YOLO is the name of the newest state-of-the-art real-timeobject detecting technology. By spatially isolating boundingboxesandapplyingasingleconvolutionalneuralnetwo rktoassignprobabilitiestoeachofthedetectedimages,itispossibl etotreattheobjectidentificationproblemasaregression problem rather than a classification task (CNN).The popularity of YOLO is attributed to its speed, detectionaccuracy, strong generalisation, and open-source nature. TherearefiveYOLOvariantsavailablerightnow(v1,v2v3,v4an d v5). Better functionality, including four connection layers,four convolution layers, and five CSP layers, was added toYOLOV5. It can hasten feature information transmission andfeature fusion. Compared to YOLOV3, YOLOV5 has higheraccuracy. Many YOLOv5 models were trained using the MSCOCOdataset.

IV. ExistingSystem

Existing system is based on detection of helmet which firststartswithmovingobjectsegmentationusingdescriptors.Th endetection of helmet tracing the Region of interest which is thehead region then classifies between helmet and non-helmet.ItusesthecircleHoughtransformtodistinguishbetweena helmetandanon-helmet,whichalsocausesamisidentificationofaheadasahelmet becausebothhavearoundshape.costsa lot of computation. Geometric features are not enough todetect the presence of a helmet; many times, the head can bemistakenforthehelmet.

V. LiteratureReview

InPaper[1]theauthorisaddressingthepressingissueof road traffic accidents, which have emerged as a significantpublichealthconcernthatnecessitatesamultifaceted approachforresolution.IncountrieslikeIndia,thealarmingincre aseinfatalitiesandinjuriesresultingfromroadaccidentshasbeco meacauseforgreatconcern.Thefrequencyofroadaccidents leading to death or permanent disability has risen,underscoring the urgent need for preventive measures

DOI: rp-9788770040723.162

to beprioritized by relevant organizations involved in public health.However, the current methods employed to implement lawsandpoliciesaimedatcurbingtrafficaccidentsoftenlackefficiencyandcommitment.

In paper [2] the author discusses the prevalence of two-wheelersasacommonmodeoftransportationtoday.However,the inherent risk associated with riding a two-wheeler withoutproper protection is significant. To address this, wearing a hel-metwhileridingabikeishighlyrecommendedasapreventivemeasure.Infact,governmentshaveevenmadeitillegaltoridea bike without a helmet, and have used manual methods toenforce this regulation. To automate the process of identifyinghelmetusagewithoutrelyingonmanualintervention, theauthor proposes a system that utilizes video monitoring of thestreet to automatically determine if a bike rider is wearing ahelmet. This system employs machine learning techniques toaccurately identify different types of helmets with minimalprocessing,makingitefficientandeffectiveinpromotinghelmetusagecompliance.

In paper [3] the author discusses the importance of licenseplate location in automated transportation systems for vehicledetection. In this work, a reliable and real-time method forlicense plate location is presented. The license plate regioncontainsrichedgeandtextureinformation,whichisuti-lized in the proposed approach. Initially, image enhancementtechniquesalongwiththeSobeloperatorareemployedtoextracttheverticaledgesfromthecarimage.Subsequently, arobustalgorithmisappliedtoeliminatebackgroundandnoise edges, retaining only the relevant features. Finally, arectangle window is used to search for the license plate regionintheresidualedgeimage,allowingforseparationofthelicense plate from the original car image. The effectivenessand reliability of the proposed method are validated throughexperimental findings, demonstrating its potential for accuratelicenseplatelocationinautomatedtransportationsystems.

In paper [4] the author discusses the concerning trend ofincreasingmotorbikeaccidentsinmanycountriesovertheyears. The growing popularity of motorbikes can be attributedtovarioussocialandeconomicfactors.However,despitethecrucialroleofhelmetsastheprimarysafetygearformotorcyclists, many riders neglect to wear them. This paperpresents and demonstrates an automated approach for classifying motorbikes on public highways, along with a system forautomatically identifying riders who are not wearing helmets.The system utilizes camera photos of the traffic to implementtheproposedapproach.

In Paper [5] the author discusses the application of helmetdetectioninimageprocessingandpresentsanewmethodfor helmet detection in their research. The proposed methodcombines two techniques to increase the likelihood of detect-ing helmets. The first technique involves utilizing a haar-likefeatureforfacedetectiontodifferentiatebetweenwearingandnotwearingahelmet.Thesecondtechniqueinvolvesusing a circle Hough transform to further distinguish betweenhelmeted and unhelmeted individuals. In the initial section ofthe method, a fast algorithm for helmet detection in coloredimages is suggested. The novel algorithm used in the proposedmethod has shown high detection rates and low false positivesin image experiments, indicating its effectiveness in detectinghelmetsaccurately.

In paper [6] the author discusses the method proposed intheir research for automatic recognition of helmet-less bikeriders in real-time surveillance videos. The suggested methodinvolves multiple steps, starting with backdrop removal andobject segmentation to identify bike riders in the surveillancevideo. A binary classifier and visual cues are then used todetermine whether the bike rider is wearing a helmet or not.Additionally,aconsolidationmethodforreportingviolationsisprovided to enhance the validity of the proposed method. Theperformance of three commonly used feature representationsforclassification,namelyhistogramoforientedgradients,scale-invariant feature transform, and local binary patterns, isalso compared in order to evaluate the effectiveness of theapproachpresented.

Inpaper[7]theauthordiscussesthechallengesinde-tectingtrafficruleoffendersforensuringsafetymeasures,such as occlusion, illumination, poor quality of surveillancevideo, and fluctuating weather conditions. In this article, asystemforautomaticallyidentifyingmotorbikerideerswhoarenotwearingprotectivehelmetsonsecurityfootageisdescribed. The proposed method involves the extraction ofmoving objects from video frames using adaptive backgroundsubtraction.Motorcycleridersarethenselectedfromthemoving objects using convolutional neural networks (CNN).Additionally, CNN is used on the upper one-fourth part of theriders to further detect those who are operating their vehicleswithoutahelmet.

In paper [8] the author discusses how motorcycles havebeenapopularformoftransportation,butthenumberofmotorbikeaccidentshasincreasedrecently.Notwearingasafetyhelmetisoneofthemaincausesoffatalitiesintheseaccidents. Currently, traffic cops manually monitor motorcyclists at intersections or watch CCTV footage to identify thosewithout helmets and fine them, but it requires a lot of effortand action from people. This study proposes an automatedmethod for identifying motorcycle riders without helmets andobtainingtheirlicenseplatesfromCCTVdata.Theheadsection of a classified motorcyclist is analyzed to determine iftheyarewearingahelmetornot.

In paper [9] the author discusses how the rapid growth ofvehiclesandtransportationsystemshasmadeitimpossibleforhumanstofullymanageandmonitorthemmanually.Asaresult,automaticrecognitionoflicenseplatenumbershasbecomeincreasinglyimportantinvariousapplicationssuch as traffic monitoring, tracking stolen vehicles, managingparking tolls, enforcing red-light violations, and border andcustoms checkpoints. However, the diversity of license plateformats, variations in scales, rotations, and non-uniform illumination conditions during image acquisition pose significantchallenges. This

DOI: rp-9788770040723.162

work proposes an Automated Number PlateRecognition System that utilizes edge detection techniques,histogram manipulation, and morphological operations to segment characters and localizelicense plates. Character classification and recognition are achieved using artificial neuralnetworks.

Inpaper[10]theauthordiscussestheconceptofAutomaticLicense Plate Recognition (ALPR), which involves extractinglicense plate data from images or a series of photographs.ALPR has various applications, including electronic paymentsystemsfortollsandparkingfees,aswellasmotorwayand arterial monitoring systems for traffic surveillance. ALPRtypicallyusescolor,black-and-white,orinfraredcamerasto capture images of licenseplates. The success of ALPRdepends heavily on the quality of the captured photos. As apractical application, ALPR must be able to process licenseplates quickly and effectively in various settings, including in-doorandoutdoorenvironments,duringdaytimeandnighttime.Moreover, ALPR must be able to handle license plates fromdifferentcountries,provinces,orstates,makingitnecessary tobegeneralizedandadaptabletodiverseplateformats.

VI. Proposed Methodology

In our suggested system, we propose a real-time and accu-rate automatic deep learning method for motorcyclist helmetrecognition,whichcomprisesoftwoparts.Thefirststepinvolves detecting motorcycles in the surveillance video usingYOLOv5-MD, an improved version of the YOLOv5 methodspecificallydesignedformotorcycledetection.Thevideofromthesurveillanceisprocessedusingthe YOLOv5algorithm to identify motorcycle regions. The second stage, known ashelmetdetection,takesthemotorcycleregionsidentifiedinthe previous step as input and uses an upgraded version of theYOLOv5 algorithm called YOLOv5-HD to determine whetherthe motorcycle riders are wearing helmets or not. The networkistrainedseparatelyforeachstageasthetasksofvehicleand helmet detection are quite distinct from each other. ThepurposeofYOLOv5-HDistoenhancethedetectionofhelmetson the motorcycle riders, thereby improving the accuracy oftheoverallsystem.Thistwo-stageapproachallowsforefficientandprecisedetectionofhelmet usagebymotorcyclistsinreal-time,makingitavaluabletoolforautomatichelmetrecognitionin surveillancefootage.

YOLO is the typical object detection technique. That is known for its fast inference speed. It uses a regression-based approach to directly generate the bounding box coordinates and class probabilities in a single pass through the network, which makes it faster compared to two-stage approaches like Faster R-CNN. YOLOv5, in particular, has introduced improvements to the backbone network and adjusted parameterstocreatefourdifferentvariantsofthemodel:YOLOv5s,YOLOv5m, YOLOv5l, and YOLOv5x. These variants differin terms of model size, complexity, and accuracy, allowing fora trade-off between speed and accuracy based on the specificapplication requirements.The regression-based approach usedin YOLOv5 allows for efficient and real-time object detection, making it well-suited for various applications such asmotorbike helmet recognition in surveillance footage, as youmentionedinyourpreviousstatement.

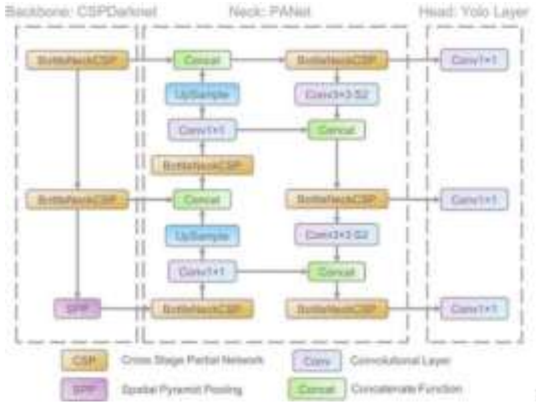

Fig.1.Yolov5 Architecture

TheYOLOv5modelconsistsofthreemaincomponents:the backbone, the feature enhancement module, and the head asshowninFigure1.Eachcomponenthasaspecificfunctionin the overall architecture. The backbone variant of YOLOv5isresponsibleforextractingfeaturesfromtheinputimage.The feature enhancement module in YOLOv5 is designed toenhancethefeaturesextractedbythebackbone.Itusesvarioustechniquessuchasskipconnections,PANet(PathAggregationNetwork),andCSPNet(CrossStagePartialNetwork)toenhancethefeaturerepresentationandimprovetheaccuracyof object detection. The head part of YOLOv5 is responsiblefor generating the final predictions, including the boundingboxcoordinatesandclassprobabilities.

VII. Results

The objective of this paper is to achieve continuous helmet detection and Number Plate Capture through a video feed as

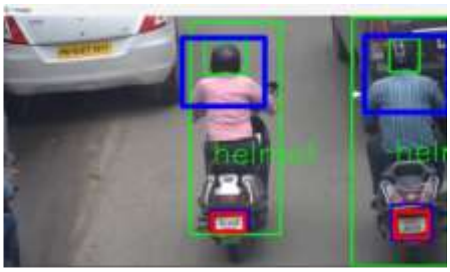

Fig. 2.The above image shows the helmet and the number plate are detectedandalsoshowtheriderhasputontheHelmet

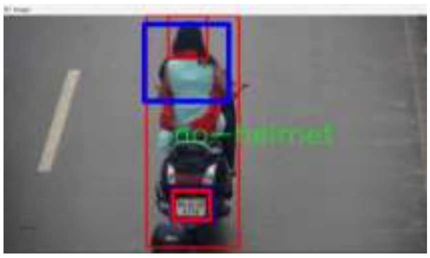

Fig. 3.The above image shows the helmet and the number plate are detected and also shows the person is not wearing the Helmet

DOI: rp-9788770040723.162

showninFigure2and3.Avideocamerawillbepositionedonthero adtoprovideinputtothesystem.Theframesfromthe video will undergo background subtraction to eliminatepedestrians and other entities, retaining only moving objects.These moving objects will then be classified and labeled usinga trained model, with the COCO model used for commodityobjects and a specialized dataset developed using Tensorflowforpersonsridingbikeswithhelmets.Webscraping wasutilizedtocollectdiverseimagesofhelmetsfortraining.Initially,apersonridingabikewillbedetectedandaboundingbox will be defined around them, restricting the search area.Thesystemwillthencheckforthepresenceofahelmetwithin thatbox,andifdetected,theboxwillbedropped.The remaining boxes will be processed by the number platecheckingsubsystem,whichwillutilizeOCRtocapturethetexton the license plate. A new entry will be created, documentingthetimeandlocationoftheoffense,asnapshotofthe bounding box as proof, and the license plate number.

VIII. Conclusion

When the rider fails to wear a helmet it becomes risk because by chance if the rider face anyaccidentitmayleadtodeath.a headgear. Many motorbike riders continue to disregard thenumerous laws regulating helmet use by two-wheeler drivers.The systems in place are highly inefficient.In this study, wehave suggested a real-time, quick, and efficient framework forYOLO-based non-helmeted motorcycle detection from CCTVfootage. After identifying the motorcyclists who are ridingwithout a helmet, optical character recognition to detect thecharactersinthelicenceplatesandsavetheminacloudsothat theviolatorscanbe heldaccountable.Motorcycles arethetargetclassforthefirststage,thesecondstageforhelmets,non-helmetsandthethirdstageisforlicenceplates.

VIII. FutureEnhancements

The proposed method outperforms the current one becausethe algorithm uses a YOLOv5 model. While many have donetwolayersofCNNtocompletethetasks,oursuggestedapproach just requires one CNN to achieve the study's goal.Thesuggestedmethodworksbetterthananumberoftheestablished techniques for detecting license plates. techniquesinclude boundary- and color-based strategies. The input Picture should have apparent bounds and is sensitive to undesiredbordersintheboundary-basedtechniques.

The proposed method and approaches addressed in relatedworkdifferfromeachotherinthatwetookadifferentstrategy.Forautomaticlicenceplatelocalization,wedevelopeda single convolutional neural network and employed YOLOv5algorithms to complete the task. The authors of and employedboundary-based techniques that are conscious of undesirableedges and depend on high-quality images for algorithm generalization. Since the suggested method does not need to relyon the information from the license plates and many imagequalities were added to the training, it is superior to the color-basedapproach.Thisaidsingeneralizingfrompreviouslyunobserveddata.

***Abstract*—AI is the emerging technology and is being extensively used now a days in every field and in every organization to gain more insights and hidden patterns in data. Data is the new oil for every organization to run and make huge revenues if one is able to find out the story in the past data and then can recommend based on it in the future. AI not only works effectively in data science related fields but is now taking grip for every work fields as well. AI devices become more interesting when they start to act more like human rather than robotic as the customer interactions increase and so does the revenue of the organization. So, emotion recognition of the users is a very important partin AI development where the device is trained to recognize the correct emotion of the customer behind his / her speech and conversation with the device. We know that random forest uses a bunch of decision trees and tries to correct the errors foundinthepreviousstepstorectifythemandthen increase the accuracy. In this article, we use CNN basedmodelwhichisaverypopulardeeplearning neural network-based algorithm to classify every emotion of an individual and then used audios to test the model. In this project, CNN model is used and 79.6% accuracy is achieved.**

***Keywords:* Speech emotion, deep learning, CNN, Artificial Intelligence, Decision trees, Random Forest.**

I. INTRODUCTION

Speechandwordsarethemostnecessarytool we use to interact with each other. Now a daysAIhasbecomeanintegralpartofourlife speciallytheAIbasedtechnologies. Welove to interact with them the whole day and give themrequestsortalksomerandomthings.As a result, we as a customer expect some interestingrepliesfromthemandthattoolike a human being with emotions. In this fast- changing world and generation we are left with a few friends and we have no time to meet or interact with them. So, in this new world,AIisournewfriend,philosopher,and guide too in many cases. Hence our inputs andcommandsareconsideredasdataforthe above-mentioned problem statement and with the help of CNN we make the audio tuning more perfect and the AI more lifelike. The model is trained in such a way to recognise emotions behind every input of the customers.

1.1. *Scope*

Data is the future of any organisation and thus AI is the emerging technology which uses data as the input and in returngivesamazingexperiencetoitscustomers. Themajor risk faced in the usage of AI is constant fall of customers interestinusingit.Thisissuecanbesolvedeasilybymaking the output responses of AI more interesting and natural sounding.For thisthingtohappen,weneed torecognise the emotionbehindthecustomersandthenteachtheAItodothe same thing. Once it will be able to recognise the emotion behindthespeech,itwillresponseinamorelucidandhuman like. The neural networks in architecture like CNN works similar to our brain neural structures with the nodes to transfer data from one layer to another. Similarly in neural network,dataispassedfrominputtooutputlayersthrougha series of hidden layers in between. Hence, this method is proposed in this project so that the AI can be transformed successfullyintoacompletehumanlikestructure.Ourmodel will not onlyrecognisetheemotions behind everyspeech of our customers but can also cheer the customers when they willbesadordepressed.Oncethismodelisbuiltsuccessfully with great precision and accuracy and minimum errors, we can collect data of our customers to classify them into depressed and non-depressed individuals based on the durationoftheirpastdataofbeinginnegativeemotionssuch as sadness, anger, fearful, disgust, etc. This entire process will not be possible without the technologies and machine learning algorithms cause data is involved. Data will in fact act as the raw material for this project, without which progress of anykind in this work is just futile. In futurethis model can be applied on any AI devices or AI applications and collecting customers data from the devices will be very important and can be used to recommend various things for their future needs.

1.2 *Methods*

1.2.1 DeepLearning

Thisbranchofmachinelearningisveryuseful asitinvolves the use of neural networks along with the multiple layers and can process complex data sets. It even is capable for developing artificial intelligence systems that can learn on their own, keep on improving themselves on their own without explicitlybeing programmed by us for a particular task. The algorithms can recognize patterns and making predictions based on large amountofdataandthisfeatureindeed isusedin therecognition of emotions behind the speech of our end users.

1.2.2 CNN

It is a type of neural network that is commonly used in image and video analysis tasks and as it has various convolutional layers so it can learn various spatial hierarchies of features and thisin turn canscan theinput datawith aset offilterstoextract relevant features. They typically consist of convolution layers, poolinglayers,andfullyconnectedlayers.Theyareresponsibl e for detectinglowlevel featuresandpoolinglayers downsample the feature maps toreduce the

DOI: rp-9788770040723.163

dimensionalityof the data. Fully connectedlayers combinethe extracted featurestomakea final prediction. As they are responsible for processing structured data, this algorithm is useful in extracting the correct emotion out of the audios we used in this project.

II. LITERATURESTUDY

Many studies on speech emotion recognition has been conductedandvariousnewalgorithmsandmethodshasbeen proposed by authors. This is a rapidly growing field of research which attracted significant attention from researchers in recent years. Let’s look at some of the important significant reviews:

S.Bhattacharyya and S. Poria [1] in 2017 provides a comprehensive review of various techniques and methods anditdiscusses the challenges associatedwiththetasksuch as the standardizeddatabase for emotions is lackingandthe need for robust feature extraction techniques.

VBalakrishnanandS.Sivakumar[2]in2019proposesane w method for emotion recognition using speech features such as pitch, energy, and formats. The proposed method was tested on the Berlin Emotional Speech Database and achieves an accuracy of 88.3%.

P.Rao and P.S.S. Avadhani [3] in 2020 proposed recent advances in deep learning based approaches for SER and discussed the use of RNN for feature extraction and classification. The paper also covers the use of transfer learning.

A. Gunavati and R. Bhavani [4] in 2021 presented a comprehensive survey of deep learning techniques and covers recent developments in multimodel emotion recognitionwhichinvolvescombiningspeechwithother modalitiessuchasfacialexpressionsandphysiological signals.

R. Mitra [5] in 2019 presented a paper which contains a comprehensive survey of various techniques and methods used for SER., including traditional machine learning approaches, deep learning techniques and hybrid models.

T.A.Rahman[6]in2020fine-tunedthepretrainedmodelon theRyersonAudioVisualdatabaseofemotionalspeechand song dataset using transfer learningtechnique andachieved 70% accuracy.

M.A.H.Akanda[7]in2020investigatedtheeffectofspeec h enhancement techniques on SER using deep neural networks.Theauthorcomparedtheperformanceofdifferent enhancement methods such as spectral subtraction, and MMSE-based noisereduction, on the Emo-DB dataset. The results show that speech enhancement can significantly improve the accuracy of emotion recognition.

W. Wang [8] in 2021 proposed a multi task learning approach for SER that integrates both acoustic and lexical features. Theauthorsuseadeepneural networkwithshared and task-specific layers to jointly learn the feature representations for emotion recognition and sentiment analysis.

G.F. Adewumi [9] in 2021 presented a review of various features, classification techniques, and datasets used for SER. It discusses the challenges associated with SER such as the variability of emotions across speakers and cultures.

M.R. Islam [10] in 2020 compared the performance of various deep learning-based approaches for SER, including LSTM networks and hybrid models. The authors evaluated themodelsontheIEMOCAPdatasetandshowedthathybrid model perform the best.

III. PROPOSEDMETHODOLOGY

3.1 SystemProposed

Deepneuralnetworks(DNNs)areatypeofmachinelearni ng model that has gained significant attention in recent years due to their ability to learn complex patterns and representations from large datasets. DNNs have shown promising results in various applications, including computer vision and speech emotion recognition.

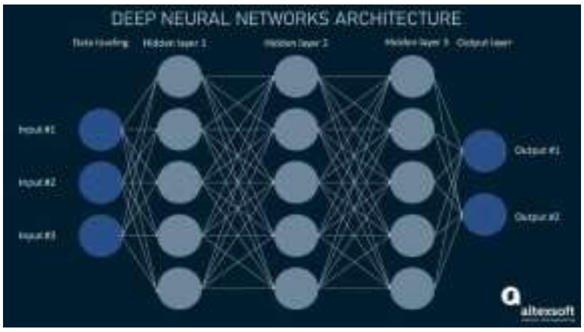

Fig1.DeepNeuralNetwork

In otherwords, DNNcanberepresentedasa functionf(x;a) wherexis the input, a represents the model parameters, and f(x;a) represents the output of the network for a given input x.

3.2 Dataset-Taken

Thedatasetcontains1440files,7356recordings,24profes sionalactors who acted out different emotional states including, calm, happy, sad, angry, fearful, surprise and disgust.

3.3 DatasetPreprocessing

Dataset pre-processing is a crucial step in machine learning anddataanalysisthatinvolvespreparingrawdatatobeused as input to a model. The goal of pre-processing is to transform the raw data into a format that can be easily analysed and interpreted by a machine learning algorithm. Data pre-processing steps include data cleaning, data normalization, data transformation, data encoding, data splitting and feature selection.

3.3.1 AugmentationOfData

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.163

It is a technique used to artificially increase the size of a datasetbycreatingnew,butsimilar,versionsofexistingdata. Thegoalofdataaugmentationistoimprovetheperformance of machine learning models by providing more diverse examples for the model to learn from. This is particularly usedwhenworkingwithsmalldatasetswhereoverfittingcan be a concern. There are various methods of data augmentationandthespecifictechniquesuseddependonthe type of data being augmented. The purpose of data augmentation is to create new examples that are like the original data but not identical. The augmented data should represent the natural variations in the data that the model is likely to encounter in real-world scenarios. Data augmentation is an important tool in machine learning and can significantly improve the performance of models, especially when working with small datasets. The idea behind data augmentation is that by creating additional training samples that are similar but not identical to the original data, a model can better generalize to new, unseen data. This can help to reduce overfitting and improve the overallperformanceofthemodel.Dataaugmentationis commonly used in computer vision and natural language processing tasks, but it can also be applied to other types of data such as audio or sensor data. The specific techniques used for data augmentation depend on the type of data and the specific task at hand, and it is often necessary to experiment with different augmentation methods to find the best approach for a particular problem statement. Data augmentation is typically done by applying a set of transformation rules to the existing data samples, such as rotating, flipping, or zooming in on images or changing the pitchorspeedofaudiosamples.Sothisdataaugmentationis an irreplaceable step in this project.

3.4 Deep-Learning

Deep learning for speech emotion recognition refers to the use of deep neural networks to classify and analyze emotional states in speech signals. The goal of SER is to automatically detect the emotional content of speech, such as happiness, sadness, anger, or fear. It typically involves multiple layers of artificial neurons that aretrainedonlargeamountsoflabelleddatatoidentifypatterns and relationships between different features of speech signals, such as pitch, duration, and spectral characteristics. These models can be trained using various architectures such as Convolutional Neural Networks, RNN, or hybrid model that combines both RNN and CNN. The training process for deep learning models involves feedingthenetworkwithlargeamounts oflabelledspeechdataand adjustingtheweightsofthenetworksparametersthrough aprocess called backpropagation in order to minimize the error between the predictedemotionallabelsandthetrue labels.Theresultingtrained model can be used to classifythe emotional content of newspeech signals. Deep learning models for SER have shown promising results in recent years and have been used in a variety of applications. However there are still many challenges to be addressed in this field such as dealing with variability in speech signals, addressing class imbalance in emotional labels, and improving the interpretability of the models.

3.5 ConvolutionalNeuralNetwork(CNN)

TheCNNfor thespeech emotionrecognitiontypicallyinvolves severallayersthataredesignedtoextractrelevantfeaturesfrom speech signals and then classify the emotional content.

1. Inputlayer:thislayerreceivestherawspeech signalas an input. This layer can be preprocessed with techniquessuchasMel-frequencycepstralcoefficients or filter bank energies to extract relevant features.
2. Convolutionallayer:thislayerappliesasetoffiltersto the input signal which extracts local features such as pitch and spectral information.
3. ReLU activation layer: this layer applies a non-linear transformationtotheoutputoftheconvolutionallayer, introducing non-linearity into the model.
4. Pooling layer: this layer performs a downsampling operation on the output of the ReLU layer, reducing spatialdimensionsofthefeaturemapandincreasingthe model’s robustness to small variations in the input signal.
5. Dropout layer: it randomly drops out a fraction of the activations in the previous layer during training, preventingoverfittingandimprovingthegeneralization of the model.
6. Fully connected layer: This layer takes the flattened output of the previous layer and applies a linear transformation to it, producing a set of scores that represent the probability of each emotion class.
7. Softmaxactivationlayer:appliesasoftmaxfunctionto the output of the fully connected layer, producing a probability distribution over the possible emotion classes.
8. Outputlayer:theoutputlayeroftheCNNproducesthe final predicted emotion class based on the probability distribution from the softmax layer.

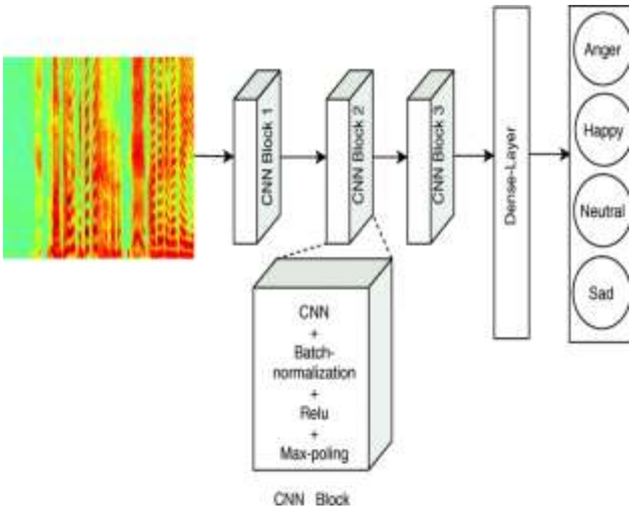

Fig.2.Architecture

DOI: rp-9788770040723.163

IV. Modules

4.1 CreationOfModels

Creatingmodelsforspeechemotionrecognition using CNN typically involves the following steps:

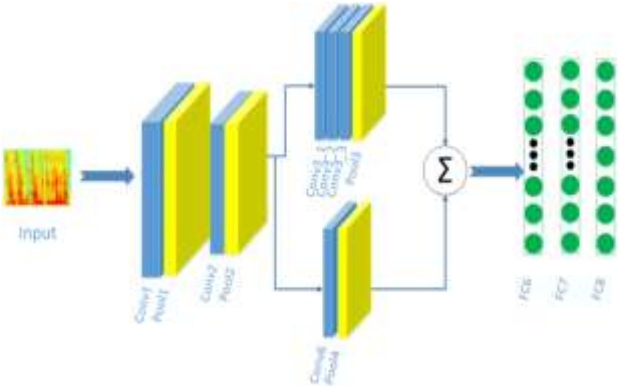

Fig3.Model Diagram

Ourapproachconsistsoffivesteps:

Step1–Datapreprocessing:

This involves converting the raw speech signal into a format that can be used by the network, such as Mel-frequency cepstralcoefficients(MFCC) or filter bank energies.

Step2-Dataaugmentation:

ThisisdonetoimprovetheperformanceoftheCNNand is often helpful to augment the training data by creating additional synthetic samples.

Step3-Modelarchitecturedesign:

The next step is to design the architecture of the CNN. This is typically done to involve selecting the number and size of convolutional and pooling layers, choosing activation functions,anddecidingonthenumberoffullyconnectedlayers.

Step4-Trainingthemodel:

Oncethemodelarchitectureis defined,thenextstepisto train the model on the training data. During training, the weights of the network are adjusted to minimize the error between the predicted emotional labels and the true labels.

Step5-Modelevaluation:

After training, the performance of the model is evaluated using a separate test set. This allows the accuracy, precision,recall,and F1scoreofthemodeltobecalculatedand compared with other models.

Step6-Fine-tuning:

If the performance of the model is not satisfactory, it may be necessary to fine-tune the model by adjusting the architectureorhyperparameters.Thiscanbedonebyevaluating theperformanceofthemodelonthevalidationsetandadjusting accordingly.

Step7- Deployment:

Once the model has been trained and evaluated, it can be deployed in a production environment to perform real-time SER tasks.

To evaluate the optimal efficiency and robustness of the algorithm, metrics such as Precision and Recall rates are evaluated and computed based on the recognition rate.That the proposed system produces the highest recall rate for all types of parameters like speech andthen findingthe correct emotionbehindthespeech.. Theaverage ofallmeasuresfor the proposed system.

Overall creating models for SER using CNN s involves several steps from data preprocessing to modelarchitecture design, training, evaluation, and deployment. Each step requires careful consideration and experimentation to achieve optimal performance.

4.2 SpeechEmotionRecognition

Thedeployedmodeltakesinnewspeechsignalsandpredictsthe emotional content of the speech in real-time. Overall, SER involvescollectingandpreprocessingdata,augmentingthe data,training and evaluating a deep learning model, fine-tuning the model, and deploying the model for real-time SER tasks.

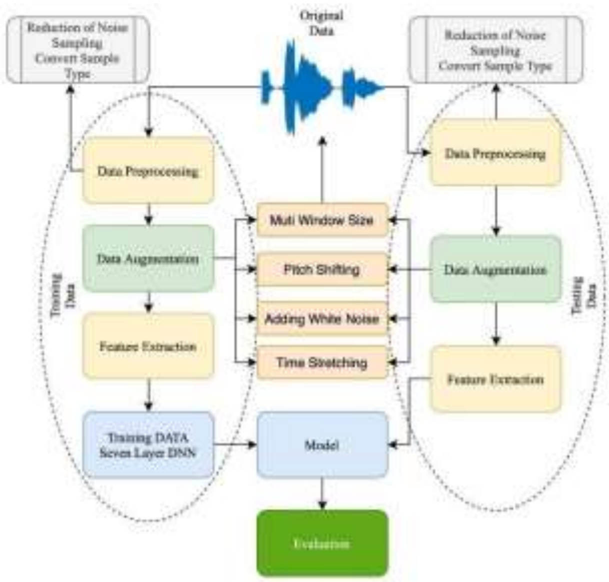

Fig:4Activity Diagram

4.2.1 Performance o f a Speech Emotion Recognition:

Theperformancecanbeevaluatedusingvariousmetricssuch as accuracy, precision, recall, and F1 score. Accuracy measures the percentage of correctly predicted emotional labelsoutofallthelabelspredictedbythemodel.Precision measures the percentage of correctly predicted positive emotionallabelsoutofallthepositivelabelspredictedbythe model.Recallmeasuresthepercentageofcorrectlypredicted positive emotional labels out of all the positive emotional labels in the dataset. F1 Score is the harmonic mean of precisionandrecall.TheperformanceoftheCNNmodelcan befurtherimprovedbyfinetuningthemodelarchitectureand hyperparameters augmenting the training data, and using transferlearningtechniquestoleveragepre-trainedmodelsin larger datasets.

DOI: rp-9788770040723.163

TABLE1:PERFORMANCEOFSERSYSTEMUSINGCNN

		Predicted Class			
		Anger	Sad	Neutral	Happy
Actual Class	Anger	43.3	12.6	33.7	10.4

	Happy	25.9	0	27	47.1

Architecture

Additionally, the performance of the system can be evaluated on different test sets and compared to other state-of-the-art models to determine its effectiveness in recognizing emotions from speech signals.

Considering a happy track from the dataset with plt.figure explaining the figsize to be (15,5).The model was able to recognisethecorrectemotionbehindtheaudioandwaseven able to figure out the gender of the speech.

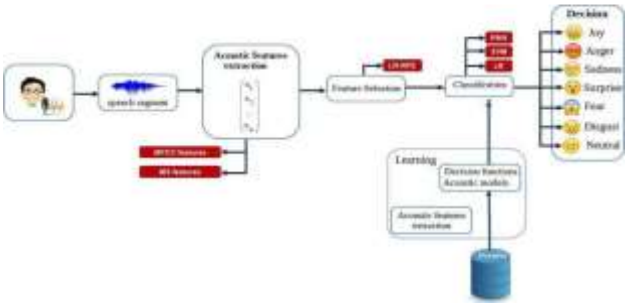

Fig5:Sequence Flowchart

GENDER DETECTION: it involves using a machine learning model to predict the gender of the speaker based on the emotional content of their speech. This is achieved by combining deep learning models like CNNandRNN.TheCNNisusedtoextracthigh-levelfeaturesfromthe speech signal, while the RNN is used to model the temporal dynamics of the speech signal. Once the deep learningmodel has been trained on adatasetoflabelledspeechsamples,itcanbeusedtopredictthegender ofnewspeechsamples.Themodelwasthenfedapre-processedspeech signal, extracted the relevant features using the CNN, and then these featureswerepassedthroughRNNtomodelthetemporaldynamics.The output of the RNN is then fed into a fullyconnected layer that predicts the gender of the speaker.

4.2.2 DecisionMaking

Basedontheinputdataintothemodelitwasdecidedwhetherthe person was a male or female and the emotion behind the speech of that individual. This step involves making a prediction for the emotional state of the speaker based on the features extracted from the speech signalbytheCNN.Aftertheinputspeechsignalhasbeenpreprocessed and transformed into a format that can be used by the CNN, the CNN extracts high-level features from the speech signal using a series of convolutionallayers.ThefeatureslearnedbytheCNNarethenfedinto afullyconnectedlayerthatmakesthefinalpredictionfortheemotional state of the speaker. During the decision-making step, the CNN takes the preprocessed speech signal as input, extract the relevant features using the convolutional layers, and passes these features through the fullyconnectedlayertomakeapredictionfortheemotionalstateofthe speaker. The predicted emotional label can then be used for further analysis ortocontrol other systemsbasedonthe emotional state ofthe speaker.

Overall, the decision-makingstep-in SERusingCNNinvolves usinga fullyconnectedlayertomakeapredictionfortheemotionalstateofthe speaker based on the features extracted from the speech signal by the CNN.

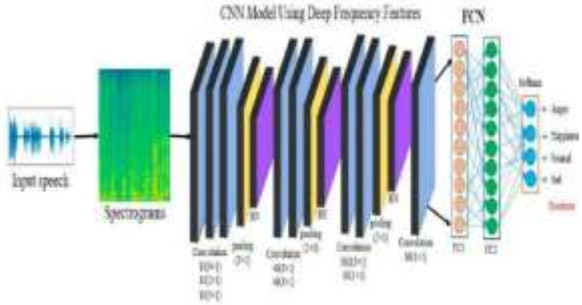

Fig 6:Decision Making Steps In The Speech Emotion Recognition

The speech component of the dataset includes 1440 recordings of 60 sentences spokenin 8 different emotional expressions whilethe song component includes 1012 recordings of 52 songs sung in 7 different emotional expressions. Each recording is labelled with metadata indicating the actor, gender, expression, and type of recording. The dataset is designed to be used for research and developmentinareassuchasemotionrecognition,speech processingandaudioanalysis.Wecarriedoutalltheseprocessesin the project.

4.2.3 FineTuningThe Model

The first step was to load the pre-trained CNN model and remove the last layer, which is typically the output layer that is specific to the original task the CNN was trained on, such as image classification. The remaining layers are frozen, meaning their weights are not updated during training.

Thenextstepwastoaddanewoutputlayer,whichisspecifictothe sentiment analysis task, with the appropriate number of output nodes for thenumber of sentiment classes. The weights ofthenew output layer are randomly initialized.

Finally, the entire network is fine-tuned by continuing the training process with a smaller learning rate. This allows the network to adapt tothedomain-specificsentiment dataset and furtherimprove its accuracy.

Fine-tuning a pre-trained CNN can greatly reduce the time and computationalresourcesrequiredtotrainanewmodelfromscratch while still achieving high accuracy in the domain-specific task of the speech emotion recognition.

ADVANTAGES

The various advantages of the implemented method or system are:

1. Improving Human- compute interaction.
2. Improving mental health.
3. Improving customer service.
4. Enhancing security.
5. Advancing scientific research.

CONCLUSION

Weproposedanewmethodtoimprovementalhealthofan y person by detecting changes in emotional state over time, which could be helpful in identifying individuals who may be at risk for mental health issues such as depression or anxiety. Wewill becollectingall thepast data of customers overagoodperiodoftime,analysethedataandwillbeable to figure out who are at risk of calling themselves as depressed or non-depressed person. This is a rapidly developingfield with a wide range of potential applications in various industries and fields. As technology continues to advance and more data becomes available, we can expect that SER models will continue to improve, providing more accurate and reliable detection of emotions in speech.

FUTUREWORK

Thereareseveraldirectionsthatfutureresearchin speech emotion recognition could take:

1. Incorporating contextual information.
2. Improving model robustness.
3. Handling multilingual speech.
4. Recognizing more complex emotions.
5. Integrating with other technologies.

III. Proposed Methodology

A. *Exploratory Analysis*

Exploratory analysis is a scientific methodology which perceivesthegeneralexamplesintheinformation.Theexamplesincorporate anomalies and elements of the information thatmaybestartling.

The first move toward quite a while investigation is EDA.Comprehensionofwhereanomalieshappenandhowthefactors are connected will assist one in the plan of factualexaminations that will with delivering ideal results. If thereshouldariseanoccurrenceofnaturalcheckinginformation, lo-cales are likely impacted by different stressors. Subsequently,beforeoneendeavourstorelatestressorfactorstonaturalreaction factors doing investigation of stressor relationship asthe underlying step is vital. EDA can give bits of knowledgeinto up-and-comer causes that ought to have been rememberedforacausalevaluation.

B. *Scatterplots*

Data on connections between sets of factors can be acquiredfrom Scatterplots and Relationship coefficient. Notwithstanding, while dissecting various factors, essential techniques formultivariate representation can give more prominent bits

DOI: rp-9788770040723.164

ofknowledge.Planninginformationadditionallyisbasicforfiguringoutconnectionsamongtests

C. Histogram basically

A histogram basically sums up the circulation of the informationbysettingperceptionsintospans(alsocalledclasses or receptacles) and by including the quantity of perceptions inevery stretch. The y-hub can address the quantity of perceptions,percentofaggregate,partofaggregate(orlikelihood),or thickness (in which the level of the bar duplicated by thewidth of the span compares to the overall recurrence of thestretch). In view of how the stretches are characterized willdecidethepresenceofthehistogram.

D. Boxplot

A smaller rundown of the conveyance of a variable is givenby Box plot. A standard boxplot comprises of (1) 25th and75th percentiles, (2) an even line on the crate at the middle,and(3)verticallines(stubbles)drawnfromeachend(quartile)to the outrageous worth. In the event of gentle variety of thestandard boxplot, hairs are the ones that stretch out to a rangedistance from the pivot, and the exceptions past the range aredistinguished. The estimation of range (S) is: S = 1.5 x (75thpercentile-25thpercentile)

E. CombinedAppropriationCapabilities(CDF)

The combined circulation capability CDF is a capabilityF(X) which is the likelihood that the perceptions of a variablearenotmoreprominentthanapredefinedesteem.TheoppositeCDF which is likewise often utilized, is the likelihood that theperceptionsaremoreprominentthanapredeterminedworth.In developing the CDF, loads (e.g., consideration probabilitiesfrom a likelihood configuration) are utilized. By utilizing thisthe likelihood that the worth of the variable in the factualpopulaceisunderapredefinedworthcanbeassessed.Intheeventthatforequivalentweightingofperceptions,theCDFappliesjusttothenoticedqualities.Aquantile(Q)plotalso called likelihood plot, which is a graphical method forportrayalforcontrastingavariablewithaspecific,hypotheticaldissemination or to contrast it with the dispersion of anothervariable.OnenormalutilizationoftheQplotistocheckwhetheravariableissimilarlyconveyed.

F. Scatterplots

Scatterplots are graphical portrayal of coordinated information plotted with one variable on the even pivot and the othervariable plotted on the upward hub. Information are typicallyplotted in the diagram with the even hub comprising of pro-portions of a powerful boundary (free factor) and the upwardpivotcomprisingofproportionsofatraitthatmightanswerthe compelling boundary (subordinate variable). Scatterplotsare one of the valuable initial phase in any examination sincethey help in the representation of connections and recognizepotential issues (e.g., exceptions) which can impact resultingfactualinvestigations.

G. Co-relationship Examination

Estimatingthecovarianceoftwoerraticfactorsinamatchedinformational index is known as Relationship examination.TherelationshipcoefficientoftwofactorsXandYarethe ones used to communicate covariance. The relationshipcoefficientisaunitlessnumberwhichgoesfrom-1to+1.The normalized level of co-relationship among X and Y is thesizeoftheconnectioncoefficient.Thesignistheheadingoftheaffiliation,whichcanbeeithersureornegative.

H. linearregression

The Straight Relapse is an AI calculation in light of directedlearning.Itplaysoutarelapsetask.Relapsemodelsanobjectiveexpectationesteeminlightoffreefactors.Itisgenerally utilized for figuring out the connection among QTYand Quality feedback full cost with the given data we are abletoidentifytheinterceptandslopeofthegivendata.

I. OLSRegressionResults

Common Least Squares (OLS) is the most popular of therelapse methods. It is likewise a beginning stage for all spatialrelapseinvestigations.Itgivesaworldwidemodelofthevariable or interaction you are attempting to comprehend orforesee; it makes a solitary relapse condition to address thatcycle.Therearevariousassetstoassistyouwithstudyingboth OLS relapse and Geologically Weighted Relapse. Beginwith Relapse investigation rudiments. Then, work through theRelapse Investigation instructional exercise. This point willcover the consequences of your examination to assist you withgraspingtheresultanddiagnosticsofOLS.

IV. Results And Discussion

A. Training performance

The data obtained as a result of this project contains information about the raw materials quantity and quality at theirmanufacturingsiteandthedataoftheirquantityandquality attheirsiteofdeliverywhichistheelevatormanufacturingcompany.ByusinganExcelsheetweareabletoidentifythetotalvalue count,materialmissing,andthegrandtotal.

***Abstract*—This study focuses on detecting racist content in Tweets using sentiment analysis to address the problem of hate speech on social media. A Gated Convolutional Recurrent-Neural Networks (GCR-NN) model was developed by combining gated recurrent unit (GRU), convolutional neural networks (CNN), and recurrent neural networks (RNN) to accurately detect racist comments in tweets. The GCR-NN model achieved an accuracy of 0.98, outperforming other models in identifying subtle and concealed instances of racism. The study suggests that the GCR-NN model has the potential to be a valuable tool for social media platforms in the fight against hate speech and promotion of a more inclusive online environment.**

Keywords—Gated Convolutional Recurrent-Neural Networks (GCR-NN) model, Recurrent Neural Networks(RNN), Hate Speech Detection, Convolutional neural networks(CNN)

I. INTRODUCTION

Social media has evolved into a powerful force in the socio-political landscape, influencing our behavior and shaping our perspectives in numerous ways. However, with the widespread use of social media platforms and the freedom of expression that they offer, a multitude of negative aspects have emerged in recent years, including the proliferation of hate speech and racism. Social media has revolutionized the way we interact with the world around us, shaping our thoughts and actions in numerous ways. However, with the widespread use of social media platforms and the freedom of speech they afford, several negative phenomena have emerged in recent years, including hate speech and racism.

Twitter, in particular, has become a new setting in which racism and related stress seem to thrive. Currently, 22% of adults in the United States use Twitter, and the platform boasts a staggering 1.3 billion accounts and 336 million active users worldwide, generating around 500 million tweets per day. Unless users opt to make their tweets private, they are publicly available and can be reacted to, shared, tagged, liked, or responded to by other Twitter users.

The growing popularity of social media platforms has led to their wide use for several old and new forms of racist practices. Hate is expressed on such platforms in different surreptitious forms such as memes and openly such as posting Tweets containing racist remarks using fake identities. Although often associated with ethnicity, hate is now thriving based on color, origin, language, cultures, and most importantly religion. Social media opinions and remarks provocating racial differences have been regarded as a serious threat to social, political, and cultural stability and have threatened the peace of different countries. Social media being the leading source of hate opinions dissemination should be monitored and hate speech remarks should be detected and blocked timely.

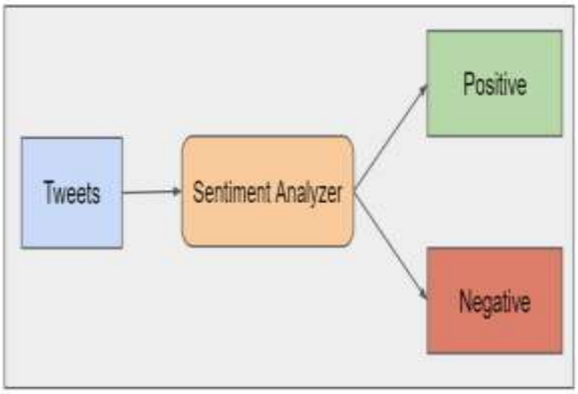

Fig.1: Example figure

Hate speech remarks and tweets on social media have been linked to a variety of mental and physical illnesses, resulting in negative health consequences [7–12]. Hate speech on social media may be classified into three types: institutionalized, individually mediated, and internalized [13]. Hate speech may be experienced personally via hate speech discrimination or unequal racial treatment, as well as knowledge of prejudice against relatives and friends. In today's society, the issue of hate conduct has become increasingly prevalent and has had a detrimental impact on individuals, causing a wide range of psychosocial stress and increasing the risk of chronic illnesses [14-16]. This is a concerning issue that has become amplified by the proliferation of social media platforms, where hate spreading organisations and individuals have been able to promote their agenda with increased skill and complexity through numerous channels and techniques. In response to this problem, various techniques have been developed and special attention has been given to the area of sentiment analysis in order to evaluate text from social media platforms for a wide range of tasks such as hate speech identification, sentiment-based market prediction, and racism detection, among others. With the help of these techniques, researchers can identify and monitor hateful content in social media platforms and take necessary actions to prevent its negative impact on society.

II. Literature Review

A. *Exploring the Role of Social Media in Addressing and Combating Hate Speech: A Comprehensive Analysis*

Authors: K. R. Kaiser, D. M. Kaiser, R. M. Kaiser, and A. M. Rackham

Abstract: Social media, including sites such as Facebook, Twitter and Instagram, provides a platform for racist ideology, making this dysfunction of American society more evident. Social media can provide insight into the world of the racist-individuals who cling to their tribal identities, irrationally rejecting those who they perceive as different. Studying social media may provide insight into processes that can assist in healing American society of its segregationist views-a way toward healing the racist. The purpose of this paper is to analyse social media posts to better understand hate speech ,its causality and to develop initial steps for addressing racist ideology. To understand the behavior and mindset of American Facebook users, a comprehensive qualitative review was conducted. The study aimed to analyze the cognitive patterns, problem-solving skills, personality structures, belief systems, and coping styles exhibited by the users in their posts. The sample size for this study consisted of 600 American Facebook posts, chosen from a variety of users, age groups, and demographics. The content analysis consists of both a descriptive account of the data and an interpretive analysis. Rackham, A. M. (2018). Using social media to understand and guide the treatment of racist ideology.

B. *Methodological and Ethical Considerations for Conducting Health Research Through Social Media: Insights and Recommendations:*

As social media platforms grow in popularity and variety, so does their value for health research. Using social media to recruit participants for clinical research and/or offer health behaviour interventions may allow you to reach a larger audience. However, evidence supporting the effectiveness of these techniques is scarce, and fundamental concerns like optimum benchmarks, intervention development and methodology, participant participation, informed permission, privacy, and data management remain unanswered. Researchers interested in utilising social media for health research have little methodological advice. We outline the content of the 2017 Society for Behavioral Medicine Pre-Conference Course titled 'Using Social Media for Study,' during which the authors shared their experiences with methodological and ethical challenges related to social media-enabled research recruitment and intervention delivery. We highlight frequent problems and provide advice for social media recruiting and intervention. We also explore the ethical and appropriate use of social media in research for each of these reasons.

C. *“Cyberracism Unveiled: A Comprehensive Review of 10 Years of Research on Online Networks of Racial Hate"*

Authors: A.-M. Bliuc, N. Faulkner, A. Jakubowicz, and C. McGarty,

Abstract: The ways in which the Internet can facilitate the expression and spread of racist views and ideologies have been the subject of a growing body of research across disciplines. To date, however, there has been no systematic reviews of this research. To synthesize current knowledge on the topic and identify directions for future research, we systematically review a decade of research on cyber-racism as perpetrated by groups and individuals (i.e., according to the source of cyber-racism). Overall, the cyber-racism research reviewed shows that racist groups and individuals use different communication channels, are driven by different goals, adopt different strategies, and the effects of their communication are distinctive. Despite these differences, both groups and individuals share a high level of skill and sophistication when expressing cyber-racism. Most of the studies reviewed relied on qualitative analyses of online textual data. Our review suggests there is a need for researchers to employ a broader array of methods, devote more attention to targets' perspectives, and extend their focus by exploring issues such as the roles of Internet in mobilizing isolated racist individuals and in enabling ideological clustering of supporters of racist ideologies.

Online networks of racial hate, commonly known as "cyberracism," has been an increasing concern in recent years. In response, numerous research studies have been conducted to understand the extent, nature, and impact of these networks. This comprehensive review examines 10 years of research on online networks of racial hate, synthesizing findings from various studies and highlighting trends and patterns. The review covers topics such as the types of racist language used, the role of social media platforms in facilitating cyberracism, the psychological effects on victims, and the legal and ethical implications of cyberracism. The review also provides recommendations for addressing cyberracism, including educational and policy interventions, online monitoring, and legal actions. Overall, the review underscores the need for continued research and action to combat online networks of racial hate and their negative impact on individuals and society as a whole.

D. *Addressing Racial Health Disparities: Leveraging Existing Knowledge to Drive Action.*

Authors: D. Williams and L. Cooper

This document aims to provide a comprehensive review of the scientific data and highlight essential actions that need to be taken in order to eliminate racial health disparities. The review emphasizes the creation of communities of opportunity as a crucial first step in mitigating the negative effects of systematic racism. These communities should focus on providing resources for early childhood development, adopting policies to minimize childhood poverty, providing employment and income assistance options to adults, and promoting healthy housing and community circumstances. Secondly, the healthcare system must prioritize universal access to high-quality care, strengthen preventive healthcare approaches, address patients' social needs as part of healthcare delivery, and diversify the healthcare workforce to better reflect the patient population's demographic composition.

Additionally, further research is necessary to determine the most effective tactics for mobilizing political will and support to address health-related socioeconomic disparities. This will include initiatives to raise awareness of the prevalence of health inequities, build empathy and support for addressing inequities, strengthen individuals' and communities' capacity to actively participate in intervention efforts, and implement large-scale efforts to reduce racial prejudice, hate speech ideologies, and stereotypes in the larger culture that underpin policy preferences that initiate and sustain inequities. Overall, the review presents a comprehensive approach to tackling racial health disparities that includes multiple levels of intervention, from creating communities of opportunity to transforming the larger cultural narrative around racial equity.

III. Methodology

In recent years, the dominance of social media in the sociopolitical sphere has led to the emergence of various forms of hate speech on the platform. Hate speech can be found in different forms on social media, including hidden forms like memes and open forms where individuals make hateful statements under false identities to provoke hate, violence, and societal instability.

The problem of racism and hate speech is not limited to ethnicity but also extends to color, origin, language, culture, and most crucially, religion. Hate thoughts and statements on social media inciting racial tensions are considered a serious threat to social, political, and cultural stability, as well as the peace of several nations. As such, social media, which is the major source of hate speech propagation, should be monitored closely, and hateful statements should be recognized and banned as soon as possible. To combat this issue, there is a need for more research and development of effective strategies and policies that can curb the spread of hate speech on social media platforms. Additionally, it is important to raise awareness and promote digital literacy to help individuals recognize and respond to hate speech effectively. It is only by taking action and working together that we can hope to create a more peaceful and just society for all.

Disadvantages:

1. Existing techniques cannot be identified and halted automatically to prevent future spread.
2. Poor performance.

In order to detect and identify instances of hate speech on Twitter, this project aims to employ sentiment analysis techniques. To achieve this, a deep learning approach is adopted, specifically a stacked ensemble model that combines gated recurrent units (GRU), convolutional neural networks (CNN), and recurrent neural networks (RNN). This ensemble model is referred to as Gated Convolutional Recurrent-Neural Networks (GCR-NN). The GCR-NN model is designed such that the GRU component is responsible for extracting meaningful features from the raw text, while the CNN component focuses on identifying key aspects that are then used by the RNN component to make accurate predictions. The use of this advanced deep learning model is expected to improve the accuracy and efficiency of detecting and identifying hate speech on Twitter.

Advantages

1. The GCR-NN model has been proposed as a superior approach in the context of machine learning and deep learning models due to its exceptional performance and accuracy in identifying hate speech tweets through the integration of GRU, CNN, and RNN.

2. The suggested GCR-NN model can identify hate speech in 97% of tweets.

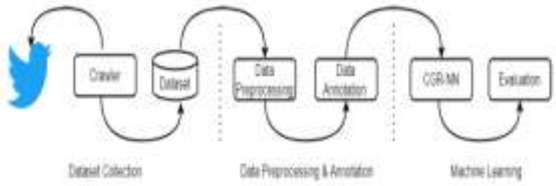

Fig.2: System architecture

Modules:

In order to execute the aforementioned project, we developed the following modules

- Data exploration: we will put data into the system using this module.
- Processing: we will read data for processing using this module.
- Using this module, data will be separated into train and test models.
- Model generation: GCN with BERT, LSTM, GRU, RNN, CNN, Ensemble Method LSTM + GCN with BERT, Logistic Regression, Random Forest, KNN, Decision Tree, Support Vector Machine, Voting Classifier.
- The user signup and login module enables users to create an account and log in to access the platform's features and functionality.
- Prediction: the final predicted value will be presented.

IV. Implementation

Algorithms

GCN: It stands for Graph Convolutional Network, which is a type of neural network that is designed to operate on graph data structures. In contrast to traditional neural networks that operate on vectors or matrices, GCNs can process data represented as graphs, which are a common way of modeling complex relationships between entities. GCNs are widely used in tasks such as node classification, link prediction, and graph clustering, and have shown promising results in various fields such as computer vision, natural language processing, and social network analysis.

BERT: BERT (Bidirectional Encoder Representations from Transformers) is a pre-trained natural language processing (NLP) model developed by Google that uses a deep neural network architecture based on the Transformer architecture. It was designed to pre-train deep bidirectional representations from unlabelled text by jointly conditioning on both left and right context in all layers. The pre-trained model can then be fine-tuned on specific NLP tasks such as text classification, question answering, and named entity recognition, among others. BERT has achieved state-of-the-art results on several benchmark NLP tasks and is widely used in various NLP applications.

LSTM: LSTM stands for Long Short-Term Memory, which is a type of recurrent neural network (RNN) architecture used in deep learning. LSTM networks are designed to handle the issue of vanishing gradients that arises in traditional RNNs, where the model has difficulty retaining information from previous time steps due to the repeated multiplication of gradient values. LSTM networks address this problem by introducing a "memory cell" that allows the network to selectively retain or forget information over time. This makes LSTM networks particularly effective for tasks that involve sequential or time-dependent data, such as natural language processing, speech recognition, and time series analysis.

GRU: GRU stands for Gated Recurrent Unit, which is a type of recurrent neural network (RNN) that is used for processing sequential data, such as text or time series data. It was introduced as a simpler and more efficient alternative to the standard RNN architecture. Like other RNNs, GRUs are able to remember information from previous inputs and use that information to make predictions about the current input. However, they are able to do so more efficiently by using a gating mechanism that allows them to selectively update and forget information. This makes them well-suited for tasks such as language modeling, machine translation, and speech recognition.

RNN: RNN stands for Recurrent Neural Network. It is a type of neural network that can process sequential data such as time series data or natural language text by using the concept of recurrence. In an RNN, each node or neuron maintains an internal memory or state, which is updated as it processes each element in the sequence. This allows the network to remember the context of previous elements in the sequence as it processes the current element, and use this context to make predictions or classifications. RNNs are widely used in tasks such as language modeling, speech recognition, and machine translation.

CNN:CNN stands for Convolutional Neural Network, which is a type of deep neural network that is commonly used for image classification, object detection, and natural language processing. The network architecture of CNNs includes convolutional layers that apply filters to input data, pooling layers that reduce the size of feature maps, and fully connected layers that classify the input based on the learned features. CNNs use a hierarchical approach to learning, where lower-level features are learned first and then combined to form higher-level features. This allows CNNs to automatically extract relevant features from input data, making them well-suited for tasks that involve processing large amounts of complex data.

Ensemble Method: Ensemble methods are machine learning techniques that involve combining multiple individual models to improve overall performance. The basic idea behind ensemble methods is that by combining the predictions of multiple models, the strengths of each individual model can be exploited while minimizing their weaknesses, resulting in a more accurate and robust final prediction. Ensemble methods can be used with a wide range of models, including decision trees, neural networks, and support vector machines, among others. Common ensemble methods include bagging, boosting, and stacking, each with its own specific approach to combining models.

Logistic Regression: Logistic regression is a statistical method used to analyze the relationship between a dependent variable (target) and one or more independent variables (predictors) when the dependent variable is binary or dichotomous. It is a type of regression analysis that is used to estimate the probability of a categorical dependent variable. Logistic regression works by using a logistic function to model the relationship between the dependent variable and the independent variables. The logistic function transforms a linear combination of the independent variables into a value between 0 and 1, representing the probability of the dependent variable being in a certain category. It is widely used in fields such as epidemiology, medical research, social sciences, and engineering.

Random Forest: Random forest is a machine learning algorithm that belongs to the family of ensemble learning methods. It is based on building multiple decision trees and combining their results to make a final prediction. Each tree in the forest is constructed using a random subset of the training data and a random subset of the features. The output of the random forest is determined by averaging the output of each individual tree or by taking a majority vote. Random forest is often used for classification and regression tasks, and is known for its ability to handle high-dimensional data and avoid overfitting.

KNN: KNN stands for K-Nearest Neighbors. It is a non-parametric machine learning algorithm used for classification and regression. In this algorithm, the data points are classified based on their proximity to the K nearest data points. The value of K is a hyperparameter that is predefined by the user. KNN algorithm is based on the assumption that data points that are close to each other are likely to belong to the same class or have similar characteristics.

Decision tree: A decision tree is a non-parametric supervised learning algorithm used for classification and regression analysis. It is a tree-structured model where internal nodes represent the attributes/features of the dataset, and the branches represent the corresponding value of these attributes. The leaves of the tree represent the decision outcomes, and each path from the root of the tree to a leaf represents a decision rule. The goal of the decision tree algorithm is to create a model that predicts the target variable by learning simple decision rules from the data features. The decision tree algorithm can handle both categorical and numerical data and is simple to understand and interpret, making it a popular choice for many machine learning tasks.

