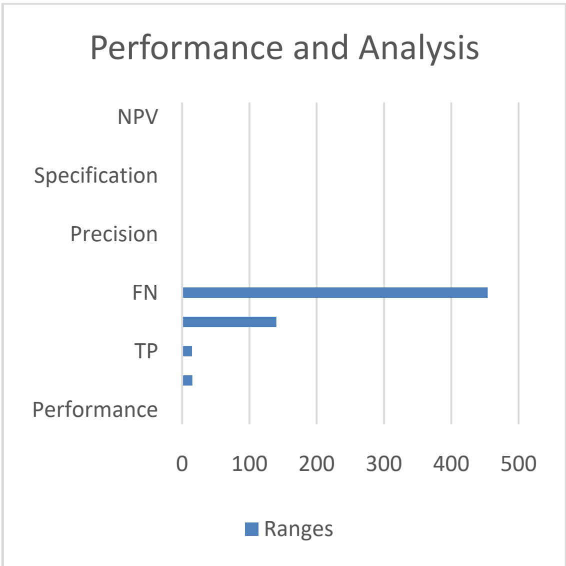

Fig.4. Performance measures of DNN

Several lacunas have been incorrectly classified as programming transcribed; consequently, using DNN classification, most mistakenly projected lacunas could well be removed from high false collections. DNN could also be used to characterize additional cranes with restricted as well as preserved information. Utilizing freshly formed permutations, extra composites changes can be made to this system. Because epigenetic patterns were also extremely complicated and could be properly understood by any straightforward quantitative tool, humans plan to use this

DOI: rp-9788770040723.080

classier on lacunas from different microorganisms in the long term, with a special emphasis on the human genome with environmental, interpersonal, as well as farming relevance, and those with pathological importance.

V. Conclusions