SVM: SVM (Support Vector Machine) is a supervised machine learning algorithm that can be used for classification or regression tasks. In SVM, a set of training data is used to train the model, and then it can be used to predict the classes or values for new data. The algorithm works by finding the optimal hyperplane that separates the data into different classes, with the goal of maximizing the margin between the classes. SVM can handle both linear and non-linear data by using kernel functions to map the data into a higher dimensional space. SVM is often used for tasks such as image classification, text classification, and bioinformatics analysis.

Voting classifier: A voting classifier is an ensemble method in machine learning where multiple models (e.g., logistic regression, decision tree, random forest, etc.) are used together to make predictions. Each model produces its own prediction based on the input data, and then the voting classifier combines the predictions of all models and selects the most frequent class as the final prediction. Voting classifiers can improve the accuracy and reliability of predictions by leveraging the strengths of multiple models and compensating for the weaknesses of individual models.

They are commonly used in classification tasks where a single model may not be sufficient to accurately classify the data.

VI. CONCLUSION

Hate speech has become increasingly prevalent on social media platforms like Twitter, making it critical to automatically detect and block such content to prevent its further spread. To achieve this, sentiment analysis is used to identify negative sentiments and hate tweets. The proposed solution leverages the ensemble technique, which stacks GRU, CNN, and RNN to build the GCR-NN model, resulting in high-performance sentiment analysis. A large dataset of 169,999 tweets collected from Twitter and annotated with TextBlob was used to evaluate various machine learning, deep learning, and GCR-NN models. The study found hate speech in 31.49% of the tweets analyzed. The results showed that deep learning models outperformed machine learning models, with the suggested GCR-NN model achieving an average accuracy score of 0.98 for positive, negative, and neutral sentiment classifications. Since the negative class is critical in detecting hate speech, a secondary analysis was performed to evaluate SVM and LR models, which correctly identified 96% and 95% of hate tweets, respectively, but misclassified 4% and 5% of hate tweets. In contrast, the suggested GCR-NN model accurately detected 97% of hate tweets with a minimal 3% error rate.The prevalence of hate speech on social media platforms, particularly Twitter, is a growing concern that has led to efforts to develop automatic detection and blocking mechanisms. This study presents a novel approach to detecting hate speech, using sentiment analysis to identify negative tweets that contain discriminatory language. To achieve high accuracy in this task, the study employs deep learning models and the ensemble technique to build a Gated Convolutional Recurrent-Neural Network (GCR-NN) that combines the strengths of gated recurrent units (GRU), convolutional neural networks (CNN), and recurrent neural networks (RNN).

***Abstract*—There are several uses for wireless sensor networks (WSNs) in a variety of industries, including environmental monitoring, healthcare, industrial automation, and military surveillance. With WSNs, coverage and connection are important factors that influence the network's overall performance. We provide a strategy for evolutionary algorithms in this study to improve connection and coverage in wireless sensor networks. We investigate how to put sensors in the network to maximise coverage and connection using evolutionary algorithms. The suggested method is contrasted with conventional deployment methods like grid-based deployment and random placement. In comparison to conventional methodologies, simulation results demonstrate that our suggested methodology delivers higher coverage and connection with fewer sensors.demonstrates how wireless sensor networks (WSNs) may be made to operate at their best in terms of connection and coverage by using evolutionary algorithms. In order to identify the best solutions, the research suggests using evolutionary algorithms to handle the issue of few resources in WSNs. The authors suggest a unique method for improving the performance of WSNs that combines two different evolutionary algorithm types, namely genetic algorithms (GAs) and particle swarm optimization (PSO). Although the PSO is used to improve network connectivity, the GA is used to deploy sensors in the best locations for maximum coverage.The suggested method is tested using simulation tests, and the findings demonstrate that it performs better in terms of network coverage and connectivity than other approaches currently in use. The authors also go over the method's shortcomings and provide lines of future investigation.The method for employing evolutionary algorithms to enhance the performance of WSNs. The suggested method has the potential to improve WSN connectivity and coverage, which can be helpful for a variety of uses including surveillance, healthcare, and environmental monitoring.**

I. INTRODUCTION

Small, low-cost, and low-power sensors that can measure a variety of environmental characteristics and wirelessly transmit the information to a base station or sink node make up Wireless Sensor Networks (WSNs). WSNs may be used in a broad variety of industries, including environmental monitoring, healthcare, industrial automation, and military surveillance. With WSNs, coverage and connection are important factors that influence the network's overall performance. The capacity of the network to monitor the whole area of interest is referred to as coverage, whilst the ability of the nodes to interact with one another and the sink node is referred to as connection. [1]

The coverage and connectivity of WSNs may be improved via a variety of deployment techniques. Although conventional methods, such as grid-based and random deployment, are easy to execute, they may result in an inefficient deployment of sensors, resulting in inadequate coverage and connection. Many optimization methods, including as genetic algorithms, swarm intelligence, and particle swarm optimization, have been suggested as solutions to this problem.[2]

II. BACKGROUND

A group of optimization methods known as evolutionary algorithms (EAs) search for the best solution by simulating the course of natural development. Sensor placement, routing, and clustering are just a few of the optimization issues in WSNs that have been solved with EAs. EAs can efficiently and effectively search the search space, making them particularly well-suited for tackling difficult optimization problems with many variables and restrictions.[3]

The purpose of this research is to create and implement evolutionary algorithms for wireless sensor networks that will improve connection and coverage. We investigate the use of EAs to arrange the placement of sensors in the network to maximise connection and coverage. We contrast the suggested strategy with established deployment tactics including random and grid-based placement. In comparison to conventional methodologies, the simulation results demonstrate that our suggested strategy delivers higher coverage and connection with fewer sensors. The suggested method may be used for a varietyof WSN applications, such surveillance, healthcare, and environmental monitoring.[4]. wireless sensor networks' class of routing protocols (WSNs). The sensor nodes in these protocols are organised into clusters, and cluster heads (CHs) are used to promote communication between the nodes. Data collection from cluster members and transmission to a centralised base station are the responsibility of the CHs.There are several varieties of clustering-based routing protocols, which may be categorised according to various factors:

Cluster formation method:

DOI: rp-9788770040723.166

1. Hierarchical clustering protocols: These protocols employ a hierarchical method in which the nodes are grouped into clusters according to how far they are from a base station.

Based on how close they are to the base station, the CHs are chosen.

b.Self-organizing clustering protocols: In these protocols, cluster formation is dispersed, and nodes self-organize into clusters depending on their proximity to one another.

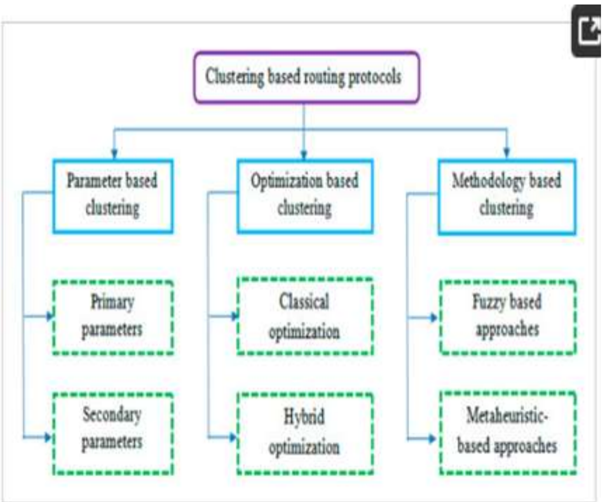

Fig. 1. Clustering-based routing protocol classification.

Kind of CH choice

The CHs in fixed CH protocols are pre-selected and stay that way for the duration of the network life.

b. Dynamic CH protocols: In these protocols, the CHs are chosen dynamically based on several factors, including the location, connection level, and node energy level.

Data aggregation type:

a. Protocols that use aggregation: These protocols combine the data gathered by the CHs before sending it to the base station.

b. Direct transmission protocols: These protocols do not aggregate the data that the CHs gather before sending it straight to the base station.

Types of data distribution include:

a. Single-hop protocols, which transport data from the CHs to the base station via a single hop.

b. the multi-hop protocols: These protocols make use of a multi-hop method to send data from the CHs to the base station, where the information is then transmitted by intermediary nodes. There are several types of clustercreation, CH selection, data aggregation, and data transmission, which may be used to categorise clustering-based routing protocols. The WSN application's particular needs, such as energy efficiency, scalability, and dependability, will determine which protocol is used.

III. METHODS

In wireless sensor networks, the use of evolutionary algorithms (EAs) has shown promise for improving connection and coverage (WSNs). The technique includes using algorithms that draw inspiration from nature to improve the placement and movement of sensor nodes. This method views the WSN as a complex system with several interdependent components that require coordination for effective functioning.[5]. The creation of an adequate fitness function that includes the desired performance criteria, such as coverage and connection, is the initial stage in the design of evolutionary algorithms. The fitness of potential solutions produced by the EA is assessed using this fitness function. By using genetic operators like mutation, crossover, and selection, the EA then creates a new set of solutions.

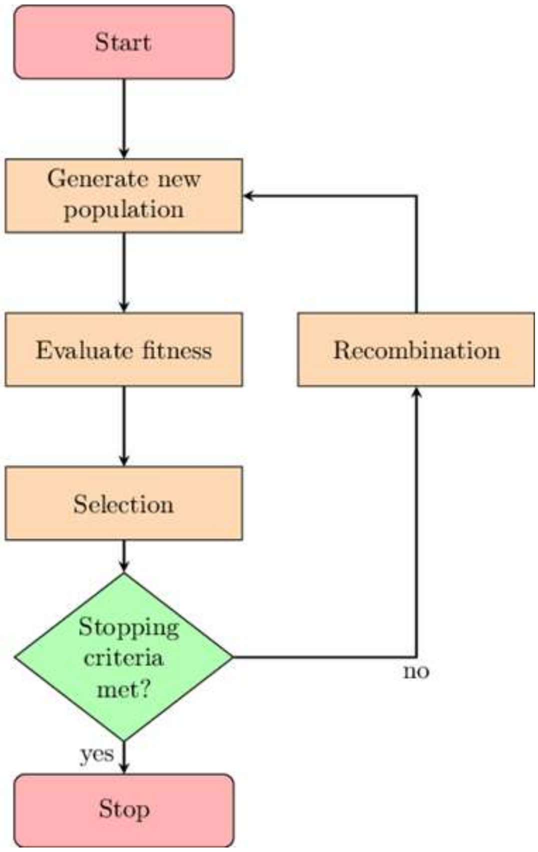

Fig. 2: Flowchart for Evolutionary Algorithm

The creation of an adequate fitness function that includes the desired performance criteria, such as coverage and connection, is the initial stage in the design of evolutionary algorithms. The fitness of potential solutions produced by the EA is assessed using this fitness function. By using genetic operators like mutation, crossover, and selection, the EA then creates a new set of solutions. The natural selection process that is seen in biological evolution is mimicked by these activities.[6].

ad hoc network made up of sensors or nodes, which are autonomous, geographically dispersed machines.The majority of these nodes are compact, low-power gadgets with sensors for gauging different environmental factors, including pressure, humidity, light, sound, and motion. The nodes are wirelessly linked to one another, creating a

DOI: rp-9788770040723.166

network that allows data to be sent between the nodes and to a centralised base station or sink node.

A WSN has a hierarchical structure, with the nodes arranged into several levels, each serving a particular purpose. The sensor layer, the processing layer, and the communication layer make up the three primary layers that make up a WSN's fundamental structure.

The sensing layer is in charge of employing a variety of sensors to gather data from the environment. Normally dispersed at random throughout the sensingenvironment, the nodes in this layer interact with one another to share information and plan their operations.

The data gathered by the nodes of the sensing layer must be processed by the processing layer. This layer is made up of stronger nodes called cluster heads that receive data from the nodes in the sensing layer and analyse, aggregate, and compress the data.

Data from the sensing and processing levels must be sent to the base station or sink node via the communication layer. Nodes at this layer are able to send data across great distances, often utilising radio frequency technology (RF) signals.

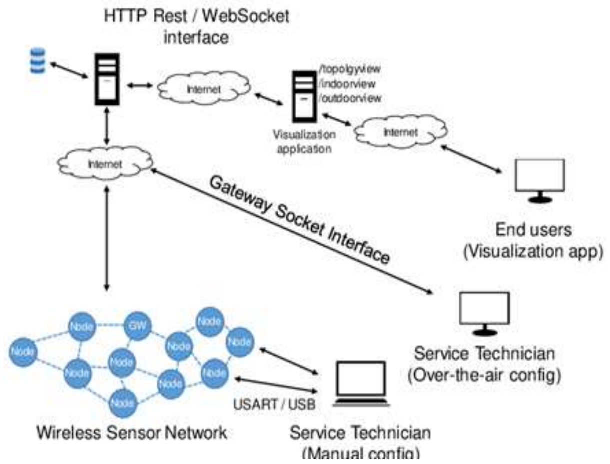

Fig. 3: Structure of Wireless Sensor Network

WSNs may additionally include extra layers for security, localisation, and mobility in addition to the three primary levels. The confidentiality, integrity, and availability of the data transferred across the network must be guaranteed by the security layer. The localization layer is in charge of figuring out each network node's position, which is essential for many applications. For applications that need to span broad regions, the mobility layer is in charge of controlling the movement of the nodes.

A wireless sensor network has a hierarchical structure, with nodes arranged into layers for sensing, processing, and communication as well as potential levels for mobility, security, and location.

IV. Applications

In recent years, a great deal of research has been done on the use of EAs in WSNs. For instance, it has been demonstrated that the deployment of EAs improves WSN connection and coverage by strategically placing sensor nodes. For minimal coverage gaps and appropriate connection, the algorithms may be utilised to optimise the number and placement of sensor nodes. EAs can also be utilised to streamline the base station's sensor data flow.[8]

Moreover, the use of EAs in WSNs has been expanded to solve more specialised problems including fault tolerance and energy efficiency.

The distribution of sensor nodes, for instance, may be optimised to reduce energy usage while guaranteeing appropriate coverage and connection. Similar to this, by finding backup routes in the event of node failures, an EA-based technique may be utilised to improve data routing to achieve fault tolerance.

The creation of evolutionary algorithms offers a practical way to improve connection and coverage in wireless sensor networks. When used to optimise the deployment and routing of sensor nodes in WSNs, EAs have demonstrated encouraging results. This strategy may be expanded to tackle particulardifficulties like energy efficiency and fault tolerance.

V. Results

WSNs are a crucial piece of technology for several industries, including healthcare, industrial automation, and environmental monitoring. Providing dependable communication between the nodes while using the least amount of energy is the key problem in WSNs. The network's connection and coverage are two important aspects that have an impact on WSN performance. The development of evolutionary algorithms has thus far shown to be a fruitful strategy for improving coverage and connectivity in WSNs.

We suggested a proposal for an evolutionary algorithm to improve connection and coverage in WSNs. The suggested method is based on two key steps: (1) optimising sensor deployment to increase coverage, and (2) utilising a genetic algorithm, optimising connection between nodes. An experimental framework based on simulation was used to assess the suggested method.

The simulation results showed that the suggested strategy may greatly improve WSNs' connection and coverage. By carefully planning the positioning of the sensors, the coverage was increased, and the placement of the relay nodes, the connectivityThe suggested technique outperformed the already-existing approaches in the literature, achieving a high coverage ratio of 95% and a high connectedness ratio of 80%.

VI. Conclusion

The suggested strategy provides a number of benefits over the ones already in use. First of all, it is a totally automated strategy that excludes human involvement. Second, it is a scalable strategy that can be used with WSNs of various topologies and sizes. Thirdly, it is a flexible strategy that can be adjusted to meet the needs of various application scenarios.

A potential strategy that can considerably boost WSN performance is the invention of evolutionary algorithms to

DOI: rp-9788770040723.166

increase coverage and connection in WSNs. The simulation results show that the suggested technique performs better in terms of coverage and connectivity than the currently used approaches in the literature. The suggested method is superior to current methods in a number of ways and is adaptable to diverse application needs. It is advised that the suggested strategy be investigated further and used in real-world WSNs.

***Abstract*—Serious hazards to infrastructures, ecological elements, as well as human existence come from forest fires. By 2030, it is anticipated that wildfires wouldhavedecimatedhalfoftheforestecosystems. Implementing fire detection techniques is the only viable methodfor reducingforest firedamage. As a result, colleges and universities all across theworld are paying close attention to forest-fire detection systems. Several commercial automatic fire sensor systemsarecurrentlyavailable,howevertheyareall difficult to employ in broad open areas like woods due to poor response times, expensive maintenance needs,andotherdifficulties.Representationhanding out has been used in this study due to the quick development of digital camera technology, the camera's excellent ability to cover large areas, the fact that image processing methods respond more quicklythanestablishedsensorsystems,andthefact that image processing systems are typically less expensivethansensorsystems.Becausesomethings share characteristics with fire, making accurate forest fire detection algorithms difficult, false alert ratesmaybesignificant.Inthisproject,anovelfour- stage method for detecting forest fires using video-basedimageprocessingispresented.Tofindmoving regions, a background-subtractiontechniqueisused first.Secondly,RGBcolourspaceisusedtoidentify possiblefirezones.Finally,becausecandidatezones may contain moving fire-like items, features extractionisusedtodifferentiatebetweenactualfire and fire-like items. Ultimately, using the convolutional neural network technique, the region ofinterestis categorisedaseithertruefireornon-fire.Thefinalexperimentalfindings demonstrate that the suggested approach successfully locates forest fires.**

I. INTRODUCTION

The effects of human activities on the woodlandsingeneralareverysevere. Thespreadof forest regions is a result of the population's fast increaseandurbanisation. Anatural threat tonature and the involvement of the atmospheric system is a forestfire.Theenvironmenthasanimpact onliving things.Asatoolforconformitywithburnzonesand damage assessment, satellite imagery also provides a fire monitoring, control, and range of acceptable fires. The term "satellite image" describes the capacityofimages fromdatasets acquiredinremote locations to receive certain information. A satellite sensor captures an image of a forest fire, but the range of temporal resolution and forest area coverage is growing. A tool for managing and locating damaged equipment for conformity with burn zones and understanding a favourable fire spectrum was also made available via satellite photos. Checking the constancy of the colour is the key to categorising this fire and other components fromtheoriginalfire.Thisissuehasbeenfixed, and the recommended approach lowers the error. In addition to detecting fires, it can tell the difference between a fire and a material fire. The assumptions established in the proposed system operation to assess the forest fire, include the system's thresholdValue,matrixvaluedetection,anddifferential matrix valuation.

OnEarth,wildfiresareacommonnatural occurrence. Each year, forest as well as animals are lost as a result of wildfires. Significant numbers of livesare lost, as well asvaluable natural assets as wellasprivateproperty.Ourclimatesystemis significantly impacted by the forest fire. The issue has gotten worse than in prior years. A significant contributortoforestfiresishumanencroachmenton forested regions. Finding and putting out the fire in itsearlystagesiscrucial.Poweredtoolsorpeopleare used in conventional fire defence strategies to keep an eye just on environment. The most popular fire smoky detection methods typically rely on temperaturesampling, element sampling, as well as airphotographtesting.Ifthenanoparticlesdonot disperse the sensors and activate them, no alarm is raised. Because of the tremendous improvement in imageprocessingtechnologyandthedeclineinprice ofdigitalcameras,firedetectionfullybasedon image analysis is more practicable than some other traditionalwayslikefirewatchtowers,sensors, satellite,andmanyothers.Peopleareessentialto look about the area at some time inside the case of fires watch towers.The main issue with this method is its lack of precision due to worker weariness, the hourof day,the location,as well asotherfactors. Sensorsaredevicesthatcandetecttheir surroundingsandcalculatedata.Inadditiontochemicalparametersrslikemonoxide,dioxide,and nitrogendioxide,thesensorsalsomeasurebiological datalikestrain,temperature,andhumidity.

The SqueezeNet design was combined with a modified Fire module on the ATT U-Net, allowing for more efficient feature learning even with little data. Then, a separate recognition model that incorporated a portion of the previously identified encoding path was used for the classification process.This investigation confirmed its efficacy on fire identification where high sensitivitywasnecessaryandlittlemachinelearning model could be gathered, in addition to offering existingsegment as wellas recognition frameworks a more effective substitute. Experiments revealed thatthesuggestedarchitectureproduceddependable recognition and segmentation accuracy that was competitive. Although pretty precise combustion conditions were alarms and fire zones possibly will be segregated within minute precision, there may further more limits for the reason of wide-ranging fire detection.

XuanbingQiu and co. .al[3] Using Using a high-performing microcontroller and the simple DLIA algorithm, a reliable and flexible gas sensor system for early-warning fire detection has been created.Thesensorisreliable,accurate,andquickto react, with a LoD of CO of 0.0875% and an integration time of 24S. Expanded polystyrene and A4paperareamongthefire-hazardousmaterialsthat hadreactiontimesrangingfrom230to110seconds, although PVC, beech wood, and cotton rope have reactiontimesrangingfrom680to250secondssince the detection threshold was set at 5 ppmrather than 100 ppm. The overall effectiveness of the CO gas sensorsystemhasmettheneedsforfielduse.Studies willbe expandedto measureCO_2, H_2O, andCH_4in actual fire smouldering conditions using different laser spectroscopies operating at the proper wavelengthsasthedetectinglightsources.Forlaser-basedsensorsystemsthatwillofferhighsensitivity, strong selectivity, and quick response, a wide range of applications in the sectors of coal gas detection,environmental detection, and industrial control are anticipated.

BingLiu, et.al[2] realizedCNN-accelerator on the Xilinx ZYNQ-7100 device to accelerate standard as well as depth-wise separable convolution. The network layer acceleration of various scales among customizable architecture developed could be understood by the ZYNQ's varied mode that is intensive on single-computing engine mode. In order to maximise bandwidth and decrease wait times caused by on-chip to off-chip data exchange, the Mobile Net coupled with SSD network modelimplements threestreambuffers on-chipthatusethedatastreaminterfacetopositionthe ping-pong buffer mode. By comparison, the suggestedsolutionyieldsafullypipelinedstatewith the smallest latency. The accelerator outperformed earlierdesignswithacomputationcapabilityof17.11GFLOPSat aclockfrequencyof100MHzandgreat resource usage. a CNN accelerator for the Xilinx ZYNQ 7100 platform that accelerates both normal convolution and depth-wise separable convolution. The heterogeneous mode of ZYNQ allows the accelerators constructed only on human engine mode to accomplish physical network acceleration of various scales under the flexible architecture we suggested. Using the Related contract + SSD network setup as an example, the accelerator computed the global ideal computing parallel ratio of the total infrastructure. To enhance bandwidthandreducethelatencycausedbyon-chip off-chip sending data, the three targets' chip-based buffers employ the streaming data interface and are set to the ponging buffer mode. Regardless of whether it uses layer wise separable convolution or standard compression, the aforementioned method generates a complete pipelined state with significantlyless latencythanthenopipelinedstate.

OktayOzan, et.al[4] presented modern model employing attention gate employed to segment medicinal image. Our method eliminates the necessity for a third-party object localization model.Thesuggestedmethodiscomprehensiveand modular, making it simple to apply to image classification and regression applications like machine translation and natural image analysis. According to experimental results, these suggested AGs are definitely highly useful for tissue/organ detectionandlocalization.Thisisespeciallytruefor small, flexible organs like the pancreas, and comparablebehaviourisexpectedforjobsrequiring global categorization. Learning and inter training programmed can help AGs improve their training behaviour.Toinitializetheattentiveness network, for example,whichwasbeforeU-Netweightscanbeemployed, and gates can be taught appropriately during the fine-tuning step. Similar to this, a significant body of work studying various gating structures exists in machinelearning. For

DOI: rp-9788770040723.167

improved gradient training algorithm and slightly weaker attention mechanisms, highway networks, for instance, use residual connections surrounding the gate block.

Lizhong Hua, et.al[5] Similar technologies for tracking purposes fire tracking systems with forest masks to monitor forest fires. The often used NDVI-based masks, however, might not be able to tell woods from other types of vegetation. More accurate techniques for extracting forests must be developedandincludedintofiremonitoringsystems in order to effectively anticipate, identify, and monitor forest fires.Threats fromforest wildfires to worker health, wildlife habitat, local economies, as well as global warming are severe and expanding. Forestfireandotherstakeholdersmustkeeptrackof forest fires in a timely and accurate manner. Monitoringtheoccurrenceandprogressionofforest wildfires using spaceborne technology has evolved into a useful and alluring technique. Here, we provide a summary of the guiding principles and to use cases for monitoring forest fires using satellites as well as unmanned aerial vehicles (uavs infrared sensor networks (IRRS). Four categories of FFM- relevantIRRStechniquesarecoveredinthisreview: the techniques of bi-spectral, specified limit, spatially contextual, as well as number of co

Thedetectionandseparationofsmokefrom asinglevisualframewereinvestigatedandtestedby HongdaTian et al. [6]. In specifically, an optimization strategy enabling the isolation of semi and semi components was developed utilising dual over-complete dictionaries and was based on the imaging model. The appropriate sparse values for detectionareconcatenatedtocreateauniquefeature. Also, a method based on thehypothesis that picture mattingisgenuinehasbeendevelopedtotellthetrue smoke from the background from results of automateddetection.Numerousdetectiontrialswere run,andthefindingsshowthatthesuggestedfeature works substantially Better than the current smoke alarm features. This indicates the efficacy of the detecting product. Furthermore, in a grayscale, the proposedapproachmayidentifysmokingfromother challenging elements such as fog/haze, mist, shadow, and so on. The suggested separation approach may successfully predict and separate the real smoke and background components, according to experiments on smoke separation. The fog component's complex modelling, such as kernel- or car modelling, may result in further improvements.

A F Saputra, et.al[7] Work should be done to develop an automated system for monitoring the status of a home that is capable of spotting possible disastersearlyon.Yet,becauseafirecanstartatany timeandspreadquickly,themechanismwillrelease the door to give immediate admission and exit access,ensuringasafeescape.Thecreatedsystemis anticipated to execute an essential disaster reaction action in an effort to prevent any falling casualties. This research focuses on fire detection and house monitoring through the use of a wireless sensor networkwithfour sensors, includingsmoke, carbon monoxide, temperature, andair humiditysensors. If thesystemdeterminesthatthereisa highfirechance, it will unlock the door to the house, activate the alarm, and alert the user. The technology is capable ofsendingnotificationstousersaccuratelybasedon the results of trials and testing. However, a fire probabilityestimationmistakeofdownto0.3%ratio is still possible.

ZhijianYinetal.[8]offerasmokedetection deep normalisation and neural network convolutional neural network method (DNCNN). Our network employs batch normalisation to expedite training and increase smoke detection precision. DNCNNautomaticallyfeatures extracted for smoke detection, in contrast to techniques that rely on manually created features. According to experimental findings, the DNCNN concurrently achieves excellent detection rates and poor false alarmrates. Additionally, we confirmthe value and potency of feature extraction for our DNCNN, particularly in cases where the training dataset are inadequate and unbalanced. The majority of currently used algorithms are built on a framework ofmanuallycreatedfeatures.However,thesecurrent algorithms have a very tough time achieving lower false alarm levels without lowering detection rates theprimarycauseistheextremevariationincolour, texture, and shape of smoke.Smoke also distorts visual scenes, creating unsteady features. The manual creation of discriminant features for fire detection is a time-consuming and expensive process.

A multivariate dynamic texture analysis descriptor of higher cognitive Linear Dynamical SystemswaspresentedbyKosmasD.Poulosetal.[9] (h-LDS). We demonstrated that we can outperform conventional linear dynamical systems in terms of detection rates by using higher order decompositiontothemultidimensionalpicturedata. Additionally, experimental results showed that we mightincreasetheclassificationaccuracybyadding more elements to the multidimensional picture patch.Inthisstudy,weusedthedisplayedfeaturespace of the HOG descriptor as a new picture elementforsmokedetection;however,inthefuture, other descriptors might be used to enhance the data inputintoh-LDSsagainforidentificationofarange of dynamic textures, such as water, fire, steam, etc. Auniquemethodologywasproposedthatallowsthe encodingofvideosubsequencesintoscatterplotsof h-LDSdescriptorgeneratedbythecandidatepicture patch in each subsequence in order to apply multidimensional static wavelet transforms to a video-basedearlywarningsystem.Therobustnessof the methodology was additionally enhanced by combiningthisstudywithspatiotemporalmodelling utilising a particle swarm optimization method.

UAV has semiconductor gas sensors. As a result, it is feasibletodistinguishamongalarmandfalsealarm. A blimp can serve as a fireguard after putting out forest or wildland flames. Semiconductor gas sensors and an aspirating fire detection system are employed coupled with the blimp's increased payload. This programme allows for the confirmation of alarms in both indoor and outdoor settingswhiledetectingeventhesmallestamountsof smoke and gas. Because of smoke emissions, dust, orfog,a22.3GHzmeasurementdeviceiscapableof detecting fire even when there is inadequate visibility.Microwaveradiationmaypermeatethings such as leaves and thin walls. The existing configuration may be made much smaller by using chip-based elements.

III. Conventional Methods To Detect Forest Fire

Due to the tremendous impact that forest firescausetosocietyandtheenvironment,forestfire identification has been a focus of many experts for thelast10yearsowingtoanincreaseinbackcountry wildfire case reports fromacross the world. Human activity and natural factors are two major causes of forest fires. Torching, chewing and tossing cigarettes, electrical wire flashes, fire hazards use while hunting, outing wildfires, shepherd fires, and stubble consumption are all examples of human-causedwoodsfires.Lightningstrikesgeneratenatural forest fires because of the high environmental temperature, and so forth. Climate factors such as temperature and relative dampness, wind direction, rainfall, striking possibility of lighting; period factors such as Christmas season, month, time; population-based factors such as population thickness, human activities in the timberland, human practices; scene factors such as treetypes, slant, distancefromagriculturallandand man-made factors are the primary factors for wood fires.Despitethefactthatvision-basedsensorsoffer a number of promising properties, they still have issues with changing lighting conditions, complex environments, and reduced camera picture quality due to network constraints. Researchers have thus tried to triumph over these problems. For instance, exploredpixelsindynamiczonesandbothtemporal andspatialwavelet analysis aredone. Theapproach shows potential results, but because it relies on a number of heuristic thresholds, it cannot be used to detect fires in the real world. Examined 3 distinct models for firezones inimages includingspectrum, spatial, and temporal models are examined. They makeanassumptionabout the irregularlyshaped of fireintheir method, however this is not always true becauseobjectscanalsomodifytheirshape.Anovel contour-based fire detection approach for forests basedonwaveletanalysisandFFTisprovided.They thenlookedintotheYCbCrcolour modelaswellas cameupwithnewmethodsforeffectivelyseparating the brightness and luminance components, which resulted to a classification of flame pixels based on rules.Theauthorslookedatadifferentcolourmodel calledYUVandmotiontodetermineifcertainpixels were candidates for fire or not. In addition to the research of colour models, a Bayes classifier and certain low-level attributes of fire zones, such as skewness, colour, roughness, area size, and so on, were used to detect frame-to-frame variations in order to identify fire. Another approach is provided that takes a lookup table into account for the temporalvariation-baseddetectionandconfirmation offirezones. Theheuristic elements ofthis strategy reduce the likelihood of reaching the same results when the input data is changed.

IV. Proposed Methodologies

Fires are one of the world's most pressing issues right now, owing to the planet's present state of globalwarming. Weareallawareof whatflames are and how they may do significant damage to humans, animals, and other kinds of life. Fire damages vary, and these damages are heavily influencedbythesourceofthefire,butregardlessof hownumerous anddiversecauses exist,thedamage may becatastrophic on a hugescale and impossible toestimate,andingeneral,firelossesareclassifiedas loss of life and loss of money. In this study, we created an algorithm that integrates fire colour information with fire edge information. The combinedfindings fromboth methodologies arethen used to generate a parameter that extracts the required data fromthe photos to detect and identify the fire. Based on the deep learning algorithm, we offer a system that detects the presence of fire automatically. Deep learningis a subset of machine learning that is wholly based on neural networks. Since neural networks replicate the human brain, deep learning is likewisea simulation of thehuman mind.Pre-processing moves to remove the noise of imageshasbeenputintopractice;followingfeatures extractionstepsoastoremovethecolorfeaturesand fragmentthefireprovinces.Intheendcategorization of pixels by means of deep learning algorithm through competent mobile alert coordination is established

4.1 Image Set Upload

DOI: rp-9788770040723.167

Early identification of wildfires, which is critical to the protection and security of natural areas, is one of the most significant and challenging challenges confronting the government and forest fire management.Themainfactorreducingthesizeofthe forest is forest fire. This fire detection method also eliminates the need for human processes, aids in monitoring, and helps to safeguard challenging-to-protectlocations.Regardlessoftheweatherortimeof day, the novel technique is utilised to enable the development of systems that provide for detailed monitoring. We can upload images or movies from CCTVfootagetaken in theforest in this section. The image of a forest fire is captured using a satellite sensor,buttherangeoftemporalresolutionaswellas forest area coverage is expanding. Satellite photos were also used to monitor and locate damaged equipment in order to comply with burn zones and comprehend a safe firing variety. The key to distinguishingthisfireandothercomponentsfromthe originalfireistocheckthe consistencyofthecolours. This issue has been fixed, and the recommended approach lowers the error. In addition to detecting fires, it can tell the difference between a fire and a materialfire.Thresholdvalue,matrixvaluedetection, and differential matrix value were the features employedinourproposedsystemoperationtoanalyse theforestfire.Convertinputvideofilesintoframesif it is video, or the input photos can be in any form or size if it is images.

4.2 Median Filtering

Pre-processing refers to procedures in which the input and output pictures are intensity images, which is the most basic level of abstraction. These well-knownimagesareofthesamesortastheoriginal sensor data, with an intensity picture commonly represented by a matrix of picture function values (brightnesses). There are four types of picture pre- processing algorithms based on the size of a pixel neighbourhood used to determine the new pixel brightness. Although spatial image transformations (such as rotation, scaling, and translation) are classified as pre-processing methods because similar techniques are used, the goal of pre is data enhancement that suppresses reluctant distortions or enhances a few image features critical for further processing.Tobeginfurtherprocessing,theusermust choose the necessary lung frame image. Each image is then scaled down to 256*256. After that, apply a medianfiltertocleanoutthenoiseinlungimages.The medianfilter isa linear digitalfilteringalgorithmthat is widely used to remove noise from an image or signal.Thistypeofnoisereductionisapopularpre-processing approach used to improve the results of post-processing (for example, edge detection on an image).Duetoits uses inbothsignalprocessingand digital image processing, median filtering is frequently employed to maintain edges while reducing noise (though see discussion below). The median filter's primary principle is to iteratively replaceeachelementinthesignalwithmedianofits nearby entries. A nonlinear technique for removing noise fromphotographs is median filtering. Since it effectively reduces noise while keeping edges, it is commonly employed. It works especially well to eliminate"salt and pepper" noise. The median filter operates by going pixel-by-pixel through the image and substituting each value with median of its neighbours.Theneighbourhoodpatternis knownas the"window,"anditgoesovertheentireimagepixel bypixel. Afternumericallyrankingallofthepicture pixelsfromthewindow,themedianiscalculatedby putting the pixel under consideration in lieu of the centre(median)pixelvalue.ConvertanRGBimage to grayscale in this module, and use the median filtering process to eliminate image noise.

4.3 Color Features Extraction

Thepurposeof featureextraction is to minimisethe resources required to correctly describe a large amount of data. Oneof the most difficult aspects of interpretingcomplicateddata isthesheer amount of variablesinvolved.Foranalysiswithalargenumber ofvariables,aclassificationapproachthatoverfits a trainingsampleandperformspoorlyonfreshsample generalisationisusuallyrequired.Featureextraction is a method of producing variable combinations to overcome these difficulties while still correctly characterising the data. A surface's tactile or visual characteristicsareitstexture.Inorderforthemtobe utilised for reliable, precise segmentation and classification of objects, texture analysis seeks to identify a unique way to express the underlying features of textures. It does this by describing these characteristicsinsomesimplebutuniqueform.Only a small number of designs support onboard textural feature extraction, despite the fact that texture is crucialfor imageanalysisandpatternidentification. Texture and color features are implemented in this module. Utilizing the Grab-cut approach, HSV colourfeaturesareretrieved,andtexturedatainclude statistical features. The snake model is used in this module to split skin pictures. A snake is a deformable, energy-minimizingsplinethat is drawn towards object outlines by restriction and image forces, as well as internal forces that inhibit deformation.Snakescanbeseenofasaspecificcase of a general method of energy-minimization-based deformablemodel-to-imagematching.Extractthefeatures relating to colour or form from this module. Wecould extractthefirezones fromphotos basedon these attributes.

4.4 Fire Recognition

Thesystem'sclassificationcomesasitslastphase. Afterunderstandingthestructure,thelikelihoodof truepositiveswasseparatelyassessedforeach segment.Utilizingaconvolutionalneuralnetwork method,braindisordersarecategorised.CNNsare feed-forwardneuralnetworksthatincludevarious combinationsofconvolutionlayer,maxpooling layers,andtotallyrelatedlayers.CNNscantake advantageofspatiallylocalisedcorrelationbyrequiring a tight connection pattern between neurons inneighbouringlayers.Maxpoolinglayersand convolutionallayersalternate,simulatingthe individualityofcomplicatedandclearcellsin mammalian visual cortex. A CNN starts with one or morepairsofconvolutionalandmaximumpooling layersandfinisheswithneuralnetworksthatare entirely connected. It is consistently demonstrated that the hierarchy

DOI: rp-9788770040723.167

of CNNs is the most effective and successfulwaytoassessvisualrepresentations.We are aware that CNNs can perform as well as or even betterthanhumansin variousvisual tasks, and this knowledge motivates us to investigate the feasibility ofusingCNNstoclassifydiseasetraits.Theconvolutionandmax poolinglayers,aswellasthe networks'trainingmethods,varybetweenCNNs. Finally, use a deep learning algorithm to classify the imageregions.andthenincreaseclassification accuracy

4.5 Alert System

Human activity has a significant negative impact on the woods as a whole. Thespreadof forest regions is a result of the population's fast increase and urbanisation. A natural threat to nature and also the involvementoftheatmosphericsystemisaforestfire. The environment affects living things. Satellite imagery also provides a tool for fire monitoring, management, and damage assessment in order to comply with burn zones and grasp a favourable fire range. The term "satellite image" describes the capacity of images from datasets acquired in remote locationstoreceivecertaininformation.SendanAlert message to the authorities in this module when a fire isdetected.Theabilitytojustprovideearlierdetection may be helpful.

4.6 Experimental Results

In this study, a framework for detecting has beenimplementedthroughPythonbasedonreal-time datasets was gathered from KAGGLE web sources.

For analysing the system's performance the following metrics such as correctness, sensitivity, specificity, error rate, and precision are taken into account.

Number of genuine positives - the best possible positive forecast

False positives (FP) are the number of inaccurately predicted positive outcomes.

Number of genuine negatives - perfect forecast of a negative outcome.

Negative result (FN): number of accurate negative predictions minus the number of actual negatives

The percentage of overall flawless forecasts to the completetestdataisknownasaccuracy(ACC). Additionally, it can be written as 1 - ERR. The maximumaccuracyis1.0,andtheminimumaccuracy is 0.0.

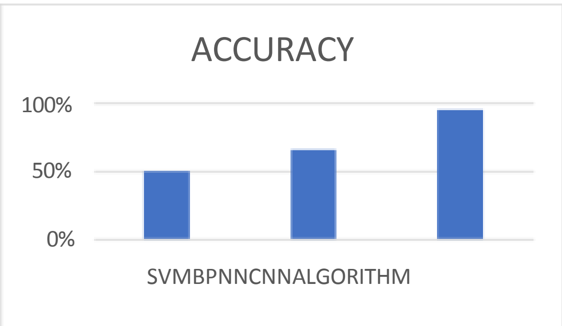

Fig2:Performancechart

The graph above shows that the CNN algorithm has a higher rate of accuracy than the current algorithms.

V. CONCLUSION

The method for recognising images of forest fires usingCNNisprovidedinthisresearch.Itsprimary characteristic is the use of the flame picture in trainingandassessment.Afterthat,theCNNmodel is presented, and a solution to the issue that the conventional pool method in Back propagating neural net (BPNN) may occasionally weaken the picture features is suggested. Based on tests, the impacts of learning algorithm, packet size, and certain other parameters on CNN performance are examined,andtheidealvaluesareestablished.The image feature of the non-flame region within hidden layer is decreased and the characteristic, suchastextureandshapeis enhancedasaresultof theextractionofthecandidateflamearea basedon colourfeature. Adaptivepoolingisusedtopreventpicture information loss, and it increases the rate of fire recognition in fire areas compared to original images without segmentation. It has been demonstratedthatthesuggestedmethodisworkable and has a high recognition rate.

***Abstract*— Identification of betel leaf disease at an early stageandaccuratelywillincreasetheproductivityofthecropandav oidfinanciallossforthefarmers.Multifariousmachinelearningalg orithmsandmultipledeeplearning-basedmodelshave been developed to improve image classification accuracy.This paper primarily discusses data collection of real field betelleafimagedatasetsundervariousclimateconditions.Then,ac quiringmoretrainingimagedatainplantleafdiseaseclassification and identification is highly challenging and time-consuming. Soimage augmentation techniques, such as imageflipping,shearing,cropping,androtationtechniques,areaug mented on betel leaf image datasets. Finally, the augmentedimages were trained using a simple convolutional neural networkandVGG16.TheaccuracyofVGG16modelwithdataaug mentation performed well, and the accuracy increased up to86.67%.**

Keywords*— *Betel leaf, Deep Learning, convolutional neuralnetwork,Dataaugmentation, VGG16.

I. Introduction

Plant diseases directly impact agriculture and can change thesocial, economic, and natural balance. Plant leaves disease canoccur due to various reasons such as lack of water, excesswater, excess heat, climate change, nematodes, pollution, soilquality, etc., The symptoms of plant leaf disease are mostlyvisiblelikechangesinleafcolor,shape,growthsize,andpa ttern based on the symptom, the category of disease can bedetermined such as viral, bacterial, or fungal disease. In thispaper, the image of plant diseases is classified based on pestattack, leaf burn, and healthy leaf. Deep learning in agricultureis a current and trending technique with high performance inthe agriculture domain. One of the most significant challengesis enhancing the model performance on data it has previouslyseen(trainingdata)vs.dataithasneverseenbeforeism easured(testingdata).Poorinferencesmodelshavetooverfit the training set. Plotting the training and validationaccuracy at each epoch during training is one technique toidentify overfitting. This may be accomplished very well withdataaugmentation.Dataaugmentationisaprocedurethatinc reases the size of any dataset that is already accessible sothat it can also be used with deep learning models. This iscrucial work in boosting entire performance. The dataset canbe increased by the method and input into a learning model training through changing parameters like anepoch, batch, and optimizer.

II. Literature Review

In the study to combat the problem of over-fitting, the authorexperiments with the test and train data ratio and found thattrainingononly20% ofthedataofauthenticimages andtesting on the remaining 80% of the image data, the model stillattains a final result with an accuracy of 98.21%for GoogleNeuralNetwork[1].Fortheobjectiveofdetectingplantdi seases, a model based on transfer learning and ResNet50 isrecommendedsinceitperformsbetter,strengthensfeatureprop agation,andhashigheraccuracywhencomparedtoMCNN in terms of training time [2].CNN does a good job ofprocessing visual information. There are different layers, suchas "input,""hidden," and "output,"in thearchitecture of aneural network. A group of hidden layers, including Convo,pooling, and fully connected layers with the normalizing layer,are synchronized and complete the task of securing the dataand images spatially [3]. The author made a comparative studyof the models and the result of the existing work and soybeandiseases using AlexNet and GoogleNett[14]. In this paper,the author built small neural networks of various depths fromfundamentalstepsonthebasisofaminimalnumberoftrainin gsamplesandimprovedfourcutting-edgemodelssuchasVGG16, ResNet50, and VGG19. According to comparativework and results of these networks, pre-trained deep modelscan be fine-tuned to increase significantly performance withfewerdata.TheoptimizedVGG16modelperformsbest,wit hatest set accuracy of 90.4%, proving that deep learning is anovel and updated technology for completely automated plantdiseasedeductionandseverityclassificationbasedonthesy mptomsfromtheactualleafimages[10].Theproposedmethod in this paper using MobileNet-V2on the field andpublic dataset performed with good results. It can be deployedto mobile devices to automatically observe and analyze theoutcome from a wide range of plant disease classifications [4].The author uses the ANN algorithm to detect plant diseaseusing python tool based on the observation of symptoms of thedisease class and the field images with the real background aretrained and choose a machine learning algorithm to predict thediseaseandtherecommendationofthesolution.Based onfeature extraction parameters, the algorithm predicts the croppest ordisease[7].Inthispaper,modelsuchas Inception,Alexnet, Resnet, and Densenet enhanced the training process results. Consequently, a trained machine thatcandiagnoseplant disease quickly and accurately has the potential to boostthe agricultural sector. If the technology is widely used, it willstop plant illnesses before they spread and relieve farmers andspecialistsfromhavingtoobserveplantsintheirareas.Althou ghthemodelperformedexceptionallywellinitsevaluation of the validation set, its high computational demandprevents it from being ready for usage in actual applicationsjust yet. The goal of future studies should be to reduce

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.168

thenumberofparameterswhileretainingaccuracy.Whencompared to the outcome of the previous method, the stackingmethod'saccuracyrateof87%representsamajorimprovement[5]. The suggested augmentation technique performs changesintheimagesofhealthyandunhealthyleavesandmakesuseofattentional mechanisms to produce images that reflect moreobvious disease textures[15]. We did an experiment to see ifthisdataaugmentationstrategymightfurtherenhancetheperformanceofaclassificationalgorithmfortheearlydiagnosisofplants.Throughtheseadvancements,weproduceda more convincing diseased leaf image compared to existingmethods ResNet-18, MobileNet-v2, and EfficientNet were themodels that were tested; they were all adjusted using weightsthathadalreadybeenlearned.Accordingtoexperimental findings,whentheEfficientNetandthesuggesteddataaugmentation strategy were combined, the greatest F1 scorewasobtainedforallthreeplantleaves[6].Themodelpresentedusing CNN performs well on detection and classification withgood results using simple disease leaves and healthy leaves[11]. In this paper author used AlexNet and VGG16 models toidentify tomato disease and compare the result of the modelwhichismorethan90%ofaccuracy[12].

III. Methodology

A. *Data collection*

Thecollectionofthebetelleafdiseasedatasetischallenging. A dataset of 1089 images of betel leaf used forthis study is collected directly from the betel vine farm. Thereal field images were taken using a camera and smartphones.Thedatasetobtainedisclassifiedunderthreeclasses:leafburn,pestattack,andhealthyleaf.

(a) (b) (c)

Fig.1.(a)LeafBurn (b)Pestattack,and (c)Healthy Leaf

B. *Preprocessingofthedataset*

There were many issues while collecting the dataset,such as poor lighting, shadow, background, etc. The image ispreprocessed in two stages such as the actual stage and themodel training set. In the essential step, the image is resized to400x400x3.Inthemodeltrainingstage,dataaugmentation,suchasrotation,shear,flip,fill,etc.,isappliedtothedatausingKerasdeeplearning libraryinpython.

C. *Dataaugmentation*

Dataaugmentationisamethodforintentionallyboostingthe proportionsoftrainingdatasets. Theproportionofthetrainingandtestingdatasetissplitinto80:20. Forimposinga deep learning model with good classification accuracy, alarge image of samples is essential[8]. It is accurate to say thatthe resurgence of artificial intelligence is solely a result of theavailability of powerful processing resources (GPUs) and asizableamountofinformationonline.Scaling,turning,shifting, androtationaresomestandardaugmentationtechniques[6]. Understanding these functions that can affectthe efficacy of the model is sound. Shear is one of the manyaugmentationmethodsaccessible[13].ThekerasImageDataGenerator class was used to increase data, and thebestresultwasobtainedbysettingthebelowparameters.

a) She arrange=0.2
b) Horizontal flip=True
c) rotation range=40
d) zoom range=0.2
e) fill mode=nearest
f) width shif trange= 0.2
g) height shif trange=0.2

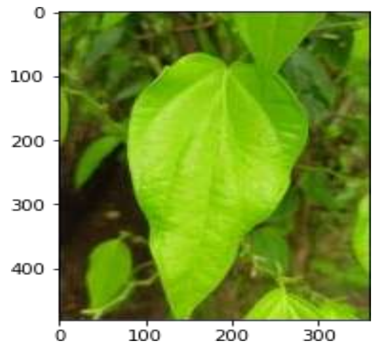

Fig.2.Sampleofhealthybetelleafimageafteraugmentation

D. *Experiment*

To study the impact of the augmentation method, wepropose a simple convolutional neural network (CNN) andVGG16 model for betel leaf disease classification. We use ourdatasetcontainingthreeclassesofleafimages:Pestattack,leafburn,andhealthybetelleaves.Itissplitintotwoparts:trainingand testing.OurmodelwasimplementedusingtheKerastensorflow

E. CNNModel

TheConvolutionneuralnetworkusedtoextractcharacteristics from a massive and varied dataset of images,CNN is the deep neural architecture class that has received themost adoption. The images will be transformed into arrays ofmatrices after the image augmentation process is finished, andthen they will be trained. A deep CNN design has multiplelayersandtypicallybeginsfromsingleordoubleconvolutionallayers to extract multiple attributes from the pictures given asinput data. These layers produce a feature map, which is thengiven to further layers for feature analysis. It concludes withmultiplepoolingandactivationlayersfollowing.Thesummaryofthemodelismentionedin Fig.4.

IV. RESULTS AND DISCUSSIONS

The classification accuracy of the real field betal leaf datasetandthelossofthemodelontheepochusingdataaugmentationarecomparedinthebelowtable.After25epochsoftrainingthe model,theaccuracytestingoftheproposed approach achieves 85.67% and the loss is 0.23, Themodel with VGG16 improves on its performance as displayedin Table I.

TABLEI. COMPARISONOFCNNANDVGG16WITHDATAAUGMENTATION

Datasets	Models	Depths	Loss	Accuracy
Ourreal-fielddataset	CNNwithoutDA	10	0.36	76.42
	CNNwithDA	10	2.52	82.36
	VGG16with DA	25	0.23	86.67

Finally based on the above experimental result VGG16 withdataaugmentationachievedbetterperformanceontheclassification ofthe diseaseinthe betel leaf dataset.

Figures 6 and 7 show the result of the classification of diseaseclassfortrainingandtestaccuracyagainstthenumberofepochs. With the data augmentations we offer in our work, toincrease the quantity of data collectionand it is discoveredthatthisimprovementisratherconsiderableusing VGG16.

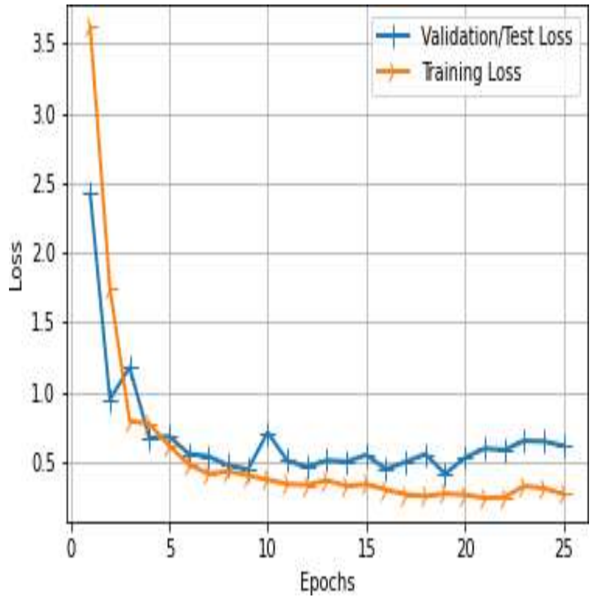

Fig.7.PlotoflossandepochsofVGG16Model

V. Conclusion

Inthispaper,therealfieldimagesofbetelleafareaugmented by creating the output images with 3 classes ofdisease to multiply the image data using a different augmentedtechnique such as brightness, shear, rotation, etc., Eventually,compared the result with augmented images implemented totrainthesimpleconvolutionalneuralnetworkmodelandVGG 16model.Inourexperiment,theaccuracyofmodelVGG16 with data augmentation improves the accuracy rate inthe betel leaf dataset. Our future direction of work can beproceed on exploring how the model performs on increasingthe disease class, enhance the quantity ofdataset to improvetheaccuracyfurtherontherealfieldimagedataset.

***Abstract*—The design and implementation of a self-service library management system utilizing radio frequency identification are presented in this study (RFID). Radio frequency technology and micro processor technology are combined in RFID. It is intended to take the role of barcode sin library applications in order to enable self-check-in and check-out as well as many other applications, as well as to manage library resources morequickly and efficiently. The use case diagram, which this article pioneers, explains the system's over all purpose and its component parts and enables intelligent management from book reception to book circulation.**

I. Introduction

Newtechnologyisbeingadoptedbylibrarieseverywhereto enhance customer service and speed up the check-in/check-outandinventoryprocedures.Onemethodforcreatingamore time-effective and safe library management system isradiofrequencyidentification(RFID).Theradiofrequencyand microchip-based technology known as RFID (radio frequencyidentification, sorting, and detection) can be used to track,identify, sort, and detect library holdings. It can be used tocreateaself-servicesystemthatenablesuserstoindependently check out and check in things, allowing libraries toinventory and monitor resources more effectively.The initialrequestforRFIDtechnologycamefromBritishmilitaryforcesduring World War Two, who used a primitive translation tocompare friendly and opposing aircraft.In the old age 1973,For welcome inactive state and write tag, Mario W. Carullawasallowedapatent.Asaresultofthisfinding,RFIDtags accompanying entrenched circuits and thought are nowsecondhandinarangeofcivilianuses.RFIDscienceisimmediately used in supply chain administration, athenaeums,andmanydifferentfields.RFIDtechnologyhasstartedtoreinstate the barcoding method in book repositories. In 1991,RFIDwasfirstusedinalibraryattheUniversityofGuelphin Canada. However, allure use in athenaeums has happenedrestricted, with just 3000 athenaeums utilising the electronicsin 2012. When distinguished from barcodes, RFID electronicsprovides a secure and effective system administration means.Thereisnownosystemworkingthattracksundergraduate habit or streamlines the check-in and check-out procedure.Furthermore,skilledisnostockorder,andasaconsequencenocurrent inventory record. This restricts scholars from utilizingthemoneycausefindingnoveltyandwinningrulingclassexaminedontimeisdisputing.Thereserveadministrationmethod proposed in this paper solves these concerns and constitutes a structure namely two together, efficient for graduatesand adept for the area. Students can use bureaucracy to lookfor belongings, check their chance, and check ruling class outwithoutdifficulty.

II. Related Work Introduction

RFID Technology Using RFID (Radio Frequency Identification)isatypeofwirelesscommunicationthatoperatesinthe high-frequency region of electromagnetic frequencies byusing electromagnetic or electrostatic coupling. The workingprinciple behind RFID structure is as follows: the reader sendsan electromagnetic wave energy at a specific frequency to theelectronic tag, the electronic tag is in the RF signal detectionarea,theinducedcurrentreceivesenergy,thelabelissentthe necessary information by the reader through a wirelesschannel, the reader has a receiver to receive the signal sent bythe electronic tag, and the reader reads the information. Thelabel is made up of a chip and a coupling piece, each of whichis encrypted with certain electronic data.The research entailedintegratingtheRFIDtechnologyandcreatingaGraphicalUserInterface (GUI) at the host PC. The project's objective is todevelop an automated library shelf management system thatwillassistlibrariansinmoreefficientlymaintainingtheshelvesand finding any misplaced books on the shelves. MicrosoftVisual Basic.Net was used to construct the interface for thesystem. The exact data for the book must be entered into thedatabase using the GUI. After that, an RFID tag with a ShelfID was created and set up. This code was then utilised by thesystem to scan the selected shelf for any lost books. RFIDtechnology and an online concept are combined to develop aninternet-based application for managing libraries. The entireprocedurethattakesplacewithinthelibraryutilisestheRFIDreader Motorola 10 MC9090. This suitable reader can readtags with any type of frequency, including low, high, and ultrahigh. Each user and each book receives an RFID Tag 107 witha unique EPC (Electronic Product Code) that is produced inconnectionwiththedatabaseforfurtherinformation.[3]

III. System Specifications

A. Interface Requirements

- Front-end: HTML, CSS, JavaScript.
- Back-end: Python, Google Cloud, google sheets, drive API which helped us access sheets using python

DOI: rp-9788770040723.169

B. SoftwareRequirements

- VSCode-IDEwhereeverythingwasperformed.
- Python-UsedasaScriptingLanguage.
- Anaconda - Aims to simplify package management anddeployment.
- gspread-ToopensthecurrentsheetorcreatesanewGoogle Sheet file, read/write the records, in addition, todowithoutadoubtformatting.
- GoogleSheets-Thatactaslocaldatabasestorage.
- ArduinoIDE-Forconnectinghardwarecomponentswiththesoftwarepart.

C. HardwareRequirements

RFID Tags, RFID Reader, NodeMCU, Jumper Wire, RFIDRC522,Breadboard.

D. NonFunctionalRequirements

While the update occurs in real-time, the Database must becorrectly connected to the project. ensuring that the databasequeries are written correctly to avoid breaking any limitationswhile updating. The system must function flawlessly with alargenumberofbooksandusers.Answerstoinformationrequestsmustdisplayonthescreenwithin5seconds.Toavoidillegal access, distinct users must use unique login credentialsthataresafe(givenbyourtags).Theprogrammewill makeuseofasafedatabase.Apartfortheirpersonalinformation anda small amount of additional information, normal users canonly view material; they cannot update it. The system willhave many user categories, and each user will have accessrestrictions.[6]

IV. Library Management System Based On RFID

A. Features of Our System

1) *Security:* Library login: To prevent the students from using the model in an abusive manner, we only restrict the editing access to Library personnel only.

2) *Privacy:* All members can access and read data but only Librarians can have access to make changes. Non-members cannot access the data thus keeping the data of members secure.

B.Architecture

1) *Microservices Architecture:* Microservices are an architectural style that structures the application as a collection ofservices.[7]

- Pros:

  ImprovedfaultisolationEaseofunderstandingSmalleran dfasterdeployments

- Cons:

  CommunicationbetweenservicesiscomplexDebugging problemscanbeharder

D. ResultsandDiscussions

Multipleliteraturepapersweretakenintoconsiderationwhichpavedthewayforthisproject.

- After the implementation we could see book details beingavailable,studentsbeingabletoregisterusingrfidtags.
- Email-Verificationwassenttostudentsregisteringforthefirsttime.
- Student/Teacherwasabletoviewallthedetailsregardingthe booksavailable.
- Adminportalhadalltheaccessibilityalongsidewithregistrationofnewusers.
- RFIDplayedanimportantroleasitwasanecessitytoscanthe usertagandthenthebooktagtoregister.
- Adminwasabletosendmailregardingthefine,duedate.
- Highsecurity,betterperformancewasensuredwiththetagsusage.
- Ithelpedincreatinganautomatedandasmartlibrarysystem.

TEST SCENARIO	OUTCOME	SOLUTION(If applicable)
User Exist	Enters library portal	N.A
User Doesn't Exist	Shows "user not found"	• Admin has to register • User gets rfid tag
Book Available	• visible during search • can checkout	N.A
Book not Available	• during search all available books are displayed	• Admin can add the book if it gets available using rfid tag
Fine functionality 1)working	After 10 days each day will add up 5 rupees as penalty	N.A
Fine functionality 2)Not working	After 10 days each day will add up 5 rupees as penalty	• Admin can access the google sheet where the issuing date is stored and calculate fine.
Checkout (RFID working)	checking out is just one click on the book id	N.A
CheckOut (RFID not working)	can't checkout by using one-click option	• Admin can delete the record from the google sheet which automatically updates the portal
Sending Notification	Admin can send a mail to users by just clicking on their respective mail id.	• email is stored in the sheet
If website crashes	Shows Error	• we have a backup using google clouds and google sheet

Fig.4.ResultTable

E. Conclusion

High security performance, more privacy, improved per-formance, ease of use, and intelligent administration are allbenefitsofRFIDtechnology.

- Traditional library management issues including manuallabour, extensive time commitment, security flaws, andothersareresolved.
- RFID readers and RFID tags should be of good quality,toyieldbestperformance.
- The modern and intelligent library is represented by themanagement system for library administration that wasbuiltwithRFID.
- The only focus of this study was to develop an RFID-based library management system, including the generalform and the hardware and software environment. Thesystemadministrationwasdesignedwiththegoalofincreasingthelibrary’soveralleffectiveness.

F. Futurework

- Providingmisplacementofbooksinformation.
- Anti-Theftfunctionalitycouldbeaddedwhichwouldbe of a very lesser cost when compared to the currentmechanismthatisbeingused.

***Abstract*—The security of single-level authentication as a graphical password entirely depends on confidentiality and strength. Even if graphical passwords are the fine stproxy approach to subdue the weak point soft he text-based password, single-level authentication is not enough to secure our dataain the devices. Hence, Facet Pass a novelmulti-level graphical authentication technique is proposed with an arrangement of 44 of 16 facets with four different colours. This approach in corporates by the process of facet touch, swap and fading an imation (manual) with deep convolutional neural network architecture for facial recognition mechanisms (automatic) which protect from exhaustive attack, technology-based recording, dictionary, and smudge attack. Visual complexity score of Facet Pass measured using Euclidean physical length. The success probability of the brute force attack is calculated based on permutation and combination. An investigation is conducted systematically on the challenges of FacetPass password in both security and usability perspectives with 113 participants of various age groups, and the people are from different educational status. The outcome of this work outperforms well with the usability and security of existing VAP code, CD-GPs, and EvoPass.**

***Index Terms*—facet, swap, fade, facial, graphical password**

I. INTRODUCTION

Many kinds of research are emerging with much authentication technique, but there is no replacement for text passwords with other alternatives to authenticate the user for the past ten years.However,password-basedauthenticationhasitsinherent security vulnerabilities, amongst which password disclosure is a significant security problem that was raised by Long et al. [1]. Text-based passwords leak through numerous attacks, including Ransomware, key loggers, secret cameras, and web accesstiminganalysis.Aspassword-basedauthorizationhasbeen generally used for service industries, online communities and some other useful services, the implications of password leakage might be catastrophic [2]. The Modified ASCII Value (MAV) is created to reinforce the wedges' encryption algorithm to protect a text-based password depending on the ASCII values [3]. Instead of typing text with a keyboard, Luis A. Leiva and Francisco Alvaro developed a captcha; the user retypes a computational statement and resolves it on a touchscreen [4]. Hence, protecting text password is another major complication in thesedays.

The graphical password entry method is sensitive to shoulder surfing threats in which a neighbouring antagonist capturesthe password while entering it on a user interface without anyadvanced recording equipment, such as a secret camera. In thiswork consists, two mechanisms (i) Touch and Swap image-based graphical password and (ii) Facial Recognition authentication. This practice enhances the resistance to shoulder surfing and attacks by brute-force attacks without modifying thepassword frequently like text-based password practices. Usersof FacetPass are required to touch and swap on the fadinganimated facets within the time when it goes invisible. If theuser fails to complete it within the single fading animationtime (standard evolving time and user configured evolvingtime) another two chances are given. The user should waitfor another 30 seconds if they miss all the three opportunities.Facial Recognition is the detection of the legitimate user by thecaptured facial images using the front camera automaticallywith the assistance of an algorithm for a deep neural network.The remaining part of the paper is organized as mentionedbelow, in section 2 the related study is explained briefly withsubtitle of recall and recognition based GPs. Then in section 3 the flow of the proposed FacetPass – a graphical password work is depicted in detail with FacetPass Registration, Facet Touch and Swap and Time-Evolving attribute. Further we analyzed about experimental result of security and usability insection4.Finallyweconcludethepaperinsection5.

II. RELATEDWORKS

A. Recall and Recognition based GPs

Nowadays, graphical passwords are other alternatives for text passwords to authenticate the user. Authentication or identity management is the tool used to allow users to validate their identity with web services. In recent decades, graphical password techniques have gained more publicity as an excel- lent alternative to the text-based password system suggested by Angeli A. D et al. [5]. For those who have a poor vision, this strategy is uncomfortable because their excessive images appear on a small screen.Azad S et al. in 2017 introduced vibration and pattern code in a 2X2 grid [6], Kim Dand Dunphy P [7] proposed Multi-touch 3X3 grid nine circular targets arranged in a system, Tiny-Lock model is proposed by Kwon T and Na s in 2014 [8]. Because of the long-term memory (LTM) issues, Wixted [9] specified

DOI: rp-9788770040723.170

text-based passwords are difficult for users to remember dynamic and unordered passwords over time to handle certain alphanumeric characters. With the enhancement of conventional graphical passwords by merging current input styles such as clicking, choosing the right and drawing, Meng [10] created a Click- Draw oriented graphical password authentication structure (CD-GPs).

A graphical password was developed by Blonder [11] to enable users to click on multiple prescribed regions over an image for identity verification. With the help of attributes and passwords, Jianghong Wei et al. [12] established a two-factor user authentication. Wiedenbeck et al. [13] introduced the authentication scheme of a pass point that allows people to click anywhere on an image to construct the passwords. Chiasson et al. [14] created a cued click points (CCP) structure that allows users to click on a series of images at one position per image.

All graphical based authentication systems may be narrowly divided into four major categories (i) recognition-based model(ii) purely recall-based model (iii) cued-recall-based model and (iv) hybrid model. This proposed FacetPass is designed based on the combination of biometric-based authentication and cued-recall of knowledge-based authentication. Majority of graphical passwords are focused on recognition of given images such as Pass faces and classification and recognition of user-uploaded images which are described by Hayashi E et al.[15].

III. PROPOSEDMETHODOLOGY

A. FacetPass: A Graphical Password -Overview

Facet means one of the tiny flat surfaces cut on a whole object, and these facets of an entire image utilized for touch and swap. In this paper, Facet touch-swap with facial recognition evolves as a new conglomerate graphical passwordfor increased usability and robustness. FacetPass incorporates recall and biometric techniques to provide all mobile devices, apps and websites with a distinct type of password. It offers several resilience measures against different attacks. Here legitimate users are required to touch and swap of the facet in the grid along with facial identification of the user for the authentication purpose.

The facial recognition task is done by the device with the set of user's face images with multiple angles to train the min the registration.Fig.1 reveals the details of this proposed scheme. This paper connects the technical contribution of facet touch, swap and fading animation with facial recognition to solve an existing problem in a graphical password. To avoid spoofing attack and to strengthen the security of a graphical password, users facial feature recognition is added in thi swork.

FacetPass Registration The subsequent actions are necessary for the password registration process. The user should touch on the facets that he wishes to swap in the first step. Even though the user swaps two facets, the initial facet alone gets the touches. In the second step, the user is swapping facets during the fading out animation. In the next step user's face is captured automatically by the device in the facet's background at the same time. The same steps follow at the authentication process as well.

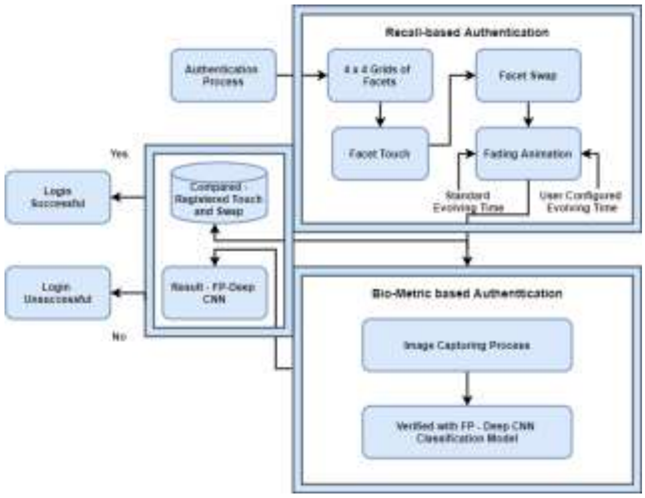

Fig. 1. Authentication process of FacetPass

B. Facet Touch andSwap

Within this proposed report, we developed an innovative method of user authentication via a grid of 16 facets in four different colors. For creating the password, the user needs to do several consecutive touching and swapping of facets on the grid. Fig.2 shows a graphical password scheme, a grid with arrangements of 16 facets and various instances of image capturing process by the legitimate user and other users. In the first level of authentication, the user needs to do a single touch or multiple touches with facet swapping, and in the second level, the system automatically capturing the image of the person who swaps the facets to validate the person is permissible or not. While login, if users sequence of touches, swaps and facial features match with the registered data, the access is acquired by the user, otherwise the access is denied. Hence, the user should provide the registered touch and swap sequence with facial features to get authentication.

Fig. 2. Avarious instances of FacetPass: i) Initial FacetPass without user image. ii)Swap instance with fading animation. iii) Visible swapped Facets with capturedimage.iv)Aninstanceofvisiblenon-swappedFacetswithcapturedimage.

C. Time-Evolvingattribute

FacetPass is using fading animation to have a more shoulder surfing resilient model by reducing the possibilities of identifying the target facets. This facet animation starts losing its original colour, at one particular point of time it becomes invisible (hidden). The user can change the progress time of facets fading and hidden duration on their

DOI: rp-9788770040723.170

own for strengthening shoulder surfing resilient. In pure standard evolving time, fading and hidden time are fixed that cannot be altered by the user. In pure user config evolving time, user set both fading and hidden time. In a combination of standard and user config evolving time, either user can change the fading time or invisible time as given in Eqn 1, 2, 3 and 4. We conducted an experiment with a different age group between 21 and 70, and Table 1 shows the observedresult.

$$\phi_s (1) = £_{sf} + £_{si} \quad (1)$$

$$\phi_u (2) = £_{uf} + £_{ui} \quad (2)$$

$$\phi_{su} (3) = £_{sf} + £_{ui} \quad (3)$$

$$\phi_{us} (4) = £_{uf} + £_{si} \quad (4)$$

1) Φs(1purestandardevolvingtime
2) Φu(2pureuserconfigevolvingtime
3) Φsu (3 , φus (4 combination of standard and user config evolvingtime.
4) $£_{sf}$- standard fadingtime.
5) $£_{si}$- standard hiddentime.
6) $£_{uf}$- user config fadingtime.
7) $£_{ui}$- user config hidden time.

TABLE I: THE PERCENTAGE OF USERS FOR EVOLVING TIME SETTING

Age	$\phi_s(1)$	$\phi_u(2)$	$\phi_{su}(3)$	$\phi_{us}(4)$	Total user
21 - 30	1%	91%	5%	3%	99%
31 - 40	11%	78%	6%	5%	89%
41 - 50	23%	57%	12%	8%	77%
51 - 60	34%	33%	22%	11%	66%
61 - 70	55%	21%	15%	9%	45%

IV. EXPERIMENT ANALYSIS - USABILITY AND SECURITY

Hackersusevarioustechniquestocrackpasswords.Inthissection, the most common prevailing cracking schemes are tested with FacetPass and described below. Table 2 indicates the evaluation of the space for password of proposed and related schemes while it is applied in mobile devices. It shows that intruders must dissipate more duration to find the correct count of touch and swaps. In Evopass, Selection of pass images from their private image increases the difficulty of mounting dictionary attacks [16]. In Facetpass, user's face capturedbyacameraofthedeviceautomaticallythathelpsto improve the ability to withstand against a dictionary attack. As a result of this experiment, we came to know most of the users selected 3-6 facets for their registration which increases the difficulty to crack the passwords with limited possibilities.

A. Touch and swap operations

The participants are classified according to their age and designation. Table 3 and 4 shows information about the number of touch and swap based on their age and category. The younger participants used a large number of tapsand swappingcomparewiththeagedpeople.Theparticipant'sages from 21 to 30 and 31 to 40 used 4-9, 3-9 touches and 5-9, 3-7 swapsrespectively.Ontheotherhand,elderparticipantsuse3-4 taps and 3-5 swapping. In the designation category, students use 4-9 touches 6-9 swapping, and the senior people use 3-6 and 3-5 touches and swaps respectively. When compare with students, elder participants are not comfortable with touchand swapping in smart devices. The result of this experiment concludes that the number of taps and swaps usage varies for different age group anddesignation.

TABLEII EVALUATION OF PASSWORD SPACE

No of Touches	[illegible]	Password space for Facet Touch	Password space for Facet Touch with Swap	VAP Code	Android PL
1	10^1	16	256	40	9

TABLE III: TOUCH AND SWAP OPERATIONS BASED ON AGE.

Age	No. of Touches	No. of Swaps
21 - 30	4 - 9	5 – 9
31 - 40	3 - 9	3 – 7
41 - 50	3 - 6	3 – 6
51 - 60	3 - 4	3 – 5
61 - 70	3 - 4	2 – 3

TABLE IV: TOUCH AND SWAP OPERATIONS BASED ON DESIGNATION

Designation	No. of Touches	No. of Swaps
Students	4 - 9	6 – 9
Teachers	4 - 8	5 – 8
Officers	5 - 7	5 – 9
Home Makers	3 - 8	5 – 7
Senior People	3 – 6	3 – 5

V. CONCLUSION

FacetPass, a novel graphical password to increase authentication for a user to gain access to a device, application or website in smart devices is proposed. To raise the password space and avoid attacks such as Brute-force assault, guessing, shoulder surfing, smudge and dictionary attacks, it incorporates recall and biometric-based GP. This proposed system is easy to use and recall than existing graphical password systems, and the user can handle facets for touch and swap manipulation effortlessly. A lab experiment was conducted with 113 participants to calculate time consumption and usability of FacetPass in diverse angle. Thus the result shows that this FacetPass is secured and user - friendly. In future, we are interested to construct this FacetPass working against spoofing attack with the standard algorithm.

***Abstract*—Electroencephalography is a non-invasive technique used to monitor brain activity and make a variety of neurological problems diagnoses. The electrical activity of the brain is measured using an EEG instrument, which converts chemical variations in the brain into voltage. With either the intracranial EEG method or the Scalp EEG approach, several electrodes are implanted at the right location on the brain to measure EEG signals. Analysis of electroencephalograms, or EEGs, has grown to be crucial for identifying many human disorders. The most crucial and straightforward step in processing EEG readings is using temporal frequency analysis to make a potential diagnosis. EEG signals are the important data for any type of analysis of brain activity. In this study, we first analysis the EEG signal characteristics that have been used in the literature for a variety of activities, then we concentrate on looking at EEG feature applications, and finally we talk about the potential and unresolved issues with EEG feature extraction. Everyone should assess the wide variety of EEG signal properties and their effects on BCI interfaces in order to improve the accuracy of different brain activity detection in the future.**

I. INTRODUCTION

The mass of nerve tissue that is known as the brain may be found in the frontal region of an organism. This mass is comprised of three different parts: the cerebrum, the cerebellum, and the brainstem[1]. The **human brain** is responsible for integrating sensory information and coordinating the activities of the muscles. The human brain is comprised of millions of neurons, each of which plays an important role in the process of controlling how the body reacts to both internal and external motor and sensory impulses. These neurons will serve as units for the flow of information between the body and the brain.

The signals that are produced by an electroencephalogram (EEG) are a representation of the electrical activity that occurs in the brain. Electroencephalography is a software program that may objectively link particular electroencephalographic (EEG) patterns to the activities of the central nervous system (CNS)[2], in addition to dysfunctions and disorders. The electroencephalogram (EEG) is a valuable modality that allows for the collection of brain signals related to a variety of states directly from the surface of the scalp.

EEG waves are the single most important source of information that can be used for successful detection. A feature is a distinguishing characteristic, a measurable quantity, and a functional element that is derived from a component of a pattern[14]. In the strictest sense, a feature is derived from a pattern piece. EEG signals are the singleimportant source of information that can be utilized in the detecting process.

It has always been difficult to identify cross-subject emotions based on brain imaging data, such as EEG, due to the poor generalizability of features across different people. This is especially true of electroencephalogram (EEG) data. As a result, it is essential to conduct in-depth research on the degree to which different EEG metrics may differentiate between the emotional information of different people.

A distinguishing characteristic, a measurable quantity, and a functional element produced from a section of a pattern are all examples of features[3]. The purpose of extracted features is to minimize the amount of significant signal-embedded information that is lost. In addition to this, they cut down on the number of resources that are needed to accurately describe a large amount of data. This is necessary in order to remove the possibility of requiring information to be compressed, to reduce the cost of processing information, and to simplify the implementation process. In recent years, several methods, including wavelet transforms (WT), time frequency distributions (TFD), Eigenvector methods (EM), Fast Fourier Transforms (FFT) and auto regressive methods (ARM), have gained popularity in the process of extracting features from electroencephalogram (EEG) recordings. The analysis of EEG signals has been the subject of a significant number of studies. EEG signals make it feasible to perform an examination of the brain activity of a person in real time.

In the past, determining an acceptable EEG characteristic was an essential aspect of the investigation of this phenomenon. This research presents a mathematical approach to the problem of extracting features from EEG data. It focuses specifically on the extraction of features from EEG signals.

II. TIME DOMAIN FEATURES

EEG is a time series signal which is a function of amplitude of electrical activities of the neurons and time [19] . EEG signals can be analyzed in various domains like Time, Frequency and time-frequency. Time domain features are extracted from the EEG signal by time domain analysis. The time domain features can be extracted from raw or preprocessed EEG signals. This time domain features extracted from EEG signal is highly relevant to describe the mental states of the person under study. Time domain feature are quick at easy to extract from the EEG signals. Time domain analysis consist lower computational complexity compared with frequency and time-frequency domain analysis. Time domain features are extensively used in medical and engineering research, since these features do not require any complicated transformation and

DOI: rp-9788770040723.171

easy to implement. time domain features are widely used because of the classification effectiveness in low noise situation. The major drawback of the time domain features is , it assumes the EEG signal as a stationary signal. But in reality EEG signals are non-stationary signals (varying with time) .

Simplest time domain features are mean, median, variance, standard deviation, kurtosis, skewness which are statistical in nature. The linear time domain features are mean amplitude, peak amplitude, RMS amplitude , peak to peak amplitude , wave form duration and zero crossing rate. The non-linear time domain features are fractal dimension, correlation dimension, sample entropy, approximate entropy, Hurst exponent, Lyapunov exponent , fuzzy entropy etc., In this paper we are discussing briefly some of the popular time domain features

Various Features

2.1.Mean

Mean is the average of the values of all data points of the signal[4].

$$\mu = \frac{1}{N}\left[\sum_{i=1}^{N} x_i\right] \tag{1}$$

2.2Median

Median is the middle value of a signal data when all the values are arranged in ascending or descending order.

Median

$$= \begin{cases} x\left(\frac{n+1}{2}\right), if\ n\ is\ odd \\ \frac{x\left(\frac{n}{2}\right)+x\left(\frac{n}{2}+1\right)}{2}, if\ n\ is\ even \end{cases} \tag{2}$$

2.3 Variance

Variance is a measure of dispersion of the signal data.It is the average of the squared differences from the mean.

$$\sigma^2 = \frac{1}{N}\left[\sum_{i=1}^{N} (x_i - \mu)^2\right] \tag{3}$$

2.4 Standard deviation

The standard deviation is a measure of how the data is spread out from the mean value and is computed as the square root of the variance. A high standard deviation indicates that the signal data are widely dispersed from its mean value[5], while a low standard deviation indicates that the signal data are nearer to the mean value

$$\sigma = \sqrt{\frac{1}{N}\left[\sum_{i=1}^{N} (x_i - \mu)^2\right]} \tag{4}$$

2.5 Skewness

Skewness is a statistical feature which measure the degree of asymmetry of a distribution. positively skewed or right skewed distribution has a long right tail which indicating an excess of low values. Negatively skewed or left skewed distribution has a long-left tail which indicating an excess of high values.

$$SKew(x_i) = \sqrt{\frac{\frac{1}{N}\left[\sum_{i=1}^{N} (x_i - \mu)^3\right]}{(\sigma^3)}} \tag{5}$$

2.6 Kurtosis

Kurtosis describes the shape of the distribution of the signal data[7][11]. Datasets with high kurtosis tend to have a high peak (more values) near the mean, decline rapidly, and have heavy tails. Datasets with low kurtosis tend to have a low peak or flat top (less values) near the mean, decline gradually and have light tails

$$kurt(x_i) = \frac{N\left[\sum_{i=1}^{N} (x_i - \mu)^4\right]}{\left[\sum_{i=1}^{N} (x_i - \mu)^2\right]^2} \tag{6}$$

2.7Zero-crossing rateZCR

The zero crossing rate (ZCR) measures how many times the waveform crosses the zero axis[8][10]. In other words, it is the number of times the signal changes value, from positive to negative and vice versa. It can be obtained counting how many times both following conditions are fulfilled for a signal X(t):

$$\{X(t)<0 \text{ and } X(t+1)>0\} \text{ or } \{X(t)<0 \text{ and } X(t+1)>0\},$$
$$|X(t)-X(t+1)| \geq \epsilon, \tag{7}$$

whereϵ is a threshold to avoid miscounting zero crossing due to noise.ZCR can be interpreted as a measure of the noisiness of a signal

2.8Peak amplitude

The peak amplitude of a sinusoidal waveform is the maximum positive or negative deviation of a waveform from its zero reference level.

Peak Amplitude = $max[X_n]$ (8)

2.9Peak to peak amplitude

Peak to peak amplitude is the difference between maximum value (positive amplitude) and minimum value (negative amplitude) of the signal x(n).

DOI: rp-9788770040723.171

Peakto peak = $max[X_n] - min[X_n]$ (9)

Hjorth parameters

2.10Activity

Activity gives a measure of the squared standard deviation of the amplitude of the signal. [9][15[[16][17].High value activity indicates higher frequency components presence and low value activity indicates the presence of lower frequency components.

$$\text{Activity} = variance[x(t)] \quad (6)$$

2.11 Mobility

Mobility is calculated as the ratio of the standard deviation of the slope of the signal to the standard deviation of the signal, expressed per unit of time.

$$\text{Mobility} = \sqrt{\frac{variance[x^1(t)]}{variance[x(t)]}} = \sqrt{\frac{variance\left(\frac{dx_i}{d_t}\right)}{variance x_i}} \quad (7)$$

2.12 Complexity

The measure of complexity of a signal is determined by its similarity to a pure sine wave. This measure is calculated as the number of standard slopes generated during the average time it takes to generate one standard amplitude.

$$\text{Complexity} = \frac{mobility[x^1(t)]}{mobility[x(t)]} = \frac{mobility\left(\frac{dx}{dt}\right)}{mobility(x)} \quad (8)$$

2.13 K-complex

K-complex is a distinct pattern in an EEG signal, consisting of a sharp negative waveform immediately followed by a positive component , with a total span of at least 0.5 seconds[6].

2.14 Energy E

Energy is the total of the squared magnitudes of all the components of a signal [12][13].

$$\text{Energy} = \sum_{i=1}^{N} |x_i|^2 \quad (9)$$

III. Materials and Methods

3.1Subjects and Data Acquisition

The EEG data is acquired from the 10 healthy yoga practitioners from different age groups.The group of yoga practitioners , who practiced yoga daily for 3 years (Surya namaskar,Asanas:Tadasana, vrikshasana,paschimottanasana,ustrasana, Mudras : chin mudra,Pranayama: Nadisuddhi)were compared with a group with no experience in yoga. Group of yoga practioner (4 F, 6 M) between 22 to 47 years old and group of non practioner (5 F, 5 M) between 21 to 52 years old participated as the study subjects. The subjects are 6 students, 5 unemployed, 9 in technical, professional and white collar occupations. The subjects had no history of any type of mental disorder and none of them take any medical treatment. The experimental procedure was clearly explained to the subjects.

3.2 EEG Recordings

EEG recordings were taken from the subjects using a 18channel RMS with a sampling frequency of of 256 Hz in aa electrically shielded room. The AC frequency of 50 Hz. Was eliminated by a line filter.The arrangement of active electrode on the scalp (FP2-F4, F4 -C4 ,C4 -P4, P4 -O2, FP1-F3, F3 -C3, C3 -P3,P3 -O1 , FP2-F8 , F8 -T4 , T4 -T6 , T6 -O2 , FP1-F7 , F7 -T3 , T3 -T5 , T5 -O1) according to the International 10-20 system of electrode placement, referenced to the linked ear lobe electrodes. The recorded duration for each subject in both groups is 2 minutes. During the entire duration of these experiments.subjects were entirely relaxed in an awake state with eye closed throughout the entire duration of this experiment. The subjects were seated in normal position. The real time signals obtained from the subjects are non-stationary, random and non-linear. The data acquired from these methods were further pre-processed for removing noise.

IV. RESULT

The EEG data waves has been analyzed in both yoga and non yoga conditions and the result shown below.

IV. CONCLUSION

Using a wide range of approaches, the purpose of this study was to evaluate the time domain properties of the EEG signal. They are consequently helpful in identifying whether an EEG signal possesses random oscillations, periodicity, or synchronicity. By analysing the EEG signals' temporal domain features, researchers are able to identify irregularities in the signals themselves.

An examination of the time domain aspects of the EEGs of non yoga and yoga practitioners is planned for a later stage of this research project. It is possible to identify the important aspects that have been influenced by yoga and meditation.

***Abstract*—This review paper examines the development of distributed Photo Voltaic (PV) systems for rural communities in Ghana. The paper provides a review of the present situation of distributed PV systems in Ghana, highlighting the benefits and challenges associated with their implementation. The review draws on several key studies, which analyse the policy landscape, the potential for co-benefits, the barriers to development, and the economic feasibility of distributed PV systems. The findings indicate that while distributed PV systems offer numerous benefits, including increased access to electricity and reduce carbon emissions, there are several significant barriers to their development, including financial constraints, limited private sector involvement, and unfavourable policies. The review concludes by suggesting that further research is needed to explore innovative financing mechanisms, effective policy frameworks, and improved public-private partnerships, which could accelerate the deployment of distributed PV systems and improve energy access for rural communities in Ghana.**

Keywords—PV system, Rural electrification, Energy policy, Ghana, Distributed system

I. INTRODUCTION

The SDG #7, which aims to provide access to energy to everyone [1-4]gives distributed renewable energy technologies a fresh push as a means of supplying energy to millions of households by 2030, notably in Sub-Saharan Africa (SSA)[5]. One of the exceedingly significant drivers for a country's socioeconomic and industrial development is the ability to obtain and use electricity. However, in many developing countries, a significant percentage of the population does not have the means to obtain or use electricity, and conventional grid-based solutions are often not feasible because of the expensive and challenging nature of expanding the electricity distribution system to isolated locations [6]. It is believed that most of the places in the world lacking electricity are in underdeveloped areas [7]. 572 million of the 733 million people around the world who lack the ability to obtain or use electricity are Africa's population [2][8]. Ghana has taken notable steps forward in enhancing the availability of electricity to its population, with an overall access rate of 86% [2], which is noted as few of the top electricity systems in the Sub-Saharan African region. But there is a notable variation between urban electrification access rate at 94.7% and rural access rate at 74% [8-9].

The lack of electricity is generally due to a variety of factors such as lack of power, challenging terrain, and inadequate transportation. Technologies that generate energy from renewable sources, such as PV systems offer a promising solution to this problem. Over the past few years, there has been a growing concern in establishing decentralized PV systems for rural areas in Ghana [10-11].

By bridging the access gap and offering lower prices and faster connection times than grid additions, stand-alone solar systems offer a possible approach to electrifying rural communities.In general, a mini grid consists of three components: a power generation system, a distribution network that delivers electricity to remote users, and an energy storage system designed to store excess power. Mini grids can operate autonomously and deliver power, especially to those with limited access to them in remote or rural regions, using one or more generation sources (hybrid systems) [12]. It covers solar residential systems, solar microgrids and solar mini grids. But the use of technologies like these as primary means of electricity in many nations are rare, and adoption of them, particularly in rural areas, is moving slowly [13].

Within this article, the development of distributed PV systems in remote areas of Ghana will be reviewed in this study along with its present research status. To commence, a concise outline of the energy landscape in Ghana, with a focus on the issues encountered by rural communities in obtaining access to electricity will be presented.Ghana's energy sector is dominated by hydropower and thermal power generation, with the country currently facing challenges of insufficient power supply, high cost of electricity, and unreliable electricity access, particularly in rural areas[14].

Literature will then be reviewed on the socio-economic, political, and environmental factors that influence the acceptance and use of PV systems in remote regions. Specifically, the study also will examine the impact of government policies and regulatory frameworks on the success of PV projects in rural communities. Several studies have highlighted the importance of favorable government legislations and regulations to facilitate the implementation of RE technologies, including PV systems [15]. The barriers

DOI: rp-9788770040723.172

to distributed PV systems for rural communities will also be discussed.

II. Literature Review

A. Electricity situation in Ghana

The growth of Ghana's total electricity generation capacity, including distributed generation, from 2,170 MW to 5,481 MW in 2011 and 2021 respectively, representing a yearly increase of 9.7%. Additionally, the dependable capacity exhibited an annual growth rate of around 9.8%, surging from 1,945 MW to 4,975 MW in 2011 and 2021 respectively.

Figure 1 displays a significant 14.3% yearly growth rate in the installed thermal generation capacity, which soared from 990 MW in 2011 to 3,753 MW in 2021.In contrast, the installed capacity of grid-integrated renewable sources rose significantly, surging from 23 MW to approximately 144 MW in 2016 and 2021 [16].

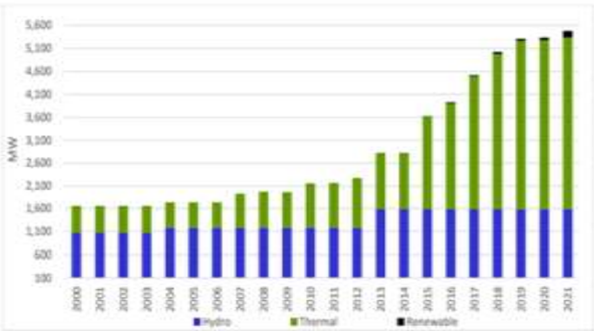

Fig. 1. Installed Generating Capacity (2000-2021) [16]

B. Solar Energy Resource Potentials and their Relevance for distributed PV system development

Ghana possesses significant solar resources and has the potential for the generation of solar power through either grid-connected or independent (off-grid) systems. Ghana's solar energy potential is estimated to be 35 exajoules (EJ), this solar potential in Ghana 100 times greater than the country's current electricity demand. According to the Ghanaian government, the average amount of solar radiation received per day ranges from 4.4 to 5.6 kWh/m2/day monthly[18]. Kumasi, which is situated in the foggy semideciduous woodland zone, experiences sunrise at 5.3 hours, while the sun sets at 7.7 hoursin Watts, Ghana [18-19], situated in the dry Savannah territory. The Upper West, part of Volta, Northern and Bono Ahafo regions receive monthly average radiation of 4-6.5KWh/m2/day, except for rain from July to September and hot, dry Harmattan winds from November to February. The areas of Brong-Ahafo, Ashanti, Western, Eastern, and some parts of Central and Volta regions in Ghana experience a mean monthly solar radiation ranging from 3.1 to 5.8 kWh/m2/day. Conversely, areas such as Greater Accra, the coastal regions of Volta, and other parts of Central Ghana receive a monthly average solar radiation of 4.0 to 6.0 kWh/m2/day, as indicated by [19], [20]. The solar resource map of Ghana is depicted in Figure 2. Given that the daily solar radiation within the country ranges from 4.0 to 6.0 kWh/m2 annually, generating solar PV power presents an encouraging opportunity to enhance the nation's electricity supply security, as noted by [21]. However, developing this resource for PV systems has received little attention until recently.

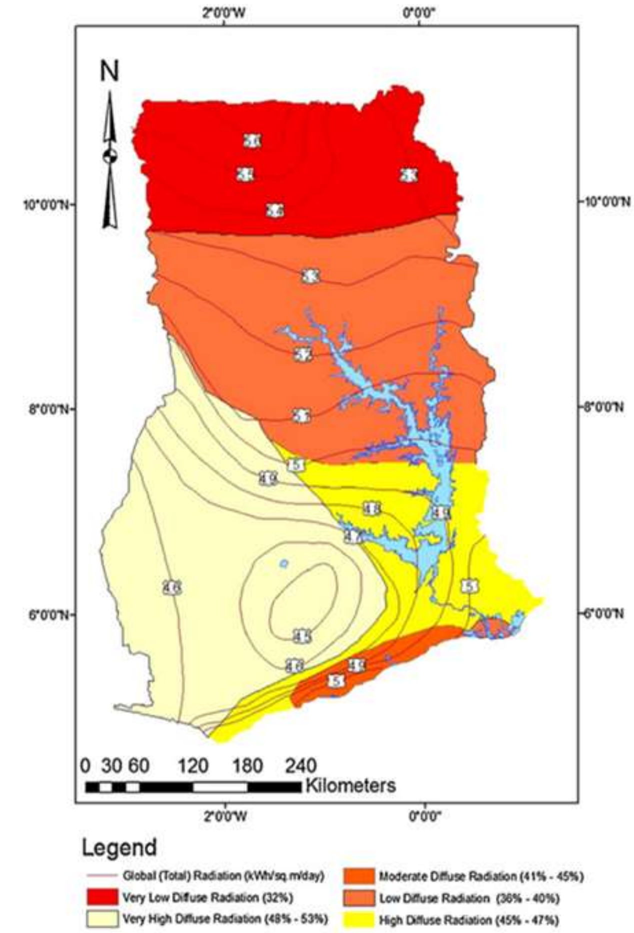

Fig. 2. Solar Resource Potential map of Ghana [18], [20], [30]

Given that Ghana experiences an annual daily solar radiation range of 4.0 to 6.0 kWh/m2, it can be inferred that solar PV power generation holds great potential as viable option to enhance the country's energy security [18], [20-21], [23] . However, this potential has been underutilized until recently, with little attention paid to developing PV systems. Therefore, various stakeholders, particularly the government, are now making efforts to leverage this resource by promoting decentralized solar PV projects such as standalone PV to facilitate the supply of electricity.

C. Ghana's Solar Power Development Status

A target of incorporating 10% RE into the nation's energy mix is stated in Ghana's RE Act and RE Master Plan. The RE Act indicated that hydroelectric dams with a capacity of 100MW or less are considered as renewable energy sources. However, presently, Ghana has not established any wind energy power plants or other renewable energy facilities. Therefore, at present, the country's renewable energy mix solely relies on solar energy[24].

Solar photovoltaic (PV) energy is produced using Photovoltaic (PV) systems that utilize solar energy are connected to either on-grid or off-grid systems. The Volta River Authority (VRA) commissioned the initial installation of a 2.5 MW solar PV system on a large scale in Ghana in May 2013 located at Navrongo in the Upper East region

DOI: rp-9788770040723.172

Ghana[25]. Additionally, there are several other solar power installations in Ghana, including a capacity of 40 MW plant located at Onyandze, in the Gomoa East District of the Central Region of Ghana.The plant is co-owned by BXC Company and Meinergy Technology, with each enterprise being accountable for 20 MW of the plant's capacity. In addition to those, there is a 6.5 MW capacity PV system situated in Lawra, a 13 MW capacity PV system located in Kaleo all in the Upper West region of Ghana, a 51 MW capacity plant positioned in Bui, and a 30.9 MW distributed generation plant that is built and operated by state-owned electricity companies[17]. Numerous projects are currently underway throughout Ghana. One example is the second phase of the Kaleo project, with an expectation to generate 14 MW of power when completed. Additionally, plans are underway to construct an additional 200 MW capacity solar plant in the northern part of the nation. Another significant project is the ongoing 59 MW solar component of the Pwalugu Hydro-Solar hybrid plant, which is set to be finalized in 2025. [17], [25], [26]. In addition, more than 89 communities in Ghana have received thousands of small-scale solar systems with a total capacity of 793 kW. These systems have been used for a variety of things, like refrigerators for vaccines, street lighting, radios, television sets, and remote mobile phone charging systems. In addition, there are several installed PV systems for residential and commercial purposes either for main electricity or backup application in Ghana not assessed and documented[27], [28].

TABLE I. ADVANTAGES AND DISADVANTAGES OF PV SYSTEM [30]

S.No.	Advantages	Disadvantages
1	The source of fuel is abundant, easily available and virtually limitless	The cost of installation is expensive
2	The cost of operation is minimal (no need for fuel)	Solar panels do not produce electricity at night, and areas with high cloud cover may have inconsistent and uncertain power generation during the day
3	It can be quickly installed at almost any location where it is needed	The absence of cost-effective and efficient energy and storage
4	The environmental impact is minimal because there is less air pollution and fewer greenhouse gases emitted	Photovoltaic cells rely on scarce elements that could face rising costs and limited availability
5	The cost of operation and upkeep is comparatively low	They need a considerable amount of space to generate only small quantities of energy

D. Classification of PV nano/micro/mini-grids

The International Renewable Energy Agency (IRENA) has classified grid systems into five categories based on their maximum capacity, capability, and complexity. These categories include stand-alone systems, pico-grids, nano-grids, micro-grids, and mini-grids. Each of these categories serves a different purpose, ranging from providing power to a single device to meeting local demand with local production. The classification considers various factors such as voltage, pricing, and interconnectivity. In this way, the IRENA classification provides a useful framework for understanding the different types of grid systems and their capabilities in meeting energy demands in various contexts [31].

Stand-alone systems have a maximum capacity of 0.1 kW and are generally used to provide power to a single structure or a single device.Pico-grids have a maximum capacity of 1 kW and are controlled by a single entity responsible for overseeing their operation.Nano-grids have a maximum capacity of 5 kW and are designed to provide power at fixed or specific voltages. Grid operators negotiate with each other to buy or sell electricity and these systems can be interconnected or stand-alone. Direct current (DC) systems are favoured in these types of grids.Micro-grids have a maximum capacity of 100 kW and are designed to balance local energy consumption and production. They offer a range of voltages and different levels of quality and reliability options. These systems incorporate generation and can offer varying pricing.Mini grids have a maximum capacity of 100,000 kW and are designed to meet local demand with local production. Transmission is limited to 11 kV and customer connections are available.

E. Ghana's Renewable Energy Development Policies

Ghana’s renewable energy policy is closely linked to its policy goals, as set out in its renewable energy frameworks, as well as its policy institutions and policy instruments. The first step in achieving meaningful progress in renewable energy adoption is to align with these policy areas, as stated by [32][33].

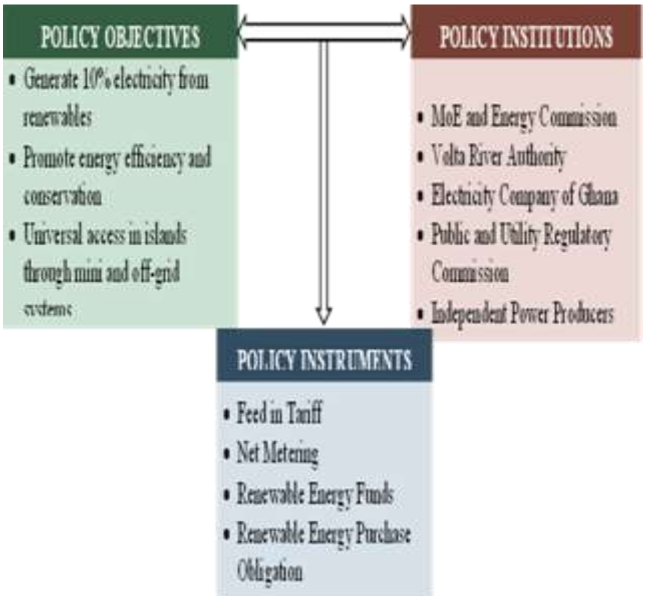

Fig. 3. The procedure of formulating renewable energy policies in Ghana [34]

F. The Renewable Energy Act

The Energy Policy paper of 2011 resulted in the enactment of a law (Act 832) that authorized Ghana's energy

DOI: rp-9788770040723.172

sector institutions to develop plans for integrating renewable energy sources into the country's electricity generation mix. It sought to achieve a target of generating a minimum of 10% of Ghana's electricity from RE sources by 2030, which marked a turning point in the energy mix of Ghana. Eventually, the Act has been amended to clarify its provisions and encourage greater private-sector involvement in achieving the 2030 target. As part of these amendments was the adoption of the 2019 Renewable Energy Master Plan (REMP), and the Renewable Energy Authority (REA) was established, with the Bui Power Authority (BPA) currently responsible for carrying out its duties under the Ministry of Energy's amendment to the Bui Power Act in 2020. The BPA now has the legal ability to carry out state-sponsored renewable energy projects, pursue its independent RE initiatives, and investigate clean alternative energy. All these actions will help the government's efforts to include RE sources into the energy mix.

G. Renewable Energy Master Plan

Even though the RE Act was passed to encourage the incorporation of regenerated electricity sources into Ghana's energy mix, it alone was insufficient to achieve the objectives and targets set for 2020, which were postponed until 2030. the REMP 2019 was introduced to bridge this gap by providing a detailed integrated plan and funding commitment and set policies for sustained growth and improvement of Ghana's RE resource potentials. Along with promoting renewable energy technologies to achieve the 10% target, the plan also prioritizes the socio-economic impact on areas without access to grid extension and aims to reduce climate change's harmful impacts by 2030. Ghana, as a participant in the Paris Agreement and other global agreements, has established these policy frameworks and plans as part of the country's Nationally Determined Contribution (NDC) of UNFCCC, to have a minimum of 10% of the country's electricity generation come from renewable sources by 2030.

H. Renewable Energy (Solar PV Mini-Grid) Policies and Institutions

Ghana's renewable energy strategy is cantered on policy incentives and flexible regulations to encourage collaboration between investors in the RE field. The regulations include the renewable energy purchase obligation, net metering, renewable energy funds (REF), and feed-in tariff, which are enforced by the Energy Ministry and the Commission of Energy to ensure that energy policies are implemented at lower levels of government. Independent Power Producers act as investors, technology developers, and renewable energy source producers, and they must adhere to a tariff threshold set by Public Utility Regulatory Commission (PURC) to prevent consumer exploitation. The Commission of Energy monitors the net metering process when the IPPs feed power produced into the grid. Although these regulations do not apply to micro-grids in remote and island communities, the PURC still controls the tariffs. Additionally, Bui Power Authority and Volta River Authority have been instrumental in driving renewable energy in Ghana by developing and managing some stand-alone solar photovoltaic and mini grids in remote areas and island locations across the country.

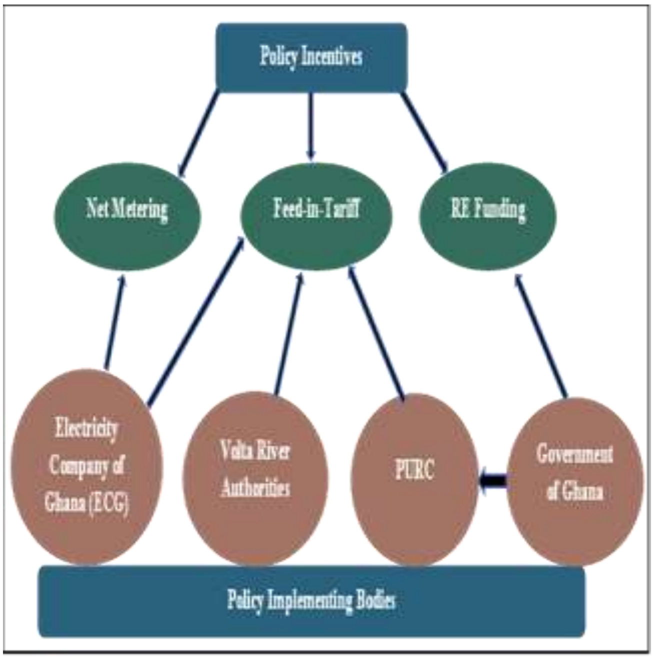

Fig. 4. Renewable Energy Policy Initiatives and Implementing Authorities [33]

The Ghanaian government's policy framework for mini-grid development and operation is an integral component of the National Electrification Scheme (NES) targeted at achieving universal electricity accessibility by the year 2030. In the public sector, the management of the policy framework for mini-grid development differs somewhat from that of the private sector. Public utilities are responsible for generating, operating, maintaining, and collecting revenue for mini grids in island locations on the Volta Lake, mainland communities within the Electricity Company of Ghana's concessional area, and mainland communities within the Northern Electricity Distribution Company's concessional area. Private sector involvement is limited to engineering, procurement, and construction (EPC) activities. The Public Utility Regulatory Commission (PURC) sets a uniform tariff rate for public utilities under Section 20 of the PURC Act (Act 538) but establishes a price threshold for private developers and operators to adhere to.

Act 832 states, it is illegal to set up or operate a mini grid that supplies electricity to anyone in any part of the country without being licensed or having a permit issued by the Energy Commission's Board. If a mini-grid's capacity is greater than 100kW but less than 1MW, it must obtain a license, whereas permits are required for a stand-alone grid with a capability of up to 100kW. Applicants need to obtain a license when they expand beyond 100kW. These permits ensure compliance with the country's environmental and spatial standards. Additionally, the Ancillary Service Charge, as a part of the Master Plan for Renewable Energy (2019), is used to support the capital cost of mini grids via the Renewable Energy Fund, which helps to apply the uniform tariff set by the PURC effectively. These policy objectives, institutions, and instruments are essential components of plans to promote private sector participation in RE development, particularly Solar Photovoltaic mini grids.

TABLE II. SUMMARY OF KEY LITERATURE WORKS

Study	Author and Date of Publication	Methodology	Findings
Support for solar energy policy development in Ghana	D. Atsu et al, 2016[30]	Policy Analysis	• The security of Ghana's energy supply is seriously threatened by its reliance on imported energy to make up for local conventional fuel shortages, making it vulnerable to outside pressures. • The objective of Ghana's Act 832 is to improve the affordability of renewable energy technology and promote the adoption of decentralized off-grid optional technologies, such as solar PV, in regions where they can rival traditional electricity delivery. • To promote the widespread deployment of Solar Photovoltaic Systems in Ghana, major efforts must be made to train highly competent employees with intermediate-level experience.
Multiple advantages of Solar PV systems in remotes areas of Ghana	J. T. Nuru et al, 2021[35]	Climate Compatible Development	• Solar mini-grids have the potential to promote development and combat climate change, but politicians and development partners have not yet acknowledged this. Similar to this, academic debates have not sufficiently demonstrated the advantages of solar stand-alone grids for remote areas. Recognizing the many advantages of solar PV can spur interest in their implementation, and help save money by preventing the need for several projects to accomplish the same goals. • When a single project is implemented, it is possible to reap many benefits and entice investment from donor organizations.
Ghana's renewable energy development and deployment challenges: developer viewpoints	Mahama et al, 2021[36]	Prepared questionnaires using a barrier scale of 1-5	• The primary challenge in the renewable energy sector was identified as the high cost of financing, with a rating of 4.13 out of 5, due to high-interest rates. • • Inadequate motivation for renewable energy developers was another significant obstacle, with 3.93. Grid limitations, currency volatility, inadequacy of incentives, a lack of technical expertise, and inadequate training facilities are some other obstacles to RE development and implementation. • • The government of Ghana should establish a specific set of subsidies and financial incentives aimed at supporting the expansion and effective implementation of renewable energy projects throughout the country.
Lessons from Ghana for expanding solar product markets in remote areas	W.F. Steel et al, 2016 [37]	Literature review	• A complete approach that takes into account need, availability, funding, reliability, and enabling methods is required to create a viable market for solar products in rural areas lacking access to solar enterprises and financial institutions.
Possibility of using mini-grid solar systems to provide an off-grid community's energy demands	E.Y. Asuamah et al, 2021 [38]	Simulation using HOMER	• The research conducted indicates that a solar mini grid would be far more economically efficient for Nkrankrom, a region in Ghana without electricity, compared to connecting to the main power grid. To achieve the best outcome, a PV/Battery/Converter system setup is recommended. The cost of energy for this system, calculated as the Levelized Cost of Energy, is projected to be \$0.107/kWh, whereas connecting to the main grid would cost \$0.124/kWh. • The study emphasized that while the study's objective was achieved with satisfactory results, it is still acknowledged that grid power is more capable of accommodating very high increases in load. Off-grid power's viability is dependent on several variables, including the cost of the property, the availability of repair facilities, maintenance workers, and community support.

I. Barriers to distributed PV systems development in Ghana

A review of literature on solar PV mini-grids in Ghana provides an overview of the obstacles across different dimensions or viewpoints of influence; technical(t), political(p), social(s), and economic(e)[36], [39-42].The following barriers are under these viewpoints: financial resources or funding(p), insufficient strong business models (e), unpredictable grid expansion in the future (p), influence from politics and delayed public procurement (s), limited ability to pay (e), unfavorable mini-grid policies (p), unattractive tariffs (p), low productive use (t), limited private sector involvement (p), uncertain licensing (p).

III. RESULTS AND DISCUSSION

The important research and scholarly works on the promotion of solar PV in with a particular focus on distributed PV systems Ghana are summarized in this review. The studies reviewed highlight the possible advantages of solar energy for rural areas as well as the difficulties the sector in Ghana is now experiencing.

One of the major conclusions drawn from the studies under review is the need for policy support to increase the affordability of RET’s, encourage the use of stand-alone grid options like solar PV in locations where they can compete traditional electricity supply, and establish a regulatory and fiscal framework that supports local exploration and innovation to lower the costs of RET’s. The Act 832 is a step at making progress towards the objective, but more actions are needed to develop skilled personnel with intermediate-level expertise to facilitate extensive adoption of solar

Photovoltaic systems in Ghana[30].Another finding from the studies under evaluation is that rural populations in Ghana could benefit from sola stand-alone grids in terms of development and reducing adverse effect of climate change. But they are still not being recognized as such by policymakers and development partners. The benefits of solar stand-alone grids for rural areas have also not been sufficiently demonstrated in scholarly discussions. Recognizing the many advantages of solar stand-alone grids can spur interest in their implementation and help save money by preventing the need for several projects to accomplish the same goals. Additionally, it is possible to entice investment from donor organizations by maximizing the benefits of a single project[35].

The most challenging barrier in the RE sector was found to be the expense of funding due to high-interest rates, which was given a rating of 4.13/5[36]. Inadequate motivation for renewable energy developers was another significant obstacle, with an average score of 3.93. Other obstacles to the development of RE have also been mentioned, such as grid limitations, currency volatility, a lack of incentives, a lack of technical expertise, and insufficient training facilities. The government of Ghana should establish a specific set of subsidies and financial incentives aimed at supporting the expansion and effective implementation of renewable energy projects throughout the country[36].

Complete approach that considers need, availability, finance, reliability, and facilitation methods is required to create a viable market for solar products in rural areas lacking access to solar enterprises and financial institutions.[37] . Off-grid power's viability is influenced by things like the cost of the land, the availability of maintenance staff, repair facilities, and community support[38].

IV. CONCLUSION

The reviewed literature shows that solar energy has significant potential to provide reliable and affordable electricity to rural communities in Ghana, but several barriers must be overcome to realize this potential. Policy support, financial incentives, and skilled personnel are critical factors in overcoming these barriers. The State should focus on the development of regulations and legislation that encourage growth of renewable energy projects and create a favourable environment for private sector investment. Donor agencies should also be encouraged to invest in solar energy initiatives that provide a range of advantages to rural communities in Ghana.

Abstract*— Currently, Solar PVs are gaining considerable acceptance because of their ability to directly convert sunlight into electric power. Nevertheless, photovoltaic-generated electricity may fail to satisfy the ever-increasing energy demand because it does not provide a consistent supply that aligns with the needs of consumers. To solve this problem, energy storage has recently gained importance in grid-connected Photo Voltaic (PV) plants. This helps in managing loads more flexibly and overcoming problems related to power quality faced by grid-distributed networks, thereby making PV plants valuable and appealing. To effectively integrate PV plants and storage systems into the power grid, various techniques for battery management have been developed to create a demand that is more responsive to prices. The wider deployment of PV systems is hindered by the lack of supporting policies. This study reviews different techniques of configuration and modeling employed for the optimal operationalization of PV grid-tied systems with battery storage. We examined numerous optimization methods and dispatch mechanisms for energy stored that capitalize on the monetary worth of battery-operated PV systems. We also discuss the grid-connected PV system-related power quality and control technology challenges. Finally, we explored several functioning and maintenance concerns of battery-operated PV systems and highlighted the financial and ecological advantages of PV grid-tied configuration. The goal of this study was to review several technical issues related to the condition of PV systems. These issues include energy regulation, various cell technologies, energy management and scheduling methods, reliability, and power quality. We also discuss whether findings from the University of Juba should be adopted.

Keywords*— *Solar PV, Grid-connected system, battery, storage system

I. INTRODUCTION

Currently, the world is facing significant challenges related to rising energy demands and reliance on non-renewable energy sources. As a result, there is a growing trend toward utilizing Renewable Energy Sources (RES) as a solution for electricity generation. Solar energy has emerged as a compelling option for numerous countries to shift away from fossil fuels and adopt a more sustainable energy source among all available renewable energy sources [1-2]. Approximately 93% of people on Earth live in nations with solar PV energy potentials between 3.0 and 5.0 kWh/kWp on a daily average. Almost 70 countries have excellent solar PV conditions, with daily average output exceeding 4.5 kWh/kWp, enough to boil roughly 25 liters of water.

From 2010 to 2015, the Solar PV installation capacity increased consistently and has since witnessed a substantial surge. Solar PV generation has reached a historic high of over 1,000TWh, with a remarkable increase of 22% or 179TWh. This achievement marks the second fastest growth in renewable technologies, after wind energy, in absolute generation growth as of 2021 [3]. China is expected to maintain its lead as the world's major PV market leader by 2050, with a projected share of more than 37% of its worldwide capacity. [4-5].

Photovoltaic energy sources have diverse uses, such as powering water pumps, charging batteries, providing electricity to homes, illuminating streets, cooling systems, heating swimming pools, running hybrid vehicles, supporting telecommunications, operating satellite power systems and military spaces, and generating hydrogen. Two categories of systems make up the global market for these energy sources: decentralized systems, which make up approximately 60% of the market, and centralized or utility-scale systems, which make up approximately 40% of the market. Off-grid or Stand-alone schemes, which formerly dominated the market, now account for roughly 1% of the market. Currently, modules of crystalline silicon (c-Si) control the majority of the PV market, accounting for approximately 90% of the total. The market share for Thin Films (TF) of all kinds is currently only approximately 10%, a decrease from 16% in 2009, while the market share for Concentrating Photo Voltaic (CPV) technology is still less than 1% despite its rapid rise [4].

Similar to wind energy, solar energy is dependent on weather patterns, which pose a major challenge. The limited capacity for PV energy production stems from the inconsistent and erratic characteristics of PV energy generation, which make it difficult to operate the grid. As a result, a fundamental challenge for PV systems is coordinating intermittent energy production with ever-changing power demand [6]. One approach to address the

DOI: rp-9788770040723.173

issue of irregular power sources is to integrate a storage element.

Although the importance of storage has been acknowledged, more research in a practical setting is required to better understand and assess the distribution of stored energy. This allows us to financially maximize the advantages of renewable energy production and storage arrangements [7-8]. To maximize the financial benefits of PV battery systems, a number of retail pricing models, including Critical Peak Pricing (CPP), Real-Time Pricing (RTP), and Time-Of-Use (TOU), have been advocated in academic literature. These programs are designed to encourage customer involvement in demand response. [9-10] investigated how it can increase the system output efficiency, streamline the process, and produce electrical energy of higher quality.

The evaluation of battery-operated Solar PV schemes for urban grid connections has substantial value for several reasons, with an emphasis on applying the findings to the University of Juba. First, it offers insightful information on how well these systems can accommodate the increasing energy demand of cities. Energy needs are increasing along with the urban population, and sources of renewable energy like solar photovoltaics have the ability to supply these needs sustainably. Second, the evaluation offers a deeper understanding of the technological elements of Solar PV and battery systems, including their constituent parts, installation, functioning, and maintenance. These data are fundamental for policymakers, energy strategists, and investors who aim to boost the use of battery-operated Solar PV systems in metropolitan regions. Finally, the assessment also analyzes the difficulties and impediments to the installation of solar PV and battery systems in urban locations. This study can assist stakeholders in creating successful strategies and policies to address these issues and encourage the general adoption of these systems by drawing attention to these concerns.

II. Literature Review

A. *PV cell technologies*

Currently, c-Si panels, which are categorized as first-generation solar cells, are used to fabricate the majority of solar cells. Owing to their affordability and greatest efficiency level, these panels, which are composed of crystalline silicon, comprise 85-90% of all photovoltaic module sales globally. sc-Si and mc-Si are common varieties of c-Si panels. Although there are numerous manufacturers of c-Si solar cells, and the technology is a mature and well-established PV technology, the cost of the raw ingredients required to make them is high. Although costs have come down recently, it is unclear whether further cost cuts will allow c-Si to successfully compete with less expensive solar resources in the wholesale power-generating sector. [4][11].

The second-generation photovoltaic technologies, which currently make up between 15% and 20% of the market, are referred to as thin-film PV technologies. Because of the low cost of materials and manufacturing, these technologies are desirable. However, it is important to consider the fact that they are less efficient and have elevated mounting costs and space requirements compared to c-Si cells. TF technologies still hold a significant market share, with the exception of utility-scale systems, although they are not as developed as c-Si PV cells. TF still have to contend with a number of issues, such as toxicity, availability, and durability of the materials, particularly in the case of cadmium. In addition, the prices of c-Si modules represent a significant threat to TF technologies [11-12].

Third-generation PV technologies, such as concentrator photovoltaic (CPV), advanced thin-film (TF), and organic cells, are still being studied and developed at this time. By using innovative conversion processes, methodologies, and cutting-edge materials, these technologies have the potential to attain higher conversion efficiency. Because they haven't yet been commercialized, their exorbitant price is still a mystery. They continue to be improved at the R&D stage right now [4], [11].

B. *Off-grid and grid-tied systems classification*

PV systems are divided into two groups: utility-interactive, commonly referred to as grid-linked systems, and standalone systems. Its operational and functional requirements, component layouts, and connectivity to other sources of power and electrical loads all affect how they are classified. PV systems offer AC and/or DC power services and can operate either independently or tied to the utility grid[13].

PV systems that are built to function with the electric utility grid are integrated with the grid and cooperate with it. These PV systems' power conditioning device, commonly referred to as an inverter, is their most important component. The inverter serve to convert the electricity generated by the PV array from DC to AC power that complies with the utility grid's specifications for voltage and power quality. The power conditioning device will automatically stop sending electricity to the grid in the situation of a malfunction of the electric utility grid. [14]. The Fig.1 shows the grid connected solar PV system.

Fig. 1. Grid-connected solar PV system [15].

The photovoltaic (PV) system features a two-way connection that enables the electricity it produces to be either used for on-site electrical needs or transferred back to the power grid in situations where the PV system produces more electricity than is required on-site. When the output of the PV system is insufficient to handle the electrical load, such as during periods of low output, as on cloudy days or at night, the required amount of power is purchased from the utility[14].

PV systems that are linked to the grid and do not have an energy storage backup are considered ecologically friendly and are commonly favored by individuals due to their low maintenance and cost-effectiveness. However, these systems rely on grid power and in cases of power outages during the

DOI: rp-9788770040723.173

night or on cloudy days, they will cease to function until grid power is restored.

It is common for PV systems equipped with energy storage backup to be connected to utility grids. This type of design has several benefits such as the ability to sell any excess electricity produced by the PV system back to the grid, charging the battery during non-peak periods, and purchasing power from utility grid to support the loads in situations where the battery-operated PV power are insufficient[14].

Independent photovoltaic (PV) systems work autonomously and are not connected to the electric utility grid. These systems operate in isolation and are usually used to supply electricity to a DC and AC load that is appropriately sized. They are powered by either a PV array alone or a hybrid PV system, which amalgamate PV array with a diesel generator acting as an additional source of power. Off-grid systems of this type typically contain an inverter, which transforms the DC voltage produced by the PV modules into AC voltage that can be utilized by appliances directly [13]. Some significant characteristics of PV technology are outlined in the table 2 below [13]:

TABLE I. AN OVERVIEW OF SOME KEY ASPECTS OF PV TECHNOLOGY

Characteristics	Exposition
Range of operation	1 kW-300 MW
Fuel	Sun
types of applications	household, utility scale, and business
Efficiency	For crystalline silicon, the percentages are 12–16%, for thin films, 11-14%, and for organic cells, 18–20%.
Ecological effect	There are no direct emissions of CO2, NOx or CO.
Advantages	Modular construction, zero direct emissions, and environmentally friendly technologies.
Downsides	Additional costs for setup, variable power output due to unreliable weather, need for mechanical and electronic monitoring devices and need for additional storage for best results.

C. *Techniques for design, size, and modeling*

Creating models in a streamlined manner to operate photovoltaic components could boost the productivity of the entire photovoltaic system. This encompasses constructing models for the photovoltaic electricity generator, interface of power electronic, storage equipment, and the devices that consume power. Various models for solar cells are available, including a basic model for PV cells, a more precise model known as two-diode model, and moderate one-diode model that is commonly used in modelling PV panels [13]. The table below illustrates the approaches used in designing PV and storage components.

D. *Scheduling methods and energy management*

Designing effective scheduling techniques is challenging because of the unpredictable availability of solar energy resources. An efficient approach would be to combine a storage system for energy with the photovoltaic panels to achieve better results. Another solution is to use Demand Side Management (DSM) technology, which utilizes dynamic pricing strategies to change consumption of energy from peak to non-peak times, thereby achieving power balancing and reducing expenses [13]. A plan for a photovoltaic lighting system that includes energy management has been suggested [29]. The findings indicated that the efficiency of the system was enhanced by solar batteries MPPT control. A strategy for energy management was optimized [30] by converting the production of photovoltaic energy, which depends on solar irradiance, into a constant output per hour. This approach enabled photovoltaic power plants to participate in electricity markets with minimal additional costs associated with the incorporation of a storage system of energy. [29-31] study involved the creation and testing of algorithms that regulate the flow of energy in PV lighting systems used in public areas. The objective was to ensure that the system remained operational during power outages while minimizing overall energy expenses. The table provided below summarizes the various methods for managing the energy of PV battery systems. An efficient power flow management system may consist of distinct stages such as prediction, optimization, and local control.

E. *PV system storage problems*

As previously mentioned, PV renewable energy sources are causing increasing concern in power systems because of their significant intermittency. This could result in complications, such as instability, difficulties in regulating voltage, and other power quality problems. In order to address these issues, storage systems of energy remain being extensively employed in electrical systems.To handle the unpredictable and fluctuating attribute of photovoltaic (PV) energy in power systems, various types of energy storage systems including thermal storage, electrochemical, electrical, and mechanical are employed. It is essential to compare these systems based on their applications, advantages, initial cost, and overall lifespan. The table 4 presented underneath displays the distinctive characteristics of various devices for electric storage that can combine with Solar PV, along with an analysis of their benefits and drawbacks.

F. *Policy in Energy*

Satisfying the current and forthcoming energy demands while minimizing negative impacts on the environment is an extremely challenging issue. Consequently, renewable energy sources are being considered as potential solutions. Several countries have implemented incentive policies to support the development of alternative energy sources, with Europe being the notable leader in photovoltaic (PV) deployment until 2012. However, recently, this technology has expanded beyond Europe, primarily in Asia, and particularly in China. Despite this dramatic shift, several economic and non-economic barriers must be overcome to achieve the International Energy Agency's vision. As a result, in order to overcome potential obstacles, it is crucial to develop new recommendations for system integration, technical, legal, and regulatory challenges.

In their study, [47] examined the policies implemented in various countries to advocate for the utilization of PV

DOI: rp-9788770040723.173

technology.The authors emphasized that to support the continued expansion of the market and user base,retail financing terms must be adaptable and accommodating. The incorporation of grid-tied renewable energy storage system is limited by regulations, which act as constraints. To speed up wider PV system adoption, which will hopefully lead to lower deployment costs in the near future, various state policies are required to provide economic incentives that compensate for the high investment costs.Various strategies are implemented to encourage the adoption of PV renewable energy, including trading mechanisms, feed-in-tariffs, investment tax credits,renewable portfolio standards, pricing regulations, quota mandates, production incentives, and other relevant policies. These policies' main goals include reducing reliance on non-renewable energy sources, promoting the development of new industrial sectors, and mitigating the environmental effects of the energy industry. The most popular policies thus far are the RPS and FIT, but countries should choose the policy that best suits their circumstances and objectives [47].

While investment and finance are crucial for creating effective policies, it has been observed that clear and trustworthy signals from policymakers can decrease risks and boost confidence. However, if policies are inconsistent and send mixed messages, they can result in higher costs for consumers and investors in the financial and energy sectors.

III. Case Study: University Of Juba, South Sudan

The Republic of South Sudan, situated in the central and eastern part of Africa, is a nation bordered by nearby countries including Sudan, Ethiopia, Uganda, CAR, DR Congo, and Kenya. The population of the country is estimated to be around 11.19 million people in 2020. Juba is both the capital and the biggest city in South Sudan.South Sudan has the lease electricity access rate in African continent, with only 7.24% of the population having access as of 2020 [2]. The current state of energy in this country is closely tied to recent conflicts. Despite the ample potential for solar energy and hydropower, the majority of electricity is generated through thermal sources, and the supply is restricted to only a handful of communities.

South Sudan experiences approximately 8 hour of sunlight every day, with horizontal surface radiation between 5 and 6 kW/m2 per day, primarily in the northern and eastern regions. The highest level of global horizontal irradiation in South Sudan is 2264 kWh-2, which is comparable to Sahara's peak of 2702 kWh-2, making it a suitable location for solar-energy production. The Fig.2 shows the Map of South Sudan depicting the feasibility of solar energy potential.

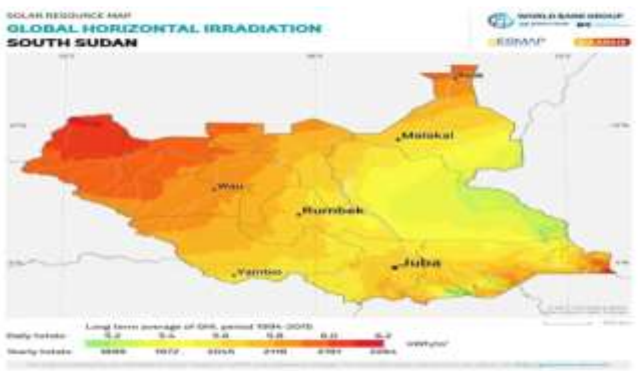

Fig. 2. Map of South Sudan depicting the feasibility of solar energy potential [2].

Despite this, the primary source of energy in South Sudan is mainly focused on oil, and the capital city relies on a power plant that runs on diesel fuel. However, this power plant experiences frequent interruptions in the electricity supply [48]. Diesel-powered power plants provide the vast majority (73%) of electricity access rate. Electricity from renewable energy sources, mainly solar PV, accounts for the remaining 27% of total access [49]. The limited availability of electricity has a negative impact on various sectors in the country, including education, agriculture, and healthcare, thereby reducing their effectiveness.

Grid-connected photovoltaic (PV) systems offer a practical solution to address electricity blackouts in Juba, achieve zero-energy buildings, and reduce the cost of solar energy generation. These systems can significantly improve the energy efficiency of a building. Many universities worldwide have ample unused areas on their grounds and buildings, making them ideal locations for installing grid-connected PV systems on rooftops and the ground. This presents a significant opportunity to expand the use of solar-power technology [50].Electricity is an essential requirement for most institutions, including universities, to perform daily activities.The University of Juba is the largest university in South Sudan and serves as a focal point for academic and research activities.

As with many other institutions in the region, it has faced significant challenges with electricity supply owing to unreliable and expensive grid infrastructure. Consequently, the university has invested in solar PV and battery storage systems to supplement its energy needs [51]. Solar PV and battery storage systems were installed on the rooftops of several buildings on a university campus. The PV system consists of 528 solar panels with a total capacity of 150 kW, whereas the battery storage system has a capacity of 468 kWh. The systems were designed and installed by a local contractor in collaboration with the engineering team of the university. To evaluate the effectiveness of the systems, data on energy production and consumption were collected over a period of one year. The data were analyzed to determine the percentage of energy supplied by the solar PV system and the percentage of energy stored in the batteries. The cost savings achieved through the use of solar PV and battery storage systems were also evaluated [52].

The solar PV system generated 221,520 kWh of electricity over a one-year period, which was equivalent to 19% of the total energy consumed by the university during that time. The battery storage system stored 190,080 kWh of energy, which was equivalent to 16% of the total energy consumed. The use of solar PV and battery systems resulted in a cost savings of $120,000 USD over the one-year period. This represents a significant cost reduction for the university, as it previously relied solely on diesel generators for its energy requirements [51].The investment of the University of Juba in solar PV and battery storage systems has proven to be a successful strategy for addressing its energy challenges. These systems have significantly reduced the university's reliance on diesel generators and have resulted in substantial cost savings. The system has improved power reliability, reduced electricity bills, and a positive impact on the environment [52].

IV. Results And Discussion

Solar PV systems have been increasingly utilized in urban and city environments for grid-connected applications, with battery storage systems playing a crucial role in ensuring continuous power supply. The global solar PV market has witnessed significant growth over the past decade [29-52], with China being the primary global market leader, accounting for almost 37% of its global capacity.

TABLE II : Illustrate The Approaches Used In Designing Pv And Storage Components

System used energy generation system	Aims	Engineering design and simulation	Findings	References
PV Hybrid system	• PV-AC grid system sizing. • Sizing & energy dispatch PV-diesel-battery power Systems.PV-wind system sizing	• Models of the PV, converter, and battery with Homer. • Model for simulating size with RETScreen® that is based on a spreadsheet.Component size optimization using Homer.	• Most affordable net present cost • Analyzing the economic impact of energy performance • Cost reduction for dependable autonomous system	[16] [17] [18]
Solar photovoltaic system	• Net Present Value-based Rightsizing (NPV). • Modelling and simulation. • Parametric analysis. • Operation and modelling. Modelling and simulation. • Design, modelling, and simulation. 1.0 Sizing a standalone PV system using regression.	• Combining demand response with the Monte Carlo method for sizing. • PV model parameterization using Simulink and Simpower. • System sizing accounting for the duration of the load and the charging low voltage disconnect. • Model of PV array-inverters operating in master mode using Simulink and MATLAB. • Single diode model with MATLAB & Simulink. • PV mathematical models, DC-DC boost converters, and comprehensive converter designs.	• NPV based-appropriate sizing of a PV system with consideration for sellback prices. • Long-term grid-tied functional modeling strategy. • Helps a PV designer determine the ideal system specifications and charge controller settings. • Improved power system voltage and frequency regulation. • Output current calculation. • PV-based power system setup for testing using a DC-DC converter.	[19] [20] [21] [22] [23] [24]
Solar-plus-storage system	• Optimum scale. • Hybrid storage technology sizing optimization	• Sensitivity investigation and direct search methodology. • Design of a hybrid system that maximizes the number of batteries, the tilt of the PV modules, and the number of solar panels.	• Optimal sizing using a systematic algorithm. • Optimal size based on utility properties.	[25-26] [27]
Grid-tied PV system	• PV performance study. • Synchronizing the inverter with MPPT and connecting to the grid.	• The utilization of MATLAB & Simulink in constructing models for PV panels, inverters, converters, filters, MPPT, and units for control & protection. • The utilization of MATLAB & Simulink for creating a model of a PV array, MPPT, and an inverter connected to the power grid.	• Adequate design control for PV system. • Improved PV system modeling and control design techniques.	[13] [28]

The PV market is primarily dominated by crystalline silicon (c-Si) modules, which constitute roughly 90% of the market share, with both single-crystalline (sc-Si) and multi-crystalline (mc-Si) modules being widespread. The market share of thin films (TF) has decreased from 16% in 2009 to only 10% today. Similar to that, concentrated photovoltaic (CPV) technology only makes up less than 1% of the market.

A. Battery Storage Systems and their Role inSolar PV

Battery storage systems play a crucial role in ensuring continuous power supply and mitigating the challenges posed by weather conditions. Lithium-ion (Li-ion) batteries are currently the most broadly utilized technology for stationary energy storage applications, with lead-acid batteries being the second most commonly used. Other types of batteries include sodium-sulfur (NaS), flow, and redox flow batteries. These batteries provide several benefits such as grid stabilization, load management, and ancillary services.

B. Battery storage and solar power applications

Solar photovoltaic (PV) and energy storage systems utilizing batteries are adaptable and can be utilized for a variety of tasks, including powering water pumps, charging batteries, illuminating streets, providing electricity to homes, heating swimming pools,refuelling hybrid cars, supporting communication networks, supplying power to military and space equipment, and producing hydrogen. These schemes are typically used for either centralized, accounting for about 40% of the market, or decentralized systems, which account for about 60% of the market.

C. Challenges and Future Directions

The adoption of solar PV and battery storage systems faces several challenges, such as high initial costs, technological limitations, and lack of policies and regulations to promote their use. However, advancements in technology, coupled with favourable government policies and regulations, have contributed to their widespread adoption. Furthermore, the amalgamation of solar PV and battery storage systems with other sources of renewable energy such as hydropower and wind power, can provide a balanced portfolio of renewable energy resources.

Solar PV and storage systems have the potential to become the leading source of electricity by 2040, with several countries already investing heavily in their adoption. The combination of PV and storage systems with other renewable energy sources can provide a sustainable solution for meeting the rising energy demands and shifting towards sources of renewable energy.

V. Conclusion

The advances of PV technology have resulted in a potentially viable solution to the world's energy dilemma and the negative environmental effects of energy production. These problems can be greatly addressed by this renewable energy source. However, the incorporation of PV technology into the electrical grid presents several technological challenges, such as fluctuations in power, instability in voltage, and storage issues. Energy storage systems such as electrochemical batteries can be employed to address the intermittent nature of PV energy in power systems. Furthermore, the implementation of effective energy policies is crucial for supporting the continued expansion of the PV market and user base. Various strategies are implemented to encourage the adoption of photovoltaic (PV) renewable energy, including trading mechanisms, feed-in-tariffs, investment tax credits, renewable portfolio standards, pricing regulations, quota mandates, production incentives, and other relevant policies. These policies' main goals include reducing reliance on non-renewable energy sources, promoting the development of new industrial sectors, and mitigating the environmental effects of the energy industry. The high initial costs associated with PV technology pose a significant challenge for renewable energy sources and energy efficiency improvements. This is because these expenses are mainly incurred upfront. Therefore, the introduction of PV technology into electrical grid requires a multifaceted approach that involves addressing technical challenges, implementing effective energy policies, and overcoming financial and non-financial barriers to achieve the International Energy Agency's vision of sustainable energy for all.

Abstract—The Internet of Things (IoT) is utilized by an intelligent transportation application to arrive at informed conclusions for the benefit of passengers. The key advantages brought about by the Internet of Vehicles have been an improvement in both the quality of the driving and riding experience and an increase in both the safety and efficiency of traffic (IoV). The characteristics of distributed processing that mobile cloud computing possesses make it possible to process local data quickly. Internet-to-vehicle (IoV) connection may become more effective with the help of the vehicle cloud. This study centers on the communication between the vehicle and the other vehicle, as well as between the vehicle and the device on the road when necessary. The brief signature method of the authentication protocol was suggested, and it was discovered that it is not susceptible to forgery while employing a fresh scenario as the testing ground. We are developing a system and management methodology for IoV mutual authentication that is quick and effective. The suggested system was subjected to quantitative performance evaluation, which revealed that it is superior to other already existing systems in terms of its ability to interact with automobiles (vehicle-to-vehicle communication) and roadside equipment. The results are encouraging because there were relatively few instances of packet loss.

On the other hand, the scenario proposed in this paper aims to reduce the amount of power consumed by the devices installed in vehicles. This will be accomplished by efficiently controlling the transmission of information, making it so that the transmission power is proportional to the distance that separates one vehicle from another rather than transmitting at the highest possible power. The scenario was created by modeling the Matlab program using version 2021 of the software.

Keywords—intelligent, networks, Internet of Things, VANETs, IoT, IoV, V2V, V2Rt ,CLSS, Vehicles, mobile cloud.

I. INTRODUCTION

More and more industries are adopting the Internet of Things (IoT), including smart transportation and the nation's power grid. The Internet of Things (IoT) has been dominated by vehicles. Ad hoc networks are becoming increasingly widespread in vehicles (VANETs). Because VANETs can receive, evaluate, and interpret data from vehicles and structures throughout the globe, they cannot make intelligent decisions[1]. In contrast to VANETs, the Internet of Things (IoT) integrates cars, people, things, and networks into a single intelligent unit via networks such as deep learning, fog computing, cloud computing, and other technologies. IoV models at three, four, and five levels have been offered by authors who are experts in their fields. CISCO presented the four-level method, shown in Fig. 1, back in 2013. Personal devices, roadside units, and sensors account for most of this. Figure 2 displays several Internet of Things communication scenarios: The V2V (Vehicle-to-Vehicle) and V2Rt (Vehicle-to-Remote) protocols are used. IoV utilizes real information transmission between vehicles and everything (V2X) using wireless communication devices based on fog/edge computer technology. It has been considered an application of Cyber-physical systems (CPS). Different ways that V2X devices can talk to each other and how they connect are also talked about

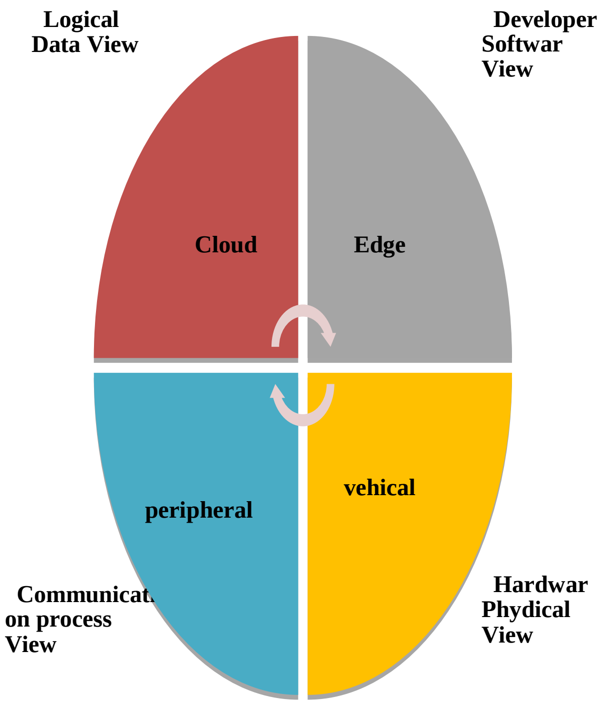

Fig. 1. IoV system model with four levels

DOI: rp-9788770040723.174

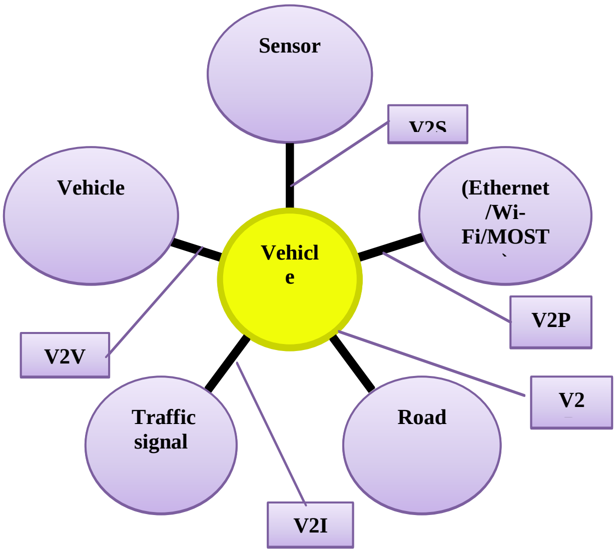

Fig. 2. IoV's multiple communications scenarios

Fig. 3. Illustration of an IoV Scenario

Integrating narrowband Internet-of-Things technologies improves vehicular communication systems' robustness, thereby enhancing service quality. This enhancement is achieved through two components that address latency and harmonic issues and a distributed antenna configuration for moving vehicles using machine learning and the across-entropy algorithm.

The proposed approach has been simulated and compared against state-of-the-art methods, demonstrating superior performance based on three key metrics: latency, mean squared error rate, and transmitted signal block error rate. The results indicate the proposed technique reduces peak power deficiency by nearly 49% at a probability of 10^{-3}, yielding an additional 23.5% improvement through self-interference cancellation and a 31% decrease in bit error rate compared to existing literature. (Hamarsheh, Daoud, Baniyounis, &Damati, 2023)

It is possible to communicate between vehicles and network nodes (V2R), as well as between vehicles and personal devices (V2P) (V2S). The Internet of Things may benefit from a new hybrid communication paradigm that combines the advantages of both wired and wireless networks. Connecting automobiles to the Internet of Things improve their services' reliability and security. It is currently being developed for mobile devices to use mobile cloud computing (MCC), a kind of cloud computing. In [3], Vehicle cloud computing mobile vehicular cloud computing is a novel computing paradigm developed by Gerla based on the MCC architecture. Three resources are often found on vehicles and remote sensing devices: *data storage, sensors, and processing*. When these resources are linked to the Internet, a "vehicular cloud" is created, which may provide smart services. For example, a cloud server housed by a vehicle manufacturer may collect data about emergency road accidents and send it to a cloud service provider. It then informs the appropriate vehicles to pay attention to any newly uncovered information. The vehicle may upload data to the Internet anytime, anywhere. However, reducing the time spent on event processing will still be beneficial. Cloud computing and big data analysis work together in the Internet of Vehicles (IoV), making it even more intelligent since the IoV utilizes all of these technologies.

There have been several previous publications [3-6] to develop the technological infrastructure necessary for the Internet of Things. However, the Internet of Things continues to experience several difficulties.[7-11].

In the Internet of Things, security risks and privacy issues have become more relevant. When an attacker pretends to be a vehicle to transmit fraudulent signals, it can potentially disrupt the traffic patterns of other vehicles on the road. Several research on the security of IoV [12-14] have lately been brought to our attention. Protecting one's personal information is important for various reasons, including security. It is necessary to prevent unauthorized users from accessing a user's private information, such as their true identity location information. Even though each compromised car should be tracked down by an authorized government department using appropriate data and technology, this should be done accordingly[2]. In 2004, Huang et al. developed the certificate-less short verification approach and security model[15]. Xiang, et al. in [16] A revised, more effective strategy was also presented in 2022. Designers are concerned with securing access to private information through the Internet of Things (IoT). Considering the above issues and limitations, we suggest an effective anonymous authentication mechanism for the Internet of Things. The following is a summary of the most important contributions made by the paper:

- The suggested technique allows for conditional anonymous mutual authentication while protecting users' privacy.
- The introduction of a global methodology for vehicles is made. Vehicle verification may be performed in conjunction with RSUs in the same area.
- When compared to earlier techniques, our scheme has a lower computational cost.

The majority of this article is structured as follows. Section II overviews the IoV scenario model and some preliminary results. Afterwards, it is recommended that use

DOI: rp-9788770040723.174

a certificate with less short signature (CLSS). Using CLSS as a foundation, For the Internet of Things, Section IV introduces an unnamed access code Section V has both a security and a performance evaluation. Finally, Section VI finishes this paper.

II. Preliminaries

Furthermore, we provide a scenario model for the Internet of Things, security protocols, and desired outcomes.

A. Scenario Model Design

The Internet of Things (IoT) scenario is shown in Fig. 3. TCC, TBA, vehicles, and RSU comprise most of the organization. A TCC handles everything from system initialization to data collecting from RSU, monitoring malicious vehicles, and updating the revocation list (Transportation Control Center). The RSU (Remote Sensor Unit) gathers and analyzes data from RSU, monitors hostile cars, and maintains the revocation list.

The TBA (Trace Back Authority) of a corrupt vehicle's function is to gather crucial information, verify harmful behavior, and impose sanctions as necessary.

Transport system: Every vehicle in the IoV has a built-in OBU that can wireless transmit vital highway safety information in real-time to other vehicles and RSUs.

Aside from that, it can receive and report data messages from other OBUs via a multi-hop mechanism.

Fixed route constructions (Roadside Units): RSUs are fixed route constructions erected along the side of the road. RSUs are normally connected to the TCC using a hardwired connection. They are in charge of capturing, transferring, and spreading real-time incoming communications from various sources. RSUs may act as access points for OBUs and offer them wireless services since they can handle messages within their respective ranges.

B. Model of Security

Constructing a CLSS involves the extraction of the private key, as well as the extraction of a secret value. Depending on the expert key's ability level, two groups will likely have attempted to break into CLSS. The AI would replace every user's public key even without passcodes. AI may access the parent vital but cannot modify any user's public key until specific conditions are met. Our approach will be irreversible in the presence of uncertainties compared to modified chosen message and ID assaults in inconsistencies in the Two attracter. Because the nodes (vehicles) in VANETs are supplied with considerable power sources, they have an advantage over regular ad hoc networks. Using VANETs, cars may interact with one another and with roadside infrastructure (V2I), allowing drivers to be more aware of their surroundings and improving safety while potentially streamlining traffic flow. The programs that operate on VANETs may be roughly divided as follows:

- Safety-related apps - for example, Emergency Messages
- Business-related applications
- Best-effort applications, such as infotainment systems
- secure Transactions, such as toll collecting

The vast majority of crucial communications To be successful, safety warnings broadcast through VANETs must go deep into the network and be sent quickly. This communication must be secure, and no personally identifiable or linkable information should be disclosed to other parties due to the legal right of vehicle owners participating in it to remain private. In this instance, VANET security is most important. Authentication is crucial in Vehicular networks since there may be both harmful and legal sources of communication. Authentication refers to the ability to distinguish between multiple sources.

For a communication to be considered anonymous, the physical identity of the sender should not be deducted from the message.

• *Data Integrity* - The authorized party's data has not been altered in any way and is received precisely as it was. The IEEE 1609 standards define Wireless Access in Vehicular Environments (WAVE) communication protocols for vehicular networks. IEEE P1609.2 specifies that [2] Private messaging protocols In this topic, the DSRC's layouts, and techniques for processing encrypted messages are discussed and standardized [3] to implement an encryption system that takes advantage of PKI (PKI). Additionally, the administrative operations necessary to provide important security services, such as canceling a vehicle's certificate after it has been given, are detailed in this paper.

III. An Overview Of Pki From The Perspective Of Vanets

The public key infrastructure relies on asymmetric key cryptography as its base. In a PKI system, each principal's keys are assigned: Keys (Private and Public Key). Unlike the private key, the public key may be shared with any of the network's other participants. Pr(.) and Pu(.) are two functions that represent the private and public keys, respectively; each function has the property of being an individual.

$$M=Pr(Pu(M))$$

$$M=Pu(Pr(M))$$

The message M provides here is how the keys are meant to guard against.

Messages are signed with a private key, and an attachment is attached to the message to secure the integrity of the message's transmission throughout transmission. When the receiver receives this message, they may use the public key of the (sender) to verify that the message has been signed. This solution has a basic flaw: swapping keys without compromising their integrity is impossible. Trusted nodes [4], known as Certificate Authorities, are one generally acknowledged solution for this problem (CA). Certificates, which assist in establishing the link between the owner of the private keys and the owner of the corresponding public keys, are used to validate data as part of this method.

To be more specific, an (unsigned) certificate must have the following parts in compliance with IEEE 1609.2:

DOI: rp-9788770040723.174

1) The public key
2) The certificate's expiration date and time
3) This list of CRLs relates to the certificate at issue. Everything described above is included in the certificate that the CA. will issue in addition to the CA's seal. Because there will only be one CA in the whole network, each PKI system entity must have access to the CA's public key. To ensure that only CA-verified certificates may be trusted. The IEEE 1609.2 Standard mandates that a verified message must include the sender's certificate, the public key used to sign the message, and the message itself since all of a CA's certificates must be distributed.

CA certificates may also be cancelled for several reasons not covered in this article. [6] The assailant's certificate may be temporarily cancelled until a connection with the CA can be established in a concept for certificate cancellation in-vehicle networks. Certificate revocation lists (CRLs) are used to send information on a certificate's revocation, including but not limited to the data stated below.

1- The following is the CRL series number: The sequence of CRLs intended by this CRL All revoked certificates are listed under

2- "Entries."A message's verification cost includes checking whether or not certificates in CRLs are present and usable at this period. Consequently, timely access to this revocation information is essential to the overall robustness and dependability of the operation. Providing real-time CRLs in car networks is a challenging problem to address.

IV. Developing The Cos for fheVanet Using Analytical Methods

There are a few permanent spots in the area that we're interested in where cars may use information-fueling stations on an as-needed basis (the duration between visits is random, with an average of several days). Information-fueling stations provide the latest current CRLs to the automobiles that stop there. This example shows how to compute a system's CoS and the various system factors that influence it.

Some mobility model is considered, and each vehicle has a certificate used to verify the authenticity of communications in this system. To count the number of other vehicles that have sent messages to a tagged vehicle in the future, examine a vehicle and define the c(t)t0 counting method (t). V2V communication between vehicles is boosted due to the tagged vehicle's higher contact rate with other vehicles.

Considering that, the limit exists nearly without a doubt. The process c(t)≥t0 is a random process.

$$\lambda = \lim_{s \to \infty} \frac{c(t)}{t}$$

Using r(t)tt0 to count the number of certificates that have been cancelled at any set moment and then using

$$r = \lim_{t \to \infty} \frac{r(t)}{t}$$

Because we're just interested in the average behavior of multiple automobiles, we'll assume that the process "c(t)" isn't significantly influenced by (or related to) the process "r(t)." Consider the potential of a coupling between c(t) and r while considering a small number of cars (t).

The CRLs of the tagged vehicle are updated in line with a method independent of the CA (either via RSUs or info-fueling stations). The identified car performs m(t)0 CRL updates. An independent and identically distributed random sequence of random variables will be utilized to estimate inter-update intervals (the time between subsequent CRL updates).

(Hamarsheh et al.)i≥1. E[T] = E[Ti] and E[T_2] = E[T_2 I then. The CRL of the tagged vehicle is presumed to be updated at time 0 since we are primarily concerned with system time average behavior (the CoS). Counting processes under examination are assumed to have limited second moment intertransition periods.

The processes 'c(t)' and 'r(t)' are expected to vary at a faster time scale than the process'm(t), i.e., the time scales of the processes 'c(t)' and 'r(t)' are shorter than the time scales of the process'm(t)' L E[T] and r E[T]. It is reasonable to assume that m(t) processes observe an averaged out representation of both procedures, given that the second moments of intertransition instants are limited. These counting procedures are thought to have constrained second-moment intertransition periods.

C(t) and r(t) are expected to vary at a quicker time scale than the'm(t)' process, which is defined as the time scale of E[T]. An averaged out picture of either method is what the m(t) process sees since the second moments of intertransition times are limited.

V. Positioning of Car

To continue data dissemination in VANETs, the suggested protocol needs a suitable categorization of neighboring vehicles. First, the number of receiving cars inside the transmission zone is determined by combining data from nearby vehicles with that obtained during the data collection phase. It then separates its transmission area into many segments, each representing a distinct area, as indicated in Fig. 4 (the source vehicle).

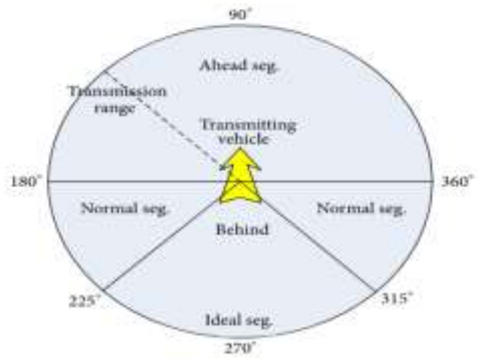

Fig. 4 Transmission range divided into segments

DOI: rp-9788770040723.174

Each receiving vehicle (denoted by) is categorized into three groups: ideal, normal, and ahead cars, once the segmentation process has been finished. As a result, the data packet's next forwarder should be one of the furthest cars in the optimum segment travelling toward the source vehicle. One vehicle at the far end of the ideal segment must retransmit a data packet with the lowest possible latency and eliminate the need for multiple retransmissions. A data packet will be sent to whichever vehicle is furthest from the optimum section if there isn't a vehicle. In the same way, if no vehicles exist inside the ideal or normal segments, the data packet will be sent to the vehicle(s) furthest from the forward segment. Data packets are intended to be sent to as many nearby cars as possible that aren't immediately accessible to the source vehicle by vehicles located inside the high-priority segments. Algorithm 1 explains how to determine whether the receiving vehicle is in the wagon wheel's ideal, normal, or forward section and how to proceed accordingly.

- ✔ Procedure for Choosing a Next Forwarder Vehicle (NFV)
- ✔ Procedure for Choosing a Next Forwarder Vehicle (NFV)
- ✔ Sourceβvehicle (S) that initiates the data dissemination process
- ✔ (Tx, Ty)β x and y coordinates of transmitter vehicle (Tj) on 2nd and subsequent hops

- ✔ Cancel planned message
- ✔ end

VI. Result and Conclusion

The suggested new protocol operates in various VANET traffic circumstances. Initially, we examined a 20-kilometre-long, three-lane highway with cars moving in the same direction. Vehicle flow production is constructed at each highway's opposing edge, producing and inserting vehicles at 30, 40 and 50, vehicles/hour. In this scenario, overtaking is performed by putting three categories of cars into the network: high, moderate, and slow-speed vehicles. Vehicles of these three categories may attain maximum speeds of 30, 22 and 26 meters/sec. An example of such a situation would be a dynamic vehicular network with three vehicle kinds. During the simulation, the speed of these vehicles varies. Each simulation comprises 40% high, 15% moderate, and 20% low-speed cars. When considering the first situation, it was taken into consideration that the cars are traveling in a straight line and at varying speeds. However, they are quite near to one another. In figure 5 demonstrates that the first vehicle, which is colored red, is only sending out information in the form of packets with a transmission diameter that is proportional to the distance between it and the car. This is done for two reasons: on the one hand, to reduce the amount of power that is being wasted, and on the other hand, to ensure that the information being sent out does not become distorted due to interference. The first car sent constant communications and information about the current state of the road to the second and third cars, which were colored black and yellow, respectively. This will result in a lower rate of lost packets and lower overall power consumption from the processor. It illustrates the ideal case for the proposed scenario, considering that there is no communication system free of packet loss., as demonstrated in the algorithm proposed in the paper.

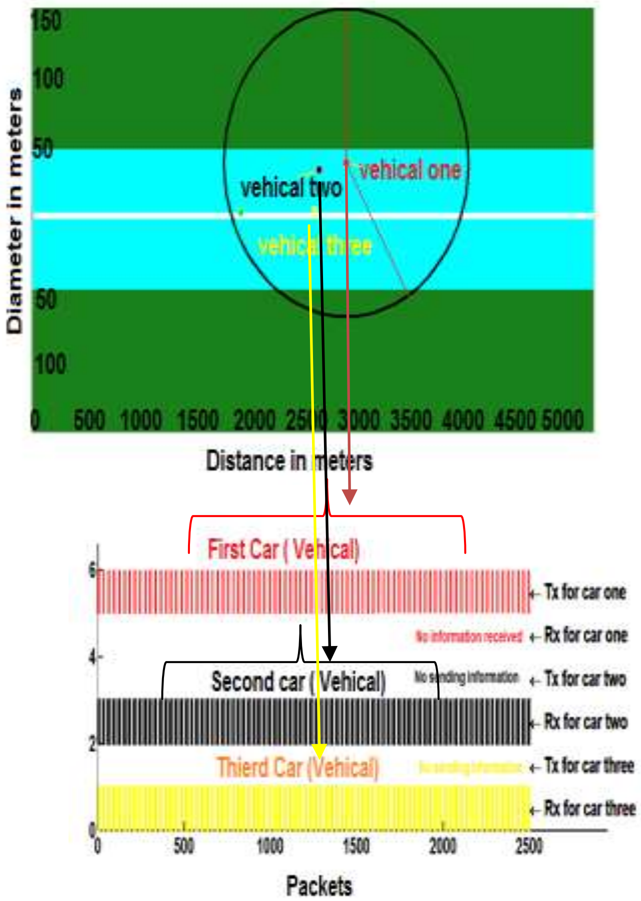

Fig. 5 vehicle transmission and received Data

DOI: rp-9788770040723.174

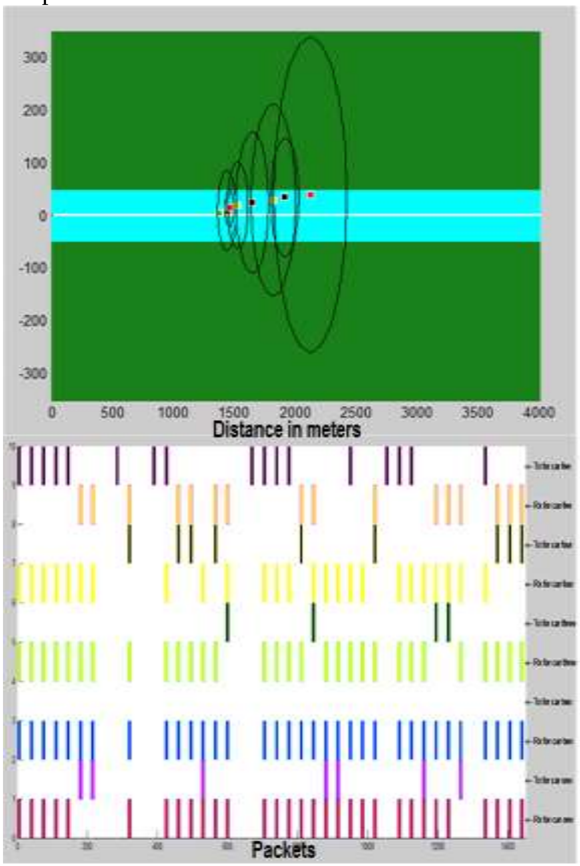

Fig. 6 illustrates the number of packets (Tx and Rx) for five vehicles.

The second scenario, depicted in Figure 6, involves more cars on the road than three, all moving at varying speeds. It should be noted that if any vehicle deviates from the prescribed diameter for broadcasting for the first vehicle, the vehicle closest to it will broadcast information with a diameter proportional to the distance it is from the car that came before it. The number of packets that were successfully received by each vehicle is depicted in Figure 6, together with the number of packets that were unsuccessfully received. The new protocol has a noticeably low packet loss figure 7, which reduces both the energy consumption of the transceiver system placed in the automobile and the consumption of the Internet package. As a result, the cost of both the Internet package and its delivery is reduced.

VII. Conclusion

The paper concludes by introducing a novel VANET protocol that performs well under various traffic conditions. The simulation results demonstrate that the proposed protocol reduces overall power consumption and packet loss, making it a financially viable solution. Given that no communication system is completely free of packet loss, the algorithm presented in the paper illustrates a perfect case for the suggested scenario. The two scenarios examined in the paper, where a high number of packets were successfully received by each vehicle, provide additional evidence of the protocol's effectiveness. Overall, the paper offers insightful information about creating effective VANET communication protocols, which can enhance the effectiveness and safety of vehicular networks.

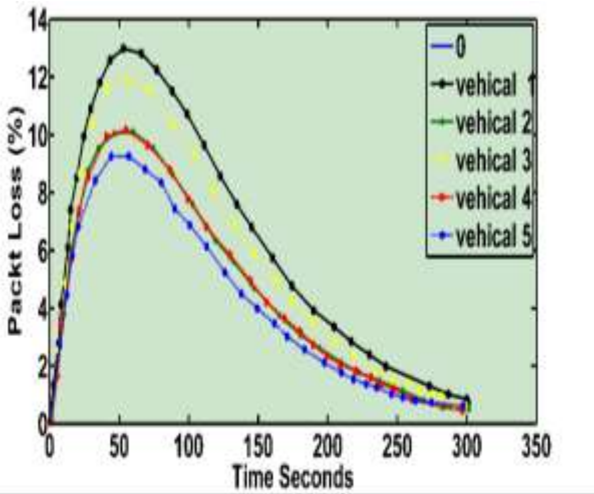

Fig. 7 illustrates the packet loss for five vehicles.

***Abstract*—In recent years online shopping and online e-commerce websites have drastically improved making shopping possible from our doorstep. The majority of businesses with an online presence use an online store and/or platform to manage logistics and fulfilment, undertake ecommerce marketing and sales operations, and more. By 2023, online retail sales are projected to account for 22% of all retail sales worldwide, up from 14.1% in 2019. While we see tremendous growth in ecommerce platforms, one of the most important aspects of online shopping in e-commerce platforms is customer feedback. The information, insights, problems, and suggestions that members of your community share about their experiences with your business, products, or services constitute customer feedback. Any business can use this feedback to improve the customer experience and bring about positive change, even when it's negative. With the use of feedback, your leadership team may get understanding that will help them map out the future of every aspect of the business. One of the most common factors we come across in every online shopping platform is the section which enables each customer to give their review about the product which they have purchased through the platform. This section enables customers to share their experience while they purchase and use the product. Customer reviews have immensely improved customers' trust in online shopping platforms. Customer reviews and feedback are an important part of online shopping. 94 percent of the people read at least two or three reviews before purchasing a product. One of the major goals of any company and their engineering teams is to create products which satisfy customer needs and desires. By employing the right tools to understand and meet the needs of the customer, companies achieve higher profits which will ultimately result in higher customer conversion rates and retention rates. From the supplier andmanufacturer'spointofviewcustomerfeedbackisessentialto provide social evidence that your prospective customers need to buy the product. But it can take a lot of time and laborious manual effort to solicit, compile, and track all of this feedback. While for the customers going through all the reviews and figuring out whether to buy the product or not is time-consuming and confusing. Most products get mixed reviews and it's hardfor the customer to decide.Our project is customer feedback automation using Robotic process automation and sentiment analysis which aims at making a unified platform for both customers and the vendors to sort the feedback. We are using the UiPathplatformtoextractcustomerreviewsfromthewebsiteand we will classify those reviews using sentiment analysis. Whenever a customer gives feedback it is extracted and grouped either into positive or negative and the negative feedback would be forwarded via emails to the respective departments so that they can take actions. When a customer browses for a product he/she can view the suggestions our platform would give based on the sorting we do and give them a rough percentage on how different people felt purchasing the product. We are using automation to speed up the shopping process and give customers a sense ofwhat other customers felt while purchasing, the problems they faced if any or any defect etc. Also making it easy for the manufacturers/ suppliers to deal with hundreds of complaints they receive by sorting the feedback and sending them to the respectivedepartments.**

***Keywords*—E-commerce platforms, customer feedback, Robotic process automation, UiPath, Sentiment analysis.**

I. Introduction

Online shopping, also known as ecommerce, is a special type of electronic commerce that uses a computer browser to link buyers and sellers all over the internet.Nowadays,it is normal to find online shops that offer a variety ofproducts to potential buyers along with descriptions, features, photographs, andprices.

There are two configurations that an online store may choose. The first is as a B2C store that links businesses and consumers. The second is as a business-to-business (B2B) internet marketplace. In either case, everyone who has access totheInternethasdonesomeonlineshopping.Ane-commerce platform is a piece of software that makes it possible to conduct business by buying and selling things online. Brick- and-mortar businesses dominated the market before eCommerce became popular. Retail establishments that have at least one physical location are known as brick-and-mortar enterprises. It is necessary for the buyer and seller to interact actively and physically when buying and selling products. Although brick-and-mortar stores still exist, eCommerceis quicklydisplacingthem.Inanevolutionarysense,themajority of physical establishments are evolving into online retailers.

Establishing an online presence and shifting essentialcorporate processes online are thus necessary. Recently ecommerce platforms started taking over the

DOI: rp-9788770040723.175

business world and this statement can be supported with statistics which talk about the growth of ecommerce platforms in Asia-Pacific region,the area accounts for more than 70% of all worldwide e-commerceactivity.WhiletheUScontributesapproximately $560billionineCommercesales,Chinaaloneaccountsfor$ 740 billion. According to projections, eCommerce sales in China would total $1,086 billion by 2023. In a similar vein, US eCommerce sales are anticipated to reach $735 billion by 2023. The key takeaways about online shopping and ecommerce platforms include the rapid growth of internet services across the world. With the rapid improvement and availability in internet services ecommerce platforms rose to the next level providing people a comfortable stay at home shoppingexperience.

One of the most important features any e-commerce plat- form provides along with search and cart features is feedback or review section. Through this feature every customer or a buyer will be able to list out the good and bad aspects about the product which they purchased and about their experience buying the product through that particular e-commerce plat- form.

Customer opinions are crucial since they act as a roadmap for your business' expansion. You can uncover pearls that make it simpler to modify and improve the client experience overtimeinboththegoodandthepoor.Inotherwords,getting input is how you can continue to put your community first in all youdo.

Today businesses sell their products to a broader network of customers or buyers through a wide range of markets. It is a must for the manufacturers of the product to get insightful feedback from the customers on the products and supplementary services provided on points regarding whether they are to compete with fierce competition and the variety of clientviewpoints.

After a company launches a new product into the market ittakes several measures to motivate customers to provide their review on the products they have purchased. The company extracts customers' feedback and opinions after a very tedious and long process and makes use of the feedback to come up with the design of their future goods. Frugal innovation is the process of adapting some product modules and module features to meet the needs and limits of regional customers while still maintaining a globally dispersed offering. The majority of people in today's world use smartphones and tablets, and the number of users continues to rise. The growing usage of mobile devices in society has given retailers andmanufacturers a wonderful opportunity to sell their products, provide3D customization apps, or even provide services with regards to their products. The high prevalence of mobile devices in society has given manufacturers a fantastic opportunity to market their goods, offer 3D product customization apps, or even offer services related to their products. In order to effectively extract client requirements and support businesses in their transition to frugal innovation, this paper handles the purpose of collecting customer feedback regarding the products offered and the services offered along with the product. The proposed system also includes feedback management that willhelp the companies to understand their customers' opinions that will help them understand more about their products and improve the design of their future goods or products. By automating customer feedback systems companies will be able to segregate the good and bad reviews which the customers have provided and accordingly make decisions about their future products based on it. We can automate the customer feedback system using robotic process automation. Robotic process automation system is a software which makes it easy to work with software robots that mimic human actions which will interact with digital systems and software. Workflows are streamlined through robotic process automation, which helps businesses become more profitable, adaptable, and responsive. By reducing menial duties from their workdays, it also boosts employee satisfaction, engagement, and productivity. RPA can be quickly installed and is non-intrusive, which speeds up digital transformation. It's also perfect for automating processes using antiquated systems that lack virtual desktop infrastructures(VDI),databaseaccess,orAPIs.

To implement the proposed model we are using Uipath in which we will build a workflow to automate the customer feedback system.

Uipathisaroboticprocessautomationtoolwhichisusedfor large scale end-to-end automation. We will use ML packages in the UiPath Enterprise version to classify the customer reviews into good and bad reviews. To classify the reviews,we will use Sentiment analysis. Sentiment analysis is a natural language processing (NLP) technique which is used to classify given text data. It is often used to understand the toneof the given textual data which will be helpful for companies to observe brand and the product sentiment in byer's reviews andtounderstandtheircustomers'wantsandneeds.

Through this study we will imply the following significant contributions:

To take input about the product the customer wants to learn about and from which website and extract the customer reviewsabouttheproductusingwebscraping.

To analyze the reviews using sentiment analysis and classify the reviews into 5 categories: very negative, negative, neutral, positive, and very positive.

To give a summary to the user about the product based on thecustomerreviewsusingvisualisationtoolslikepiecharts.

The remaining of the paper is structured as follows: Section IIbelow contains of Background about RoboticProcess Automation, UiPath, WebScraping, Section IIIbelow contains Related Work which is literature survey for previous works done related to customer feedback automation, Section IV below contains Proposed System which explains the architecture and approach of the customer feedback automation system developed, Section V below contains the software and the packages used and even about the ML models used to develop the customer feedback automation system, Section VIbelow contains Implementation and Analysis which explains about the

DOI: rp-9788770040723.175

workflow built and the results obtained, Section VIIbelow contains Conclusion which gives an overview of the systemdevelopedandexploresfuturefindings

II. BACKGROUND

A. Robotic ProcessAutomation

Robotic Process Automation (RPA) is a rapidly growing technology that automates repetitive and mundane tasks that are performed by humans. It involves creating software bots or robots to perform tasks that are otherwise done manually. The botsinteractwithdigitalsystemssuchassoftwareapplications, websites,anddatabasestoexecutethesetasks.

RPA is used across various industries and sectors, including finance, healthcare, insurance, and customer service, to streamline processes, improve efficiency, and reduce costs. By automating manual processes, organizations can free up employees to focus on higher-value tasks, reducing thelikelihood of human error, and increasing the speed and accuracy of tasks. RPA works by emulating human actions, such asdata entry, form filling, and document management. The bots can also be programmed to handle exceptions and make decisions, enabling them to perform more complex tasks. The bots are highly flexible and can be easily configured to work with different systems, reducing the need for extensive IT involvement.

One of the benefits of RPA is that it requires minimalprogramming skills. Non-technical users can create and con-figure bots using drag-and-drop tools, reducing the time andresources required to develop and deploy bots. Additionally,RPA provides real-time data and insights, enabling organizations to make informed decisions and improve their operations.Another benefit of RPA is that it can be easily integratedinto existing systems and processes. Organizations can startsmall with a single process and gradually expand their use ofRPA, reducing the risk of disruption to their existing systems.RPA also provides a cost-effective alternative to traditional ITsolutions, as it does not require extensive hardware or softwareinvestment. However, RPA is not a solution for every problem. It is best suited for highly repetitive, structured, and rule- based processes. It may not be the best option for tasks that require creativity or complex decision-making. Additionally, RPA may not be suitable for processes that involve sensitive information, as security measures must be put in place to ensuretheconfidentialityandprotectionofthisdata.

In conclusion, RPA is apromisingtechnologythathasthe potential to transform the way organizations operate. By automating manual processes, organizations can improve efficiency, reduce costs, and free up employees to focus on higher-value tasks. RPA is flexible, easy to use, and provides real-time data and insights, making it an attractive solution for organizationslookingtostreamlinetheiroperations.

B. UiPath

UiPath is a leading Robotic Process Automation (RPA) software platform that helps organizations automate repetitive, manual, and time-consuming tasks. UiPath enablesorganizations to streamline their operations and increase productivity by automating manual processes and reducing the likelihood of humanerror.

UiPath uses a drag-and-drop interface, making it easy for non-technical users to create and configure software bots, or "robots," to perform tasks such as data entry, form filling, and document management. The platform supports a wide range of applications and systems, including web-based applications, desktop applications, and databases. This makes it possible for organizations to automate a variety of processes across multiple departments andfunctions.

One of the key advantages of UiPath is its ability to handle exceptions and make decisions, enabling it to perform more complex tasks. The platform also provides real-time data and insights, allowing organizations to make informed decisions and improve their operations. Additionally, UiPathintegrates with other systems and tools, such asMicrosoft Excel, SharePoint, and SAP, making it easy for organizations to extend their automationcapabilities.

UiPath has a large and growing community of users and developers, providing organizations with access to a wealth of knowledge and resources. The platform also provides extensive training and support, helping organizations to get themostoutoftheirinvestment.

In conclusion, UiPath is a powerful and versatile RPA software platform that enables organizations to automate manual processes and improve their operations. Its drag-and-drop interface and support for a wide range of applications and systems make it easy for non-technical users to create and configure software bots. Additionally, its scalability, security, and integration with other systems make it an attractive solution for organizations looking to streamline their operations.

C. WebScraping

Web scraping is a technique for extracting data from web- sites and transforming it into a structured format that can be used for further analysis and processing. The process involvessending automated requests to websites and then parsing the HTML or other data that is returned in response. The data can then be stored in a database or spreadsheet for later use.

One of the advantages of web scraping is that it is fast and efficient. It enables organizations to gather large amounts of data quickly, reducing the need for manual data entry. This can save time and reduce the risk of human error. Additionally, web scraping can be automated, allowing organizations to gather data on a regular basis and keep their databases up to date.

Another advantage of web scraping is that it is cost-effective. Unlike other data collection methods, web scraping does not require the purchase of expensive data sets or software licenses. This makes it an attractive option for organizations that need to gather large amounts of data but have limitedbudgets.

Web scraping is also flexible. It can be used to gather data from a variety of websites, including e-commerce sites,

DOI: rp-9788770040723.175

news sites, and social media platforms. This enables organizations to gather data from multiple sources, providing a more com- prehensiveviewoftheirmarketortargetaudience.

In conclusion, web scraping is a powerful techniquefor gatheringdatafromwebsites.Itenablesorganizationstogather large amounts of data quickly, reducing the need for manual dataentryandsavingtime.Additionally,itiscost-effectiveand flexible, allowing organizations to gather data from multiple sources. However, it also has some limitations, including the potential to put a strain on websites and the risk of inaccurate or outdated data. Organizations that use web scraping should be aware of these limitations and take steps to ensurethe accuracyandreliabilityofthedatatheygather.

III. RELATEDWORK

DimitrisMourtzis A et al. [1] conducted a literature review on customer feedback gathering and management toolsfor product-service system design. The review focuses on the use ofthesetoolsinthecontextofproduct-servicesystems,andthe authors examine various methods for collecting and managing customer feedback in order to improve the design of such systems. They also identify gaps in the literature and areas for future research. The authors conclude that effective customer feedback gathering and management is crucial for improving product-service systemdesign.

The paper authored by OleksiyKhriyenko explores the development of customer feedback systems towards incorporating semantic technologies. The literature survey included in the paper assesses the current state of customer feedback systems and the benefits and limitations they possess. [2] The study highlights the significance of semantic enhancement in customer feedback systems and how it can result in improved data analysis and decision-making processes. The paper provides valuable insights for researchers and professionals in the field of customer feedback systems and the utilization of semantictechnologies.

The paper "Robotic Process Automation at Telefónica O2" by Mary Lacity et al. [3] examines the implementation andimpact of Robotic Process Automation (RPA) at TelefónicaO2, a telecommunications company. The authors analyze the implementation of RPAatTelefónicaO2anditseffects on the company's operations, processes, and workforce. The study highlights the challenges and benefits of using RPA ina large telecommunications company and provides insights for other organizations considering implementing RPA. The findings of the study are expected to contribute to the broader academic and practitioner discussion on the use of RPA in largeorganizations.

MichalBańkaetal.[4]examinesthepotentialofbusinessintel ligence technology to enhance the process of collecting and analyzing customer feedback in urban public transportation companies. The paper "A Feedback Analysis Automation Using Business Intelligence Technology in Companies Organizing Urban Public Transport" explores the use of business intelligence technology for automating feedback analysis in companies that organize urban public transportation. Thestudy provides insights into how business intelligence technology can be used to automate feedback analysis, leading to improved data processing and decision-making capabilities. The authors also discuss the benefits and limitations of using this technology in the context of urban public transportation companies. The findings of this study are expected to provide valuable information for organizations looking to automate their feedback analysis processes using business intelligence technology.

The paper "Robotic Process Automation as an enabler of Industry 4.0 to eliminate the eighth waste: a study on better usage of human talent" by explores the use of Robotic Process Automation (RPA) in the context of Industry 4.0 to reduce the "eighth waste," which refers to the underutilization of human talent in organizations. The authors examine how RPA can be leveraged to automate repetitive tasks and free up human talent for more value-adding activities. The study provides insights into the benefits of using RPA in Industry 4.0, including improved efficiency and productivity, as well as better utilization of human talent. The authors also discuss the limitations of RPA and the importance of a strategic approach to its implementation. The findings of this study are expected to provide valuable information for organizations looking to adopt RPA as a tool for improving their operations and better utilizingtheirhumantalentinanIndustry4.0context[5].

The paper "Minimizing the number of robots required for aRobotic Process Automation (RPA) problem" focuses on the optimization of robotic process automation (RPA) deployment. The authors, Sara Seguin, Hugo Tremblay, ImeneBenkalai, David-Emmanuel Perron-Chouinard, and Xavier Lebeuf, aim to minimize the number of robots required to complete an RPA problem. The study provides insights into how the deployment of RPA can be optimized through the use of mathematical models and algorithms. The authors discuss the challenges associated with deploying RPA, including the high cost of implementation, and the importance of finding the optimal number of robots required to complete a given RPA problem. The findings of this study are expected to provide valuableinformation for organizations looking to adopt RPAasa tool for improving their operations, and for practitioners and researchers interested in optimizing RPA deployment. The authors'approachofminimizingthenumberofrobotsrequired for an RPA problem could lead to significant cost savings and improved efficiency in RPA implementation [6].

The paper "Comparative Analysis of RPA Tools: UiPath, Automation Anywhere, and Blue Prism" provides a comparison of three popular robotic process automation (RPA) tools: UiPath, Automation Anywhere, and Blue Prism. The author, SameeraKhan,aimstoevaluateandcomparethefeatures,benefit s, and limitations of each tool to help organizations choose the best RPA tool for their needs. The study provides insights into the key capabilities of each tool, including automation of repetitive tasks, process visualization, and scalability. The author also compares the ease of use, deploymentoptions, and support services provided by each tool. The findings of this study are expected to provide valuable information for organizations looking to adopt RPA

DOI: rp-9788770040723.175

as a tool for improving their operations and for practitioners and researchersinterested in the comparison of RPA tools. This paper could help organizations make informed decisions when choosing anRPA tool and ensure that they select the best tool for their specific requirements[7].

The paper "Customer Perception Driven Product Evolution: Facilitation of Structured Feedback Collection" by OleksiyKhriyenko focuses on the importance of collecting customer feedback in the evolution of a product. The author argues that customer perception plays a crucial role in product development and should be considered throughout the product lifecycle. To facilitate structured feedback collection, the author suggests the use of semantic technologies to enable the analysis of large volumes of customer data. This, inturn, provides organizations with insights into the customer experience and helps them make informed decisions about product improvements. The author further elaborates on the benefits of using a semantically-enhanced feedback system, including improved accuracy, efficiency, and scalability. The paper concludes by highlighting the potential of semantic technologies in facilitating customer-driven product evolution and providing organizations with a more structured approach to collecting customer feedback. This study provides valuable insights for organizations looking to improve their customer experience and product offerings[8].

The paper "Data Collection using Web Scraping with Robotic Process Automation" by KomalTathe, SanjotSharma, and Prof. Dr. JyotiKharade explores the use of Robotic Process Automation (RPA) in data collection. The authors argue that data collection is a critical aspect of business operations and that traditional methods can betime-consuming and resource-intensive. To address these challenges, the authors propose using RPA in conjunction with web scraping to automate data collection processes. The authors discuss the benefits of this approach, including increased accuracy, efficiency, and cost savings. They also provide an overview of various RPA tools and frameworks that arecommonlyused in data collection and web scraping, such as UiPath, Automation Anywhere, and Blue Prism. The paper concludes by highlighting the potential of RPA in enabling organizations to collect, process, and analyze large volumes of data, thereby providing valuable insights into their business operations. This study provides valuable insights for organizations looking to streamline their data collection processes and make more informed business decisions [9].

IV. Proposed System

The aim of our project is to extract customer reviews of the desired product from the website chosen by the customer and to classify the reviews into positive and negative reviews. The proposed architecture consists of a UiPath workflow which will prompt users for the website name in which they want to browse the product and the product which they would like to purchase and learn more about it. Using web scraping reviews will be extracted into an excel file. We will perform Sentiment analysis by using Uipath AI Fabric which consists of ML packages and through this we will classify the extracted reviews into 5 categories: very negative, negative, neutral, positive, verypositive.

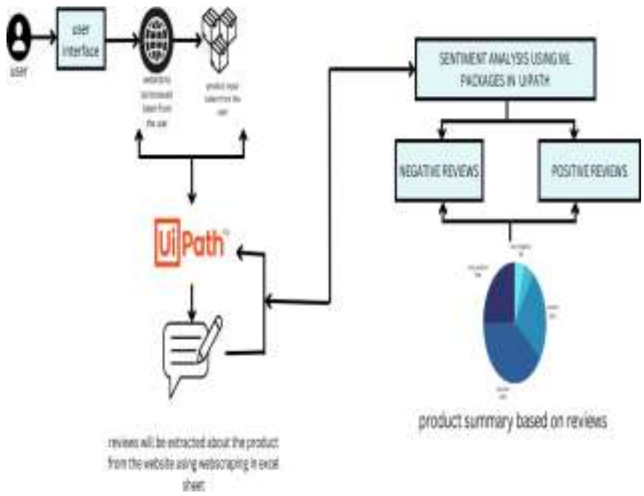

Fig. 1. System architecture of the customer feedback automation and classification.

The system constructed to accomplish the aim has fourmain modules:

- user inputmodule
- Review extractionmodule
- Review classificationmodule
- product summarymodule

A. *User InputModule*

The **user input module** in the system deals with taking input from the user regarding the product they want to learn about and the website in which they want to browse the product. To achieve this we are using Uipath activities like message box and input dialog to get the information from the user. We are using “INPUT DIALOGUE” activity to get the product name and website from the user. We are using another “INPUT DIALOGUE” activity to get the product link from the user. Then we will use “OPEN BROWSER” activity to open the website which the customer is planning to purchase their product in.This part of the user-input module will automatically open the website and enter the product name which they want to browse using “Open browser” and “Type Into”activities.Outoftheproductsdisplayedthecustomer can choose the product which he/she wants to know more about and copy the link of the product and paste the link in the input dialog that popsup.

B. *Review Extractionmodule*

It consists of Data scraping. It is a technique used to extract information from websites and other sources and store it in a structured format, such as a database or spreadsheet. It involves making automated requests to the source and then parsing the response to extract the desired information. Data scraping can be used for various purposes, such as market research, lead generation, and price comparison. We extract reviews of the product from the website. To do this first we will run the activities in the user-input module to open the product link in thewebsite.

DOI: rp-9788770040723.175

We are using a data scraping sequence which consists of activities such as“ATTACH

BROWSER” which is used to the website and in the DO section we are using “EXTRACTDATA” activity which extracts data from the indicated webpage. By using this activity we canspecify what information to be extracted by providing the XML string. The extracted data will be stored in variable “EXTRACT DATA TABLE” of variable type which will furtherbecopiedintoanexcelsheet.

C. Review classificationModule

After extracting the reviews about the product from the website we will perform sentiment analysis ML package from AI fabric in Uipath. This will classify the reviews into five categories: very negative, negative, neutral, positive and very positive.

The classified reviews will be stored in an excel sheetwhere the first column will be the review, second column will be the classification of the review i.e., if the reviews are very positive/ positive/ very negative/ very negative or neutral. The third column of the excel sheet displays confidence of the classification. This module helps inclassifying the reviews and reduces the task of reading all the reviews for the user and helps in understanding if the product is worth buying or not. Though the ratings of products do give us brief information about the quality of the product, learning about experiences of userswho alreadyboughttheproducthelpsthecurrentusertounderstand the product in a much better way and even help the user to decideiftheproductoverallishelpfulforhimornot.

D. Product summarymodule

After classifying the reviews into 5 different categories by performing sentiment analysis an overall summary about the product based on the review will be displayed using a pie chart from the excel sheet.

This pie chart helps us visualize the summary of classification clearly and quickly. Going through the overall classification of the review will be a tedious job for the user so we have automated this by creating a pie chart with an overall summary of the reviews of the product. The pie chart depicts whether the product majorly has positive reviews or negative reviews.

E. SentimentAnalysis

Sentiment analysis, also known as opinion mining, is a field of Natural Language Processing (NLP) that focuses on determining the sentiment expressed in a piece oftext. It involves analyzing text data, such as social media posts, reviews, and customer feedback, to determine whether the sentimentexpressedispositive,negative,orneutral.

The goal of sentiment analysis is to provide businesses with insights into the opinions and emotions of their customers and stakeholders. This information can be used to inform product development,improvecustomerexperience,andmonitorbrand reputation.

Sentiment analysis algorithms typically use a combination ofmachinelearningtechniquesandNLPtechniquestoidentify patterns in text data and classify the sentimentexpressed.There are two main approaches to sentiment analysis: rule-based methods and machine learning-based methods. Rule- based methods use a set of predefined rules to classify the sentiment expressed in a piece of text. For example, a rule- based approach might classify a sentence as positive if it contains words such as "good" or "great."

Sentiment analysis has several applications in a variety of industries.Inthemarketingandadvertisingindustry,sentiment analysis can be used to monitor brand reputation and customer sentiment towards products and services. In the customer service industry, sentiment analysis can be used to identify customer pain points and improve the customer experience. In the financial industry, sentiment analysis can be used to monitormarketsentimentandmakeinvestmentdecisions.

In conclusion, sentiment analysis is a field of NLP that focuses on determining the sentiment expressed in text data. It provides businesses with insights into the opinions and emotions of their customers and stakeholders, and has a wide range of applications in a variety of industries. However, sentiment analysis also has some limitations, includingthe challenge of accurately determining sentiment and ensuring the quality of training data. Organizations that use sentiment analysis should be aware of these limitations and take steps toensuretheaccuracyandreliabilityoftheirresults.

V. EXPERIMENTALSETUP

A. SoftwareUsed

1) UiPathStudio: UiPath Studio is a powerful and user-friendly platform for automating various business processes.The software is easy to use, even for non-technical users, and offers a visual interface that allows users to build automated processes using drag-and-drop functionality.UiPathStudio integrates with a wide range of applications, includ- ing web and desktop applications, and provides advanced capabilities such as machine learning and computer vision. The platform is scalable and can be deployed across large enterprises, small businesses, and even individuals. Addition- ally, UiPath Studio has a large and active community, which provides users with access to a wealth of knowledge and support resources. In summary, UiPath Studio is an ideal tool for organizations looking to automate their business processes andachievehigherlevelsofefficiencyandproductivity.

2) UiPathAI Fabric: UiPath AI Fabric is a cloud-based platform for managing and deploying AI models. It supports a wide range of AI models including computer vision, natural language processing, and predictive analytics. Ai Fabric in Uipath helps us to manage ML packages with Uipath workflows.AI Fabric connects seamlessly with UiPathstudio and Orchestrator to create a unified enjoy inside all UiPath Platforms. Through this device, customers’ growing automations can better orchestrate all functionalities of AI; deploying, consuming,

DOI: rp-9788770040723.175

handling and enhancing gadget studying models. For the automation of customer feedback analysis we areusing the Uipath Studio Enterprise version. We used a free 60-day trial version to implement the necessary ML packages using theAIpathCentreinUiPathStudio.

B. PackagesUsed

1) *UiPathExcel Activities:* The UiPath Excel activities in UiPath Studio allow you to perform various operationson Excel spreadsheets such as reading, writing, updating, and manipulatingdatainthecells.Withtheuseoftheseactivities,you can automate repetitive tasks such as copying data from one sheettoanother,formattingcells,addingformulas,etc.Theactivities include reading and writing data, formatting cells, adding formulas, sorting, and filtering data, and more. These activities can save a lot of time and effort by automating tasks that would otherwise require manual intervention, reducingthe possibilityoferrorsandincreasingefficiency.

2) *UiPath.MLServices.Activities:* The ML Skills page, available from the ML Skills menu after deciding on a project, shows all of the fashions deployed on your UiPath AI Center service, whether or not they use ML or OS programs. This package enables users to incorporate machine learning models into their automations, making it easier to extract insights from data and improve the accuracy of decision-making. The activities provided in this package are user-friendly and intuitive, allowing even non-technical users to leverage the powerofmachinelearningintheirautomations.

3) *UiPath.System.Activities*

UiPath.System. Activities is a set of activities in UiPath Studio that provide various system- level functionalities, such as managing files and directories, interacting with the operating system, executing external processes, and more. These activities allow automating processes that involve the system and external applications, making it easier to manage tasks that would otherwise be manual and time-consuming. The UiPath.System.Activitiesinclude activities such as "File Exists", "Read Text File", "DeleteFile", and "Execute Process". These activities help in making the automation process smooth and efficient, leading to increased productivity and decreasederrors.

4) *UiPath.UIAutomation.Activities*

TheUiPath.UIAutomation.Activities is a set of activities inUiPath Studio that enables automation of user interface elements such as buttons, text boxes, and drop-down menus in desktop applications. These activities can be used to automate repetitive tasks and improve the efficiency of processes. The activities provide a wide range of options to interact with user interface elements, such as clicking buttons, entering text, and selecting items from drop-down menus. With UiPath.UIAutomation.Activities, automating desktop applications becomes easy and straightforward, and saves time andresources.

5) *UiPath.WebAPI.Activities:*

The UiPath.WebAPI.Activities package in UiPath Studio allows for automation of RESTful web APIs. It includes activities for sending HTTP requests and parsing the response, such as HTTP Client, JSON, XML, and REST activities. These activities enable users to perform actions such as retrieving data, updating records, or performing a specific action on a web API. These activities can be combined with other UiPathStudio activities to create a complete automation solution that interacts with a web API to automate a wide range of businessprocesses.

VI. Implementation AndAnalysis

For implementation purpose we used UiPath. We checked our model with two websites for the same product. We used Amazon and Flipkart websites to extractand classify reviews and the product we used is “boat red earphones”. We extracted reviews for this product from both Amazon and Flipkart for the same product to compare which website provides better dealer and delivery for the same product.

The software when run first displays a Welcome message and the proceeds with the USER-INPUT module where it further asks the user for the website, they want to browse to purchase the product, next it displays another message box asking the user for the product they wish to purchase. After taking the above-mentioned input from the user it asks opens the website the user has mentioned previously and searches for the product mentioned by the user. Then again, a message box will be displayed asking the user to provide link for the producttheywishtobrowseaboutmore.

Review Extraction and classification

Fig.2. (a)

Fig.2. (b)

Fig.2. (a) and (b) are extracted revies of boat red earphones in Amazon website and have been classified to fivecategories: verynegative,negative,neutral,positive,verypositive.

International Conference on Recent Trends in Data Science and its Applications

Fig. 3. (a) and (b) show the extracted reviews of boat red earphones from Flipkart website and have been classified into five categories: very negative, negative, neutral, positive, very positive.

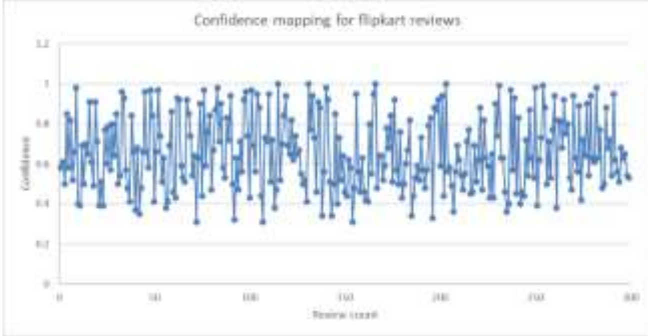
Product Summary based on review classification.

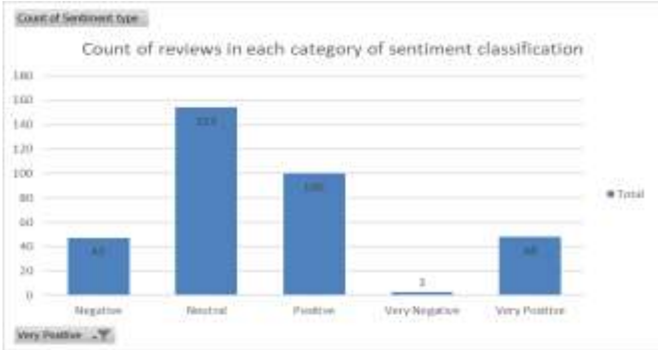
Row Labels	Count of Sentiment typ
Negative	47
Neutral	154
Positive	100
Very Negative	3
Very Positive	48
Grand Total	**352**

Fig. 4. The above figure gives overall summary of the count of reviews which fall under each category i.e., how many reviews are classified as very negative, negative, neutral, positive and positive about the reviews extracted from Amazon website.

Row Labels	Count of Sentimer
Negative	23
Neutral	64
Positive	113
Very Negative	6
Very Positive	92
Grand Total	**298**

Fig. 5. The above figure depicts the summary of the count of reviews which fall under each category about the reviews extracted from Flipkart website.





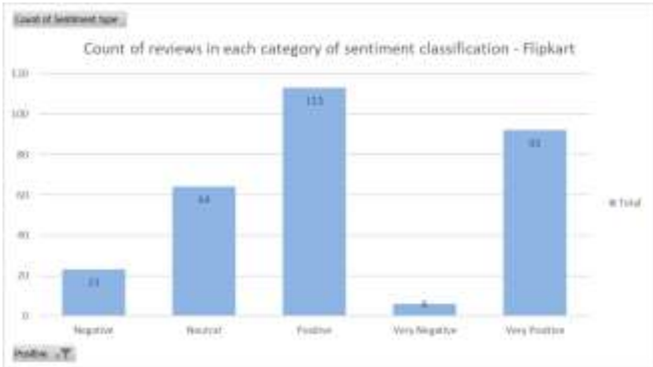


Fig. 6. The above graph is a bar graph on sentiment type vs Count of reviews graph which depicts how many reviews fall under each sentiment type for reviews extracted from Amazonwebsite

Fig. 7. The above graph is a bar graph on sentiment type vs Count of reviews graph which depicts how many reviews fall under each sentiment type for reviews extracted from Flipkart website.

Fig. 8. The above graph is confidence mapping graph for reviews extracted from Amazon website. The graph plots the confidence level of review against review count.

Fig. 9. The above graph is confidence mapping graph for reviews extracted from Flipkart website. The graph plots the confidence level of review against review count.

VII. Conclusion

In conclusion, customer feedback automation using UiPath is a valuable tool that helps businesses improve customer experience, increase customer satisfaction, and drive business growth. By automating the process of collecting and analyzing customer feedback, businesses can gain valuable insights into their customers' preferences,

DOI: rp-9788770040723.175
needs, and pain points. This information can then be used to make informed business decisions, develop targeted marketing strategies, and improve customer service.

The following major findings were obtained:

1. To take input about the product the customer wants to learn about and from which website and extract the customer reviewsabouttheproductusingwebscraping.
2. To analyze the reviews using sentiment analysis and classify the reviews into 5 categories: very negative, negative, neutral, positive, verypositive.
3. To give a summary to the user about the productbased onthecustomerreviewsusingvisualizationtoolslikebargraph

Thedevelopedsystemhelpsuserscompareproductsbasedontheirreviewsratherthanjuststarratingandhavebetterunderstandingabouttheproduct.Theuserswillbeabletocompare same product in different websites anddecidewhichwebsiteprovidesbetterdealerordeliveryforthe sameproduct.UiPath'sadvancedfeaturessuchasnaturallanguageprocessing,sentimentanalysis,andmachinelearningalgorithmsenablebusinessestogainadeeperunderstandingofcustomerfeedback and improve their customer experience.

Abstract—Social media platforms have become a vital platform for individuals to share their thoughts, opinions, and experiences, making them an important source of information. The emergence of social media has led to a growing interest in using social media data for event detection - the process of identifying and analyzing significant events or incidents in a given area. Social media has already been utilized successfully in monitoring and predicting epidemics caused by viruses like Zika, Dengue, MERS, and Ebola. More recently, it has been used to track and predict the spread of the COVID-19 pandemic. To evaluate the publicly available crowdsourcing data frequently required to stream, aggregate, filter, and process original data, information retrieval techniques are essential. However, academic literature reveals limited understanding of the crowd power that can be leveraged to foresee or respond to events. This study focuses on analyzing the literature on event detection using social media data, exploring the various techniques and methods utilized to identify and classify events, as well as the challenges and limitations of utilizing social media data for event detection.

Keywords—rowdsource, streaming data, big data, disaster management, unstructured data, social media, outbreaks

I. Introduction

Identifying events is an important activity in many areas, including crisis management, news analysis, and social science research. The growing use of social networking sites has made it a vital resource for event detection. Social networking sites have become principal outlets for individuals to express their viewpoints, sentiments, and encounters. This has resulted in an increasing interest in utilizing information for event identification. The platform is also a common pastime for billions of people worldwide, resulting in a massive amount of data production. For instance, Facebook (Menlo Park, CA) generates four million posts every minute. Minority opinions and private information are given a platform that are not covered by other sources. According to Bazarova et al. (2015), social media can create a feeling of isolation that enables individuals, especially young people and when discussing intimate topics, to express themselves without filters, more so than in conventional meet and talk. ShengLu, Mingqing Ma, and Qiangqiang (2022) suggest that social media provides an extra, unauthorized source of data that can be used to uncover health content that hasn't been shared with healthcare professionals or health organizations, as well as to express opinions on sensitive health-related topics. Middle East Respiratory Syndrome (MERS), Ebola, Zika, and Dengue disease monitoring efforts may be augmented and improved by using data from networking platform interactions, according to research. (Househ M 2015, Odlum M, and Yoon S 2015; McGough SF et al., 2016; Marques-Toledo CA et al., 2017; Shin SY, Seo DW, An J, et al., 2016).

Researchers can use data processing techniques to automatically collect and analyze social media activity for important insights. This research can be applied to disease surveillance, targeting vulnerable populations, and addressing unsolvable health concerns like adolescent drug and alcohol use. Charles-Smith et al. (2015) emphasized the effectiveness of these tools in monitoring disasters, disease outbreaks, and other events. In this article, we discuss the background, approach, and benefits of utilizing social media for event monitoring. In this article, we provide an overview of the background, methodology, and advantages of utilizing social media to monitor various events, including disasters, outbreaks, and other incidents.

II. Background

2.1 *Social media essentials*

Kamruzzaman et al (2019) have suggested that the emergence of social networking sites has drastically transformed the methods through which individuals collaborate with each other and disseminate the details globally.

- These platforms offer exchange of contents in any format, allowing users to express themselves in various ways.
- Furthermore, social media platforms encourage cross-platform communication through social sharing, email, and RSS.
- Users can participate in the platform to varying degrees, posting content and leaving comments. The objective of social platforms is that it enables the rapid and broad distribution of knowledge.
- Additionally, social media platforms allow for one-to-one, one-to-many, and many-to-many communication and can be used synchronously or asynchronously, making communication possible across time.
- Social media websites offer a variety of features that allow users to interact with each other and the platform itself. These includes
- Social bookmarking, where users can tag and browse websites that others have bookmarked

DOI: rp-9788770040723.177

- Social news that enables commenting and voting on articles
- Social networking where users can join groups, add friends, and comment on profiles
- Social photo and video sharing where users can comment on submitted images and videos, and
- Wikis such as Wikipedia where users can create or modify entries.

Beyond these examples, any website that encourages user interaction falls under the definition of social media.

2.2 Social Media in Natural Disasters

Disasters occur frequently, which is difficult for government agencies and emergency services. Individuals and local communities, however, can contribute to the crowd's knowledge to forecast disasters and perform emergency response actions when they occur. Social media makes it possible for the public to participate in disaster relief efforts and allows information to be promptly transmitted from catastrophe-affected areas to those who need it most.

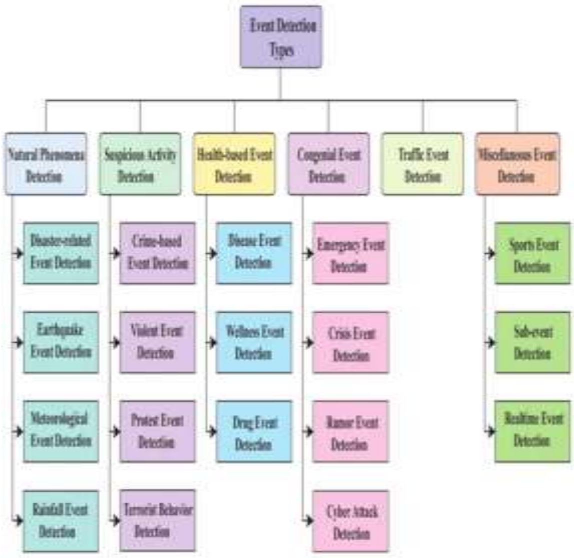

Fig. 1. Detecting a range of events through analysis of crowd sourced data.

Crowdsourcing offers a chance to facilitate the flow of knowledge, resources, money, and labor to anticipate and respond to a crisis in the era of the internet. Natural disasters can seriously harm people and property and are frequently unanticipated. Technology and societal advancements help us respond to disasters more effectively (Tuladhar et al., 2015). The response is faster and more accurate when a modern, powerful, and complicated decision-making system is used. Disasters are happening more frequently, which is making it difficult for government agencies and emergency organizations to respond. Relief efforts may be delayed as a result of unpredictable events, frightened reactions, and incomplete information about affected areas (Kankanamge et al. 2019).

To ensure the successful resolution of a crisis, it is important to first determine the effectiveness of today's disaster relief and rescue services. It's important to spread awareness and understanding about various systems, such as those related to geography, search and rescue procedures, and adapting to extreme circumstances. Sharing knowledge about these systems can play a crucial role in disaster preparedness. Studies in information systems have demonstrated that advancements in technology, particularly the use of internet-based platforms that encourage public participation, can help individuals and communities become more resilient in the face of disasters (Nan and Lu 2014).

One approach to improving disaster response systems is to use crowdsourcing to understand the connection between environmental disasters and human actions. By leveraging crowdsourcing, we can gather more data, scale potential solutions, and respond more rapidly to emergencies. Despite the recognition by scholars from various fields on the significance of mass media, community participation, and civic activism in disaster scenarios, these phenomena are not often considered as forms of crowdsourcing (Elbanna et al. 2019, Guo et al. 2021).

Poblet et al (2014) identified two technological approaches for managing disasters in literature: (i) sourcing and (ii) collaboration. The sourcing approach focuses on gathering and analyzing text from social networking sites to produce the timely alerts. Conversely, the collaboration approach aims to improve human and disaster management technology interaction to enhance overall communication.

Applying crowdsourcing to disaster management makes it easier to tap into collective wisdom and mobilize social forces to overcome a variety of challenges, including delayed situational awareness, a shortage of personnel to process and analyze data, and a lack of personnel to conduct rescue operations. Crowdsourcing can help make disaster aid more effective and affordable in this way (Callaghan 2016).

Crowdsourcing involves people from all around the world in disaster management and emergency response to natural disasters. Researchers have examined several types of natural disasters, which include floods (Schumann et al., 2010; Zeman, 2006; Kuhlicke et al., 2015; EMS, 2018; Trambauer et al., 2016), earthquakes (DE A, 2014; Wang J, 2019; TL and J, 2017), and wildfires (Thom, 2016; Quapp et al., 2017).

2.3 Social media in outbreak detection

Before the era of vaccinations, infectious diseases typically followed seasonal patterns and progressed through various phases. It is critical to identify a seasonal outbreak promptly to respond more efficiently and effectively to medical professionals. Failure to do so can lead to fatal diseases like influenza or influenza-like illnesses (ILI) in a region where an epidemic has broken out epidemiologically (Alessa and M. Faezipour, (2018), E. Lau and P. Wark, (2019)).

To lower the risk of illnesses and stop epidemics, early discovery is crucial, but current outbreak detection methods have a lengthy delay between diagnosis and public action (Tao et al, 2020). Additionally, presumptive techniques such as QMRA might not be effective in rapidly identifying

DOI: rp-9788770040723.177

outbreaks as they rely on structured data from pre-planned field trials (Tao et al, 2020).

Online social media (OSM) can be utilized to detect and contain epidemic outbreaks in health surveillance systems (S. Amin, 2021), forecast public illness outbreaks, and spread accurate information (C. Feng et al, 2020, K. Yu, 2021). Rapid disease diagnosis can lessen the impact of seasonal epidemics on population safety (Maharana, A. et al, 2019). Combining machine learning techniques with crowdsourcing provides novel ways to conduct risk assessment and communication for food safety. Social platform monitoring is also an effective tool to disseminate information for disease monitoring and engage with the public to prevent epidemic breakouts (X. Zhang, et al, 2021).

2.4 Understanding Events in Social Media

According to Zhao, Qiankun, and PrasenjitMitra (2007), an event refers to a collection of social player relations on a specific topic within a certain timeframe. According to Hearst and Marti (2009), incidents in social media analysis can be characterized as observable occurrences that involve multiple entities. The process of monitoring the incidents utilizes cognitive processes to accurately detect incidents by analyzing data. Events are noteworthy occurrences at specific times and locations that can be regarded as a single chapter of a larger narrative (Sayyadi, Hassan, Matthew Hurst, and Alexey Maykov, 2009; Panagiotou N et al, 2016). In social media analysis, it's necessary to examine the cumulative trend changes in the data stream to comprehend events. According to KarthikSubbianet all (2012), streaming data analysis involves recognizing significant incidents as they happen. The analysis of social networking sites data can be beneficial for detecting various incidents, whether they are limited to a particular location or widespread, such as traffic congestion on a street or floods in Florida, as explained by McCreadie et al (2013).

The platform has been used for multiple purposes,such as identifying activism, supporting emergency responders, tracking disease spread, analyzing user functions and behaviors, measuring media coverage, providing tourist information, detecting traffic, exposing people to diverse viewpoints, and facilitating political participation. It has also been used to study migration patterns, food preferences, and happiness levels in real-time. Some people still significantly rely on networking platforms for governmental updates and data, despite the fact that the majority of its content has nothing to do with news or public problems (Gil de Ziga et al., 2012). For these research aims, studies have used several billions of tweets or messages (Xu et al., 2014; Avvenuti et al., 2016, 2018; Lampos and Cristianini, 2012; Martinez Teutle, 2010; Cresci et al., 2020; Mazza et al., 2019; Prieto Curiel et al., 2019; Silvestri et al., 2015; D'Andrea et al., 2015; Himelboim et al., 2013; Ausserhofer and Maire, 2013; Coletto, 2017; Amato, 2017; Dodds et al., 2011).

2.5 The challenges of crowdsourcing in crisis / limitations of social media

Crowdsourcing in crisis situations refers to the process of collecting and utilizing information from a large group of individuals, often via social media platforms, to aid in crisis management and response efforts. However, there are several challenges and limitations associated with crowdsourcing in crisis situations.

Due to the use of terms with numerous meanings in social platform streams, ambiguity is a significant issue with human feeds or text (Carbezudo MAS and Pardo TAS, 2017, Gutierrez-Vazquez et al 2016) Although humans can use context and common sense to disambiguate text, computer programs struggle to do so (Alkhatlan A, Kalita J and Alhaddad A, 2018). Moreover, the presence of informal language, shortened words, and initialisms in social networking sites makes it even more challenging to understand their meaning..Unfortunately, most of the techniques used to predict or identify the current events are not equipped to handle this issue. Making it difficult to accurately analyze social platform content.(Katragadda S, Benton R and Raghavan V 2017).

Social networking sites data gathering and monitoring present many opportunities for multiple entities. However, there are several challenges associated with this field,

1. Data cleansing - One of the key challenges in this field is the need to effectively preprocess the textual data, particularly the high volume of on the fly data, in order to ensure its quality and reliability.
2. Scraping - There is limited academic access of content from the platforms, However, news services such as Thomson Reuters and Bloomberg charge a fee for access to their data, while Twitter recently introduced the Twitter Data Grants program, which provides academics with access to Twitter's historical data and public tweets to enable them to obtain fresh insights from its vast data collection (Twitter has over 500 million tweets each day).
3. Verification and reliability: One of the main challenges of crowdsourcing in crisis situations is verifying the accuracy and reliability of the information that is collected. Social media platforms can be a source of misinformation and rumors, which can lead to confusion and impede crisis response efforts.
4. Privacy concerns: Crowdsourcing in crisis situations can raise privacy concerns, as personal information can be shared and used without consent.
5. Data overload: Social media platforms can generate a large volume of data, which can make it difficult for organizations to effectively process and utilize the information (Agarwal, Liu, Tang, & Yu, 2008).
6. Bias: Crowdsourcing can also be affected by bias, as certain groups of people might be more likely to share information than others, leading to a lack of representation and a narrow perspective of the crisis.
7. Limited data quality: Social media data, although useful, can be unstructured, incomplete and unreliable. This can make it difficult to extract useful information and make accurate predictions.

DOI: rp-9788770040723.177

8. Lack of context: Social media data can lack context and background information, making it difficult to understand the information and to make sense of the events.

9. Streaming data - The real-time handling of crises can be challenging due to the vast amount and speed of social media data. Identifying and categorizing events in real-time can be difficult, which can hinder efforts to respond to crises.

10. Relevance in Context - Social media information is contextual and varies from user to user. For example, some Twitter users may appreciate updates on daily activities while others find it bothersome.

11. Use of Slang Terms and Intentional Spelling Errors - Informal language is prevalent on social media, with people using colloquialisms and intentionally misspelling words for emphasis, such as "so coooooool..." This form of language conveys sentiments, phrases, and feelings and adds a new dimension to written texts. These aspects of communication should not be disregarded as mere typos, as they can provide valuable information. Online dictionaries like UrbanDictionary can be used to decode the meaning of slang, acronyms, and other informal language used by people. However, the abundance of off-topic discussions and noise can distort the analysis.

12. Recency of data - Platforms allow for fast conversations and responses, and people's interests tend to be diverse and changeable over time, as observed in the blogosphere (Hayes &Avesani, 2007). This results in a shift in both people's interests and the social media environment. Additionally, the freshness of the information on social media is constantly evolving.

In conclusion, crowdsourcing in crisis situations can provide valuable information for crisis management and response efforts. However, there are several challenges and limitations associated with crowdsourcing in crisis situations, such as verification and reliability, privacy concerns, data overload, bias, limited data quality, lack of context, and inability to handle crisis in real-time. Thus, organizations should be aware of these challenges and limitations and develop strategies to address them.

III. Methods and Techniques

Two different approaches used to identify incidents from social networking sites data.

The first one is, based on the rules. This approach relies on predefined patterns, policies and guidelines, such as keyword-based and location-based techniques. Keyword-based methods use specific keywords or hashtags to detect events, while location-based methods rely on geographic information to identify events in a certain area.

On the other hand, machine learning-based methods involve the use of algorithms to learn patterns and classify events. These methods can be supervised or unsupervised, where supervised methods use labeled data to train a model, while unsupervised methods use unlabeled data to detect patterns.

IV. Big Data framework for social media analytics

4.1 *Big Data*

A big data framework is a collection of technologies and tools used to handle, examine, and visualize the terabytes of data. To facilitate social media analytics, such a framework can be employed to acquire, retain, process, and analyze voluminous data generated by platforms like Twitter, Facebook, and Instagram.

A data management system typically consists of several essential components, including data collection, storage, processing, analysis, visualization, and governance.

1. The data collection component involves acquiring data from different sources, such as social media platforms, APIs, and web scraping, in various formats, such as text, images, and videos.

2. The data storage component includes preserving the collected data using various storage technologies, like Hadoop Distributed File System (HDFS), NoSQL databases, and cloud storage.

3. The data processing component involves cleaning and processing the collected data using various technologies, such as Apache Spark and Apache Storm, capable of handling large data volumes in real-time.

4. The data analysis component includes analyzing the processed data with the help of big data technologies, which provide machine learning and data mining functionality.

5. The data visualization component involves presenting the analyzed data through various technologie to create interactive visualizations.

6. Lastly, the data governance, security, and compliance component involves ensuring compliance with legal and regulatory requirements and ensuring data security.

The big data framework for social media analytics should also include an orchestration and scheduling layer to schedule and monitor the data pipeline, such as Apache Airflow, Oozie, or Apache NiFi.

Newman et al. (2016) explains that the term "Big Data" implies a vast amount of data, denoting its magnitude or quantity. However, contemporary literature highlights a set of characteristics that distinguish big data and underscore their value. These characteristics, known as the three Vs of big data - volume, variety, and veracity - are widely accepted among scholars. The concept of the three Vs was first introduced by Laney and has been elaborated upon by subsequent authors (Uddin et al., 2014). Volume refers to the size of the data generated, which can range from terabytes to exabytes and even beyond. Big data is continuously produced from various sources such as social media, cloud-based services (such as Amazon), business-related data, and Internet of Things (IoT)-related data (Khan et al., 2014; Storey and Song, 2017). Radicati and Hoang (2011) predicted that the global number of email accounts generated would increase to over 4.3 billion by late 2016, up from 3.3 billion in 2012. According to a survey conducted by IBM in mid-2012, data amounts exceeding one terabyte

DOI: rp-9788770040723.177

are considered to be big data (Schroeck et al., 2012). However, this threshold is relative, as the quantification of data volume depends on other factors, such as time and data type. With advances in storage capabilities, larger datasets can be managed over time. According to Chen and Zhang (2014), the concept of Big Data is not only about the volume of data, but also encompasses various dimensions, starting with the letter V and ending with the "Vs" of Big Data. It is evident that a terabyte of textual data is not always equivalent to a terabyte of video data, highlighting the importance of the data-type component. The data sources and types are diverse, and different formats are used to describe data coming from various sources. For instance, structured data can be distinguished from frequently administered Structured Query Language (SQL), which is a programming language designed for maintaining and accessing data within Relational Database Management Systems (RDBMS) (Hashem et al. 2015). Structured data is simple to enter, search for, and save, while unstructured data, such as multimedia (videos, photos, and audios), which has a fixed format, is the primary format that defines Big Data (Gandomi and Haider 2015). Managing unstructured data poses a significant challenge for data scientists. Semi-structured data, such as Extensible Markup Language (XML) and JavaScript Object Notation (JSON) data, are also generated. The incoming and outgoing data are characterized by their velocity, which is assessed in terms of batch size, near real time, and real-time to achieve streaming (Chen and Zhang 2014).

Yaqoob and colleagues (2016) argue that the proliferation of internet-connected mobile devices and sensor-equipped devices has a significant impact on data velocity. Fan and Bifet (2013) suggest that delivering timely responses and updates is critical for evaluating an application's effectiveness. In addition, interpreting and organizing streaming data is a challenge that requires relevant technologies and techniques (Orgaz et al., 2016). Big Data is characterized by additional features, such as veracity, which refers to the reliability and messiness of data, according to IBM and Microsoft (Gandomi and Haider, 2015). Storey and Song (2017) maintain that veracity poses problems with data quality, such as accuracy, completeness, timeliness, consistency, and accessibility. Value, the fourth V of Big Data, was introduced by McKinsey and Oracle to highlight the value of hidden insights in Big Data (Chen and Zhang, 2014). Wang et al. (2017) expand on this concept by proposing five V dimensions for Big Data that consider both value and veracity. Uddin et al. (2014), on the other hand, identify seven Vs of Big Data, taking into account both the validity and volatility dimensions. They define volatility as the retention policy for structured data typically used in organizations, while validity refers to data accuracy and correctness regarding its intended purpose. The many Big Data dimensions and their associated names are shown in Figure 1.

Fig. 2: Big Data dimensions

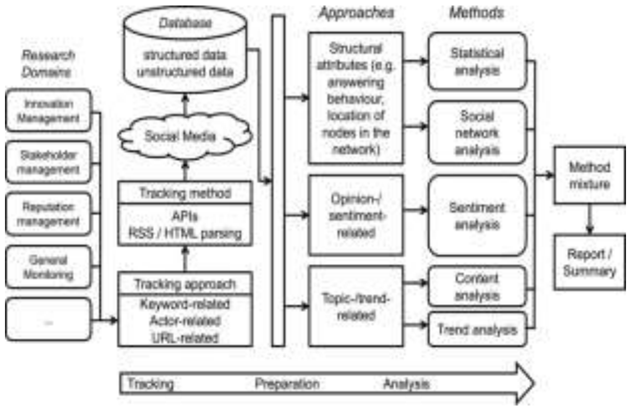

Fig. 3. The Social Media Analytics Framework (Stieglitz et al., 2014, Stieglitz and Dang-Xuan, 2013).

To effectively analyze social media data, organizations can employ a big data framework that involves the use of various technologies and tools. This framework enables the collection, storage, processing, evaluation, and visualization from social media platforms. With this approach, businesses can gain insightful information and use social platform data to guide decisions.

4.2 Natural language processing

Utilizing natural language processing (NLP) is crucial in enhancing event detection through evaluating the online networking platforms data. By employing NLP techniques to extract and scrutinize text data from social media platforms like Twitter, Facebook, and Instagram, events can be identified and classified effectively. One important NLP technique that can be used for event detection is text classification. This technique can be used to classify social media posts into different categories, such as events or non-events. Text classification algorithms can be trained on labeled data to learn the characteristics of events and non-events, and then applied to new data to classify it. For instance, a text classification algorithm can be trained to classify posts that mention a keyword or hashtag as events.

Another NLP technique that can be used for event detection is named entity recognition (NER). This technique can be used to identify and extract entities. NER can be used to extract relevant information from social media posts, such as the location of an event or the people involved in an incident. In addition to text classification and NER, Sentiment analysis is also an important NLP technique that can be used for event detection.

Depending on the polarity of posts, the NLP model can be used to categorize the sentiment.Sentiment analysis is used to determine how the public feels about a specific occurrence or event, which can be useful for crisis management and news analysis. Finally, NLP techniques, such as geotagging and geocoding, can extract geographic information from text data to facilitate geolocation, enabling the identification of the location of an event or incident. This information can be used to identify events in specific areas and to understand the spatial distribution of events.

The authors (McCreadie R et al. 2013) investigated scalable distributed event detection using Twitter feeds and lexical key partitioning technique. The research suggested a framework for automatic distributed real-time event detection that employed Storm topology and utilized Locality Sensitive Hashing (LSH) to handle noisy, temporal, and slang-filled Twitter streams. Authors (Kaleel SB, Almeshary M, Abhari A, 2013) proposed using LSH, which was used for the incident identification. The proposed model compared with leading social platforms Facebook, Twitter.

In 2015, Musaev et al. proposed a system called LITMUS to identify "landslides" related information from social media using a keyword-based approach. The system extracted categorization features from Wikipedia and utilized an enhanced Explicit Semantic Analysis (ESA) algorithm to categorize the data into relevant and irrelevant categories. The location was approximated using semantic clustering that relied on measuring the semantic distance. However, only data that had been tagged with location information were taken into consideration, and the analysis did not take into account the handling of SAB words in the semantic-based approach. The system was later used to identify crossover activities between two social media streams.

TABLE 1 :AN OVERVIEW - ADVANTAGES AND LIMITATIONS OF MODELS IN EVENT DETECTION.

Category	**Unsupervised ML**	**Semi-supervised ML**	**Supervised ML**	**Semantic approach**
Benefits	Approach can detect events without considering their nature, and can handle a large volume of data.	The method is especially beneficial when it's challenging to identify important characteristics in the data. Additionally, even a small dataset can produce a substantial increase in accuracy.	The outcomes are very precise and reliable.	More accurate and precise results due to its ability to consider the context and meaning of the text being analyzed.
Shortcoming	Working with data streams that have many attributes or features, using this technique may pose a challenge. This technique may not account for the spatial relationships within the data, which can be a limitation in certain applications.	Iteration results are not stable and accuracy is low.	Challenges, including the need for significant time and resources, dealing with large and complex datasets, addressing the issue of concept drift, and the requirement for expertise to properly label input and output variables.	A crucial time and resource commitment, in addition to a detailed understanding of algorithms, are needed to develop semantic-based techniques.

(Romero and Becker, 2019) and (Sun et al., 2021) proposed different approaches for event detection in social media using natural language processing techniques. Romero and Becker used a hybrid approach that combined with multiple traditional approaches NER, TF-IDF and others to classify events in tweets. On the other hand, Sun et al. proposed scoring and word embedding for the same which employed Word2vec with enhanced embeddings. Both studies employed pre-processing steps. However, neither of the approaches addressed the ambiguity related to SAB terminologies in social platforms. Overall, natural language processing techniques have the potential to improve event detection in social media by extracting and analyzing text data using methods such as text classification, named entity recognition, sentiment analysis, and geolocation.

V. CONCLUSION

In conclusion, studies on social networking sites have shown that it might be a useful data resource for incident detection. Various natural language processing techniques have been used to extract and analyze text data from social media platforms, including text classification, named entity recognition, sentiment analysis, and geolocation. While these techniques have shown promising results, there are still challenges to overcome, such as handling ambiguity and variability in language, improving the accuracy and scalability of models, and addressing ethical and privacy concerns. Overall, more investigation into this topic has the potential to improve our capacity for real-time recognition and response to events, with significant implications for sociology, health services, and emergency preparedness.

VI. FUTURE WORK

There are several potential areas of focus for future research that explore the use of online networking platforms for event detection. These include:

1. Ambiguity and variability in language: Social media language is often informal and ambiguous, making it difficult to accurately detect events. Existing natural language processing techniques have been successful in addressing some of these challenges, but more

DOI: rp-9788770040723.177

sophisticated approaches could be explored to improve accuracy.

2. Scalability and efficiency: Social media platforms generate vast amounts of data in real-time, making it difficult to process and analyze the data in a timely manner. Future work could focus on developing scalable and efficient algorithms for event detection.

3. Ethical and privacy concerns: Important ethical and privacy issues are brought up by the use of social media data to identify events, notably in relation to data privacy, informed permission, and potential bias. Future research might concentrate on creating moral standards and best practices for gathering and utilizing social networking websites.

4. Incorporating multimedia data: Social media platforms also contain a wealth of multimedia data such as images and videos, which could provide valuable information for event detection. Future research could explore how to effectively integrate multimedia data into event detection models.

5. Adapting to new social media platforms and evolving language: As new social media platforms emerge and language use evolves over time, it will be important for event detection models to adapt to these changes. Future research could explore how to build models that are flexible and adaptable to new platforms and changing language use.

6. Application to specific domains: The method of event detection from social networks has multiple applications across diverse industries including crisis management, public health, and social sciences. Future work could focus on applying event detection models to specific domains and assessing their effectiveness in real-world settings.

7. Real-time event detection: Social networking platforms produce vast amounts of data in real-time and event detection algorithms need to be able to operate in real-time as well. Future research could explore how to improve the speed and efficiency of event detection algorithms to enable real-time monitoring of events on social media.

8. Handling bias and overfitting: One potential challenge with event detection algorithms is that they may be biased towards certain types of events or may overfit to the data used for training. Future research could explore how to minimize bias and overfitting in event detection models, for example, by using more diverse training data or by incorporating regularization techniques.

Overall, event detection through the social platform is a crucial and also complex task with the potential to improve our understanding of various events and incidents. The forthcoming investigations in this field can concentrate on several significant challenges including the development of methods that can be applied to stream data, improving the ability to handle noise and ambiguity in social media language, integrating other sources of information such as multimedia data, addressing issues related to bias and overfitting, and finding ways to ensure privacy and security concerns are addressed. By addressing these challenges, we can make significant strides towards developing more accurate and effective event detection algorithms that can be applied in diverse domains, from crisis management to marketing and beyond.

***Abstract*—Building Integrated Photo Voltaic (BIPV) systems are a promising technology that offer numerous benefits, including energy savings, reduced carbon emissions, and improved aesthetics. However, designing and implementing BIPV systems that are efficient and effective requires careful consideration of several factors. These include high building design, colored PV modules, optimization systems, and policies and regulations. By integrating PV modules into the building's design and using advanced control and monitoring systems to maximize energy generation, BIPV systems can achieve significant energy savings and carbon emission reductions. The deployment of BIPV systems is also influenced by financial incentives and building codes. This review paper, will first discuss the various definitions proposed for different types of energy consumption, followed by the concept of "prosumer." The next section will focus on policies, followed by the different types of technologies for BIPV proposed in the literature, including pioneering countries in the sector. After reviewing the costs of various models and the different optimization techniques proposed in the literature, it will conclude by discussing the various challenges and opportunities of such systems.**

Keywords— BIPV, Building integration PV, Photovoltaic, Optimization, Genetic algorithm.

I. INTRODUCTION

Renewable energy options such as wind and Photo Voltaic (PV) power have the capacity to revolutionize the energy system currently dominated by fossil fuels, and shift it towards a completely sustainable energy system[1]. By balancing economic and social concerns while simultaneously preserving the environment, using clean energy helps to achieve sustainable development goals. [2]. Global energy usage is classified into three main categories: buildings , industry and transportation. Recent figures show that, all three of these sectors equally contribute to overall energy consumption, highlighting the need for a comprehensive approach to energy reform that targets efficiency improvements across all sectors [3].

However, the world's population is growing, and with it comes a greater demand for primary energy and an increase in greenhouse gas emissions, particularly CO2. The sector of building is responsible for 38% of the primary energy used in the world and contributes to around half of emission of greenhouse gas worldwide, with 20% of those emissions coming from building operations[4-5].

Buildings have an enormous energy intensity, and reducing it is vital from both economic and environmental perspectives[6]. Undoubtedly, integrating solar Photo Voltaic (PV) systems is an appealing option for partially meeting the electricity needs of buildings. [7]. The solar energy usage in the construction industry is becoming increasingly popular in many countries[8]. The declining costs of technologies of solar conversion, coupled with the increased PV module efficiency and growing worldwide interest in producing green electricity, make solar energy an increasingly attractive option[9-10].

BIPV (Building Integrated Photo Voltaic) concepts have become more popular in recent times due to several appealing aspects besides energy generation. These include integration into the building envelope without visible attachments, cost reduction compared to retrofitting with PV panels, and improved architectural aesthetics[11].This approach merges architectural design with renewable energy generation, thereby increasing buildings efficiency in terms of energy through the optimization of electrical, thermal, and optical properties of the PV elements [12]. Based on the existing European regulations on performance of energy efficiency in buildings, including Ordinances 2010/31/EU and also 2012/27/EU, respectively [13-14]. The buildings efficiency in energy must be evaluated using a methodology that takes into account various factors, incorporating the structure's thermal characteristics, adequate natural illumination levels, systems for cooling and heating , the use of renewable sources of energy, the addition of passive air conditioning and heating elements, quality of interior air , shading, and architectural design [15].

II. DEFINITIONS

A. NZEB NetZEB PEB

According to the regulations set forth by the European Union, NetZEBs are described as buildings with exceptional performance, which are distinguished by their extremely low energy requirements that are offset by renewable sources-based energy that are generated on-site or in the vicinity of the building [16].

For newly constructed buildings, numerous different terminologies and concepts were proposed in addition to the NetZEB idea. There were also discussions in the literature about how to interpret these significations [17]. Generally, a

DOI: rp-9788770040723.176

Net Zero Energy Building maintains a null balance of energy over the course of a year, where the energy quantity coming from the utility grid equals the quantity exported back to the utility grid. On the other hand, a Zero Energy Building (ZEBs) is designed to be highly efficient and has a yearly delivered energy that is equal to or lower than the on-site exported energy [18-19]. Positive Energy Buildings PEB, which were first established in France and Denmark, are characterized by generating more renewable energy on-site than the amount used over the course of a year [16].

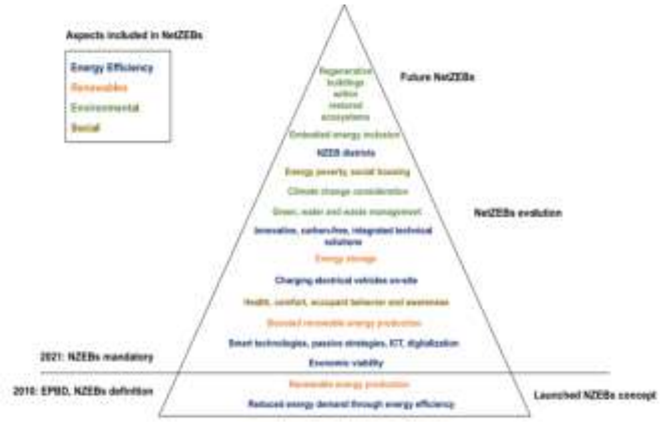

Fig. 1. Evolution of the NZEB concept with aspects [20]

III. Prosumer And Energy Transaction Policies

The importance of sustainable energy extends beyond the protection of the environment, as it is also essential for the growth of economies and societies around the world [21]. The United Nations has created Sustainable Development Goals (SDG) to combat issues such as famines, droughts, wars, plagues, and poverty caused by recent climatic changes and promote sustainability worldwide. One of these goals, SDG 7, is to guarantee inexpensive and green energy access to all [22].

A prosumer is an individual or entity that not only consumes electricity from the grid but also generates their own electricity using solar PV or other renewable sources. They may even be able to sell excess electricity back to the grid depending on the feed-in policy in place [23,24]. In number of countries the Feed in Tariff (FiT) has been a crucial policy in promoting the development of renewable energy-based power integration into the utility grid [25]. The difficulties associated with the FiT approach resulted in the introduction of net billing net metering, which have been recognized as effective tools to promote the adoption of electricity prosumption worldwide [26].

IV. Penetration Of BIPV

Currently, the BIPV idea has been warmly embraced in North America and Europe. Many European nations, including Germany, France, and Italy, have made substantial contributions to the regional expansion of the BIPV industry. In 2014, these three countries alone accounted for 87% of the European market share. Additionally, financial incentives in the form of subsidies on photovoltaic integration from supportive directives by the European Commission are anticipated to aid the market's quick expansion [27]. Based on the Becquerel Institute's 2018 estimates, France now holds the title for the highest installed capacity of BIPV in the world, with 2.7 GWp. This accounts for approximately 27% of the total BIPV capacity installed worldwide. The global BIPV installed capacity in 2018 can be seen in Figure 2 [28].

The commercial segment has become the largest contributor to the BIPV 2020 market share, mainly because more people are becoming aware of green building infrastructure with zero emissions. BIPV installation improves the aesthetic of commercial buildings and dramatically lowers energy usage, which promotes product adoption in this market area [27]. The commercial sector, typically found in densely populated areas, often requires buildings to be designed in a vertical, narrow, and high-rise style [29]. Designers of solar energy face new challenges urban high-rise structures' limited PV roof space panel placement. This has led to an increased interest among researchers to find solutions, including integrating semi-transparent and colored PV in building facades, windows, and walls [30].

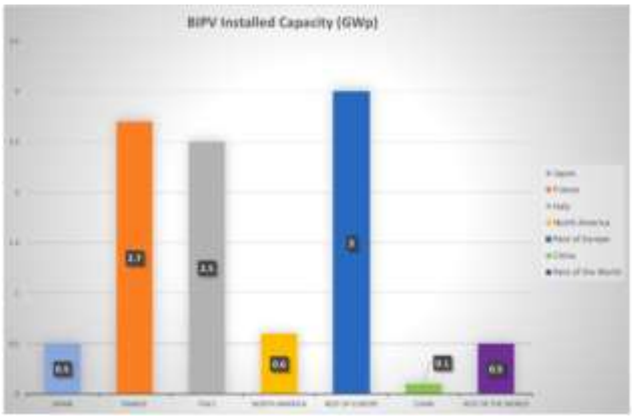

Fig. 2. BIPV estimated capacity gloabllay installed in 2018 [28]

A. *Type of BIPVs configurations*

BIPVs may be categorized into four broad groups: PV shadings, façades, balconies and roofs integration (as depicted in Figure 3). louvers and lamellas or overhangs are all options for installing PV in shading mode. Applied PVs, continuous or intermittent skylights PVs, and PV tiles are all examples of roof integration. Applications for walls and windows that are (semi)transparent have been considered in the context of façades. When it comes to wall classification, there are four categories based on integration: rain screens, curtain walls, double skin which are non-structural and opaque PV which are structured [16].

The double skin wall integration may be divided into two types. One category is the ventilated façade that is positioned near the wall and expands the building's thermal barrier up to 30 cm away from the existing wall. The second method of integration involves using heat dispersion, increasing daylighting, and allowing enough area for maintenance of walls over greater lengths of up to 1.0 m. With PV Curtain Walls, the conventional glazing system of façade is swapped out with PV glass with the right amount of transmittance, enabling it to produce energy, offer internal illumination, and provide shaded circumstances [16].

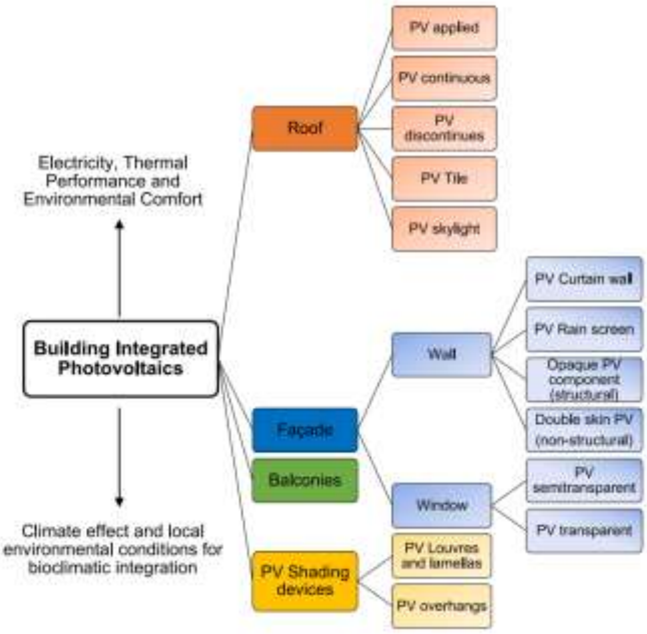

Fig. 3. Building integration design and appliaction based categories of BIPV [16]

B. BIPV on high-rise buildings

In today's big cities, high-rise buildings are seen as necessary and offer various benefits to the country. In addition to providing a good ratio of rentable floor surface per area of land , high-rise buildings have become in some countries a symbol of economic advancement. Szolomocki categorized current and future building shapes into four categories: extruder, rotor, twister/tordos, and free form. The extruder type has the same cross section for the entire height of the building. Rotor-shaped buildings are similar to extruders, but their shape resembles a drill bit. Tordos or twister buildings have a solid, twisted form with an identical "twister" façade on each level. Finally, the free-form configuration is a blend of straightforward geometrical elements, such as lines, solids and surfaces. According to Szolomocki, these shapes represent the trend in building shapes for current and future generations [29-31]. Implementing BIPV system into the building envelope could be a significant challenge, given the current trends in building shapes. As the available roof area is often limited, it may be necessary to utilize the façade area with the purpose of achieving optimal energy output [29].

From a technical perspective, BIPV applications on the façade of tall buildings have promising potential, according to the research conducted by Hoseinzadeh on the energy efficiency of BIPV in a tall building situated in Tehran [32]. Regarding the EN 50583-1:2016 standard, the BIPV module should not only serve as a traditional material for building but also perform extra functions such as structural stability, thermal barrier properties, weather and fire protection, and more. Therefore, integrating BIPV into a building envelope provides the building with multiple capabilities, including on-site energy production, self-consumption, and solar shading, which can help cool down the building interior, thanks to the silicone-based solar PV module [33].

C. BIPV technology

The "Frame of Horizon 2020 projects Dem4BIPV and PVSITES" report included a survey that focused on finding solutions to increase the interest in BIPV. The survey revealed the following factors that have the most significant impact on driving BIPV interest [28]:

- Reduced component prices for PV systems,
- System improvements that boost competitiveness,
- Enhanced BIPV product customization choices and easthetic,
- Variety of product manufacturers that stimulate competition,
- Growing regulatory exigencies to improve building sustainability.

[34] states that significant research has been conducted in previous years to increase the performance of BIPV systems, focusing on both the PV cell and its system levels. The BIPV system is divided into three groups by Biyik: PV technology, market names and application type. Several studies highlight the significance of aesthetic of the structure design, stating that function, aesthetics, technology, and cost, are more significant than large integration [29]. Lu and Law conducted a study demonstrating that reduction of the heat obtained from windows can be linked to the utilization of semi-transparent technologies of BIPV by approximately 65%, thereby lowering energy consumption required for cooling [35]. Another study on semi-transparent technologies of BIPV conducted by Joseph showed that for windows the use of semi-transparent result in energy savings ranging from 11% to 19% [36].

D. Colored PV

To achieve the goal of having buildings with net zero energy consumption, numerous parties choose to incorporate renewable energy technology into their structures. This is particularly evident in Europe, where the Efficiency in Energy Directive 2018/2020 mandates that the Renewable Energy Sector (RES) must reach a target of 32% by 2030 [37]. Many are aware that a significant portion of European buildings consist of historic structures. In the optic to achieve the energy efficiency goals set by the EU, it's necessary to improve all existing buildings, including those of historical significance. However, there's a concern that implementing BIPV may diminish the architectural value of these historic buildings [29].

Fig. 4. PV cells as element of building patterns [38]

Considerable research has been conducted thus far to address the aesthetic concerns of PV technology, with colored PV emerging as a popular solution. Colored PV was developed to provide a means of camouflaging or integrating PV modules with a building's appearance. For instance, the PV modules can be manufactured to mimic the same pattern or color as the original building material, effectively concealing them from view. Utilizing colored PV

DOI: rp-9788770040723.176

in a creative fashion has the potential to increase social acceptance of incorporating building-integrated photovoltaics (BIPV) into existing historic buildings. [39].

Several varieties of colored PV are currently accessible on the market [30], including: Solar cells equipped with an anti-reflection coating. PV-active layers that are colored and/or semi-transparent. Special solar filters in the form of coatings, layers or interlayers with different colors or patterns. Encapsulant films made of colored polymers. Front glass altered via the use of coating, printing, or other finishing processes.

The choice of colored PV is determined by the desired aesthetic appearance and the location of the building where the PV module will be installed. The newest colored PV technology uses a printing digital ceramic on the PV glass's front, which provides a way to hide the solar cell produced by crystalline silicon. Nevertheless, on the front glass any printing will reduce light transmission, thereby affecting module efficiency, despite being a technology that harnesses solar energy [29].

E. Colored PV module sensitivity analysis

In [43] To determine the best colored photovoltaic (PV) module for integrating with a building, a sensitivity analysis was performed. Four different types of colored PV modules were examined in the analysis. The PV layout was created using PVSyst and an inverter was incorporated to create a complete Building Integrated PV (BIPV) system, the design of the PV layout using 1418 square meters on the building rooftop was also discussed. To provide a benchmark for comparison purposes, a conventional PV module type was also included in the study. The total annual production of the conventional PV module was significantly greater than that of all the colored PV modules considered in the analysis, with a production of 435,105 kWh/year. Nonetheless, the conventional PV module will serve as a reference point for evaluating how well the colored PV modules perform in comparison. Without the traditional Silk Plus PV module included, the colored Silk Pro module is the one giving the highest production of energy, with an annual total production of 326,101 kWh/year [29].

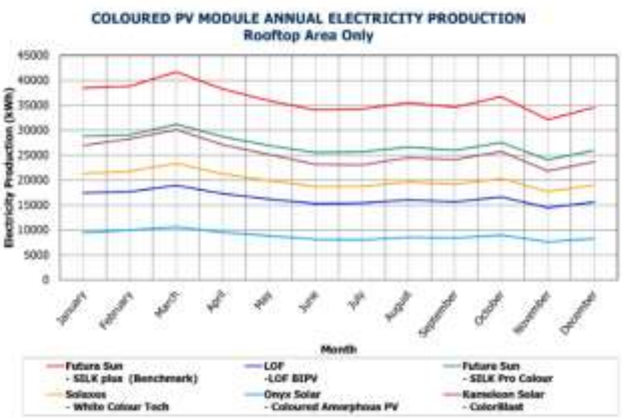

Fig. 5. Colored PV module annual electricity production [29]

F. Façade PV module tilting angle sensitivity analysis

In this study conducted by [29], to determine the best angle for tilting PV modules on the east and west sides of a building an analysis based on the sensitivity has been performed. The methodology described above was used, and the analysis was conducted using the colored Sun Silk Pro Futura, which is based on research findings. Like the colored PV module analysis on sensitivity, the optimal angle was chosen based on the highest production of energy by year. The study found that the best angles for both facades were 50 and 60 degrees, with production of energy annually of 201,236 kWh/Yr and 200,979 kWh/Yr for the façade east-facing oriented. As there was negligeable difference in yearly energy output between these two angles, more analysis of the ratio of performance is required to establish the ideal angle [29].

V. ECONOMIC ANALYSIS

A. Battery cost

To compare battery costs, power capacity ($/kW) and energy capacity ($/kWh) are commonly used metrics. Nevertheless, the best measure to employ may vary depending on the application and battery size. Customers with high peaks in their power usage may need more power capacity (kW), but not necessarily a larger amount of energy discharge (kWh). Conversely, customers with stable power usage may need more energy discharge according to their power capacity. Consequently, customers with high peak load profiles may seek to reduce expenses of power used ($/kW), while those with flat load profiles may seek to reduce expenses in proportion to the capacity of energy ($/kWh) [40].

Numerous research studies have documented the expenses associated with domestic energy system of storage, with a particular focus on lithium-ion batteries, which are the most widely used technology for residential energy storage. These studies frequently use €500/kWh (~$600/kWh) as their baseline cost for hardware of battery [41-43]. The hardware costs of batteries decreased by approximately 50% per year between 2014 and 2016. The installation expenses, however, remained mostly the same [44,45]. Fares and Webber [46] report that installed costs for batteries range from $700 to $1800/kWh. Comparing several costs of battery hypotheses across different studies can be difficult since each study uses different techniques and system size hypotheses. Nevertheless, based on the literature, the typical estimate for the cost of installation falls within the range of $700 to $1500 per kilowatt-hour [47].

B. Load control cost

Devices for the control of loads make use of home appliances that are commonly owned by residential customers. As a result, the additional costs of implementing load control are relatively low when compared to the cost of batteries. The supplementary expenses usually involve incorporating extra hardware to household appliances and acquiring any necessary software for configuring the system. As an illustration, a smart thermostat has the potential to convert the thermal mass of a residence into an energy storage mechanism, all while avoiding the need to replace

DOI: rp-9788770040723.176

the using heating and air conditioning infrastructure. The supplementary expense would solely consist of the price for acquiring the thermostat hardware and installation, which is generally only a few hundred dollars as opposed to thousands. [47-49].

C. Empirical result discussion

Although the literature on solar devices spans diverse geographic settings and research methodologies, there are at minimum three common discoveries [47]:

• Solar plus devices add value to PV systems, resulting in financial benefits for PV system owners across various technologies, regions, and rate structures. However, these benefits may vary significantly due to differences in technology expenses, rate structures, and energy consumption patterns.

• Considering the current cost of batteries, load control devices are a more economical solution. Nonetheless, batteries provide greater versatility and are more efficient in boosting self-use and backup power. Consequently, the implementation of batteries may surpass initial predictions derived solely from solar plus analysis in the short term.

• A reduction in compensation rates for exporting energy to the grid reduces the worth of solar plus, but concurrently amplifies the added value of solar plus in comparison to a standalone photovoltaic (PV) system. In spite of optimal design strategies for solar plus systems, there is still the possibility of excess output of PV being sold to the utility grid. The devaluation of grid export rates lessens the monetary benefits that customers receive from both solar plus and standalone PV systems. However, solar plus technology can mitigate the unfavorable economic effects of declining grid export rates by amplifying self-consumption.

VI. BIPV OPTIMIZATION APPROACHES

Authors have employed objective optimization techniques to explore how modifying system parameters and limiting performance degradation could enhance BIPV performance. Algorithms for optimization compared to an analysis based on basic parameters, may examine a wider range of possible solutions and also generate trade-off solutions among the desired goals [50]. To improve PV in louver system configuration, Taveres and colleagues used Evolutionary Optimization of Multi-Objective, which depended on a Genetic Algorithm (GA). Measurements of the energy need, daylighting levels and PV generation were used to the evaluation [50]. Gao and colleagues [51] employed the same algorithm to achieve an equilibrium a way to balance daylight transmissions and solar heat uptake in PV overhangs. The Non-dominated Sorting Genetic Algorithm II (NSGA-II) by Ref. [52] was another approach used to assess BIPV and viable (adjusting costs and PV energy) rooftop designs during the early design level.

Figure 10 illustrates a common process for optimizing a BIPV system with adjustable parameters. This process includes a) input data parameters of data input such as climate geometry and operational schedules, b) a simulator that conducts thermal, electrical and daylight analyses, and c) an optimizer that utilizes single or multi-objective algorithms [16].

Conversely, designing and assessing BIPV systems involves scrutinizing factors that cannot be solely measured through explicit values, such as PV power or cooling/ heating loads. Multiple authors have utilized various decision making analysis using a multi-criteria (MCDA) techniques or a blend of them to choose and optimize in buildings PV systems. For instance, Stamatakis et al. [53] used the Preference Ranking Organization Method for Enrichment Evaluations (PROMETHEE) method to research in the Mediterranean area the best BIPV system for office structures. In Refs. [54,55], the VIKOR (VlseKriterijumskaOptimizcija I KaompromisnoResenje) technique was used to find the best way to integrate PV into a tall residential building. This was accomplished by taking into consideration aesthetic standards, web polls, and qualitative interviews. Ref [56] Uses neural network to predict the output power from a building-integrated bifacial solar PV system that has an improved roof surface Albedo.

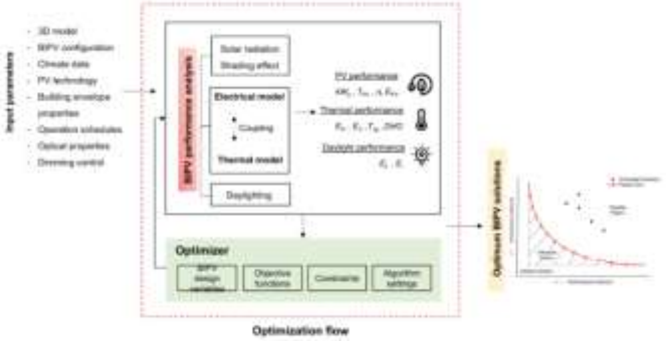

Fig. 6. Standard process for optimizing a BIPV system with variable parameters [16]

VII. CHALLENGES AND OPPORTUNITIES

The previous section of this paper reviewed and discussed studies on the integration of various types of PV modules in buildings. The findings suggest that using these systems, especially in buildings, has the potential to substantially decrease the usage of fossil fuels and the release of greenhouse gases. Therefore, it is recommended that policies be put in place to encourage builders to incorporate these systems in their upcoming projects. Offering incentives can increase the attractiveness of using these systems. Since economic feasibility is crucial for large-scale deployment of these systems, it is important to focus on developing more effectiveness and cost savings systems. Additional research and development efforts are necessary for the advancement of PV-integrated and heat HPs. The introduction of new, more efficient systems and reduced construction cost will promote advancements in related technologies. Buildings that are heated and cooled by HPs can incorporate PV systems by utilizing surplus power generated during low cooling or heating load hours. By integrating PV panels associated with HPs installed in buildings, surplus power can be used for other electrical appliances or sold to the grid. To enhance the cost-effectiveness of these systems, a PV/T (Photovoltaic/Thermal) system that uses water as a cooling

DOI: rp-9788770040723.176

agent for the PV modules can be utilized to generate a portion of the necessary domestic hot water [57].

Although there are many opportunities for developing PV with heat power in buildings, there are also several challenges to be addressed. Most of the buildings that currently exist do not utilize HPs for the purposes of cooling and heating, which presents a noteworthy hindrance to the widespread expansion of PV coupled with HPs. Another obstacle that arises in the advancement of PV coupled HPs is the comparatively lower performance of PV cells, which can result in insufficient power generation to meet the heating or cooling load requirements of HPs. It is necessary to have enough space available to install PV cells with appropriate capacity to fully supply the power needed by HPs. In addition, the intermittent nature of solar energy can cause fluctuations in power generation, such as during cloudy hours, which may require the use of other systems or connection to the grid. In addition, PV modules alone are not sufficient to provide power during night hours, making them ineffective without the use of storage units or connection to the grid, which can increase the overall system cost. Furthermore, the evolution of PV coupled HPs in the residential sector is hindered by a lack of social awareness and acceptance of the benefits of these systems, as highlighted in a study by [58]. To promote the development of these systems, increasing awareness of their benefits is suggested [57].

VIII. CONCLUSION

The use of building-integrated photovoltaic (BIPV) systems shows great potential to meet the growing energy demands of the building sector and to decrease greenhouse gas emissions. Various types of PV modules have been developed and integrated into buildings, ranging from transparent to colored and flexible modules. The integration of PV modules with the existing buildings can also help to utilize surplus generated power during low cooling or heating loads or sell it to the grid. However, there are still some challenges in developing BIPV systems, such as the intermittency of solar energy, the relatively low efficiency of PV cells, and the lack of social awareness of the benefits of BIPV systems. To overcome these challenges, it is necessary to develop more efficient and cost-effective systems, integrate them with storage units or the grid, and increase public awareness of their benefits. Policymakers and building constructors should also incentivize the utilization of these systems in the upcoming building projects to achieve a sustainable future.

***Abstract*—**The aim of this paper, is to gain insights in to dynamicsofKabaddi.Thissporthasbecomeincreasinglypopular, by analyzing teams' performance in national leagues. To do so, theresults of each round of matches the participating teams play are usedto create a dissimilarity matrix. This matrix is then processed throughtwo algorithms, Multidimensional Scaling (MDS) and t-DistributedStochasticNeighborEmbedding(t-SNE),tovisualizetheperformanceofeachteam.TheMDSalgorithmprovidesalow-dimensional representation of the teams' performance, allowing for avisual representation of complex data linkages. The t-SNE algorithm,on the other hand, captures the non-linear relationships in the teams'performance. By using data from the 2017-2018 Kabaddi season andcomparing the results obtained through MDS and t-SNE, this studyaims to identify critical factors that influence team performance andprovideadeeper understandingof thedynamicsofthesport.

***Keywords*— Data Visualization, Feature Projection, Sportsanalysis,Statistical analysis.**

I. Introduction

The digital data produced in various industries has grownexponentially in recent years. Teams of seven players eachcompeteinthepopularsportofKabaddionarectangularpitch. There is a 5-minute intermission in between each of the twohalves of the game's two 20-minute halves. To outscore youropponent, you must send raiders through their defense, touchas many players as you can on the way back to your side, andtackle your opponent's raiders to stop them from scoring. Theteam with the greatest number of points at the conclusion ofthe contest is deemed the winner. To make the informationcontainedinhigh-dimensionaldataeasilyaccessibleandcomprehensible, visualization is crucial. However, because thedata is computationally costly and has numerous dimensions,this can be a difficult task.[1]. Despite the challenges faced byhuge, multi-dimensional datasets, the display of data plays akey role in understanding and interpreting it. Although it canbe difficult to spot patterns and relationships because of theuncertainty in these sorts of data, visualization tools enable thediscovery of insights that might not be immediately apparent.A deeper comprehension of the facts can be attained by visualexploration, resulting in better decision-making. Additionally,data visualization can assist in identifying areas that requireadditionalresearchandanalysis.[2].Formanyyears,approaches for minimizing the dimension of the data, such asPCAandMDS,havebeenessentialtools.FeatureMappingis atechniquethataimstosimplifydatabycreatingacompressedrepresentation that retains as much of the original form aspossible. The goal is to maintain the important features andrelationshipswithinthedatawhilereducingitscomplexityandpresentingitinamoremanageableformat.Thedataarefrequentlyreducedtotwoorthreedimensionsduetothisprocedure. It is frequently visualized using scatterplots, whichplacecomparabledatasets closetogetherandunlikeonesapart. [1]. The concept of "t-SNE" is offered as a method forvisualizing high-dimensional data transformed into a matrix ofsimilarities between pairs of points. While also revealing moresignificant patterns and clusters in the data at various sizes, t-SNEisefficientincapturingthelocalizedstructureofthedata.[3]. MDS is an analytical tool that examines the variances orranges between quantitative points to help visualize complexinformation. It seeks to decrease data dimensionality whilemaintainingconsistentlinksbetweendataelements.Itmakes itsimple to visualize and analyze the data by displaying it in areduced-dimension space. Multidimensional scaling (MDS) isa technique employed in data analysis that aims to understandand interpret high-dimensional data. This approach identifiespatternsandlinkagesthatmightnotbeimmediatelyobviousinthe actual data by examining the distances between data pointsand modeling the data in a lower-dimensional space. MDS hasa wide range of applications in various fields such as scientificcomputing, computational linguistics, biostatistics, and imageprocessing. Its purpose is to simplify and present informationinamoreunderstandableandnaturalformat[4].

II. RELATEDRESEARCH

Incontrasttotypicalmultivariatedata,whichonlyconsiders individual items, multidimensional scaling (MDS) isassessing data that refers to the similarity or distinction amongpairsofdata's.[5].Multidimensionalscaling(MDS)isadimensionality reduction algorithm that analyses the similarityor difference between pairs of objects in a dataset, as opposedtotypicalmultivariatedataanalysiswhichonlylooksatindividual items.[5]. A novel method for assessing non-metricMDS was createdby Taguchi and Oono [6] and utilized tofindpatterns.ResultsusingnonparametricMDShighlydependontheinitialconfigurationbecauseitjustpreservesthesequenceofcommonalitiesratherthantheoriginalscale.

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.178

Despite this, it is still difficult to shorten the computation formetrics.TheSupervisedt-StochasticNeighborEmbeddingtechnique proposed a new metric for determining dissimilaritythat takes class information into account. With the updated t-SNEmethod,high-dimensionaldatacanbeeffectivelyprocessedforvisualrepresentation,dataextraction,andclassification purposes within classification applications. [7].Thet-SNEtechniqueaimstopreservetherelationshipbetween features by transforming high-dimensional data into alower-dimensionalrepresentation.Theresultisavisualrepresentation in which points that were close together in thehigh-dimensional data will still be close together, and thosethat were far apart will remain so in the lower-dimensionalrepresentation. Maintaining the Integrity of the Specifications.Pezzottiet.Al.[8]aimedtosolvetheissueoffinding approximatenearestneighboursinlargedimensionsbyutilizing adecision tree of approximation K-d trees, whichresultsinafastercalculationprocess.Currently,therearemanyadvancedtechniquesforselectingapproximateneighbours in multi dimensions that make the computationeven moreefficient.

III. DATADESCRIPTION

The national pro kabaddi league can be found on the website"https://www.prokabaddi.com," which provides a database ofmatch results, team names, final scores, top scorers, and otherdetails of each match. The league, which is now in its 6thseason, has 12 competing teams, with the Bengaluru Bullscoming out as the winner after defeating the Gujarat FortuneGiants in the final. For the next season, all 12 teams will playeach other twice and the top six teams will make it to theplayoffs, while the bottom four teams will have eliminationrounds. In the 7th season, Bengal Warriors emerged as thechampions after defeating Dabang Delhi. This season also sawmany records being set, such as Pardeep Narwal achieving1,000pointsintheleague,NaveenKumarscoring21consecutive Super 10s, and three raiders reaching 300 raidpoints. Additionally, Neeraj Kumar and Mohit Chillar tied forthemostdefensivetacklepointsinagame.

IVMETHODOLOGIES

A. MultidimensionalScaling

The Multidimensional scaling method was applied to analyzethe performance of kabaddi teams at the league level. Eachround's results were used to calculate the differences betweenteams, and an MDS technique was used to show the teams'performance. To highlight the disparities between the teams,threestrategieswereadopted.Theinitialstrategyrequiredcreatingonemdsandonedissimilaritymatrixforeachround. The second method created a single global MDS chartbycombiningalltheinformationintoadatadissimilaritymatrix. The thirdstrategyproduceda time series for eachteam based on the outcomes of each round. The efficiency oftheteamscanthenbevisualizedusinganMDStechnique using these differences. An example of how to use MDS in thecontextofakabaddileagueseasonisbyconstructingadissimilarity matrix founded on points of every match. ThedissimilaritymatrixcreatedintheanalysisofthenationalKabaddi league reveals the difference between each pair ofteams,withtheentryinthei^{-th}rowandj^{-th}columnrepresenting the difference between team i and team j. ThismatrixisthenprocessedusingMultidimensionalScaling(MDS)toproduceavisualrepresentationoftheteams'performanceintheformofa2Dor3Dplot,wherethepositionofeachteamconveystheir overallperformancethroughoutthegame.Atechniqueforevaluatingthecorrelationbetweenlow-dimensionaldatapoints$y_i$andy_j,which correspond to high-dimensional data points $x_i$and x_j,can be established using a method that involves computingconditionalprobabilities.[7].Todeterminetheconnectionbetween low-dimensional data points y_i and y_j that correspondtohigh-dimensionaldatapoints$x_i$andx_j,adissimilaritymatrix D with dimensions m between the two items is used.This matrix measures the distance between i and j, with d_{ij}beingthevaluerepresentingthatdistance.Theresultisamatrix X, which has a reduced number of dimensions (oftend=1, 2 or 3), that is optimized through the use of gradient descentmethodknownas "teaming". [14].

$$\mathrm{Strain}_D(x_1,x_1,\ldots\ldots,x_N)=\left(\frac{\sum_{i,j}\left(b_{ij}-\langle x_i,x_j\rangle\right)^2}{\sum_{i,j} b_{ij}^2}\right)^{1/2} \quad (1)$$

TheMDSTechniqueisawaytoconverthigh-dimensional data into a low-dimensional format byreorganizing data points that are similar to be neareach other, while data points that are dissimilar areplaced farther apart. This is achieved by creating amatrix B from the dissimilarity matrix D, and thenusing a double-centering transformation. Output isproduced by calculating the eigen-decomposition ofmatrixB.[10].nThetraditionalMDSalgorithmstarts by computing the square dissimilarity matrixD2fromthedissimilaritymatrixD.Then,itcalculatesthecenteringmatrixJand thematrix.

$$B=-\frac{1}{n}JD^2J \quad (2)$$

After that, it determines matrix B's d largesteigenvalues and eigenvectors. finally calculates thelow-dimensionalrepresentation matrix,

$$X=E_d\Lambda_d^{1/2} \quad (3)$$

B. K-NNAlgorithm

The The KNN algorithm groups of observations based ontheirsimilaritiestootherobservationsinadataset.Thealgorithm calculatesdissimilaritymeasuresbetweenallobservationsofindthekclosestobservationsofagivenobservation. It then assigns the new observation a categorylabeldependingonthemostcommoncategorylabelofitsk

DOI: rp-9788770040723.178

closestobservations.heKNNapproachalsoappliestomachine learning, where the objective is to locate clusters ofsimilarobservationsorcomparableobservationsthatdifferfrom oneanother.InthecontextofKNN,thealgorithmcategorizesnewo bservationsbasedontheirsimilaritiestoother observations in a dataset. The dissimilarities between allthe observations are calculated, and the k nearest neighbors ofa given observation are determined using these dissimilarities.The class label for the new observation is assigned based onthe most frequent class label among its k nearest neighbors. Inan unsupervised learning scenario, KNN can be utilized todiscoversimilarobservationsorclustersofsimilarobservations based on their differences. This is achieved byperformingclustering,calculatingthecentroid,anddetermining the k nearest neighbors for each observation. Thecentroid is found by taking the average of the cluster. Thelikelihoodofaconnectionbetweentwolow-dimensionalobservations can be determined using a similar method basedon the calculationofconditional probability.

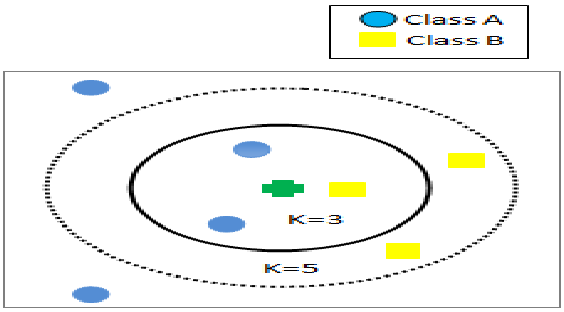

Fig.1.K-NearestNeighnorClassifier

In Figure 1, a diagram depicts the design of a K-NearestNeighbor(KNN)classifier.Thegreenrectangularsphere, representing a test case, will be assigned to differentclassesbasedonthevalueofk.Forinstance,ifkissetto3,the test case will be classified as part of the blue circular class.But if k is increased to 5, the test case will be classified as partof the yellow square class. [8]. A K-Nearest Neighbor (KNN)classifierisusedtoidentifytheclassthatatestsample,represented byx,belongsto.Theclassificationprocessinvolves calculating each group's likelihood based on the K-NN of x, using a specific distance metric, d. The example isassigned to the group with the highest likelihood, which isdetermined by evaluating the distance between x and the knearestneighbors.

C. t-DistributedStochasticNeighborEmbedding(t-SNE).

t-SNEisatypeofnon-linearandself-governingmachinelearningmethodutilizedforsimplifyinghigh-dimensionaldata,suchasimages,audiosignals,ortext,intoalower-dimensional representation. T-SNE aims to maintain the keyinformation contained in the original high-dimensional datawhile condensing it into a more manageable form, usually 2 or3 dimensions. The advantage of using t-SNE is that it cansimplify high-dimensional data into a lower-dimensional form,making it easier to comprehend the relationships between thedatapointsandunderstandthedata'soverallstructure.

Traditional methods of analysing high-dimensional data cansometimes fall short in visualizing it in a way that retains itslocalandglobalaspects,makingt-SNEavaluabletool inthese situations. [3]. The t-SNE algorithm is used to deal withthe problem of visualizing high-dimensional data effectivelywhilepreservingbothlocalandglobalstructures.Ittransforms the distances between high-dimensional data pointsintoprobabilitiesofsimilaritythroughaprocesscalledStochasticNeighborEmbedding.Thisresultsinalower-dimensional representation that retains important informationfrom the original data. The t-SNE technique is a widely usedtoolinfieldssuchascomputervision,naturallanguageprocessing,andbioinformatics,asithelpsconverthigh-dimensional data into a more manageable and interpretableform. This allows for deeper insights into the structure andrelationships within the data, making it a valuable tool for dataanalysisandexploration.[5].

$$p_{j|i} = \frac{\exp\left(-\|x_i - x_j\|^2/2\sigma_i^2\right)}{\sum_{k\neq i}\exp\left(-\|x_i - x_k\|^2/2\sigma_i^2\right)} \quad (4)$$

The t-SNE algorithm aims to compute a similar conditionalprobability between the low-dimensional data points y_i and y_j,whichcorrespondtothehigh-dimensionaldatapoints$x_i$andx_j.Thedifferencebetween$x_i$and$x_j$isrepresentedasthemagnitude of their separation $||x_i\text{-}x_j||$, and the spread of datapoints in high-dimensional space is represented by σi. Theobjective is to compute the straight-line distance between $y_i$andy_j,whichisrepresentedasthemagnitudeoftheirseparation$||y_i\text{-}y_j||$,inordertocalculatetheconditionalprobability between the low-dimensional data points. The aimis to find a way to calculate the relationship between the high-dimensional feature vectors of each Kabaddi teamandthecorresponding low-dimensional data points, while preservingthesimilaritiesbetweentheteams.Todothis,t-SNEcalculatestheprobabilitiesbasedonthedistancesandvariancesbetweenthehigh-dimensionaldatapointsandminimizes the difference between these probabilities and thecorrespondinglow-dimensionalpoints.Thisprocessallowsforareductionofthehigh-dimensionaldataintoamoremanageablelower-dimensionalspacewhileretainingimportant information about the teams' performance, such astheir record of wins and losses, the points they score, and thestrategies they use for defense. By using t-SNE, it is possibletogainvaluableinsightsintotheperformanceofKabadditeams,whichcanaidcoaches,players,andanalystsinunderstanding thestrengthsand weaknessesofeach team.

IV. RESULTANDDISCUSSION

Theoutcomesofthestudyindicatedthatutilizingt-DistributedStochasticNeighborEmbeddingandMultidimensionalScalingasameansofreducingthedimensions of the data was effective in comprehending theintricaciesofthegameofKabaddiandidentifyingsignificant

DOI: rp-9788770040723.178

variables that influence a team's success. The t-DistributedStochasticNeighborEmbeddingmethodwasparticularlyeffectiveinvisuallyrepresentingcomplexandnon-linearrelationshipsinthedatabycreatingareduced,simplifieddepiction of the team's success over time. In Figure 2. Showthe team who won the match according to the win points therearefourclusters,cluster1representsthehigherwinningpoints above13to17,andcluster2denotesthepointsbetween 12 to 14. After which, the winning point from 6 to 10comesunderclustering3.Finally,cluster4representstheremainingpoints.Infigure3.Showsthetwo-teamperformance analysis within the season 2017-2018. The teamU Mumba Played the game in two seasons and score the highpointsitisrepresentedinfigure 3.

V. Conclusions

In order to understand Kabaddi effectively, this researchcontributes in analysis of a team's performance over severalseasons.MDSandt-SNE,twodatavisualisationmethods,were applied to accomplish this. These techniques made iteasier to evaluate the progress of the team and determine thekeyfactorsthataffectitssuccess.Theanalysis'sfindingsprovided a crucial new understanding of the dynamics of thegameandthevariablesaffectingateam'sperformance.The study was able to offer a thorough insight of Kabaddi and itscomplexities by evaluating the MDS and t-SNE data. Teamsand coaches who desire to perform better might take use ofthese insights. They can design strategies and techniques thatwill enable them to excel in the game by being aware of theimportant success factors. Overall, the study has added muchto our understanding of Kabaddi and is likely to be of greatinterest to fans of the game. Future research could considerusingmachinelearningtechniquessuchasclustering,classification, and regression to identify patterns and makepredictions based on the data applying the findings to practicalapplications such as team selection, training strategies, andgametacticstoimprove performance.

Abstract — **One-class classification (OCC) is used to construct classification models even though the outlier samples are inadequate, weakened and not clearly defined samples. The OCC network has been dominantly employed in diverse application of machine learning. One-Class Classification (OCC) is an exceptional condition of multi- class classification in which the data used during the training phase is generated from a single positive class. The intent of a OCC network is to learn a representation and a classifier that deals with positively labeled queries. In the recent years adversarial learning One-class classification (ALOCC) method has outperformed the efficiency of the OCC performance. Since it has some limitations such as instability within the training phase and issues in reconstruction of data between inlier and outlier data. In this paper work, we have propounded a Multi head Driven Self Attention mechanism incorporated in the ALOCC network. The proposed MDSAL-OCC network outperforms other self attention network in OCC and effective in elevating the OCC accuracy. In this paper, we also presented a discussion about the comprehensive elaboration of the proposed framework of one-class classification Multi head Driven Self Attention Adversarial Learned One Class Classification (MDSAL-OCC) and also discussed about the role of MDSAL-OCC in train One Class Classification networks in detecting fetal congenital heart diseases (FCHD).**

I. Introduction

The model One-class classification (OCC) builds a predictive analysis model using poorly sampled data. Over the past decade, Deep Convolutional Neural Networks (DCNNs) has exhibited remarkable performance improvements in object detection. In this paper, the work is primarily focused on image detection in medical image analysis. Because of the availability of huge multi- class annotated datasets, deep networks can easily learn discriminative features and also the classifier can exploit to perform recognition. One-class classification (OCC) is defined as the concept of conceding test data which has been disseminated in a different way from the data presented during the training phase [2]. This method of classification has established significant research in various areas of domains such as biomedical field [3], fault diagnosis detection system in manufacturing systems [4], financial systems [5], and security and communication systems [6]. The data's of different classes needed to be labeled in all the applications. But in the real- world scenario, data's from unusual classes tend to be inadequate volume for effective modeling. In order to overcome the former situation, the OCC does the task of performing training only on the usual classes and latter identifies the unusual classes from the usual class distribution. Thus, OCC differ from the traditional classification network. OCC also solves imbalanced dataset issues in an effective way. Many methodologies are employed to explain one - class classification (OCC). These approaches are categorized in to different methods. The Density estimation methods emphasize on calculating the density of the data points, and threshold value setting. The boundary methods are based on the parameters such as distances and boundaries encompassed within a set of data points called target points and optimizes the volume of the data. The reconstruction method relies on building a model using prior knowledge [1].

In the contemporary situation, the end-to-end networks are widely used for one-class classification. Dimokranitou et al. [7] introduced an integrated framework comprising of Autoencoders and Generative Adversarial Networks. This work reached remarkable benchmark performance in detecting anomalies in video sequences. In 2018, Zenati et al. [13] propounded about the GAN based Anomaly detection system, which can produce excellent results than the earlier one. In the latter work, GAN models were implemented for anomaly detection in medical images and network intrusion. The GAN called BiGAN is used in this work and applied combined training for bidirectional mapping between the image space and the latent space which achieved better performance accuracy. In a research work by Akcay et al. [8], using conditional generative adversarial network (CGAN) has been used to develop an anomaly detection model which utilizes learning of high-dimensional image space and the inference of latent space. This model contains an encoder- to- decoder and a decoder - to - encoder networks. In the generator part, mapping of the input image to a lower dimension is carried out. Later, the lower dimension vector generated by the Generator network is in turn used to reconstruct the output image. This model achieves better efficacy over several benchmark datasets, domains and previous state-of-the-art approaches.

DOI: rp-9788770040723.180

Later in a research work conducted by Sabokrou et al. [9], reconstruction-based OCC network which consist of encoder-decoder architecture was developed. In this architecture, two deep networks were used. In that architecture, one network acts as a novelty detector, whereas the other network enhances the inliers samples and deforms the outlier class samples using adversarial learning technique. This framework can be incorporated in different domains for the application of anomaly detection in image and video processing system. Later, the attention techniques were introduced with the aspect of diminishing the quantity of parameters, thus improving the accuracy of the classification models [14]. Self attention Generative Adversarial Network (SAGAN) [15], proposed by Zhang, elucidated about the framework consisting of the technique of self-attention incorporated in a GAN framework. It achieved best GAN efficiency specifically on class-conditional image generation in ImageNet. Zhang, Yingying, et al.[16] Proposed an improvised self-attention mechanism embedding multi-heads which outperformed the earlier methods in improving the aspect of reconstruction quality and efficiency. In unified approach comprising GAnomaly and Adversarial One Class Classification, it is very tedious to perform the reconstruction process between the inliers and outliers class labels. For better reconstruction of inliers class samples, the visual attention mechanism is incorporated in to OCC networks. Apart from that, the newly proposed self-attention technique uses features in various latent subspaces to provide observation controls to improve the inliers class labels. It can be used in broad in various anomaly detection networks such as medical image analysis, security systems, etc.

II. Related Work

A. Adversarial Learning-based Network

GANs [19][20] is a great achievement developed for the purpose of performing data augmentation used in learning models. GANs can also be used as a classification model in the case of insufficient training data. GANs are unsupervised deep networks generally used for the data generation. The supervisory information is obliquely provided by an adversarial gaming between two networks: a generator (G) and a discriminator (D). In the training phase, G generates new data and D understands the new data generated by the G and evaluates the condition that the data is a real or a fake input.

B. Attention

Attention is one of the most important emerging technique in the area of machine learning. The attention mechanism has been stimulated by the biological organization of human being aimed at differentiating various organ substructures while handling huge volumes of information [23]. Visual attention is a technique which incorporates some cognitive operations for handling issues in large volumes of data in an efficient manner by extracting valid information and excluding invalid information. Attention is a amenable technique applied on regions of interest such as specific features of an object, or the whole objects. Attention mechanism is widely used in different domains such as computer vision, natural language processing etc,. In computer vision, visual attention mechanism is incorporated in to the neural network structure for achieving better performance results. In neural networks, attention mechanism performs various tasks such as image caption generation [25, 26], image-based analysis [27,28], machine translation [29], text classification [30,31], action recognition [32], speech recognition, recommendation [34], and graph [35] in enhancing performance. Apart from this, it also serves as a tool for elucidating neural network architecture behaviour.

TABLE I. ATTENTION MECHANISM AND TYPES BASED ON VARIOUS CRITERION

Criteria	Type
The Softness of Attention	Soft/hard, global/local
Forms of Input Feature	Item-wise, location-wise
Input Representations	Distinctive, self, co-attention, hierarchical
Output Representations	Single-output, multi-head, multi-dimensional

C. Attention Mechanism

The different approach of attention mechanism has been classified based on the aspects such as softness related to attention, different types of input features, various input representations and output representations. The self-attention network [36] encompasses an attention mechanism involving different sequence correlated with one another for generating a prototype of a same. It finds usage in machine reading comprehension, abstractive summarization in natural language processing, or image description generation. A multihead self-attention [37] consist of a network called Transformer and employs the data from various multi-subspaces to improvise the process of feature extraction . This multihead enhanced self-attention technique [38] shows exemplary performance results thereby improving the accuracy as well the reconstruction efficiency.

III. Adversarial Learning One-class classification (ALOCC) network

The Adversarial Learning One-Class Classification network contains two components ‘R’ called a reconstruction network and ‘D’ called a Discriminator network. The component ‘R’ reconstruction network is an encoder-decoder part,

The encoder part GE(z) is a convolutional network used for compressing noisy input image ‘z’ to feature vector ‘s’. The noisy image z is denoted as follows:

$$z = (x \sim pt\ ) + (\eta \sim N\,(0, \sigma^{2}I)) \tag{1}$$

In the above representation of noisy image z, x denotes original image, pt denotes the inliers class samples distribution, The parameter ‘η’ denotes the normal distribution noise .The standard deviation present in the normal distribution noise is denoted as ‘σ’. In ALOCC network, the image noises are employed to upgrade the

DOI: rp-9788770040723.180

robustness of the Reconstruction network ‘R’.

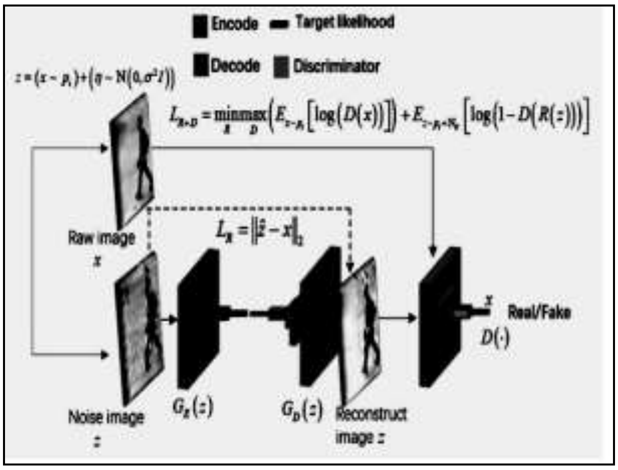

Fig. 1 Functionality of an ALOCC Network

The decoder network G_D (z) performs up scaling. In up-scaling, the vector s is converted to the reconstructed image zˆ. The discriminator D determines whether the reconstructed image zˆ is in line with the target class p_t. The component discriminator ‘D’ also evaluates the condition that if the input has been derived from the target class or not. The target class is denoted by p_t .

The ALOCC network, reconstruction and discriminator (R+D) are jointly adversarial learned in order to optimize a objective function represented as below,

$$L_{R+D} = min\ max\ (E_{x\sim p}t\ [\log\ (D(x))]) + E_{z\sim p}t + N\sigma\ [\log\ (1 - D(R(z)))] \quad (2)$$

The training process involves the task of integrating the loss L_{R+D} of joint network R + D and the contextual loss L_R between the original and the derived image in the ALOCC network.

The contextual loss L_R is denoted as follows,

$$L_R = ||z\hat{} - x2\ || \quad (3)$$

The overall loss function in an ALOCC network is represented as,

$$L=LR+D + \lambda\ \ LR \quad (4)$$

The trained network is represented as,

$$R(z;\ \theta_r) \quad (5)$$

The trained network is used to reconstruct and enhances the inliers class samples. The ALOCC uses $D(R(x))$ to represent OCC.

The complete OCC process is denoted as,

$$OCC\ (x) = \text{target}\ class\ if\ D(R(x)) > \tau \quad (6)$$

If D(R(x)) is higher than the τ, sample x is treated as an inlier class. If D(R(x)) is lower than the τ, sample x is treated as an outlier class.

In multi-head attention mechanism, input sequence is mapped to various subspaces based on the parameters, followed by attention mechanism employing scaled dot-product attention to its representation in each and every subspace. Then the output of each subspaces are concatenated together to generate the output. The multi-head attention mechanism imparts a unified approach to process information linearly from various representation subspaces achieved at different levels of positions [37].

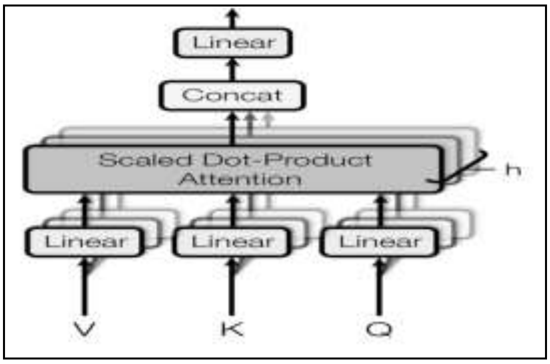

Fig. 2 Block diagram of a Multi-Head Attention mechanism.

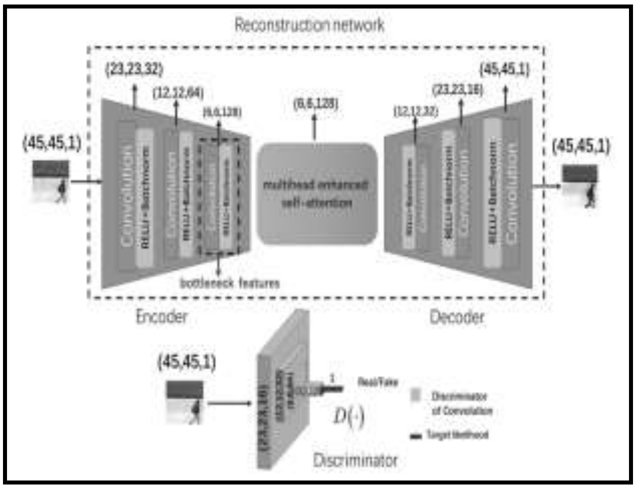

Fig. 3 Block diagram of a MDSAL-OCC network

In self-attention mechanisms, a single head performs feature learning at various subspaces, so it has to deal with issues such as handling different types of information, integrating representation in all subspaces for improving the contextual information. Multihead enhanced self-attention network can be applied to the concept of image attention [38].

IV. Multihead Driven Self Attention Adversarial Learning based One Class Classification (MDSAL-OCC)

Multi-subspaces features captures different range of correlations in various latent spaces and merging of representation leads to obtain an improved reconstruction. But if the heads are increased, the proposed attention

DOI: rp-9788770040723.180

mechanism will minimizes the dimensionality of a single head. If the number of heads is more, it will lead to insufficient quantity of relevant feature. Hence it has been inferred that the number of heads and convolutional channels automatically affects the performance of attention mechanism. Both the factors needed to be maintained in a bias condition. A simple image seldom requires more number of heads . The reason is that the multi subspace rrepresentations cannot able to extract more information from it because of over-fitted representations. The latter in turn leads to reduce the quality of reconstruction process. The proposed MDSAL-OCC overcomes the training problems of adversarial learning such as parallelism, GAN failure, vanishing gradient problem, and unbalancing between the GAN components. The proposed attention employs more 1 × 1 convolutions and two channels of self-representation. The channels are used to determine the attention map in a multi-feature space. In this mechanism, loss function is reduced. The minimized loss function is achieved in two aspects through reconstruction loss and contextual loss. In order to improve the performance of the reconstruction network, a new adversarial-balance loss in the discriminator loss is implemented. The objective behind the adversarial-balance loss is to reduce the disimilarity between the real and reconstructed fake images.

A. MDSAL-OCC in Fetal Congenital Heart Disease Detection

Multihead driven self attention adversarial learning based one-class classification network is exceptionally satisfactory in screening fetal congenital video slices. In the traditional ALOCC network, the encoder cannot does the task of extracting features from complex fetal ultrasound heart images. In the proposed MDSAL-OCC network, feature learning is done linearly through multihead attention mechanism. Screening videos in medical image analysis to obtain FCH video slices using the proposed ALOCC network are useful for the medical practitioners to easily extract the FCH images. The proposed mechanism also provides solutions for acquiring video slices from a video dataset. The acquired video slices both normal and diseased are used for data augmentation.

The proposed MDSAL-OCC model is an integrated framework combining convolutional network incorporating multi-heads in attention network. The proposed model needs to implement a consistent mathematical relation between the convolution layers and heads. The convolutional layer plays a significant role in constructing neural networks specific to image processing domain.

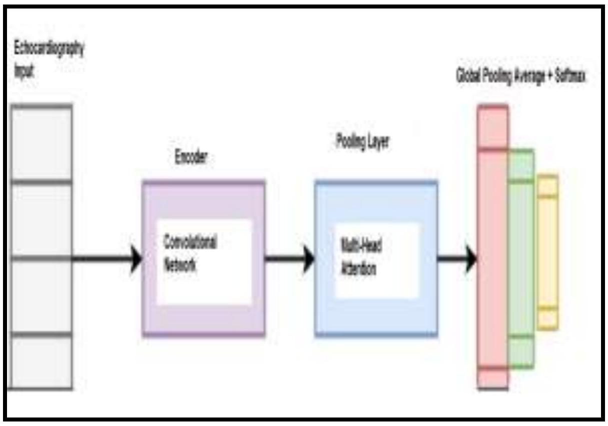

Fig. 4 Proposed MDSAL-OCC Model

In the proposed model, for processing an image of representation $W \times H \times C_{in}$

The CNN model incorporates several convolutional and sampling layers. The filters kernel sizes are represented as '$k \times k$'. Input feature is represented as C_{in} and output dimension as C_{out}. The bias vector is denoted by b. The self attention layer is implemented by the following functionalities such as D_k, denotes the key/query size, D_h, denotes the head size, N_h denotes number of heads and D denotes the output dimension .

The key is denoted as, $M_{key}^{(h)}$

The query matrix is denoted as $M_{qry}^{(h)}$,

The value matrix is denoted as, $M_{val}^{(h)}$ for each head h,

For concatenating all the heads together, the projection matrix denoted as *Mout* .

The n the layers in the models are parameterized as follows,

$$X_q = M_{qry} M_{key} M_{val}$$

Blocks	Parameters
Convolutional Blook	Input Conv. Layer 1 (Stride 1 x 1, Padding 'same') Batch Normalization ReLU 0.5 Dropout Conv. Layer 2 (Stride 1 x 1, Padding 'same') Batch Normalization ReLU Conv. Layer 3 (Stride 1 x 1, Padding 'same') Batch Normalization Softmax 0.5 Dropout Conv. Layer 4 (Stride 1 x 1, Padding 'same')
	Sequence Input
Multi-Head Block	Encoding Layers Heads (4 / 8) 0.3 Dropout
Output Block	Global Pooling Average Softmax

$$HeadsValue, H_q(h) = \sum_{[M]\times[H]} softmax(X_q^h) M_{val}^h$$

$$OutputValue, Y_q = concat(H_q^{(1)}, \ldots\ldots, H_q^{(N_h)}) M_{out} + b$$

Fig. 5 Summarization of the proposed model

DOI: rp-9788770040723.180

B. *Experiments*

For detecting fetal congenital heart disease, there are four views used in fetal echocardiography. The four views used in echocardiography are four chamber view, Three-vessel Trachea view, Three-vessel view and Five-chamber view. Among all the views, the four-chamber view was considered to be optimal one, since it has the capability to visualize the overall structure of the heart. The fetal echocardiography was taken during the second trimester anomaly scan. The fetal cardiac imaging is a tedious procedure to construct a consistent classification model to detect anomalies. For this model, we gathered the dataset from various diagnosis centers in and around our place of locality. The datasets were acquired from pregnant women of gestational age of 21-38 weeks. The dataset comprises of both normal and disease videos. Initial the dataset was preprocessed by converting the raw image to normalized image. Then cropping of ROI is done. Then the normalized image is converted to grayscale image. In the training phase, data synthesis using GAN is carried out. Data synthesis is done in order to adapt to GAN. The model is validated to ensure the strength of the model by increasing the training data in each class. In the training phase, epochs have been set to be 3000 and the epoch's interval has been set to be 300.

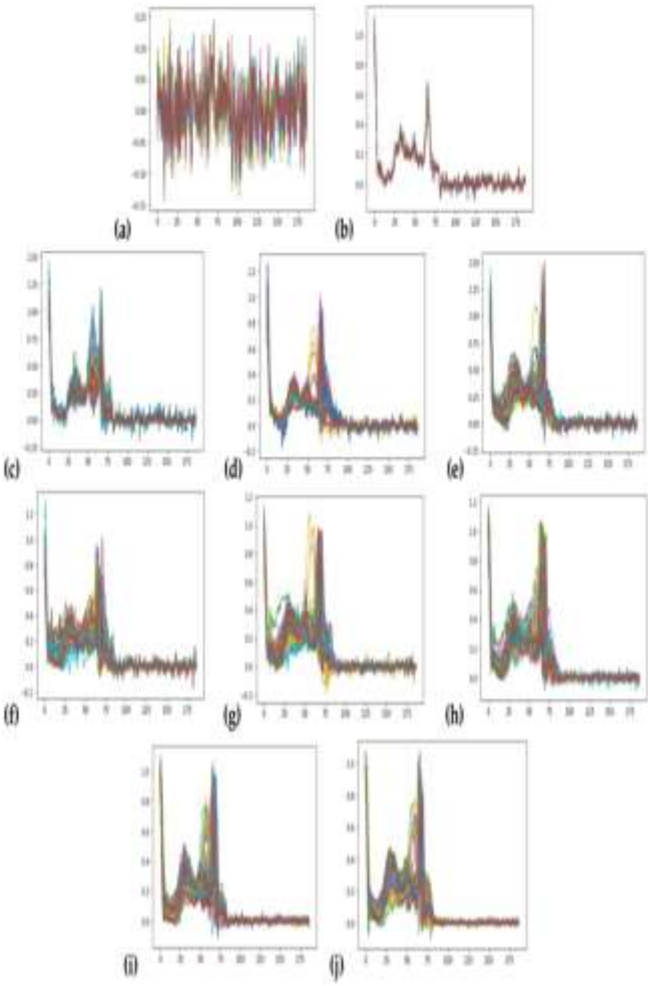

Fig. 6 Diagram depicting the GAN during Data Synthesis in 3000 Epochs.

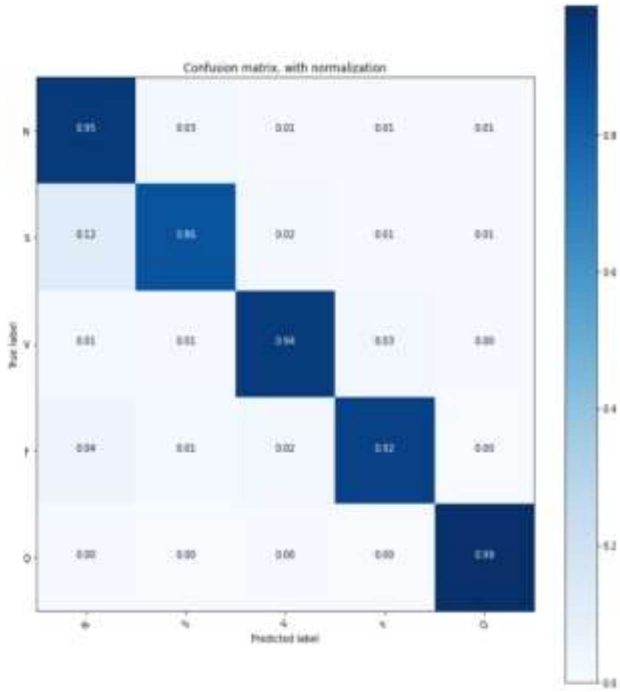

Fig. 7 Confusion matrix of our model.

The proposed model is a multi-classification model. It outperforms the general Adversarial one class classification. It achieved an accuracy performance of more than 85 % in detecting fetal congenital heart disease.

V. Conclusion

In this paper, we illustrated how the Adversarial learned One-class Classification network and described in detail about the attention and attention mechanisms. Then we presented a elaboration about the Multihead self attention network architectures used in machine vision and natural language generation and understanding. It has been presented about the various aspects of attention mechanisms provided for the generating a classification model in collaboration Adversarial Learned One-class Classification network. In conclusion, it has been explained about Multihead Driven Self Attention Adversarial Learning based One Class Classification (MDSAL-OCC) used in various fields of deep learning applications and specifically explained about the context with reference to medical image analysis domain. It has been inferred that MDSAL-OCC can attain predictive performances with equivalent model complexity (i.e., number of parameters).

***Abstract* — Blockchain is a novel technique for securing digital data transmitted over the internet. The distributed database is used to store data in a digital format. Blockchain is well-known in a variety of fields including education, government, healthcare, and financial services. It relies on distributed ledger technology and establishes trust in digital data to provide secure services for digital information to record transactions. In a decentralised system, blockchain creates blocks for each transaction. The features of blockchain, as well as their platforms and applications, were explored in this case. Blockchain is a digital data transaction security method based on cryptography. A hash function connects the blocks and creates a database record.However it can be implemented in automated software. This survey describes the benefits of blockchain technology in a distributed system and their features in many facilities. It is more efficient than other security services, and sharing the information across a decentralised network . In a distributed system, blockchain enhances traceability and allows for immutable transactions. It is a system that allows remote nodes in a network to agree on something. Market places have recently adopted blockchain technology for critical applications. This section will inform us about the necessity of Blockchain in current trends.**

***Keywords* — Blockchain; distributed ledger technology, automated software, platforms**

I. Introduction

A computer network is a collection of computers that connect several nodes. The term "internet" refers to the connection between a network and the internet. A network is a computer system that has communication channels and transmission medium connected to it. Over the internet, a network can exchange resources. The internet was created in 1982, and it connects computers all around the world. Business agencies began using the internet in 1991 to share information and communicate with a large number of people. Web browsers, electronic mail, search engines and other internet services are examples. Communication, research, education, financial transactions and other current technology are all supported by these application services. The Internet is a worldwide information system that provides end users with unique resources and information. Internet Service Providers can give the user access to the information. During the transmission of resources over the internet,they need security services in order to secure the digital data.In the past year,multiple number of security techniques can be introduced to secure digitalized form of information. Recently, to introduce the word 'Blockchain Technology' is a newly security techniques to secure digital data from online hackers and malware attackers in decentralized network.The methodology as blockchain to serve digital verification and records of digital files and security mechanisms provide services to identify the status of digital data and protect them.In order to protect the resources over the network transmission,security mechanisms perhaps cryptography techniques.In which follows encryption and decryption,the technology to protect resources,devices over the network.

Blockchain is the decentralized system to provide the security services against unauthorized access to digital data.The most important aspects of blockchain are govern,protect,detect and respond.The service identity and manage security rules.In order to implement the security controls to reduce security risks.Blockchain respond and recover from threats,it involves the practice of hardware and software solution and they provide recent technological information,security services are confidentiality,integrity and availability.Blockchain technology were intrwoduced in 2009 by Satoshi Nakamoto.Initially it creates the digital cryptocurrency called Bitcoin.Blockchain is a structure that store transaction history of digital records known as Block,several database in public called as chain.Blockchain is a network connected through peer-to-peer nodes,the data in blockchain is referred to as digital ledger and it creates a decentralized distribution chain.

The Blockchain developed using cryptography, hash functions, digital signatures, and distributed consensus algorithms. The document's integrity is preserved by the transparent ledger, which builds trust in the asset. Third parties cannot interfere with a transaction that has already been registered. Permissioned and permissionless blockchain technology exist, with the permissioned blockchain providing additional blockchain security by allowing specific actions to be conducted only by identifiable participants. Permissionless blockchain is a sort of decentralised blockchain. Members have the ability to conduct all operations such as creating and validating transactions, smart contracts and participants set the layout and scale of the blockchain.

Blockchain Feature

We explored the context of blockchain technology and its uses in this paper. Blockchain is an technological ecosystem has a large number of data-gathering actions and monitoring devices. Recent techniques is efficient data-sharing with security services. Blockchain is a combination of peer-to-peer network,cryptography keys and digital ledgers. The cryptographic keys are used to create digital signature to provide unique identity is the important aspect in blockchain technology. The transaction in the blockchain are approved and verified in the distributed network. In this section,we discussed the following contributions of blockchain technology.

Immutability

DOI: rp-9788770040723.179

Blockchains [2] are immutable in nature, meaning they can't be updated or altered. Every node in the network contains a copy of the digital ledger and every operation checks its validity and adds to the ledger on a continuous bbasi. According to the technology, the blockchain enables transparency and proof of corruption, as well as backing up the key list. Integrity can be provided by the feature of immutability. It strengthens the system of trust and auditing, the information verification is essentially redundant. It maintains the full historical records and enables the shared source of truth. In the Bitcoin,it plays the core benefits for the businesses and immutable gains control of the hash power. Each block generates the alphanumeric hash value and digital signature for the previous block and the consensus righty maintains the originality of the digital data. The immutable nature bringing more efficient secure transaction.

Decentralized

Decentralized means that the network is maintained by a group of nodes with no central authority. The blockchain technology allows people to obtain information directly from the web. It distributes the common control over the decentralised structure on their assets using cryptocurrency technology. The decentralized nature has various drawbacks such as lower failure rates and greater user control, as well as digital data transparency and authenticity. The decentralization environment is inherently untrustworthy, in the distributed ledgers. Each member owns a copy of the exact same type of digital data. With the common view of data, it enhances data reconciliation and access to each entity. Decentralization can improve resource distribution performance and consistency while reducing the risk of catastrophic failure. In the blockchain uses the decentralized Application (dApp) and Decentralized Autonomous Organization (DAO) for the digital transaction.

Enhanced security

Using [3] encryption it ensures security over the internet built by cryptographic algorithm that provide the firewall.Every information is hashed cryptographically hide the true nature during the data transmission.The block in the transaction built by hash value, it is difficult to tamper the data due to mathematical algorithm.Digital data related to blockchain is cross-checked and remain backed in the network.Rapid advancements in digital data by implementing authentication and cryptography key mechanisms.The high level of security offered in blockchain to secured business records in immutable form,without require the third party trust and they can disrupt global services and solutions for business customers.It offers the validation and encryption mechanisms in a distributed system to enhance security in digital data storage.Blockchain is a revolutionary technology is used in industries,education and so many applications.

Distributed Ledgers

Every transaction is recorded in a public ledger that everyone in the system may access. digital transactions benefit from distributed computational power because they execute better results. Distributed ledgers are synchronous ledgers that are implemented by independent computers. It enables peer-to-peer communications and the sharing of digital data value. They have the technology infrastructure and standards in place to undertake simultaneous digital data validation access and recording in an immutable manner across many entities. It allows the secure transmission of digital data across a decentralized network. The data is stored in a secure environment using a cryptographic technique that follows the network's regulations. DLT (Distributed Ledger Technology) has a lot of promise for businesses, institutions and government. In addition to many industries such as micrisoft,IBM reaches the DLT rules over the blockchain.

II. Blockchain Architecture

Immutability, decentralization, transparency, distributed ledger and tamper-proof transactions are all aspects of blockchain. The blockchain in a peer-to-peer network is made up of a large number of nodes. Blocks, nodes and miners are the three components of the blockchain, every chain has several blocks and each chain is made up of three essential elements: data in the block, generation of the block and creation of the hash value for the blocks. Miners are individuals who mine digital data in a distributed system to create new blocks.

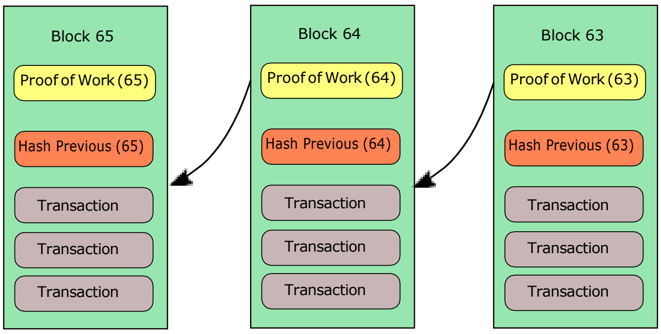

Fig. 1. Structure of Blockchain Technology

In the blockchain technology commit transaction stores list of blocks.The new block are grown appendendly,each block consist of two hash value as one for current block and another value for previous block. The hash value can be operated by SHA-256 cryptography algorithms to provide user security and ledger consistency. Blockchain distributes the user information in the open record format,it cannot be alter or eradicated by someone in it. The activity of book keeping mechanism can be followed in the process of each and every digital data in the network. The proof of work and proof of stake are the consensus mechanisms involved in cryptocurrency blockchain application achieve distributed consensus over the network. Due to the cryptocurrency techniques, to avoid the security issues over the network. It can be used for startup and business people, there is no possibility of corruptibility by the implementation of blockchain. The new method is an innovative technology and it provides self examining biological system. The five phases of blockchain are distribution, tokenization, encryption, immutability and decentralization. Blockchain sorted out the database, it keeps historical backups of every data.

DOI: rp-9788770040723.179

A blockchain protocol operates on a distributed system and peer-to-peer network to deliver ledger transactions across the network. The distributed ledger is based on pre-defined rules that are agreed upon by all system members. Blockchain is a new technology that eliminates risks and fraud in distributed applications by bringing transparency.

III. Related Surveys

Blockchain described the database system designed by unitary memory unity, the blocks are connect by hash identifier value for the previous block (Nikola Bozic, Guy Pujollie, Stefano Secci 2016). Blockchain technology is highly effort for shape the urban future and highly destructive (Charles Shen and Feniosky Pena-Mora 2018). Blockchain has become the security breaches and innovative potential and database structure using the format as STIX (Pieter Hartel, Quingze Hum 2018). Blockchain objects are inter connect and interact with environment to collect information, performed certain tasks (Tiago M.Fernandes-caramas and Paula Fraga-Lamas 2018).

The study "Securing digital data using blockchain technology" is based on papers obtained from Scopus, Web of Science, and a variety of open access journals. The first section describes blockchain criteria and features, while the second section discusses blockchain security applications in real-world settings such as healthcare, education, social media and contracts. Secure digital data, contract-based application between 2012 and 2019 that contains the consensus algorithm and SHA 256 security services are the subjects of the survey. Furthermore, the survey study provides a comprehensive overview of blockchain technology.

A. Government

Blockchain technology[19] can be used in government resource models to share information. It promotes the shift of government affairs from management to service by increasing trust in government resource sharing. The service-oriented e-government paradigm is built on blockchain. It creates the architecture for analysing interactions between the government and users. It detected the fault and ensures the security of distributed storage, consensus, plugins and asymmetric encryption. Blockchain can be used for information sharing with security service-oriented models thanks to a legal agreement. It allows the framework to provide legal agreement in government financial services. In a legal agreement, API provides the verification and voting system in the blockchain technology. Blockchain allows the transformation of smart services and attracts government attention. Distributed Ledger Technology can facilitate information sharing (DLT). The government sector keeps track of scattered transactions.

B. Finance

Blockchain shaping the financial and banking services of the future. The information is stored in GoogleLevelDB in a financial service. In this scenario, the stack is maintained by stacking blocks on top of each other, with the bottommost block serving as the foundation. The hash function can be used to identified each individual block. [20] The hash value sequence connected the other blocks to their parent block. The ancestor block of all other block is the Genesis block. The secure root is created by the structure of the genesis block and hash value. Genesis block is used in financial services as an SMS message. It satisfied the security services are authentication, integrity and non-repudiation

Decentralization, reliability and transparency are the characteristics of financial services.

The financial investors are provided by RES (Renewable Energy Sources) [21]. All the nodes in distributed system are monitored the performance of system. The smart contract with turing comprehensive language provided by blockchain technology linked to financial services and the digital tokens transferred under the smart contracts. Electricity Grids shaped Renewable Energy Sources. In a decentralized system, RES presents reverse power flow. DLS-OCS (Distributed Ledger Services for Online Contract Settlement) was used to do research for digital financial systems.

A. Healthcare

In the previous year, the proposed paper introduced MedRec, a decentralized record management system that included an Electronic Medical Records (EMR) system that shows an immutable log and easy access to the treatment site. As blockchain miners, design integrated manage sensitive information and the public health authority. Health records are in a jumbled state. The data is retrieved by the patient and shared on the decentralised system.

In [22], two sorts of chains are introduced: private and public in the side chain, which scanned the patients genuine IDs, while the main chain scannned the patients temporary IDs. The completed transaction is saved in a peer-to-peer network. In a distributed system, main chain transaction generates additional transaction. The medical institution keeps track of the timestamp, data type, data link, hash value, and prior the hash block. The transaction verification mechanism is described in this case.

The integrated design's underlying technique has evolved via several rounds of hash function such as mathematical processes and human fingerprints. The hash function can be quickly identified and replicated the data.

B. Education

In higher education, new technology is introduced. To make effective interaction between the faculties and students to store the record untampered and validated in centralization system. To enhance the education system by innovate the various method and contract based on blockchain. The learning data form the hub to the students and subjects. In [17] Learning Management System (LMS) and Learning Record Pools (LRP) provide availability, reliability and immutability,access control, security and privacy in learning process. The resources and study material in digitalized form as e-Books,video and audio to minimized the budget of governing body.

In the learning process, [18] uses computerised evaluation software for professional credentials. The term "electronic learning contract" refers to a contract between a teacher and a student. The periodic meetings are held to facilitate decision-making in the learning process. POA is an entirely consensus-based combination of quantitative and qualitative student evaluation. The student's curriculum evaluate their performance.

As a result, the blockchain is transformative in terms of enabling and coordinating economic activities. Intermediaries costs and time are reduced, making the transaction and information sharing easier and safer. To improve an ecosystem's trust, blockchain records are permanent and irresversible.

OUTCOME OF THE LITERATURE SURVEY

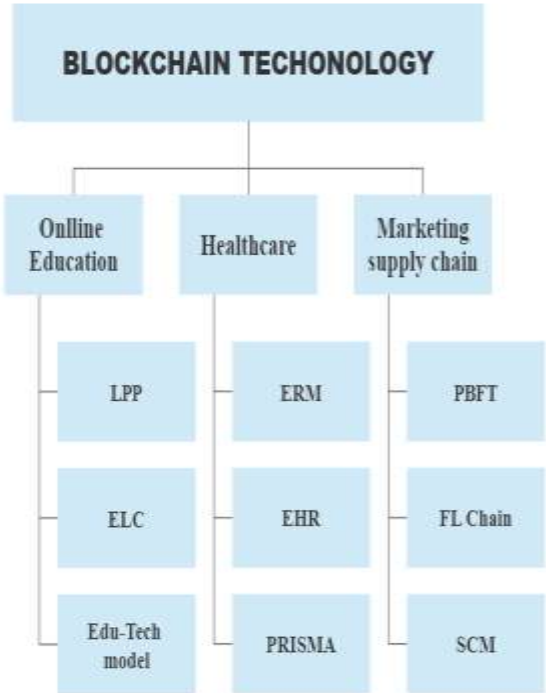

Fig 2. Blockchain Diagram for Literature Survey

According to a thorough analysis of the literature, a security method that is scalable, dreadfully inefficient, mutable, and not truly decentralised is required. Congestion in the network is a problem caused by the breakdown of the consensus mechanism in a current security measures. In the conventional system, network data loss is the result of the lack of chronological order. Therefore, this research suggests creating a blockchain technology that can address the shortcomings of current efforts.

IV. BLOCKCHAIN PLATFORMS

Blockchain is a network-wide distributed digital ledger. Platforms are decentralised and implemented as public and private blockchain. Public network release the data in public and the information is secure and immutable. Public blockchain creates the cryptocurrency with open source computing code. The major advantage of blockchain provide maximum security,open source environment, retrieves the anonymous,decentralized and transparency. Public blockchain limitation as data modification and uses private keys. The most common examples of public blockchain as Bitcoin and Ethereum.

A. Bitcoin

The first digital asset approaches based on the cryptocurrency mechanism were introduced in 2009, after Bitcoin's invention in 2008. ([5] Bitcoin is a peer-to-peer network that uses public key cryptography, a proof-of-work and proof-of-stake system to validate node processing, and a new block is generated every 10 minutes. The output for unspent transactions A byproduct of the bitcoin cryptocurrency, the UTXO paradigm offers transactions that handle independent data while avoiding heavy traffic in legal organisations. The blockchain is a public distributed ledger that stores transactions made by digital nodes using the cryptography method. Bitcoin generates rewards through a process known as mining, and these rewards can be used to exchange for goods, services, and other currencies. Several local and national governments use this technology.

B. Ethereum

In order to facilitate cryptocurrency transactions and apply the technology to regulate fraud, downtime, or interference from a third party, Ethereum launched decentralised digital applications, or Dapps, in 2015. [5] We are able to reach agreements, carry out transactions, and process the digital assets automatically by the vending machine thanks to Ethereum, which operates on a global network of computers. To achieve coordination between the digital transmission systems, the POW and alternate POS can be built using a consensus mechanism. Ethereum currently uses the Dagger-Hashimoto memory hard hash algorithm, which creates a lower block time than the other systems, leading to a higher rate of block stale.

Private blockchain design by private key access by single organization.The permission from the govern body of the blockchain to read and write on the ledger.The mechanism of blockchain access depends on the network creator.The benefits of private blockchain process the higher number of transaction per second and to reduce the consensus time,stability etc.The limitations of blockchain as private or permissioned as space complexity and reservation of block The most widely used private blockchain is Hyperledger.

C. Hyperledger

A cross-industry, global corporate blockchain system called Hyperledger was developed in 2016. Because consensus protocols require a network that may be customised, they can offer the Practical Byzantine Fault Tolerance (PBFT) consensus protocol to increase the network's latency. Hyperledger is a term for a permissioned blockchain where the participants in a consensus process are industry leaders in banking, manufacturing, the internet of things, and finance. To develop high-performance blockchain-based distributed ledger technology, Hyperledger fosters widespread collaboration. It serves as a focal point for distributed systems' digital data transactions and offers the framework and guidelines needed to build a blockchain. With everyone coming to a consensus, Hyperledger is able to create a commercial blockchain.

TABLE 4. COMPARATIVE STUDY OF BLOCKCHAIN PLATFORMS

Blockchain platform name	Blockchain platform type	Advantages	Limitations	Cost (Rs)
Bitcoin	Public	Maximum Security and open source environment	Uses private leys and data modification	26,87,285.13
Ethereum	Public	Autonomous and uses compuehensive set of tools	Platform generator is much more	1,92,569.90
Hyperledger	Private	High speed	Block reservation	19,885.69

V. CONCLUSION AND FUTURE SCOPE

Thus a review of a various blockchain technology with respect to platforms and applications is prescribed.We discussed multiple number of domains and their applications. The database records the digital data and stored in a blocks with the formulation of hash function. Blockchain completely depends on DLT technology,the data loss rate is minimized.The blockchain framework is a foundational technology,it is potential for engender applications.

Blockchain technology majorly lies in field of cybersecurity and its shows the unfold potential.And,there will be a huge demand for blockchain engineers,across all these markets.By 2024,blockchain is expected to become a 20 billion market.

***Abstract* — Brain tumors have garnered significant attention in recent times as one of the most lethal diseases affecting both children and adults. Most of the primary central nervous system cancers or CNS are found in the brain. With roughly 12,000 individuals receiving a diagnosis of a brain tumor each year. There are various categories of brain tumors including Benign, Malignant, Pituitary, Glioma and others. To enhance the life expectancy of patients, it is crucial to employ appropriate care, preparation, and accurate diagnostics. Magnetic resonance imaging (MRI) is widely considered to be the most effective method for detecting brain tumors. However, due to the intricate nature of brain tumors and their characteristics, manual examination can sometimes lead to inaccurate results. The utilization of an automated system for detecting and classifying brain tumors can help doctors and patients identify and categorize these tumors at an early stage, initiate treatment sooner, and reduce mortality rates. Deep learning research is rapidly advancing, with new algorithms being developed every day to enhance accuracy. We use a combination of deep learning techniques such as Convolutional Neural Networks (CNN) and Artificial Neural Networks (ANN) to accurately detect tumors. Our approach leverages the transfer learning technique to train a new CNN model on top of the efficientnetB0 base model, allowing us to alter the final layers to match the classes we want to identify and categorize, such as benign, malignant, pituitary, and normal. This approach allows us to improve the accuracy of tumor detection and classification. Also we have done a comparative study between the pre trained heavy weight model called as Efficientnet b0 and Efficientnet B1 and we found there is a significant increase in the model performance and accuracy.**

Keywords — Central Nervous System (CNS), Magnetic Resonance Imaging, Machine Learning, Convolution Neural Network, Artificial Neural Network, and Transfer Learning.

I. INTRODUCTION

The human brain is the most crucial and noteworthy organ in the body, with brain tumours being a frequent cause of brain dysfunction. Essentially, a brain tumour is an accumulation of cells that are growing uncontrollably, resulting in a lump or unhealthy cell growth in the brain. There are numerous types of brain tumours, including both noncancerous (benign) and cancerous (malignant) varieties. Primary brain tumours originate in the brain, whereas secondary (metastatic) tumours originate in other parts of the body and spread to the brain. The rate of growth for brain tumours can vary significantly. While benign tumours do not spread to other tissues and grow slowly, they can still cause major problems despite not being carcinogenic. Additionally, they typically have more distinct borders, which facilitates surgical excision, and they do not frequently reappear following removal. On the other side, malignant brain tumours can spread to other regions of your brain or central nervous system, are carcinogenic, develop quickly, and pose a serious risk to your life. The proper functioning of your nervous system is reliant on the growth rate and location of any brain tumours you may have. The type of tumour, along with its size and placement, are all factors that determine the available treatment options. Brain tumour cells consume the nutrients intended for healthy cells and tissues, leading to brain dysfunction. Currently, manual examination of a patient's MR images of the brain is required to identify the tumour's location and size, which is time-consuming and can result in inaccurate detection. Brain cancer is a severe disease that claims many lives each year, making early detection and classification methods essential. Deep learning algorithms have been shown to be effective in detecting brain tumours from medical images such as MRI and CT scans.[1] The use of MRI scans, a non-invasive procedure that utilizes a powerful magnet, radio waves, and a computer, allows for the structures and components inside the body to be viewed with stunning clarity. Open MRI devices, however, do not produce as sharp of images as closed-bore MRI equipment. The brain is a crucial and critical organ in the human body and brain tumours have emerged as one of the leading causes of brain malfunctions. A tumour is a cluster of cells that have grown in an uncontrolled manner and form a mass in the brain. There are various types of brain tumours, ranging from benign (non-cancerous) to malignant (cancerous). Primary brain tumours originate in the brain while secondary (metastatic) tumours are those that originate elsewhere in the body and spread to the brain. In contrast, malignant tumours can grow rapidly and spread to other parts of the brain or central nervous system, posing a major threat to one's life. The treatment options for brain tumours are influenced by their type, size, and location, as well as the patient's nervous system's ability to function. The growth of brain tumour cells eventually depletes the nutrients intended for healthy cells and tissues, leading to brain failure. Convolutional neural networks (CNNs) are commonly used in brain tumor detection due to their ability to automatically learn features from images.[2] Currently, clinicians manually examine patients' MRI images of the brain to determine the location and size of the tumour, which is a time-consuming process prone to inaccuracies. Early detection and classification of brain tumours are crucial for survival, and MRI scans are the preferred choice for imaging because they produce clear and detailed images without the use of radiation. Open MRI machines, which have larger spaces on two sides and reduce the claustrophobia commonly associated with closed-bore MRI scanners, are available for patients with a fear of enclosed spaces. However, open MRI machines may not produce as sharp images as closed-bore MRI machines.

DOI: rp-9788770040723.181

II. Overview of Data

A. DataSet Description

The primary source of data is from Kaggle. Brain tumours can be complex and unpredictable in terms of their size and location. This makes it challenging to fully understand the nature of the tumor. An experienced neurosurgeon is required for MRI analysis. In underdeveloped countries, the lack of skilled medical professionals and limited knowledge of malignancies can make it challenging to effectively analyse MRI results. This problem can be solved with a cloud-based automated solution. The dataset includes around 4,000 MRI images of the brain. There are 400 images designated for testing and 4,000 for training. A large dataset is necessary for proper training of a Convolutional Neural Network (CNN).

B. Contents of the Dataset.

• Glioma Tumour: A type of tumour called a glioma develops in the brain and spinal cord and arises from glial cells, which support nerve cells. Gliomas are classified based on their genetic characteristics, which can help predict their behaviour and effective treatment options.

• Meningioma Tumour: A tumour called a meningioma develops from the meninges, the membranes covering the brain and spinal cord. Although not strictly a brain tumour, it can affect nearby structures like nerves, blood vessels, or brain tissue. Meningiomas are most common in women and often found in older individuals. They grow slowly and may not show symptoms, thus, they may be monitored rather than treated immediately.

• Pituitary Tumour: Tumours of the pituitary gland are abnormal growths that affect the production of hormones. Most pituitary tumours are benign (noncancerous) adenomas and don't spread to other parts of the body. Treatment options include removal, hormone management, and growth control, and observation may be recommended.

• No Tumour: A tumour doesn't always indicate malignancy. The term "tumour" refers to a swelling of any kind, including benign or malignant cell growth. Technically, even a pustule can be considered a tumour.

This dataset contains 6 different features i.e. date, open, high, low, close, volume.

III. Motivation

The detection and classification of brain tumours are critical in providing effective medical intervention. In addition to detecting the presence of a tumor, the ability to accurately classify its type is crucial in determining the best course of treatment. For instance, it is important to determine if the tumor is malignant or benign. By analysing MRI images, our project seeks to revolutionize the current approach to brain tumor detection and classification. Transfer learning, where a pre-trained CNN is fine-tuned for brain tumor detection, has been shown to improve performance and reduce training time.[3]

The primary objective of our project is to develop a cutting-edge system that can accurately identify various types of brain tumours using MRI images of patients. Our goal is to create a system that is more efficient, accurate, and reliable than current methods. By leveraging advanced imaging techniques, our system will provide medical professionals with valuable insights into the characteristics of brain tumours. This will allow them to make informed decisions regarding patient care and treatment options.

Ultimately, our project aims to contribute to the advancement of medical science by improving the way brain tumours are detected and classified. Through the development of a sophisticated system that can accurately analyse MRI images, we hope to facilitate early detection and effective treatment of brain tumours. The system uses convolution neural network algorithms to detect tumor blocks and classify the type of tumor present in the image. The system is designed to be user-friendly, where doctors can simply upload an MRI image, and the model will predict the presence of a brain tumor and the type of tumor present, with high accuracy. This project has the potential to save lives by detecting brain tumours at an earlier stage, leading to early treatment and better outcomes. Brain tumours are a significant concern worldwide and are responsible for taking many lives every day. Our aim is to tackle this problem head-on by developing a reliable and innovative solution that can accurately detect and classify brain tumours. By doing so, we hope to help improve the lives of patients, and ultimately, save lives.

C. Application

Brain tumours are a pressing concern worldwide, causing many fatalities on a daily basis. Early detection of these tumours by patients, doctors, and healthcare specialists can significantly improve the chances of survival and lead to happier outcomes. Our aim is to develop a solution that is both innovative and reliable in detecting brain tumours. Our project involves the creation of a system where doctors can upload MRI images and the model will predict whether there is a presence of cancer and the type of tumor present. The current state of brain tumours is one of the most dangerous issues in the world and it has become a matter of great concern. However, early detection can be life-saving for many individuals. That is why we aim to create a solution that is both precise and dependable in detecting brain tumours.

D. Scope of the Project

With the help of the AI and DL we can use the methods and algorithms effectively for predicting and detecting diseases like these. Brain Tumor detection is one of the most important and efficient way to detect brain tumor. The main scope of the project is to deliver this product to health care services and health care workers and doctors for detecting brain cancer with high accuracy. If this project is made as a full-fledged product surely it will be a great success for the college and also we can make a good profit from it. Ensemble learning, where multiple CNNs are combined, has also been shown to improve performance in brain tumor detection [4]. Brain tumor detection is a crucial and effective method for detecting brain cancer, and with the use of AI and DL, we can utilize these techniques and algorithms for accurate predictions and diagnoses. Our

DOI: rp-9788770040723.181

project's main objective is to deliver this product to healthcare services, staff, and doctors for efficient brain tumor detection. If this project is developed into a full-fledged product, it will bring great success to the college and provide financial benefits. As a benefit to users, we can also offer a free trial period for those who want to test the product before committing to it.

E. Problem Statement

To counter this, we aim to bridge the gap and ensure that predictions and diagnoses are accurate and precise. By utilizing AI and DL technologies, we can assist or guide doctors in determining the type of cancer present in an MRI image and detect the tumour at an early stage. This will greatly increase confidence in the results, as these models are trained on vast amounts of data to achieve high accuracy and reliability. The outcome of this solution will be a higher level of trust in the doctors' diagnostics and the ability to provide appropriate treatment accordingly.

IV. LITERATURE STUDY

The use of deep learning for diagnosing and classifying brain tumours remains a prominent area of research. Early detection and treatment of brain tumours has the potential to save millions of lives each year. Researchers have explored using machine learning and deep learning algorithms to address medical image diagnosis problems. Convolutional Neural Networks (CNN), one of the most well-known deep learning algorithms, have yielded significant results in the field of brain tumour classification.

A. Works Related To Brain Tumour Classification Using Deep Learning Approach And Idea for transfer learning

If a tumour is detected early, doctors can treat the patient and improve their chances of survival. According to statistics, in 2016, over 200 studies were conducted using deep learning on medical images, with 190 of them utilizing CNNs. Some of the most widely used CNNs for classifying medical images include AlexNet, VGG, and GoogLeNet. This section delves into the recent studies used for categorizing brain tumours. The use of Generative Adversarial Networks (GANs) in computer vision is becoming increasingly popular. Data augmentation, where synthetic data is generated from existing images, has been shown to improve CNN performance in brain tumor detection.[5] These networks can be trained to generate a variety of images, including style transfer, image synthesis from noise, image-to-image translation, and image segmentation. In the field of medical imaging, where datasets tend to be smaller, GANs have gained traction as a solution. When it's not possible to gather multiple imaging modalities for each patient, CycleGAN, a novel algorithm, can be used to compensate for the missing data. In this research, we explored the different entropy functions used in MRI image analysis to segment and detect tumours. The choice of entropy function has a significant impact on the threshold values and, subsequently, the segmentation results. Attention mechanisms, where important regions in the image are highlighted, have been shown to improve CNN performance in brain tumor detection.[6] Gliomas, the most common brain tumours, are classified based on the presence or absence of mitotic activity, necrosis, and vascular growth, resulting in a WHO grade of II, III, or IV. Both types of brain tumours can be detected easily, but they grow in a diffuse, infiltrative manner and are accompanied by an increase in water in the area around the tumor. Early detection and classification of these tumours are crucial for effective treatment. With the help of advanced technological advancements in automated healthcare systems, medical professionals can now provide more effective treatment for patients. GANs, where synthetic data is generated by a generator network and evaluated by a discriminator network, have been shown to improve CNN performance in brain tumor detection.[7] This article presents a new MRI-based method for classifying and identifying brain tumours by combining the properties of deep convolutional neural networks (CNNs).

The MRI images undergo normalization and enhancement before being input into three different CNN models for feature extraction. The Fuzzy C-Means (FCM) segmentation method is used to divide the brain into tumor and non-tumor regions, and wavelet features are extracted using the multilevel DWT method. 3D CNNs, where image volumes are used instead of individual slices, have been shown to improve performance in brain tumor detection.[8] Finally, a Deep Neural Network (DNN) is employed for highly accurate brain tumor classification. This method of brain tumour classification and identification using deep CNNs is compared to other approaches such as KNN, LDA, and SMO. AlexNet filters were utilized in the convolution layers of the CDLLC with a size of 3 x 3. The training process employed SGD as an estimator and the activation function used was ReLU. Transfer learning combined with data augmentation has been shown to achieve state-of-the-art performance in brain tumor detection using deep learning algorithms.[9]

This study aimed to diagnose normal and malignant brains using Artificial Neural Networks (ANNs) and Convolutional Neural Networks (CNNs). ANNs, with their ability to learn and store information through multiple interconnected layers of neurons, were able to train on the training data using basic processing units. The idea of this project was to use transfer learning, which has been previously explored in the field of brain tumour diagnosis

V. PROPOSED METHODOLOGY

The main aim of the project is to deliver a useful and effective solution for doctors who need to detect and diagnose what type of cancer a patient has using the MRI scanned image photographs of the scan from the patient. This project mainly focus to improve the accuracy to the maximum extent and provide a reliable deep learning model which will effectively identify the cancer present in the tumour image. Deep learning-based brain tumor detection methods have the potential to significantly improve diagnosis accuracy and treatment planning for patients with brain tumours.[10] We have used a latest technique called as the transfer learning which will help us identify the model input more accurately.

DOI: rp-9788770040723.181

A. Transfer Learning

Transfer learning is a branch of machine learning that focuses on the reuse of knowledge acquired from one problem and its application to another, similar but unrelated problem. Deep learning algorithms have been shown to be effective in differentiating between low-grade and high-grade gliomas, which can help in determining the appropriate treatment for patients.[11] For example, the skills learned from identifying vehicles can be transferred to identifying trucks. This concept has similarities to the psychological literature on learning transfer, where knowledge obtained from one task can be used to improve efficiency in learning new tasks. In transfer learning, the learned features from a base network trained on a base dataset and task are transferred to a target network trained on a target dataset and task. The success of this process depends on the generalizability of the learned features, as opposed to being task-specific. Transfer learning is the process of training a base model with another model and then training our target model on top of the base model. Using a pre-trained model as the base model improves accuracy and efficiency in detecting new information.

B. Efficientnetb0

The efficientnetb0 model is the foundation of our transfer learning approach. Typically, convolutional neural networks (CNNs) are constructed with a fixed resource budget and then expanded as additional resources become available to enhance accuracy. The use of multi-modal imaging, such as combining MRI and CT scans, can improve the accuracy of brain tumor detection using deep learning. [12] For example, ResNet can be scaled from ResNet-18 to ResNet-200 by adding more layers, and GPipe recently improved a baseline CNN by a factor of four, resulting in 84.3% ImageNet top-1 accuracy. Traditionally, scaling a model involves arbitrarily increasing the CNN depth or width or using higher-resolution input images for training and testing. Although these methods increase accuracy, they require time-consuming manual adjustments and often yield suboptimal outcomes.

Our approach is different. In our ICML 2019 paper, "EfficientNet: Rethinking Prototype Scaling for Deep Neural Networks," we proposed a novel model scaling method that employs a simple yet highly effective compound coefficient to scale CNNs in a more systematic way. This allows for the expansion of CNNs in an ethical manner, achieving impressive accuracy without requiring laborious fine-tuning. Our approach revolutionizes the way we scale CNNs, making the process more efficient and effective. Our innovative scaling strategy, combined with the latest advancements in AutoML, has led to the development of a family of models known as EfficientNets that significantly outperform state-of-the-art accuracy while achieving up to 10 times greater efficiency.

To better understand the impact of scaling the network, we conducted a comprehensive analysis of the effects of scaling various model dimensions. While scaling individual dimensions can improve model performance, we discovered that to optimize network performance, it is essential to strike a balance between all network dimensions - width, depth, and image resolution - and the available resources. Our findings demonstrate the importance of a comprehensive and coordinated approach to model scaling, which can result in dramatic improvements in efficiency and accuracy. With our approach, we are redefining what is possible in the world of model scaling and making it easier for developers to build powerful, efficient, and accurate models for a wide range of applications.

C. EfficientnetB1

EfficientNet-B1 is a pre-trained computer vision model developed by Google Research that aims to improve image classification accuracy while reducing the amount of computation needed to process each image. It is part of the EfficientNet series, which is designed to perform well on a range of image sizes and is scalable to accommodate larger image inputs while maintaining high accuracy. EfficientNet-B1 has been trained on the ImageNet dataset, which consists of over 14 million images, and has achieved state-of-the-art performance on the benchmark leader board. The model uses an efficient scaling method that balances the depth, width, and resolution of the network to achieve a high accuracy-to-computation ratio. EfficientNet-B1 can be fine-tuned for specific applications by retraining its final layers, or used as a feature extractor by taking the activations from the intermediate layers. It has become a popular choice for many computer vision tasks such as object detection, segmentation, and classification

D. Efficientnet Architecture

The effectiveness of the models is largely influenced by the baseline network. To enhance performance, a new baseline network has been established by performing a neural architecture search with the AutoML MNAS framework. This framework optimizes both accuracy and efficiency to produce a more optimal result in terms of FLOPS. The architecture incorporates MBConv, which is similar to MobileNetV2 and MnasNet, and has a higher FLOP budget. This baseline network serves as the foundation for the creation of the EfficientNets series of models. The baseline network is a crucial component that determines the success of scaling up models.

Deep learning algorithms can also be used for predicting patient survival and disease progression based on brain tumor imaging data. [13] To achieve better performance and accuracy, we employed a neural architecture search using the state-of-the-art AutoML MNAS framework. The search resulted in a new baseline network that utilizes the digital inverted limit convolution (MBConv) layer, similar to MobileNetV2 and MnasNet. This layer allowed for a larger FLOP budget, leading to improved model performance. The new baseline network was then used to create the EfficientNets family of models, which are known for their superior accuracy and efficiency compared to traditional models. Additionally, this approach of using neural architecture search and baseline network scaling can be applied to various applications in computer vision and natural language processing, leading to improved model performance in these domains as well.

DOI: rp-9788770040723.181

E. Performance Of Efficientnet

The EfficientNets models were rigorously tested against other pre-existing CNNs on the ImageNet dataset. The results revealed that our models outperformed the competition with regards to accuracy and efficiency. By reducing the parameter size and FLOPs by a substantial margin, our EfficientNet-B7 model achieved a remarkable 84.4% top-1 and 97.1% top-5 accuracy on ImageNet, while also being 8.4 times smaller and 6.1 times faster than the prior Gpipe model. Transfer learning combined with domain adaptation can improve the performance of deep learning algorithms for brain tumor detection when transferring knowledge between different imaging modalities or institutions. [14] Additionally, our EfficientNet-B4 model leveraged a similar amount of FLOPs compared to the popular ResNet-50 model but delivered a significant increase in top-1 accuracy, from 76.3% to 82.6%. The success of EfficientNets on ImageNet is just the tip of the iceberg. To truly evaluate the potential of EfficientNets, we conducted experiments on eight popular transfer learning datasets. To support the machine learning community, we have open-sourced all EfficientNet models, along with the TPU training scripts and source code. The Keras efficientnet function returns the Keras object recognition model that is pre-trained on ImageNet and ready for dynamic weight and training data input. The efficientnet pre-processing is designed to fit the specific input format required by every Keras application.

VI. RESULTS AND EVIDENCE

The current system in medical image analysis has utilized GANs (Generative Adversarial Networks) to some extent, but they have fallen short compared to CNNs in terms of accuracy. To determine the final output, some researchers have turned to SVMs (Support Vector Machines). However, this approach has limitations in terms of both accuracy and processing time. The use of attention mechanisms in deep learning algorithms can help in identifying important regions in brain tumor images, which can aid in accurate tumor segmentation. [15] One commonly used technique for separating tumor and non-tumor regions in the brain is the Fuzzy C-Means (FCM) segmentation method. Although this method has some potential, it can be very complex and unreliable in practice. To overcome these limitations and improve the accuracy of medical image analysis, it may be necessary to adopt more advanced techniques and approaches that better balance accuracy and efficiency.

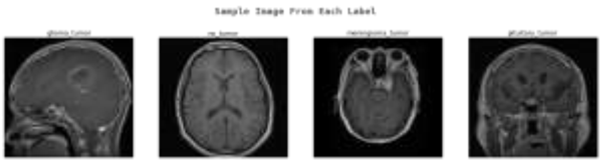

Fig 1. Sample image of dataset *(Contains Four classes)*

In the dataset sample image, we observe the presence of four distinct classes: glioma, meningioma, pituitary, and no tumour. These images will undergo a process of resizing and reshaping to meet the input specifications of the CNN model. Once the input is fed into the model, transfer learning will be applied, and the final layer will produce the desired output in the form of classified results. This process enables the efficient utilization of knowledge gained from previous similar problems to enhance the accuracy of the current task.

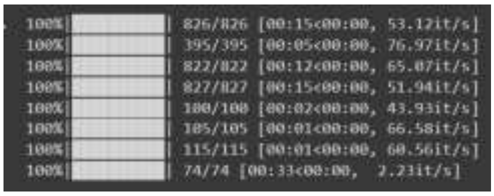

Fig 2. Data loading

The dataset consists of a total of 3624 images, which are divided into four classes: glioma, meningioma, pituitary, and no tumour. Each class is further divided into training and testing folders, with a different number of images in each folder. For example, the first folder, belonging to the glioma class, contains 826 training images and 100 testing images. The second folder, belonging to the meningioma class, contains 395 training images and 105 testing images. The third class, pituitary, has 822 training images and 115 testing images. The combination of deep learning algorithms and radiomics features can improve the accuracy of brain tumor detection and segmentation.[16] The fourth class, no tumour, has 827 training images and 74 testing images. These images will serve as the training and testing data for building a model that can accurately predict the presence of cancer and tumours. To prepare the data for model building, it must be first split into training and testing sets using pandas and a data frame. This will allow for the training of a robust and reliable model for future prediction tasks.

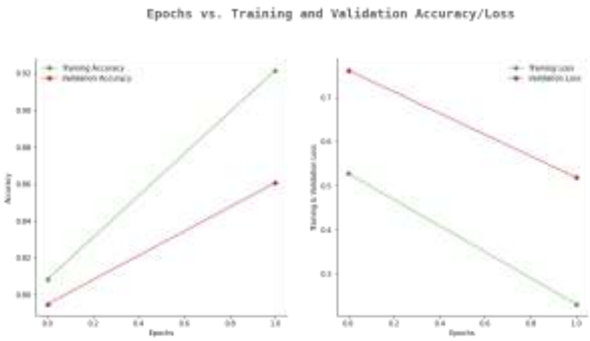

Fig 3. Accuracy of CNN

The Convolutional Neural Network (ConvNet/CNN) is a powerful Deep Learning tool that can analyse and differentiate various aspects of an input image. In the above image, we can see the accuracy comparison of a CNN model that was trained using an efficientnetB0 pretrained model as its base. Semi-supervised learning can improve the performance of deep learning algorithms in brain tumor detection by leveraging both labeled and unlabeled data. [17] The results are quite impressive, with a training accuracy of 92% and validation accuracy of 84% after only two epochs of training. The loss is also reduced to a low value of 0.1 for training and 0.55 for validation. This shows the remarkable performance of the CNN model from the first epoch to the second epoch. To further analyse these results, a confusion matrix can be used for comparison.

DOI: rp-9788770040723.181

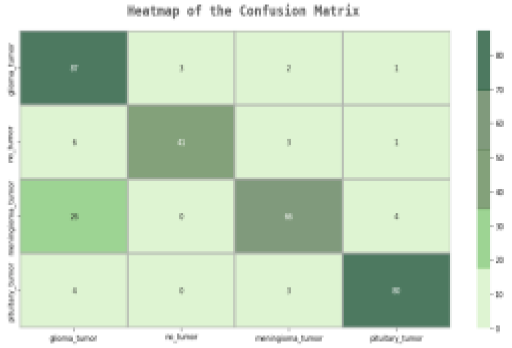

Fig 4. Heatmap of the confusion matrix for 2 epochs

The training process of a Convolutional Neural Network (ConvNet/CNN) becomes more effective as the number of epochs increases. An epoch is a complete iteration through the entire training set in the context of deep learning. More epochs provide the network with more opportunities to learn from the training data, resulting in better generalization. The number of iterations in an epoch is determined by the number of batches or iterations over the partitioned training data. The use of multiple epochs allows the network to revise its parameters and improve its performance, especially with large training sets. Additionally, heat maps can be used to help focus on important aspects of a dataset by using color-coding to visually represent the volume of data points.

Fig 5. 2 epochs training

From the above figure, it is evident that the training accuracy for 2 epochs is relatively low at 0.92, and the validation accuracy of 0.86 is not desirable for the CNN model. To ensure that the model can learn more effectively from the images, it is crucial to both increase the number of epochs and decrease the batch size. This way, the model will be exposed to more diverse training data and will have the opportunity to better understand and extract features and parameters for accurate output classification.

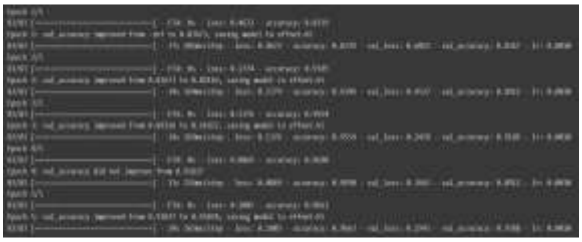

Fig 6. 5 epochs training.

By increasing the number of epochs to 5, we can observe the improved performance of the model. The results are remarkable, with a training accuracy of 0.9663 and a validation accuracy of 0.9388, both of which are great for a CNN model predicting brain tumours. The comparison of confusion matrices and classification reports of different epoch sizes will now be performed to understand the impact of epochs, verbose, and batch size on the accuracy of the model. These factors have a significant impact on the training and validation accuracy and must be carefully considered before training the model.

```
print(classification_report(y_test_new,pred))

Fig 7. Classification report for 2 epochs.

The term "verbose" in programming refers to the production of extensive logging output. When verbose is set to true, the program provides detailed information about its actions. This can be useful for monitoring the progress of a neural network during training. By setting verbose to 0, no output will be displayed. Verbose mode is a common feature in operating systems and programming languages that provides additional information about the activities of the computer or program, including startup processes, software and driver loading, and comprehensive output for diagnostics. By increasing the number of epochs to 5, we can train the model and evaluate its performance with a classification report.

```

```

Fig 8. Classification report for 5 epochs.

To evaluate the performance of a classification algorithm, a classification report is generated to show the number of correct and incorrect predictions. The report is based on four metrics: True Positives (TP), False Positives (FP), True Negatives (TN), and False Negatives (FN), which are used to measure the accuracy of the predictions. Additionally, the classification report displays the model's precision, recall, F1 score, and support scores. Upon analysing the results of the trained model, we found that the accuracy was 0.84 after two epochs of training. The use of generative models, such as GANs, can generate synthetic images to augment the training data, which can improve the performance of deep learning algorithms in brain tumor detection. [18] However, by increasing the number of

DOI: rp-9788770040723.181

epochs to 5, the accuracy significantly improved to 0.95, indicating that the model's performance has improved considerably. To further elaborate, a classification report provides valuable information on the performance of a classification algorithm by breaking down the number of correct and incorrect predictions for each class in a dataset. Precision refers to the percentage of correct positive predictions out of all positive predictions, while recall refers to the percentage of correct positive predictions out of all actual positives.

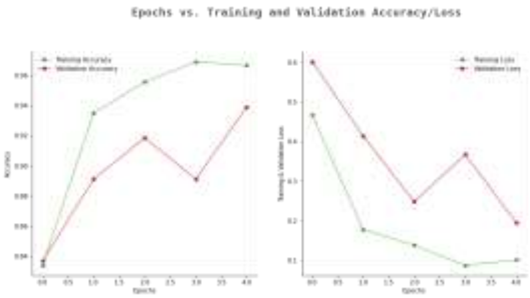

Fig 9. Accuracy comparison for 5 epochs.

The F1 Score, a combination of precision and recall, is used to evaluate the model's overall performance. In the context of machine learning, the accuracy of a model can be improved by increasing the amount of data used for training, increasing the number of epochs, and fine-tuning hyperparameters. The loss function is another important metric to monitor during training as it indicates how well the model is performing at each step. In the field of web analytics, heat map analysis is a method of visualizing user behaviour on a website by displaying the areas where users click or hover their mouse the most. This type of data can provide valuable insights into how users interact with a website and can be used to improve the site's design and user experience. By studying heat map data, web designers can identify which parts of a page are most engaging to users and optimize the layout and content to improve conversion rates.

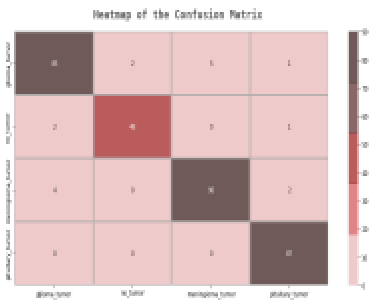

Fig 10. Heatmap for confusion matrix with 5 epochs

The graph shows that when it comes to image processing projects, especially in the domain of brain tumor detection and classification, the Convolutional Neural Network (CNN) outperforms other algorithms in terms of efficiency. This can be attributed to the CNN's ability to automatically learn and extract features from images, making it highly suitable for tasks that involve image data. However, it is important to note that the accuracy of the results can be further improved by increasing the amount of training data and the number of epochs used in training the model.

In the context of the MITRE heat maps, the color-coding system is designed to provide a visual representation of the level of confidence in the mapping of techniques to strategies. Lighter colours indicate a lower level of confidence, while darker colours indicate a higher level of confidence. This is an important consideration when using the heat maps to evaluate the effectiveness of different strategies and techniques, as it helps to identify areas where additional research or refinement may be needed. Overall, the heat maps can be a valuable tool for understanding the relationships between different techniques and strategies in complex domains.

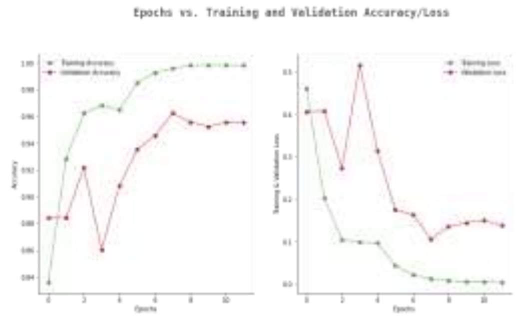

Fig 11. Accuracy comparison for 12 epochs from Effnet B0

By increasing the number of epochs from 5 to 12, we observed that the performance of the model improved significantly. The training accuracy reached 0.97, which is a highly impressive result. This indicates that the model is now better suited for the task of brain tumour detection and classification using deep learning. Deep learning algorithms can also be used to segment brain tumor regions for radiation therapy planning and monitoring, which can improve treatment outcomes. [19] The validation accuracy also improved and reached its highest value of 0.96. This further confirms that our model is performing well and is able to generalize well to new data. The training loss decreased to 0.05 and the validation loss decreased to 0.1. This suggests that the model is now able to learn the underlying patterns in the data more effectively. The classification report and the confusion matrix also indicate that the model is performing well, with a high precision, recall, F1 score, and support.

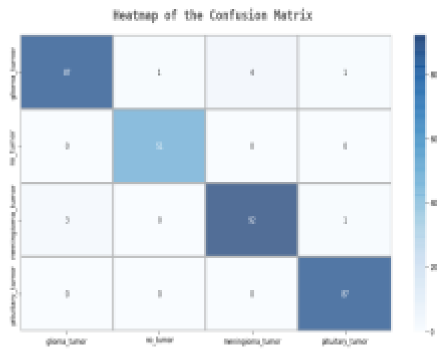

Fig 12. Heatmap for confusion matrix with 12 epochs

DOI: rp-9788770040723.181

A confusion matrix is an important evaluation metric for machine learning models, particularly in classification tasks. It provides an overview of the model's performance by comparing the actual and predicted values. By increasing the number of epochs from 5 to 12, we observe that the model's performance improves. This can be seen in the confusion matrix where the number of correct predictions (True Positives and True Negatives) increases, resulting in a higher accuracy of 97%. The confusion matrix helps us to understand the model's behaviour and evaluate its performance in a more visual manner. It is a crucial tool for debugging and optimizing the model's performance.

EfficientNet-B1 is a convolutional neural network architecture introduced by Google in 2019, as part of their EfficientNet series of models. It is designed to be more efficient than existing architectures, both in terms of computational cost and accuracy. The "B1" refers to the fact that it is the first model in the series, with subsequent models (B2, B3, etc.) having larger architectures with improved accuracy. EfficientNet-B1 is designed using a compound scaling method that balances accuracy and efficiency, by scaling the network's depth, width, and resolution. This allows the model to achieve high accuracy while using fewer parameters and less computation than other architectures. The architecture is built on top of MobileNetV2 and uses depth wise separable convolutions and a mix of global average pooling and global max pooling to reduce the computational cost. EfficientNet-B1 has been trained on the ImageNet dataset and achieved state-of-the-art performance on multiple benchmarking tasks. It is widely used in a variety of computer vision applications, such as object detection, image classification, and semantic segmentation, due to its efficiency and effectiveness. Deep learning-based methods have shown promising results in differentiating between true tumor progression and pseudo progression in patients with glioblastoma undergoing treatment, which can aid in clinical decision-making. [20] The confusion matrix can be used to evaluate the model's performance, showing the number of true positive, true negative, false positive, and false negative predictions.

FUTURE ENHANCEMENT

The With the introduction of EffNetB1, the accuracy of the model increased to 98%. This showcases the potential of using advanced deep learning algorithms in the field of brain tumour detection and classification. In the future, we can leverage large amounts of data and a range of CNN algorithms, including accurate efficient nets and pre-trained models like VGG16, to further improve the accuracy. By training the model for a higher number of epochs and fine-tuning the parameters such as batch size, we can achieve even better results. Additionally, there is a possibility to develop a system for the early detection of various types of brain cancers. With the advancements in technology, the training process can be completed quickly and the model can be prepared for prediction. AI has the potential to revolutionize this field and bring us closer to achieving a significant milestone in the area of brain tumour detection and classification.

CONCLUSION

The aim of this project is to achieve a precise and dependable detection and classification of brain tumours from MRI images using deep learning algorithms such as CNN. We will evaluate a range of algorithms with different feature engineering and training parameters and carry out a comprehensive comparison to determine which algorithm, with the optimal parameters, performs better than others. The field of brain tumour detection and classification has seen significant progress in the past few decades, with numerous researchers contributing to the cause. Our objective is to find a more efficient and accurate model, as well as a simplified and high-performance approach in this project In order to determine which algorithm with the best parameters outperforms other algorithms, we will also analyse multiple algorithms using a variety of feature engineering and training settings. From the above result and evidence we can infer that the EfficientNet B0 has performed well even in 5 epochs but when comparing it with the EfficientNetB1 the accuracy has increased to a significant amount to 98%. Thus, the Transfer learning technique is highly useful for this project. Our project aims to develop a highly efficient, accurate, and straightforward methodology. Based on the above results and evidence, we can conclude that the EfficientNet B0 model performed well even after 5 epochs. However, when compared with the EfficientNetB1 model, the accuracy increased significantly to 98%.

***Abstract* — Predicting the sales of a product or demand for a service is an utmost need in any industry. With the changes and increase in the channels and modes through which the products are sold, the prediction of sales in the future becomes tedious. The number of features that would help in predicting sales differs and increases. This leads to the usage of Machine Learning and Deep Learning Models in sales forecasting. A deep survey of various works that employ machine learning and Deep learning approaches for sales prediction is done and inferences are made. Every work studied has a list of models which are used as baseline models for comparison and the same is listed for better inferences. Works that address the problem of predicting the sales of new products are also discussed. A list of publicly available sales forecasting datasets is also given.**

Keywords—Sales forecasting, Machine Learning, Deep Learning, Time Series.

I. Introduction

The overall operations of any industry either service or product depend on the sales that they can make in the future. Hence, predicting sales will be an integral part of any system. The correctness of the sales predicted has an impact on both the internal and external processes of an organization. Any sales forecasting model should address two questions. First, the number of sales that will be made and the time in which they will be made. Sales forecasting is commonly done with the following Techniques,

- Time Series/Statistical Models
- Machine Learning Models
- Deep Learning Models

The conventional time series models [1-3] use historical sales data. But the historical data has certain drawbacks.

- Non Availability of Sufficient Historical Sales Data.
- Nonconsideration of the other factors that affect the Sales.

The former may be true in the case where new products are introduced and also when there are missing data for the existing products. The other problem is, historical sales data is not the only factor that can be used to predict future sales. Various other factors have an impact on sales. This includes basic data such as the seasonal data and leaves data in most cases and more complex data such as the features of the images which are required in the fashion industry. The models that address these issues should be capable of handling multivariate data and also possess efficient feature engineering.

These requirements are addressed by machine learning and deep learning models. The objective of this work is to study the available machine and deep learning approaches. The models studied are observed to be applied in the various datasets and the commonly available public datasets are [4-13]. This includes commonly used datasets such as the Walmart dataset, Rossman dataset, multivariate dataset as well as time series data.

The paper is organized as follows. The next section gives a comprehensive list of machine learning algorithms and the observations made from them. Similarly, the third section gives the list of deep learning approaches and the inferences made from them. The fourth section gives a summary of the inferences made. The final and fifth section gives the conclusion.

II. Machine Learning Approaches

[14] Applied five different regression techniques and 7 different Time Series Analysis methods in the Walmart dataset for predicting the sales. The models are implemented in the azure machine learning model. The performances of the models are compared in terms of different performance parameters and Boosted decision tree model performs than the other models. The models are used to predict the number of weekly sales. [15] Uses Rossmann Data for sales prediction. 15 features are used. As part of the features, the significance of the individual parameters is also analyzed by the users. Three different Machine Learning Models are used, LR, RF, and XGBoost. XGBoost performs well than the other two models. [16] Predicts the sales of the magazine using the Hearst Dataset. The work employs support vector regression. [17] Claims they have incorporated a better feature engineering approach for sales prediction in the Walmart dataset and applied three machine learning models. The catBoost model performs better than the linear regression and support vector regression models. [18] Uses both the time series models and the machine learning models for sales prediction in the automobile industry. The model is trained and tested with data that contains yearly, quarterly, and monthly features. The forecasting model seems to perform well in the case of monthly forecasting. Another Model that uses the Walmart dataset is [19]. It concludes that the LightBGM model performs well than a model called the prophet model which is a blended approach of time series and machine learning model.[20] uses the recursive feature elimination method for removing unwanted features and extracting only the necessary features from the Walmart dataset.

Three different machine learning Models are compared and LightBGM is found to perform well among the three models.

DOI: rp-9788770040723.182

[21] Have worked on individual oral care products and predicted their sales in the future using a back propagation neural network model. The comparison is made between the individual products.[22] have made a detailed exploratory data analysis of the E-Fashion Store for retrieving the appropriate features. They have compared three different machine learning models and found Gradient Boosting tree performs well. [23] Combined the XGboost and LightGBM models to create a hybrid model for detecting Walmart sales. An effective feature engineering approach is also applied which extracts features from past data. The combined model performs well than the other machine-learning approaches. In [24] in addition to making a sales forecast in general, analysis is made to identify the factor that drives high sales of medical products. Two factors, distribution channels, and marketing campaigns are considered and the corresponding sales can be predicted. Stacking of different machine learning models is used in [25] for predicting sales. Stacking helps in improving the accuracy by considering the variations in results obtained in the previous models. [26] Also uses the stacking approach and achieves better accuracy in predicting the sales of auto parts. In this case, as in various stacking processes, the dataset is split into different groups and used for training the individual models separately. The outcome of which is used at the next level. To the best observation made, [27] is the only work that uses multivariate adaptive regression splines for sales forecasting. The model is compared with the various machine learning models. In addition to predicting the sales it also clearly defines the relationship between the impacting factors and sales. [28] Uses particle swarm optimization with the various machine learning models and the Naïve Bayes algorithm is found to provide better results than other models.

Comparison is also made with the stand-alone conventional models. [29] Uses various machine-learning approaches for forecasting the sales of the components of the truck. [30] Proposes a model called the ForeXGBoost algorithm which combines the efficient missing value filling and feature extraction methods with the XGBoost model to predict the sales of passenger cars. This is the best performing model in the vehicle sales forecast competition.

[31] Combines various machine learning models to forecast drug sales. Around nine variants including the individual and combined models are experimented with and compared for better results in predicting the sales seasonally and in nonlinear trends. Holt-Winter's model is a traditional approach that is best suited for handling the trends of sales data as well as seasonal data. [32] Builds a neural network with Holt-Winter's model as its base. It roves to provide better results in predicting the sales of the wheel covers. [33] Compares various machine learning models for predicting the sales of retail stores.XGBoost algorithm along with efficient Feature Engineering is used for predicting the sales of Walmart data [34]. The model is compared with two other models and found to produce better results.

21 machine learning models are studied. The keywords used for retrieving the papers are “Sales Forecasting with Machine Learning", and "Sales prediction". The search is made in Science Direct, IEEE Xplore, and Google Scholar. The models are summarized in Table 1. The observations made are summarized below. The commonly used dataset is Walmart dataset as observed in “Fig. 1”.

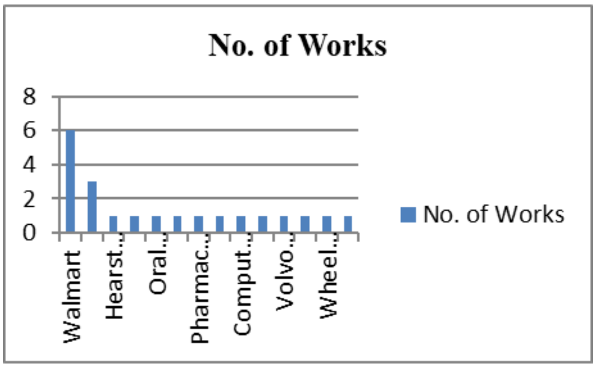

Fig. 1. Usage of Different Datasets

It has been noted from the figure that the Walmart dataset is the most commonly used and hence the results obtained with them are analyzed further. The best-performing models observed in the various works and depicted in table 1 are summarized in “Fig. 2”.

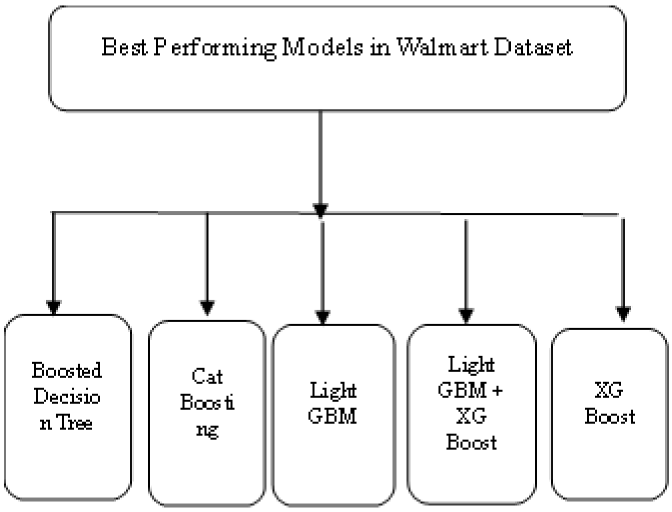

Fig. 2. Best Performing Models of Walmart Dataset

After doing cross-validation tuning across the pertinent algorithm's parameters, the comparison of five distinct methods on a test set is shown.

	Boosted Decision Tree	Cat Boosting	LightGBM	XGBoost	LightGBM + XGBoost
Retail Sales data (Walmart)	0.9614	0.9617	0.9600	0.9600	0.9623
Auto parts sales data	0.9455	0.9534	0.9453	0.9438	0.9536
Fashion store datatset	0.9826	0.9833	0.9851	0.9814	0.9856
Grocery data (Big-mart)	0.8739	0.8767	0.8732	0.8751	0.8771

Fig. 3. Cross-validation of five algorithms

When compared to the other algorithms, CatBoost Algorithm was more complicated, which meant that the

DOI: rp-9788770040723.182

final model almost always contained more trees and a deeper layer. The best option will be the LightGBM model if training speed is the only deciding factor.

Compared with all other combined Boosting algorithm outperforms the competition in the Retail dataset by a significant 0.8–1% margin. The discrepancies are less pronounced in the other datasets.

TABLE I. SUMMARY OF MACHINE LEARNING MODELS USED FOR SALES FORECASTING

Ref	Title	Dataset	Methods Used	Performance Parameters	Best Performing Model
14	Benchmarking of Regression and Time Series Analysis Techniques for Sales Forecasting	Walmart Dataset	**Time Series** ▪ SARIMA ▪ Non-SARIMA ▪ Seasonal Exponential Smoothing ▪ Non-Seasonal Exponential Smoothing ▪ Naïve Method ▪ Average Method ▪ Drift Method **Regression Methods** ▪ Linear Regression ▪ Bayesian Linear Regression ▪ Neural Network Regression ▪ Decision Forest Regression ▪ Boosted Decision Tree Regression	Mean Absolute Error Root Mean Square Error Coefficient of Determination	Boosted Decision Tree Regression
15	Sales Forecasting for Retail Chains	Rossmann Data	Linear Regression Random Forest XGBoost	RMPSE	XGBoost

DOI: rp-9788770040723.182

The number of times the common machine learning models are used and tested in various studies is summarized in "Fig. 4". There are also models that are not specified in the figure but are used in a couple of works.

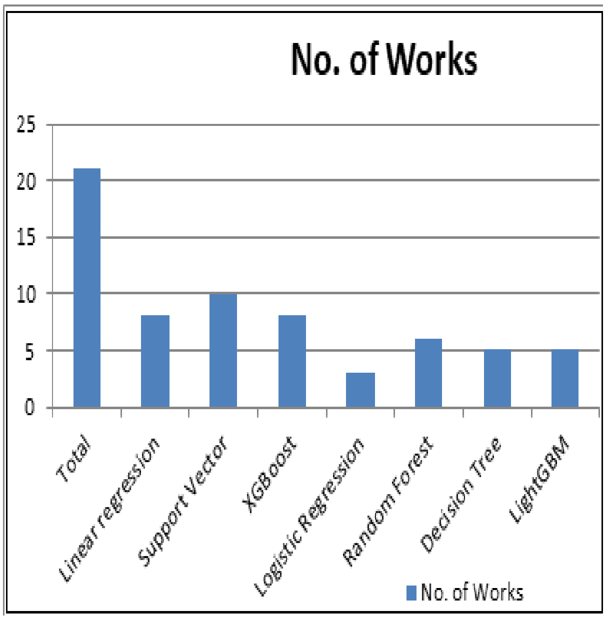

Fig. 4. Usage of Machine Learning Models

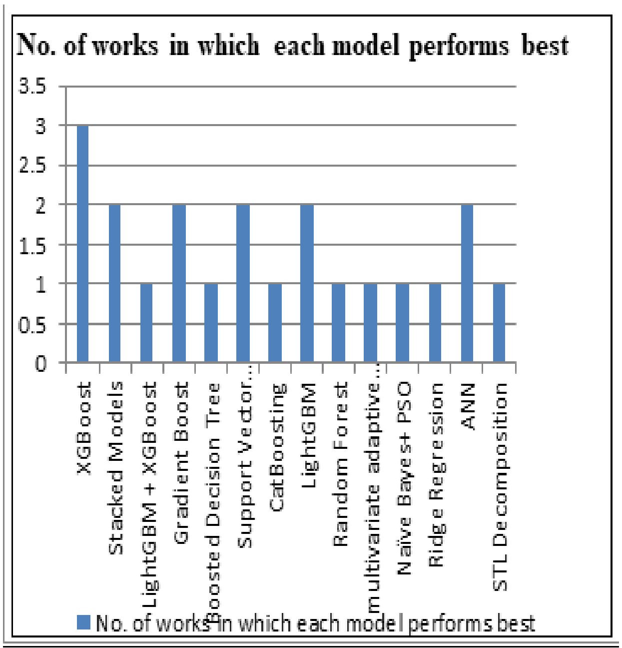

Fig. 5. No. of works in which each model performs best

The number of times a particular machine learning model performs well is given in "Fig.5." Although the datasets employed are different, this data would help in getting a general observation on the best-performed models.

III. Comparative Study of Deep Learning Models

With the trend of E-Commerce applications and the increase in the size of the data employed for forecasting, the usage of Deep Learning approaches in sales forecasting increases. TABLE II summarizes it.

TABLE II. Summary of Deep Learning Models Used for Sales Forecasting

[35] uses the capability of the convolutional neural networks to extract the features effectively from the available dataset and predict the sales forecast. [36] Uses a novel model that combines the convolutional neural networks and LSTM. It differs from the other works in the way that it also considers the sales data of the neighboring stores along with the sales data of the considered store. The combined model is compared with the other statistical model and the individual RNN model and the combined model perform well. [37] Designed a deep neural network model for forecasting sales in the fashion retail market. The preprocessing includes various aspects such as the aspects of the company and the domain expert's decision. The deep neural network model performs well than the other machine learning models. [38] Have tested various variants of the recurrent neural network model for forecasting sales. RNN with LSTM is found to perform well when compared with conventional artificial neural networks and RNN.[39] have developed a model for predicting sales at three different levels, Item, day, and store levels. It employs RNN and Transformers and also introduced the concept that using dynamic time for learning to avoid overfitting. [40] Uses particle swarm optimization for selecting the features from the sales dataset and LSTM for Training and Sales Prediction. The approach is tested with different datasets and compared with different machine learning models. [41] Introduces a layer for correcting the trend with the help of the predicted sales value and the weight value. This results in better accuracy. To address the problem of forecasting the sales of the newly introduced data, [42] introduces the transfer learning approach in deep neural networks.

The model is trained with the existing products and used for predicting the sales of the new products. [43] Designed a deep neural network model for forecasting the sales of Walmart data. An effective visualization mechanism is also used for enhancing the model. The deep neural network performs well than the linear regression model and support vector machine. [44] Combines the prophet model with the gated recurrent unit for predicting the Sales of the clothes. The combined model performs well than the other individual deep-learning approaches and Time series Models.

[45] Uses LSTM with hyperparameters tuned with search grid optimization for predicting Walmart sales. Since the sales of the products like fashion clothes depend on the style and other similar attributes, [46] uses image features as parameters along with sales history data for predicting future sales.

A variant of the CNN model is used for feature extraction and a neural network is used for prediction. [47] Uses a deep learning approach with L1 regularization for predicting the sales of the supermarket data. [48] Proposed a model which combines the concepts of gated recurrent unit, Auto regression, and Attention models to create a prediction model which takes into consideration the structural and temporal details of the products and the relation between them. [49] Also uses multiple deep learning approaches for predicting the sales, CNN for extracting the Features, Gated recurrent unit, and attention mechanism for finding the relations at the consecutive levels. This is used in the service industry for forecasting the demand for shared bicycles. While most of the works combine CNN with LSTM, [50] combines CNN with Bi-LSTM for predicting the demand for store items. The model is found to perform well than the CNN-LSTM and other machine learning algorithms. [51] Has been the only work that predicts the demand for Pharmacy products. Prediction of the weekly demand and daily demand is made and it is observed that the former performs well than the latter model.

When most of the works use multivariate data for forecasting [52] and compare the performance of the deep neural networks and Gradient Boosting algorithm in predicting the sales with the univariate data. [53] Combines CNN with LSTM for predicting the sales data of different stores. A new activation function called the Swish activation function is employed which results in better performance. [54] Tested LSTM for predicting sales. The work compared various LSTM models that are differentiated by the number of hidden layers, number of epochs, size of the batch, etc.[55] also uses hyperparameter tuning in LSTM for making a better prediction. [56] Combines convolutional neural network and long short-term memory for predicting the sales of the big mart dataset. Both historical sales data and time series data are used.

The following are inferred from the study made with the deep learning works. The commonly used model is LSTM. LSTM is used in combination with other models for better performance. As a surprise in a specific case of predicting the sales of the pharmacy products, the

DOI: rp-9788770040723.182

conventional SARIMA performs better than the Deep learning models. As stated earlier, with the increased usage of e-commerce sites, the decision of the users to buy a product depends on the characteristics of the products as in the case of fashion products, Deep learning models are useful. Consider an e-commerce site that sells apparel, the buying decision may depend on the color and style. Such parameters should also be considered for sales prediction. This demands a mechanism to extract features efficiently. CNN plays the role. The such basic architecture is shown in “Fig. 6”.

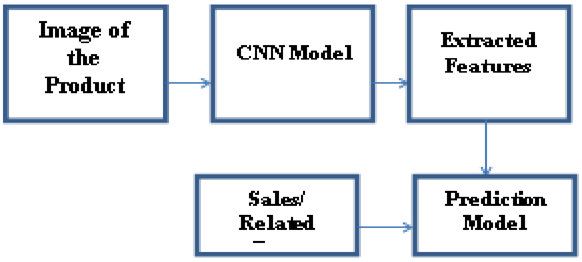

Fig.6. Basic Architecture of Feature Extraction and Prediction

Another Key problem is the prediction of sales of the new products. This is solved by the concept of Transfer Learning. The features learned from the previously existing products are applied to the new similar products. The basic architecture is shown in “Fig. 7”.

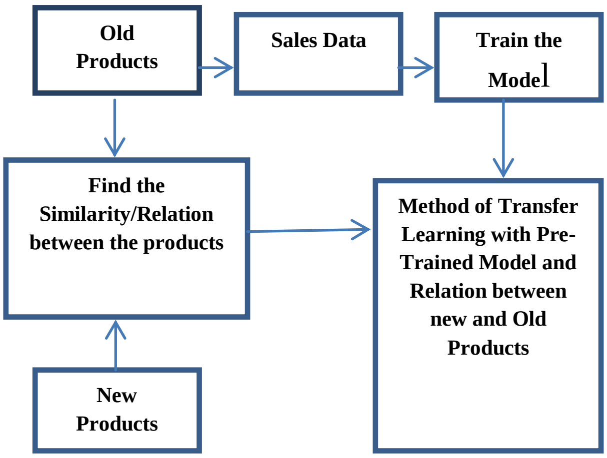

Fig. 7. Architecture of Transfer Learning approach

When the transfer learning approaches are studied, it has also been noted that it is not the only approach to handling new products. Earlier, combined models [57,58] which use clustering for identifying the relationship between the products and regression for prediction are used for addressing this issue.

With the introduction of e-commerce sites, another parameter called the reviews from the users has also gotten attention in predicting sales. Every product displayed on the e-commerce site is reviewed and commented on by the buyers. It could be either positive reviews or negative reviews. The important part of the process is to identify the sentiment of the review as either positive or negative. Although many works have used this approach[59-64], these works are not in the scope of this work.

IV. INFERENCES

The following inferences are made from the above-discussed works.

- In the case of machine learning models, XGBoost performs well than the other models in a few works.
- The usage of stacked models increases the performance
- In predicting the sales of new products, clustering is combined with regression models to achieve better performance
- In the case of the deep learning approaches, LSTM plays a key role in making predictions.
- Deep Learning approaches address the problem of predicting the sales of new products with the Transfer learning approach
- In the case where the image features are also included as the parameter for sales prediction, Convolutional neural network models are used for feature extraction.

V. CONCLUSION

State of art machine learning and deep learning approaches are studied. Problems with the time series data and models are stated. The need for machine learning models and deep learning models in sales forecasting is also discussed. The commonly used datasets and the best-performing model in each of the datasets are given. The changes that have occurred in the sales of the products and the resulting needs to be incurred in the sales prediction approaches are also discussed. The available solutions for them are also illustrated.

Abstract **— The implications and implementations of the data science and machine learning frenzy as it sweeps the country are broad. Each of them is examined in this study through the prism of a national issue, at least in the United States. The words used by past Presidents of the United States are the subject of this discussion. The focus of this research is on Natural Language Processing and its applications in important historical speeches. Natural Language Processing serves as an effective method for the analysis of text-based data. Using Natural Language Processing, sentiment analysis was used on the collection of different Addresses to achieve a better understanding of the tone used by various Presidents over the course of history. This sentiment analysis provided a collection of sentiment-based scores about important topics and issues in the United States. A feeling can be expressed via natural language processing (NLP). The Addresses were analyzed with the purpose to attain a deeper and broader understanding of the tone used throughout history by presidents.**

Keywords — Natural Language Processing (NLP), Latent Semantic Indexing (LSA), Bidirectional encoder representation from the transformer (BERT), Graphical User Interface (GUI), Hypertext Markup Language (HTML), Extensible Markup Language (XML)

I. Introduction

Elections contribute a significant amount to proper democratic governance. In light of the fact that a directly democratic form of governance in which political decisions are decided directly by the entire assembly of qualified people is unachievable in most present environments, ballot government should be carried out through intermediaries. Democratic institutions give the public the ability to pick their leaders and hold them accountable for their actions while in office. Elections contribute to the soundness and legitimacy of the social and political system by creating an enabling environment for participation.

All of the Presidential State of the Union addresses were gathered and processed as the core textual data. We obtained the text from a Presidential Address Repository. To make processing easier, the text was divided into individual text files for each individual address from a big text file that comprised every speech. The previous works are listed so that readers can quickly see what's been done.

Vader et al., in his work discussed the practical applications of sentiment analysis face significant obstacles due to the fundamental nature of social media information. The author explores various techniques to understand the behavior of the sentiments using the features of data points from text, moreover, the high frequency of words in the data corresponding to adjectives or helper verbs affects the model on a larger scale than expected. Researchers build and try to validate a top-tier collection of language features that are specifically tailored to sentiment in blog-type contexts using a merging of qualitative and quantitative methodologies. Then, consider five broad pillars that include grammatical and language patterns for expressing and highlighting sentiment intensity, in addition to these lexical aspects [6].

Helen Balinsky et al., proposed text summarization by computer is a difficult problem to solve. In recent times, the text available electronically has massively increased. As a result of this growth, the demand for automatic text summarizing methods and tools is increasing. Data compression can be regarded as a sort of automatic summarization. To get compression, improvement in modeling and implementation to reduce noise in the data and create networks with more depth [7].

Muhammad Fachrie et al., used data from the General Election Commission to investigate the use of Machine Learning (ML) to forecast candidate win in Indonesian Regional Elections (KPU). Each candidate's political party affiliations are included in the data. The researchers built a Machine Learning model-based data provided by official institutions to predict the winner of each candidate in a regional election in Indonesia, rather than using social media data as in previous studies. The forecast is a classification-type task with two categories: 'win' and 'loss.' [8]

II. Dataset Description

The data is collected from various online resources such as using a web crawling-based technique. In web crawling,

DOI: rp-9788770040723.183

data from a website is fetched using a script that renders HTML content and converts it to text-based content. After conversion to text-based content, it is then downloaded in the desired format such as pdf, XML, etc. After fetching the data from the source, it is subjected to a data cleaning process. In data cleaning undesired text, spaces are removed and converted into a table format so that it can be subjected to a model for training. This data is also segregated based on the parties i.e., democratic and republican as shown in Figure 1.

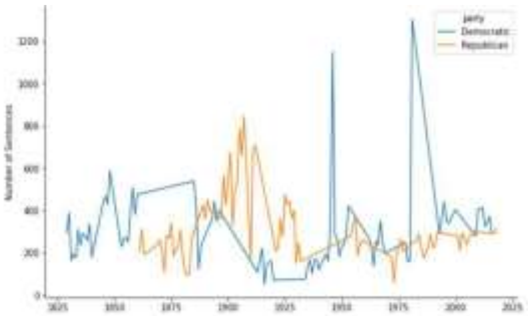

Fig. 1. Number of sentences used by each political party

Data is then analysed based upon the number of sentences and to which party they belong, in order to understand dataset composition of both parties Vs timeline as shown in Figure 2.

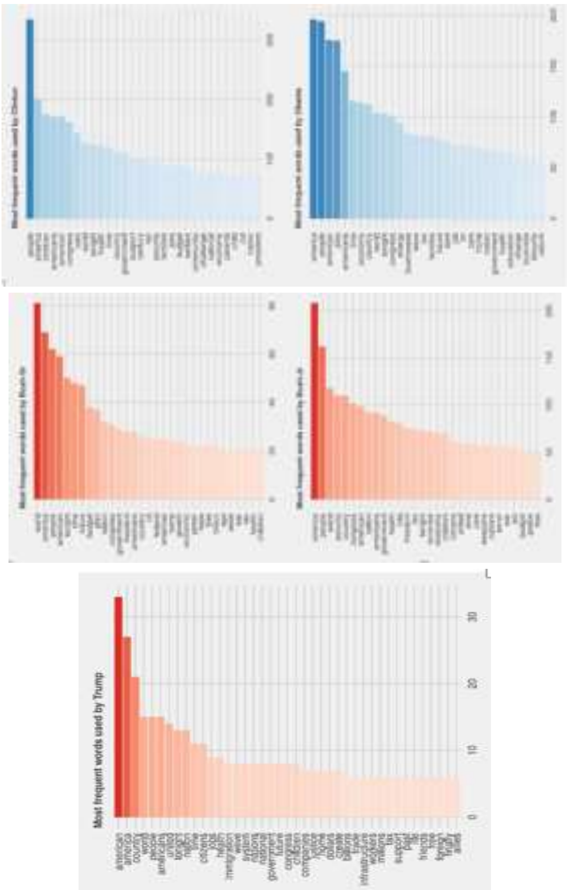

Fig. 2. Most frequent words used by each President

This figure shows how the number of sentences vary compared to the timeline of their delivery. Using this chart it can be concluded that the data is well balanced and does not have significant bias towards a particular label. The density of words Vs sentences is plotted in Figure 3, to check in which range our data lies. Only 91 words or fewer make up 99% of the data. Data padding is therefore done to this length to guarantee consistency throughout.

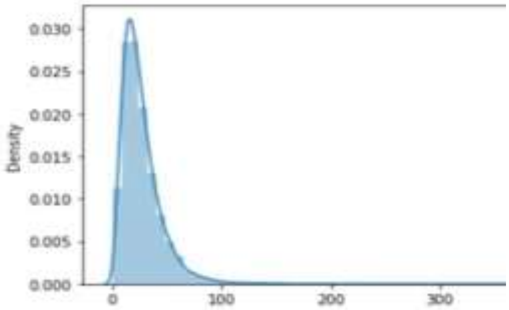

Fig. 3: 99% of all SOTU sentences are under 91 words

To classify the sentiment of a given text the following processes are used:

i. Data preparation

Data set is scraped from online resources using web scraping libraries in .py format. once data is extracted it is subjected to a data cleaning process where each data point is scanned and type errors, redundant spaces are removed, and these data points are made in the form as to map them into a pandas data frame so they can be easily interpreted by the model for use. Then each data point is subjected to frequency check, null imputation, and data process. Each process such as cleaning, stemming, and lemmatization / lemma formation. When web-scraping, we make use of a library called "When web-scraping, utilize a "regular expression." "to substitute and replace data in order to eliminate unwanted phrases The stop word is then eliminated from the sentence by combining all these techniques data is converted to form which can be used by the model, further techniques have been discussed below.

ii. Text Input

Any data that is entered into a model must be in vector format. The following transformations will be carried out:

- Remove all numbers and punctuation.
- Change all of the words to lowercase.
- Remove any stop words (for example, the, a, that, this, it, etc.).
- Texts are tokenized.
- Using a bag-of-words format, convert the sentences into vectors.

iii. Tokenization

Each word in the sentence has meaning and tries to interpret something that might or might not be important to the context. Tokenization helps us in breaking sentences into words also known as tokens which represent one keyword in the data point. Each token has some meaning

DOI: rp-9788770040723.183

associated with it and hence affects model training according to the weight assigned to them.

iv. Stop Word Filtering

In all human languages, there are a plethora of stop words. These words add unnecessary overhead while training the model. They don't impact the model but increase the size of the dataset. Removal of stop words is very important to make the model more robust and faster. Many libraries such as sklearn python library help in performing this task after the removal of stop words unnecessary data are removed and model accuracy and training become more robust.

v. Negation Handling

Sentiment Analysis includes a sub-task called negation handling. In written literature, negatives play an important role. Contrary terms in sentences frequently shift the sentiment of the sentence while the opposite makes it more aligned so both things have equal importance. Negation handling is important so that the context is well balanced and the model does not become biased towards negation.

vi. Stemming

Stemming is a method that involves converting the words which have similar meanings, such as eat, ate, eaten, eating, and will eat, but are represented differently in the dataset. So here stemming is a method of mapping each of these words to eat so that they correspond to similar things and the model can understand that they have the same meaning in the context which was different earlier as in data representation.

vii. Classification

Using a plethora of machine-learning or deep-learning models to classify sentiment.

III. METHODOLOGY

3.1 Text Summarization

The process of shortening the text so that it is presented in a summarized fashion is known as text summarization. Text summarization is done in such a way as to ensure the summarized part can describe the whole text in a brief manner. Text summarization becomes very important when the given text is very long, for companies that show news updates, summarizing text is important for adding more users to the platform more features need to be added that can interact with users and their emotions by interpreting sentiment in a concise manner. To automate the process of text summarization, Machine learning and deep learning-based techniques involve natural language processing. Using these techniques, automatic text summarization can be performed. There are two major types of text summarization:

- Abstractive Text Summarization
- Extractive Text Summarization

3.2 Abstractive Text summarization

In this technique, data is interpreted using advanced natural language processing-based approaches and then it tries to extract information and summaries it in such a way that the summarized part may or may not appear in the text but presents a clearer summarized text as shown in Figure 4. The part presented in the summarized version consists of the most critical information around which the whole context revolves. This technique takes advantage of sequence-to-sequence models which helps them understand the context line by line. Recent developments have helped this technique to improve its accuracy to a greater extent but this technique is still far from reaching the level where it can be used in a real-time production-based environment. Lots of researchers have recently taken a keen interest in this field and improvements are being made incrementally

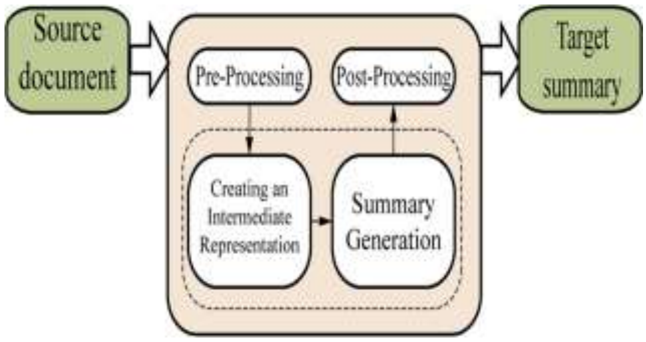

Fig. 4. Abstractive Text summarization

3.3 Extractive Text Summarization

According to this technique, direct sentences are chosen from the text. In this method, scores from the text content are directly correlated with the scoring algorithm to provide a summary based on those results. It contains the most important information from the text and can include pagination. A high probabilistic score ensures that the sentence will be chosen for the summary. Probabilistic scores are used in the scoring process. Summary is generated from top s sentences where s is the hyper parameter that can be adjusted based on the model performance and accuracy as shown in Figure 5.

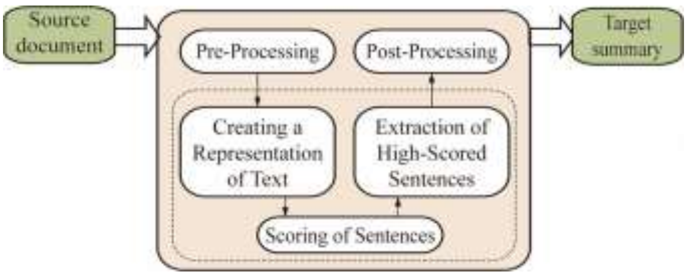

Fig. 5: Extractive Text Summarization

3.4 Lex rank

It is a graph-based approach that is used for summarizing text. It takes in any kind of text and converts it to summarized text. It detects relationships in the graph using clauset Newman algorithm. Its working can be classified into 7 stages.

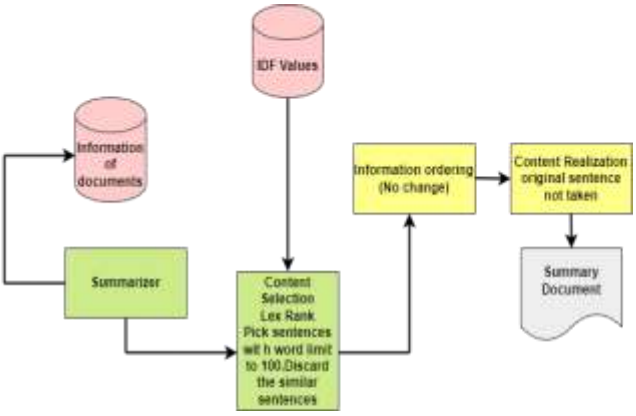

Fig. 6: Lex Rank summarizer

3.5 *Luhn*

Luhn text summarization is a method that aids in text summarization and is based on the TF-IDF approach. This method summarizes sentences based on the significance of the root words present in the sentence. After scoring these sentences then only the summarization is done. After scoring the sentences, ranking is done, and based on ranking text summarization is concluded.

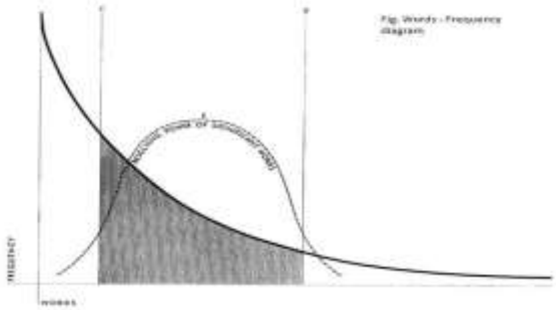

Fig. 7. Luhn summarizer

3.7 *Latent Semantic Indexing (LSA)*

LSA is Latent Semantic Indexing. It relies on extractive-based summarization. This technique tries to identify relationships between different words in sentences using a technique known as SVD i.e. Singular value decomposition. Using this it tries to weigh the importance of each word and then produce the desired ranking of words and summarizes the top ones.

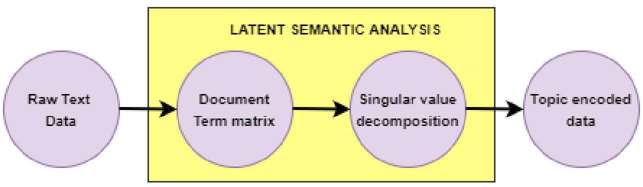

Fig. 8. LSA Summarizer

3.8 *Text Rank*

As the name implies, it is a ranking-based text summarization technique. It relies on extractive-based summarization. Using a graph-based unsupervised method, it breaks each sentence down into its constituent words and rates them. This technique produces superior results for the current problem statement.

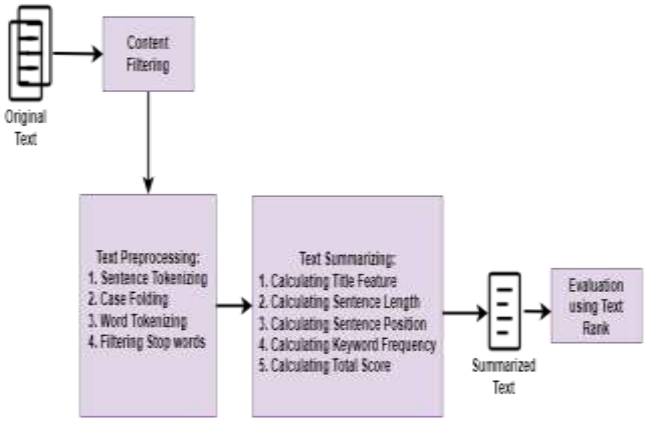

Fig. 9. Text Rank

3.9 *Bidirectional encoder representation from the transformer (BERT)*

BERT stands for Bidirectional encoder representation from the transformer and is a pre-trained model developed by Google. This model comprises an encoder with the same structure as the transformer. It has 12 multi-heads, an embedding dimension of 784, and 12 repeated blocks. An even bigger configuration is available for this model known as BERT-Large. This model is used for training purposes and produces state-of-the-art results. The model learns on the training dataset using a transfer learning-based technique. All the data points are preprocessed using natural language processing and then passed in as input to the model. The model tries to learn the features of the data and then can be tested in real-time to produce desired results.

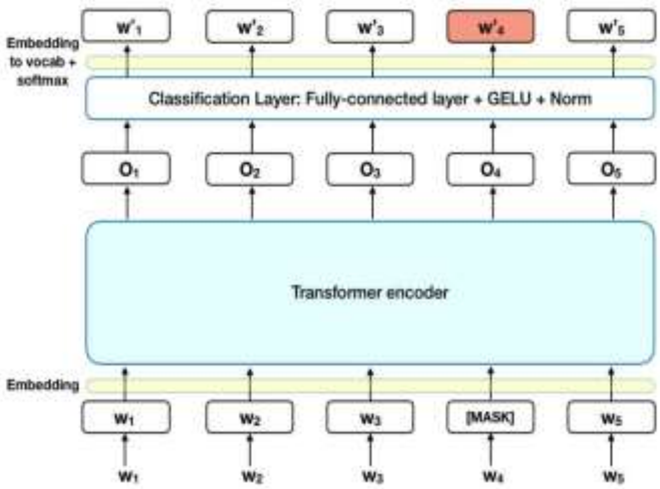

Fig. 10: BERT model

DOI: rp-9788770040723.183

IV. Simulated Results

The significance and goal of the SOTU speech are important because it has a big impact on the content and message of presidential addresses. There are 26 Republicans and 16 Democrats, therefore it's important to note that the parties have 62 percent and 38 percent of the vote, respectively. The results here depict a text summarization of the president's speeches at the state of the union. All the speeches have been summarized using 4 major techniques: Luhn, lex rank, LSA, and Text rank. Although each technique for condensing speech has its own advantages, Text Rank yields the best results when used with this dataset.

Sentiment analysis is done on the president's speech and sentiment accuracy is depicted along with the label whether it is positive or negative. This sentiment accuracy shows how much the model is sure that a given label is valid or not. This functionality has been created for testing in real-time. A GUI has been developed to display the results. In fact, it takes in the input text and speech, produces it in real time with the aid of a trained model, and displays the outcomes as a pop-up.

TABLE 1: Simulated Results of Sentiment Analysis

Data	Sentiment	Accuracy
Barack Obama, 2012 I'm proud to announce that the Department of Defense, the world's largest consumer of energy, will make one of the largest commitments to clean energy in history with the Navy purchasing enough capacity to power a quarter.	Positive	93.97%
George W. Bush, 2012 I ask Congress to move forward on a comprehensive health care agenda with tax credits to help low-income workers buy insurance, a community health center in every poor country, improved information technology to prevent medical error and needless costs, association health plans for small businesses and their employers, expanded health savings accounts, and medical liability reform that will reduce health care costs and make sure patients have the doctors and care they need.	Positive	91.88%

V. Conclusions

Firstly, text analysis is done where the frequency of words, the density of sentences, and their importance were analyzed using natural language processing techniques. Understanding the dataset, and tradeoffs were covered. Secondly, text summarization was covered using different techniques such as Luhn, Text Rank, LSA, and Lex Rank. Both the summarization i.e. extractive and abstractive techniques were covered. Thirdly, Sentiment analysis was performed, and both machine learning and deep learning techniques were used. BERT model is used for conducting real-time sentiment analysis and UI is made for real-time testing of models. In the future, more datasets can be incorporated to train BERT Large versions. Multiple labels can be included such as very negative, negative, positive, and very positive. Other models can also be incorporated and reinforcement learning can also be applied by making sentiment analysis fun and interesting. Moreover, semi-supervised learning techniques can also be used to train the model on an unlabeled dataset.

Abstract— **The study proposes an efficient method that employs the power of "machine learning" to make the "workplace safer" through the use of "computer vision" or image processing. It employs the "object detection" and "image segmentation" algorithms, which have been trained to detect workplace dangers such as an employee not wearing the safety equipment properly, and then the object detected is passed to the image segmentation part of the algorithm, which is used to highlight the object that causes the abnormality in the workplace environment, "Mask Region-Based Convolutional Neural Network" is an efficient algorithm to detect objects, classify, and to produce pixel-wise mask. If the system detects an abnormality, it sends a warning via the cloud to an application where the administrator can take action to remedy the problem as soon as possible. It also alerts nearby people to solve the situation. It also makes use of an existing surveillance camera, making this system relatively simple and cheap to set up. Thus, this system takes advantage of the capabilities of machine learning and computer vision to improve worker safety and avoid accidents by alerting the employee who is not taking proper safety measures in the workplace atmosphere.**

Keywords— ***Machine Learning, Image Segmentation, Object Detection, Mask Region-Based Convolutional Neural Network, Workplace Safety, Computer Vision.***

I. INTRODUCTION

Machine learning has huge potential for use in workplace safety. Machine learning might be used to discover potential workplace safety issues, predict when accidents are likely to occur, and develop new strategies for preventing mishaps. Machine learning may be used to improve workplace safety by automating risk assessment and detection operations. By recognizing and monitoring things and people in an environment, object detection and segmentation can help to improve workplace security. An object detection system can be used to scan an environment for possible dangers. Security professionals can be informed when a possible danger is discovered and take the necessary action by recognizing and monitoring items and individuals in a monitored area.

Artificial intelligence is being used to improve workplace safety in a variety of ways. AI tools are employed to collect, process, and store real-time data and safety information. Automatic categorization algorithms are used by safety analysts to detect accidents or events (or possible accidents) in a certain location or with specific personnel. These algorithms may also be used to identify possible risks by analyzing certain patterns of behavior, such as those that signal exhaustion or stress.

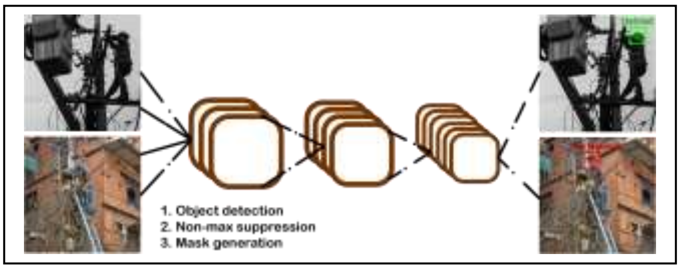

Fig. 1 Overview

A. Need For Ml In Workplace Safety

When it comes to sensitive situations, workplace safety is extremely important for the following example: -

- Dangerous chemical spills in the chemical industry
- On construction site employees not wearing safety helmets
- In the lab researchers not wearing safety jackets and glasses.

Human surveillance isn't even practical in some places, like: -

- Nuclear power plants
- In vast places where a lot of labor is required for surveillance, humans watching an environment for a long time causes many errors.

On the other hand, machine algorithms can be used for long-term surveillance with higher accuracy.

B. Objective Of The Project

The goal of workplace safety is to keep employees safe while they are at work. This includes the following: -

- Provide a safe working environment.
- Ensuring that employees are wearing proper safety equipment.
- Preventing the organization from being negatively impacted.
- Preventing harm to employees.
- Protecting organizational property due to accidents.
- Eliminating the death rate due to workplace accidents.

II. Literature Survey

Annotated pictures are required for training in a deep learning-based workplace safety strategy. Engineers have difficulties when annotating photos with annotations indicating violations of safety norms. The true-negative rate of majority vote-based crowdsourcing annotation is low.

Artificial intelligence is increasingly being utilized to detect safety infractions in public spaces. A Bayesian network model is utilized to predict the likelihood of an accident occurring. The model predicts the likelihood of future incidents using data from previous accidents [1]. AI can detect trends that people may miss, such as harmful working conditions or defective equipment. To effectively detect safety violations in public spaces using the input data, a Bayesian network model may significantly raise the genuine negative rate of annotation.

This strategy can be utilized in our model to determine the probability of the predicted bounding box, in the model we utilize this data to perform non-max suppression to discover the best-fit bounding box for a specific item.

The main challenge with picture segmentation is that training time on a high-quality image dataset is long. This technique addresses this issue by stacking the entire problem into four layers.

The split/merge technique is used to suggest a four-layer picture segmentation procedure. The watershed algorithm is used to divide a picture into many sections in the first layer [2]. In the second layer, a co-evolutionary mechanism is used to produce final segment centers by combining related main areas. In the third layer, a meta-heuristic method connects the remaining areas to their corresponding determined centers using two operators. An evolutionary method is utilized in the last layer to integrate the generated comparable and nearby areas.

This model is used to comprehend the divide and concur technique, which swiftly generates predictions on the input image. This method also provides predictions on a wide range of images, including greyscale, colorful, and even textured images.

Due to picture speckles and pixel similarities, image segmentation is extremely challenging in crowded tiny images. This suggested method employs a Convolutional neural network (CNN) to build a region-based segmentation that is effective at recognizing segmental events in pictures with a high degree of pixel similarity.

Convolutional neural networks are fed images as input. In architecture, image input is given as a matrix, and the input enables regions to be analyzed by filtering and shifting scanning the whole matrix [3]. This is how the working time and savings from convolution computations are calculated. The pooling strategy is used to mix images while the convolution procedure is used to scan the image. The final stage produces Rectifier Linear Negative Interference that Interferes with the Image (ReLU). Completely Connected Layer. The prediction layer (FCN) is reached, and an estimate of the item or area is generated.

The region-based object detection is a fundamental building block for developing a Mask region-based convolutional neural network. The main difference between these architectures is that it loses a lot of information during the pooling process, resulting in the generation of harsh edges on the feature map so we use RoI Align for the pooling process which does not produce any data loss with the help of non-quantized strides.

Image segmentation may be carried out using a variety of approaches with varying degrees of accuracy and precision. This study compares techniques used for Image Segmentation Based on Edge Detection.

The proposed image segmentation model is based on edge detection and a convolutional neural network.

The suggested approach employs edge detection to determine the borders of various objects in an input picture. It then uses a convolutional neural network to categorize the various items based on their borders and appearance [4]. The architecture of the network is made up of convolutional layers, a pre-trained model, and two fully-connected layers with a SoftMax layer in between.

This study compares the impact of different thresholds on the canny operator. As a result, these tests receive varied results. Canny outperforms the other approaches, and the low and high thresholds can affect edge accuracy.

Object detection and image segmentation in real-time with high-resolution resources is difficult in complicated crowded contexts. This suggested methodology employs an ideal strategy to generate a class, bounding box, and mask for the identified item in real-time on extremely high-resolution resources.

A precise mask region convolutional neural network (precise Mask R-CNN) is proposed for object recognition and instance segmentation in high-resolution images. This model makes use of RoI Align, which employs a non-quantized stride to provide lossless feature map pooling [5]. Each time an item appears in the image, this model creates segmentation masks and bounding boxes for that particular occurrence.

This model is used to identify infractions in the workplace, such as determining if an individual is wearing a helmet correctly on a construction site. The algorithm's object recognition component aids in locating the anomaly-causing item, and its mask creation component is used to draw attention to the specific anomaly-causing event.

III. PROPOSED METHODOLOGY

Workplace security with humans will be labor-intensive, yet fault tolerance will be high. This proposed system uses data science and machine learning methods to monitor its surroundings for abnormalities using object detection and image segmentation algorithms. The initial stage in image segmentation is object detection; at this point, anomalies are also discovered, and a mask must be constructed; the major goal of instantaneous image segmentation is to emphasize the event that triggers the anomaly and the segmentation is carried out with the architecture of Mask Region-Based Convolutional Neural Network which takes input frame detected by the object detection phase of the algorithm.

A. Object Detection Phase

The video stream from the surveillance camera is split into individual frames and then resized to fit the input frame size supported by the constructed Mask Region-Based Convolutional Neural Network. The parsed frames are passed through a series of convolutional layers to generate a feature map for those input frames. Using the feature map, object detection can be carried out using the Region Proposal Network (RPN), Then it is passed to the RoI Align then to CNN architecture to classify the object, and regression to define the boundary of the detected object. It is qualified if the predicted boundary box and the actual boundary box have more than 50% value on Intersection Over Union (IOU) during the training phase. Non-max suppression is employed because the RPN will predict several boundary boxes for a single object. Non-max suppression looks at the output accuracy for each bounding box for an object and selects the box with the highest accuracy as the resultant bounding box for that specific class.

B. Segmentation Phase

The segmentation section takes the feature maps and passes them to the RoI Align for pooling, which resizes the feature map created by the Region Proposal Network (RPN) to a fixed-size feature map before passing them to the fully connected convolution layer for image segmentation. The segmentation algorithm is a binary classification algorithm that takes each object in the feature map and generates a binary mask for the object and the background. Finally, the object detection step of the algorithm returns the class and the boundary box, and the mask is applied on top of the object.

C. Advantage of the proposed system over the existing system

The proposed system can be implemented in a workplace for cost-effective monitoring, reducing the amount of labor required for surveillance. Some existing methodologies only detect abnormal workplace instances, but the proposed system highlights the instances with the mask generation part of the algorithm and generates real-time alerts.

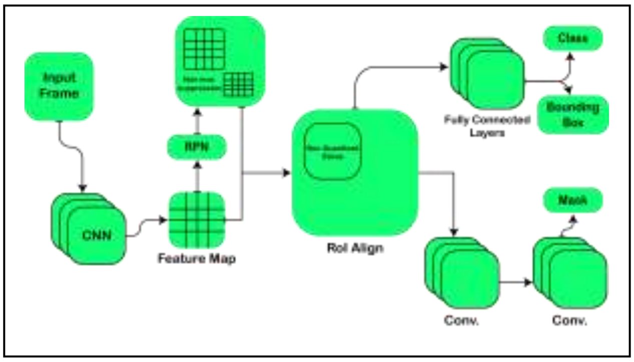

Fig. 2. System Architecture

IV. SYSTEM STRUCTURE

The proposed system takes the camera feed to manipulate each frame to the desired format then pass to the machine learning model to classify and segment the image frame finally classification of alerts and warnings is passed to the dashboard of the application.

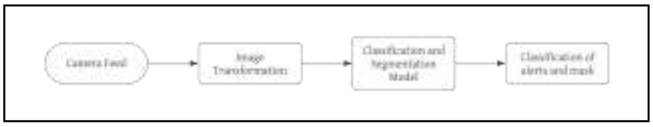

Fig. 3. General WorkFlow

A. Admin Dashboard

The system administrator may construct a new host network for their organization and then configure all of the surveillance cameras. Once configured, the administrator can watch live forecasts and can receive alerts & warnings.

B. Employees Dashboard

Each employee in an organization may connect to their organizational network to receive live feeds, the location of the anomaly that causes events, alerts, and warnings.

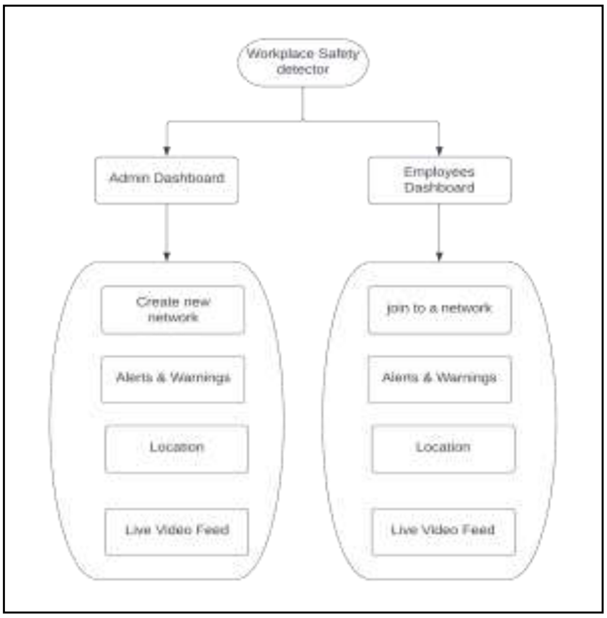

Fig. 4. Application Dashboard

C. *Mask RCNN To Generate Alerts and Mask*

The processed image from the surveillance camera is fed into the Mask Region-Based Convolutional Neural Network for the generation of the mask, boundary box, and classification of alerts, warnings, and suggestions and to forecast prediction.

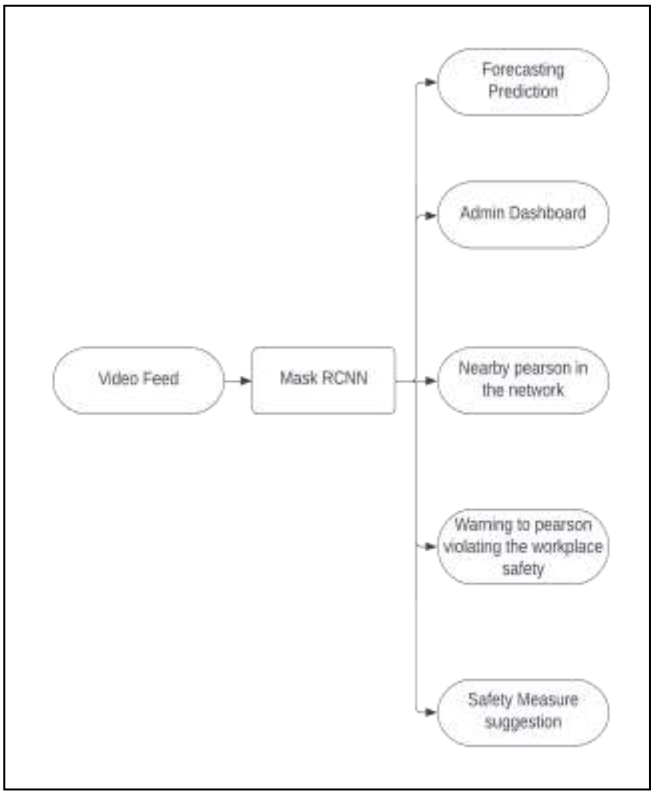

Fig. 5. Algorithm's Outcome

V. Module Description And Performance

The methodology proposes several layers to provide great modularity

- Image Transformation
- Object Detection
    - Feature Map Generation
    - Region Proposed Network
    - Non-max Suppression
    - Classification
    - Regression
- Image Segmentation
    - RoI Align
    - FC Layer (Mask Generation)
- Desktop Application (Server)
- Mobile Application (Users in the network)

D. *Image Transformation*

The process of extracting, resizing, and recoloring a picture that is in the desired output format for a trained model is known as image transformation.

The following processes are done in the image transformation module: -

- The video feed from the surveillance camera is collected and the frame rate is trimmed to the desired level
- The FPS trimmed video then pass for extraction of each frame in the video.
- The extracted frames or images are converted to greyscale by normalizing the RGB values between 0 to 255
- The grayscale image is then resized to match the required input resolution by the trained model.
- The reshaped images are then flattened to load into a data loader.
- Then the appropriate images with their paired annotation

E. *Object Detection*

Detecting instances of semantic objects of a specific class (such as people, buildings, or cars) in digital images and videos is the task of object detection, a branch of computer science related to computer vision and image processing. Well-researched object detection domains include pedestrian detection and face detection. Application areas for object identification in computer vision include picture retrieval and video surveillance.

The following process is carried out in the object detection module: -

- Feature Map Generation:

Apply filters or feature detectors to the input picture using the activation function to build feature maps or activation maps. Feature detectors or filters aid in the identification of various characteristics in a picture, such as edges, vertical lines, horizontal lines, bends, and so on.

- Region Proposed Network:

A Region Proposal Network, or RPN, is a fully convolutional network that predicts object limits and scores at each place at the same time. The RPN is fully trained to create high-quality region suggestions. RPNs are intended to anticipate region proposals with a broad range of sizes and aspect ratios efficiently. Anchor boxes are used as references in RPNs at various scales and aspect ratios. The technique is conceptualized as a pyramid of regression references that avoids enumerating pictures or filters with different scales or aspect ratios.

- Non-max suppression:

Non-Max Suppression (NMS) is a computer vision approach that is employed in a variety of jobs. It is a type of algorithm that selects one entity (e.g., bounding boxes) from a set of overlapping entities. To achieve the desired outcomes, we may pick the selection criteria. Most typically, the requirements are some type of probability number and some form of overlap measure (e.g., Intersection over Union).

- Classification

The pooled feature map is used to classify the object that which class it belongs.

- Regression

The detected object will have a bounding box this was detected by the regression.

F. Image Segmentation

Image segmentation is splitting a digital image into several image segments, also known as image regions or objects, in digital image processing and computer vision (sets of pixels). The purpose of picture segmentation is to simplify and/or transform an image's representation into something more relevant and easier to examine. Image segmentation is commonly used to find objects and boundaries (lines, curves, and so on) in pictures. Picture segmentation is the process of labeling every pixel in an image so that pixels with the same label have specific properties.

G. Desktop Application

The desktop application is used to process the input feed in real-time with the proposed machine learning algorithm and push the prediction to the user end (Mobile application) through the cloud.

H. Mobile Application

The mobile app fetches information from the cloud database and storage to display the alerts, and live video feed and to specify the location where the anomaly is detected

I. Performance

Fig. 6. Graph Epoch Vs Loss

VI. Conclusion

AI technology can assist to improve safety by automating procedures and delivering alarms, when possible, risks are recognized; but, in bigger areas, human-based surveillance may not be effective so machine learning algorithms can be utilized to rapidly discover patterns and trends in workplace safety incidents, assisting in the addresses these issues of potential safety dangers. This could result in the development of preventative measures and the implementation of improved safety regulations.

***Abstract* — The prevalence of DR is steadily rising, which necessitates the automatic disease severity extraction and classification. About 2% of those with this illness are entirely blind as a consequence of the diabetic mellitus problem and 10% get vision impairment after 15 years of diabetes as a result of the DR complication. It is also a significant contributor to blindness in both middle aged and older age groups. The patient may develop to severe stages of irreversible blindness if the condition is not detected early. The growing number of diabetic patients face a major issue due to a lack of ophthalmologists. It is suggested that an automated DR screening system be created to aid the ophthalmologist in making decisions. One of the primary symptoms of the DR is hard exudates. The detection of hard exudates is crucial for screening purposes and aids in disease monitoring and diagnosis. Thus, utilising Lloyd's clustering technique, this work offered a unique techniques to segment the exudates and irregularities in DR were found.**

Keywords— Diabetes Mellitus, Cat Swarm Optimization,, Diabetic Retinopathy, Mean Squared Error.

1. Introduction

The primary consequences of diabetes mellitus are DR. For working people, it is the main source of acquired blindness. Before the age of 50, DR is the main ocular pathologic cause of blindness in adults of working age. To diagnose DR, ophthalmologists typically look for haemorrhages, exudates and micro aneurysms. Ophthalmologists are able to identify microaneurysms and haemorrhages utilising fluoresce in angiograms. NPDR and PDR are two general categories for DR. The stages of DR can be determined based on the presence of characteristics on the retina. Diabetic Macular Edoema (DME) is the main cause of people with diabetes for losing their central vision. DME is characterised by Hard Exudates (HE), macula-regional blot Diabetes affects the blood vessels in the human retina. DR is one of the main causes of vision loss and patients might avoid losing their vision if the disease is not identified earlier a dot-like appearance. It may results in detachments, optic nerve ischemia, vitreous haemorrhage or retinal vascular occlusions. In the recent years, DL techniques have been widely used for a variety of automatic classification problems. When classifying images, the typical process entails first extracting the crucial features using a set of convolutional layers and then using these features, classification is carried out. Thus, an innovative hybrid classification method is suggested in this work to identify DR in order to avoid above discussed problems.

1.1 Proposed System Model

The two main subgroups of DR disease are PDR and NPDR. Mild Non-Proliferative Retinopathy, Moderate Non-Proliferative Retinopathy, Severe Non-Proliferative Retinopathy and Proliferative Retinopathy are the four stages of the DR classification. The ML technique was used to recognise these four steps. It is crucial to classify and forecast normal and abnormal circumstances in the DRearly. Numerous different classifiers are discussed in the literature for the detection of DR, but they fall short of flawless detection. The suggested methodology introduces the DCNN based methodology to address these shortcomings. Figure 7.1 depicts the block diagram of the suggested technique.

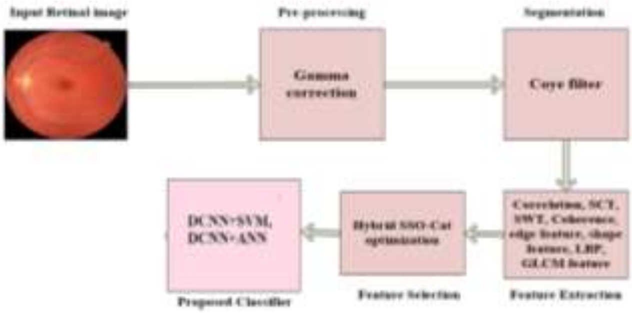

Fig. 1. Architecture of the proposed system

The open source system is used to acquire the retinal image datasets. Five distinct processes, including

- Pre-processing,
- Segmentation,
- Feature Extraction,
- Feature Selection and
- Classification

are included in the proposed system's design. Gamma correction is used at the pre-processing stage to get rid of noise in the input image. Unwanted noises are eliminated and increased contrast is accomplished with the use of pre-processing techniques, which are crucial for the prediction and classification of DR. Important features should be retrieved from the segmented image to detect DR. The features like Correlation, SWT, LBPetc., are retrieved from the segmented image. Among those, the essential features are chosen from the retrieved features with the aid of the hybrid SSO with Cat optimization technique. Finally, the DCNN classifier receives the extracted features as input to make predictions. Features are used to train the classifier during the training phase and retinal images are used during

DOI: rp-9788770040723.185

the testing phase to achieve the best results. UNet and modified Unet models are considered for classification in the suggested system.

1.2 Pre-processing Phase

The pre-processing stage is crucial for DR prediction because it removesnoise present in the input retinal image. The local brightness and contrast variation will not be homogeneous in retinal pictures. At certain points, the illuminations may be greater. Retinal imaging cannot show lesions clearly in low contrast and low brightness conditions. It is best to improve image clarity based on colour and quality. Pre-processing techniques are therefore crucial for enhancing image contrast and reducing noise. Gamma correction is applied to the input retinal image during pre-processing.

1.3 Segmentation Phase

The retinal image should typically be a light-sensitive tissue lining the inside surface of the eye. It can also be a layered structure with multiple layers of neurons connected by synapses. In the middle of the nasal side, the central retinal and vein retinal artery are present close to one another. When compared to the other portions of the retinal images, the segmented images include information. The blood vessels can serve as a marker throughout the segmentation process and helps to classify the severity of disorders. Edges from the retinal image are emphasised in the first stage. Following edge enhancement, retinal images can be converted to grayscale to remove uneven noise using filters and histogram equalisation.

1.4 Coye Filter

Coye filter is a novel method for segmenting retinal blood vessels in which cosiders RGB of the retinal image rather than only the green channel. The RGB image is transformed into a grey image and then PCA is used to find hybrid lesions. Following is the algorithm of Tyler Coye adopted for segmentation of images.

Coye Filter Algorithm

1 Consider retinal RGB image.
2. Apply CLAHE over gray image to increase contrast.
3. Remove the background by using an average filter and comparing the grayscale and average filtered images.
4. Binarize the image.
5. Divide the blood vascular network into segments

II. Feature Extraction

For the purpose of illness prediction, many features are retrieved from retinal images. With the use of various feature extraction approaches, which are described below, the characteristics are extracted:

2.1 Correlation

The similarity between the grayscale distribution of microaneurysms and the Gaussian function can be evaluated using the correlation coefficient. The correlation coefficient will be high if the two images coincide and low if they don't. The coefficient's ranges from 0 to 1. The following are the definitions of the correlation coefficient:

$$r = \frac{\sum m \sum n (A_{mn} - \bar{A})(B_{mn} - \bar{B})}{\sqrt{\sum m \sum n (A_{mn} - \bar{A})^2 \sum m \sum n (B_{mn} - \bar{B})}}$$

Where,

A and B - mean.

Different sigma values for the Gaussian kernel are needed because microaneurysm sizes may vary.

1.2.2 Discrete Cosine Transform (DCT)

The discrete cosine transform of an image, is defined by,

$$F(u,v) = C(u)C(v) \sum_{X=0}^{(N-1)} \sum_{Y=0}^{(N-1)} f(x,y) \cos \frac{(2x+1)u\pi}{2N} \cos \frac{(2Y+1)v\pi}{2N}$$

The inverse transform is defined by,

$$F(x,y) = \sum_{X=0}^{(N-1)} \sum_{Y=0}^{(N-1)} C(u)C(v)f(u,v) \cos \frac{(2x+1)u\pi}{2N} \cos \frac{(2Y+1)v\pi}{2N}$$

Where,

$$C(u) = C(v) = \frac{1}{\sqrt{N}}, for\ u, v = 0$$

$$C(u) = C(v) = \frac{1}{\sqrt{N}}, for\ u, v \neq 0$$

2.2 Stationary Wavelet Transform (SWT)

The fundamental idea behind the wavelet transform is to visualise any function as a superposition of waves created by stretching and shrinking the mother function. To make the wavelet decomposition invariant, the Stationary Wavelet Transform (SWT) was developed. The SWT approach is characterised as follows.

$$v^i = \frac{\mu^i}{\sigma^i} (i = 1, \ldots..7)$$

where

,- mean and standard deviation.

2.3 Shape Features

Shapes can be described using a few basic geometrical characteristics. Simple geometric features are employed as filters to weed out false positives or in conjunction with other shape descriptors to distinguish shapes because they can only distinguish shapes with significant variances. Center of gravity, digital bending energy, circularity ratio, etc., are some of the shape attributes. In this work,

DOI: rp-9788770040723.185

Eccentricity, solidity and circularity are taken into consideration as shape characteristics. The ratio of the distance between the main and focal axes of an ellipse can be used to define eccentricity. It ranges from 0 to 1. The formula utilized to calculate shape characteristics can be expressed as

$$Ecentricity = \frac{\sqrt{(major\ axis^2 - minor\ axis^2)}}{major\ axis}$$

$$Circularity = \frac{area\ of\ shape}{area\ of\ bounding\ circle}$$

$$Solidity = \frac{area}{convex\ area}$$

Many properties that are computed based on these aforementioned formulas are believed to be the major features for recognising DR situations. The following is an explanation of how the LBP characteristics are utilised to extract features from input retinal images:

2.4 Local Binary Pattern (LBP)

An image is converted into an array of integer labels using the LBP approach, which trains the texture image's pixel-level in detail. These labels can be seen as a histogram, which can be used to determine the texture of the image under analysis. LBP has two key characteristics that make it appealing for describing textures. It is invariant to monotonic grey level variations, such as those brought on by changes in illumination and it is computationally simple. The operation of LBP is depicted below.

$$s(x) = \begin{cases} 1, if \quad x \geq 0 \\ 0, otherwise \end{cases}$$

III. Feature Selection

Utilizing the various feature extraction approaches stated above, the features are extracted. With the help of a hybrid SSA-CSO optimization technique, necessary features are selected from among the many retrieved features. With the aid of the CSO algorithm, the SSA can be further enhanced in order to update the salps process. The required features can be quickly and efficiently chosen from the entire list of features. The following section contains a presentation of the SSA and CSO algorithms.

3.1 Salp Swarm Algorithm (SSA)

The salp swarm algorithm was created by Mirajalili to address optimization issues. In this case, SSA is used to choose the necessary features from the features collection. In essence, the salp belongs to a family called Salpidae. The SSA is based on the salps' swarming behaviour. They are able to set up cooperative chains while foraging in deep oceans. Through pursuing the food source, salps use this behaviour to get greater kinetic energy. For escaping from the local optima problem in the optimization, the salp chain can be used as a guide. The salp in the SSA algorithm is made up of two distinct classes that are dependent on both followers and leaders. At the top of the chain, the leader salp is situated, and the followers obey him. Members of the chain are also referred to as the followers. While the followers make use of their fellow followers, the leader salp aids the direction and movement of the swarm. The design of salp chain is illustrated in the Figure 7.2.

Fig. 2 Structure of Salp chain

For searching in an n-dimensional space, each salp's position vector is described. The SSO's initial population is made up of N salp and d dimensions. The below equation is the N-dimensional matrix that represents the salps' location vector:

$$Y_i = \begin{bmatrix} Y_1^1 & Y_2^1 & \cdots & Y_d^1 \\ Y_1^2 & Y_2^2 & \cdots & Y_d^2 \\ \vdots & \vdots & \cdots & \vdots \\ Y_1^N & Y_2^N & \cdots & Y_d^N \end{bmatrix}$$

All slaps are directed to the food supply. The following equation describes the leader's position:

$$Y_j^1 = \begin{cases} E_j + D_1((UB_j - LB_j)D_2 + LB_j) & D_3 \geq 0.5 \\ E_j - D_1((UB_j - LB_j)D_2 + LB_j) & D_3 \leq 0.5 \end{cases}$$

Where,

and - random vectors generating values which mentioned as the limit [0, 1],

- upper limit of jth dimension,

- the lower limit of jth dimension,

- Position of food source,

- Leaders position of salp and the core parameters of is described as

$$D_1 = 2e^{\left(\frac{4t}{T_{max}}\right)^2}$$

Where,

- exploration and exploitation tendencies of SSO algorithm in balanced state,

- iteration

- maximum number of iterations.

Additionally, the position of follower salps can be expressed as.

DOI: rp-9788770040723.185

$$Y_j^i = \frac{Y_j^i + Y_j^{i-1}}{2}$$

Where,

- start of ithsalp at the jth dimension.

3.2 Cat Swarm Optimization (CSO)

In CSO, the initial number of cats will be chosen. Every cat has a unique position made up of M dimensions, velocities for each dimension, a fitness value that shows how well the cat has adapted to the fitness function, whether the cat is searching or tracing. The best position in one of the cats would be the final solution because CSO retains the best answer till the end of iterations.

Seeking Mode

This model is intended to represent the scenario of the cat, which is lazing around, scanning its surroundings and looking for a new spot to settle down in.

$$P^i = \frac{|FS_i - FS_b|}{FS_{max} - FS_{min}}, where, 0 < i < j$$

The mutative ratio for the chosen dimensions is announced by SRD. When a dimension is chosen to change in searching mode, the difference between the old and new values won't be outside of the SRD defined range. The CDC reveals how many variables will be changed. All of these elements are significant contributors to the searching mode. The value of SMP will not be impacted by whether the SPC value is true or not.

Tracing Mode

Simulating the case of the cat when tracing some targets is the tracing mode. Once a cat enters the tracing mode, it moves in all directions at its own speeds. The following is a description of the tracing mode:

$$V_{k,d} = V_{k,d} + r_1 \times c_1 \times (X_{best,d} - X_{k,d}) \quad where\ d = 1,2, \ldots .M$$

Process of CSO algorithm

Step 1: To update the salp position, create N cats in the process.

Step 2: Distribute the cats randomly over the M-dimensional solution space. At random, choose values for each cat's velocity that fall within the range of its maximum velocity. Select a random number of cats, place some of them in seeking mode according to MR, and others in tracing mode.

Step 3: Assess each cat's fitness value by plugging their locations into the fitness function and memorise the best one.

Step4. Reposition the cats in accordance with their flags. Apply the cat to the searching mode process if cat is in that mode. If not, apply the cat to the tracing mode process.

Step 5: Select the same number of cats this time, place them in tracing mode in accordance with MR and the remaining cats in seeking mode.

Step 6: Verify the termination condition. If it is met, end the programme. otherwise, go back and repeat steps 3 through 5.

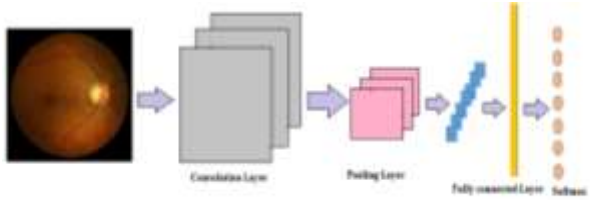

Fig. 3 Architecture of the DCNN network

UNet

The need for localization in biomedical image processing necessitates the implementation of deep learning algorithms to acquire required output. However, Standardized CNN are ineffective for biomedical image segmentation because they are designed for classification tasks, such as assigning a class label to each image rather than identifying the segmented region. Hence, a deep learning methodology based on fully CNN named U-Net model was developed for segmentation purpose.

comprises two 3 × 3 unpadded convolutions, trailed by a rectified linear unit (ReLU) and a 2 × 2 max pooling operation which can be utilized for down sampling.

Fig. 4 U-Net architecture

In this study, during every downsampling stage, the feature channels number is increased. An unsampled feature map followed by a 2X2 convolution network reduces the feature channels to half the number. However, the loss occurring at the boundary pixels necessitates cropping technique. Thus, a 1x1 convolution is incorporated at the last layer of the topology, which converts 64 component feature vector into the anticipated number of classes. As a result, U Net networks are divided into two parts:

Modified UNet algorithm

Patch-based networking is suggested in this network architecture. The encoder path is on the left side, while the decoder path is on the right, much like in the original U-Net architecture. To create multichannel encoder feature maps, each encoder layer conducts convolution (with batch normalisation and rectified linear unit (ReLU) activation) and densely connected convolution. Thus, the down sampling operation follows this.

The decoder path up-samples the feature maps using the deconvolution layer. The skip connections combine the encoder path's feature map with the appropriate up-sampled decoder feature map. A softmax function activates the feature maps. It is possible to derive two channel probabilities: one for vessels and the other for non-vessels.

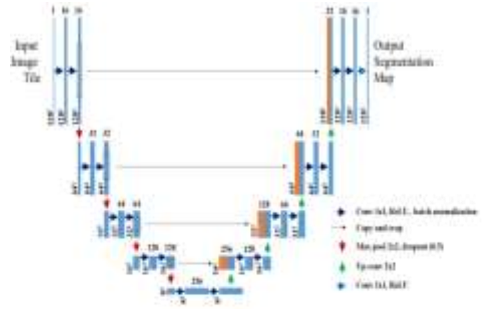

Fig. 5 Network architecture of the modified U-net

III. Results and Discussion

Table 1.1 displays the effectiveness of the proposed method's on the messidor dataset. Figure 1.8 displays the segmentation results of the two chosen images The original retinal and ground truth images are displayed in Figures 1.8(a) and (b). The segmentation results of the traditional UNettopology are shown in Figures 1.8(c1) and 1.8(c2), while the segmentation results of the modified UNet topology are shown in Figures 1.8(d1) and 1.9(d2). The segmented images demonstrate how effectively the proposed approach can identify retinal blood vessels.

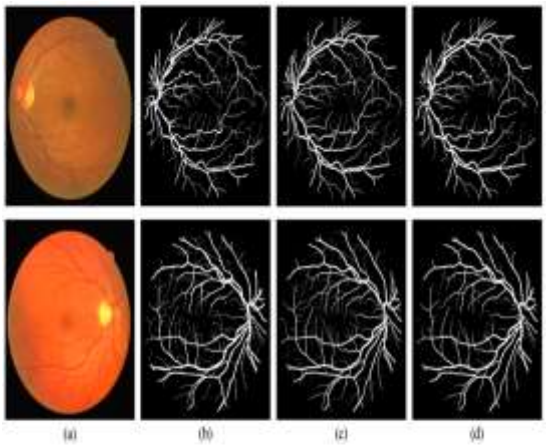

Fig. 6 Segmented analysis of proposed topologies

TABLE 1.1 Performance Measures (Hybridized CNN)

S.No	Classifier	Accuracy	Sensitivity
1.	DCNN (modified Unet)+SVM	98.12%	96.59%
2.	DCNN (modified Unet)+ANN	92.56%	88.25%
3.	DCNN (Unet) + SVM	97.45%	96.29%
4.	DCNN (Unet) + ANN	91.13%	86.51%
5.	DCNN+SVM	97.38%.	96.07%
6.	DCNN+ANN	90.19%	85.29%

The accuracy and sensitivity of the proposed topology is discussed in the table 1.1. From the table 1.1, it is observed that the accuracy of the proposed topology with DCNN and SVM classifier is about 97.38% and it outperforms than ANN. Similarly, the SVM with Modified Unet is 98.12%. The accuracy obtained with traditional Unet is 97.45%. Hence, it can be concluded that the proposed topology with modified Unet as classifier will exhibit higher accuracy. While considering the sensitivity, it's about 96.59% for modified Unet, 96.29% for traditional Unet and 96.07% for DCNN.

Thus, the results demonstrated that the proposed method extracted the blood vessels quite skillfully and precisely. The hybrid classifier comparison demonstrates that the DCNN with modified Unet and SVM outperforms all other known topologies.

IV. Conclusion

In this study, the DCNN based algorithm is used to detect and classify DR. Gamma correction is used at the pre-processing stage to get rid of noise in the input images. The Coye filter is introduced during the segmentation process. With the aid of a hybrid Salp Swarm Optimization (SSO) and Cat Swarm Optimization (CSO) method, the necessary features are chosen from the extracted features. Following extraction, the blood vessels is identified using a DCNN, which combines the U-net and modified U-net structures. The hybrid classifier comparison demonstrates that the DCNN architecture with modified Unet and SVM outperforms than all other known topologies.

***Abstract* — With the advancement of the Medical Internet of Things (MIoT) technologies, the accurate and continuous monitoring of the patients has become easy. A Smart Healthcare monitoring system is capable of monitoring different vital body signs such as blood pressure, heart rate, oxygen level and temperature. The sensors used in the monitoring system will capture the physiological signals and then the data can be sent to the cloud through IoT. Then the doctors or consultants can access the data from the cloud when needed to analyse the patient's condition. When sending the data to the cloud as such is prone to various attacks and can lead to misuse. So, it is advisable to use any of the techniques that are already available to prevent such attacks. One is, to encrypt the data that is being sent and then store the data. This type of system should follow certain rules to provide better security and also provide privacy to the data. This paper discusses the importance of encryption and decryption of data in a healthcare monitoring system. Healthcare monitoring systems are used to collect and analyze patient data, which is often sensitive and private in nature. Therefore, it is critical to ensure that the data is protected from unauthorized access or interception. The paper explores various encryption and decryption techniques that can be used to secure healthcare data, including symmetric and asymmetric encryption methods. Additionally, the paper discusses the challenges and limitations associated with the implementation of these techniques in healthcare monitoring systems. The study concludes that encryption and decryption of healthcare data is necessary to protect patient privacy and ensure the confidentiality of their sensitive information. Moreover, the study recommends that healthcare providers implement strong encryption and decryption techniques to ensure the security of patient data.**

Keywords—MIoT, Encryption, Decryption, healthcare monitoring, Unauthorized access

I. INTRODUCTION

The health care system has long struggled with issues like illegible diagnoses printed on paper, difficulty for healthcare professionals in accessing patient data, and a lack of resources (staff, time, and space) for patient monitoring. Hospitals and other healthcare centers have seen a significant increase in the use of healthcare monitoring systems, and many nations across the world are now very concerned about portable healthcare monitoring systems with emerging technology. The development of Internet of Things (IoT) technologies makes it easier for healthcare providers to move from in-person consultation to telemedicine. The health care delivery process will gain a lot from these technologies. These days, patient records are kept in digital form for subsequent use and easy access by anyone to assess the patient's condition. The storing of patients records in digital format is called Electronic Health Record (EHR). The electronic health record (EHR) or electronic medical record (EMR) is a computerised repository for data, diagrams, patient medical information, prescriptions, hospital or clinic records, radiological images, billing data, and other sensitive patient data. These records can also be shared among the health care providers and consultants with ease of access. However, there are a variety of security and privacy considerations that must be considered in order to promote and maintain essential medical ethical values and social expectations, even though these data are more practically useful than the traditional paper records.

The Electronic Health Records should follow certain security and privacy regulations and should ensure that the data that is being stored should be used for the right purpose and should ensure the privacy of the patient's personal information. Data security and privacy may be seriously jeopardised since they are sent electronically across the internet. Security is defined by the point at which access to someone's personal information is restricted and permitted for those with the required authorization. A person's right to decide for themselves when, how, and to what extent their personal information is shared or transmitted by others is referred to as their right to privacy. Sensitive information can be stolen via eavesdropping and skimming the sent data. Hackers gain access to the electronic health data information through data mining, which they may use to analyze patient data and spot trends and links. Using the data, they may classify and characterize the patients. Discriminatory and exclusionary consequences may result from this.

The use of lightweight, hardware-based authentication is one strategy that shows promise for data security. When the data is encrypted, others cannot access the data and make drastic changes to the data. In this way, it provides security and privacy of the data. The health care monitoring system usually consists of various sensors collecting data from the patient and all the sensors are connected to a microcontroller, where the data is converted to suitable format and stored for later purpose. The data that is being collected from the sensor, are encrypted by the microcontroller and then only the data should be sent to the cloud to store the data. Without encrypting the data, hackers can get access to the data and can change the data. If the data is encrypted, the hackers cannot formulate the data, so they would not be able to change the data. So, we proposed a system where the data being sent from the sensor to the server is encrypted first and then sent to the cloud.

Encryption and decryption are two fundamental concepts in information security that are used to protect sensitive data from unauthorized access or interception. Encryption involves converting plaintext or readable data into ciphertext or coded data, using a mathematical algorithm and a secret key. The ciphertext can only be read by someone who possesses the secret key to decrypt the data. Decryption, on the other hand, is the process of converting ciphertext back to its original plaintext form, using the same algorithm and the secret key that was used for encryption. By encrypting data, sensitive information can be protected from unauthorized access or interception, ensuring its privacy and confidentiality.

II. LITERATURE REVIEW

The first official encryption algorithm that was used was Data Encryption Standard (DES) [1] algorithm. Developed by IBM in 1975, Can be implemented in special purpose electronic devices, to provide cryptographic protection to binary coded data. This algorithm uses a single key for both encrypting and decrypting the data. The major drawback of this method is the small key size of 56-bit. This encryption algorithm is outdated as it became easy to break the encryption with the keys. So, to improve the existing method, Triple-DES [2] was developed. In this method, the data is encrypted three times using the same key, so it can improve the efficiency and makes it difficult to break the encryption. The major setback of this method is the processing time as the data should be encrypted three times.

In the year 1997, Joan Daemen and Vincent Rijmen developed a better and efficient encryption algorithm compared to the DES algorithm, which is called Advanced Encryption Standard (AES) [3] algorithm. It became the successor of the DES algorithm. In this method, different key sizes of length – 128 bits, 192 bits, 256 bits are used. Due to the increased key size, it makes it difficult to crack the encryption. Xin Zhou and Xiaofei Tang in their paper [4], talked about the implementation of the RSA algorithm, which is another Asymmetric encryption algorithm, that uses public key to encrypt the data and private key to decrypt the data. The public key is a product of two non-negative prime numbers. Their proposed method is easy to implement and difficult to crack the algorithm. Rajan and Geeta, in their paper [5] proposed a method to encrypt the data stored in files and can be shared with others. They used the RSA algorithm to encrypt the data. So that the data in the file is immune to any attacks and data leakage. The only drawback of their method is, they can only encrypt only one file at a time.

Mousa and Hamad [6], in their paper, talked about the RC4 encryption algorithm. RC4 is a stream cipher encryption algorithm. It uses a key of variable-length and also it encrypts one byte at a time. The data stream is simply XORed with the generated key sequence. This method is easy to use and fast, but it is an insecure algorithm.

Blowfish encryption algorithm [7] is a symmetric-key block cipher algorithm founded in the year 1993. It provides a successful rate of encryption at software level. But it was preceded by the AES algorithm [3] since it is similar to the DES algorithm [1]. It is an open source, non-patented and freely available for use and modifications. It uses the same key for both encrypting and decrypting the data. Blowfish is faster compared to other block cipher algorithms as it takes advantage of the built-in instructions imposed on the microprocessors for basic operations like bit shuffling. Blowfish algorithm found to be secure after several tests. Homomorphic encryption algorithm [8] is a type of encryption algorithm where the data can be used to perform computational analysis even if the data is encrypted. The patient's data that is being collected are sent to the cloud after encrypting to perform analysis on the patient using those data. There is no need to decrypt the data first to analyse the data, so it can prevent misuse of data, while storing in the cloud. But this process is slow since computation should be made on encrypted data.

Diffie-Hellman protocol [9] is an encryption algorithm where two users exchange a secret key among themselves and that key is then used to encrypt the message that they want to share among themselves. The protocol uses the multiplicative group of integers modulo p and g, where p is a prime number and g is a primitive root modulo of p. This protocol itself is limited to only the exchanging of the keys between the two users. Secure Hash Algorithm [10] is a cryptographic hash function algorithm which uses hash function to map the data of arbitrary size to a bit array of fixed size called hash value. It produces a message digest of larger hash value. The family consists of various versions of varying output size with increase in security and immunity to attacks. Currently SHA-3 is the latest version of the SHA family.

Searchable Symmetric Encryption [11] is an encryption algorithm, where it is easy to search over a collection of encrypted files even without decrypting the files first. With the encryption key and keyword that need to be searched, a search token is generated and using that searching is done. It is useful in implementing cloud storage servers, where the servers are unreliable and cannot be trusted. In this paper [12], they proposed a method to perform predictive analysis tasks on encrypted data. It is achieved by using a Homomorphic encryption scheme to encrypt the data and then the data can be used to perform analysis. As already said in [8] this method is incredibly slow and has performance issues. In this paper [13], they proposed a simple and efficient method to construct a Chosen-Cipher Attack (CCA) secure public key encryption scheme from an already existing Chosen-Plaintext Attack (CPA) secure Identity-Based Encryption (IBE) scheme. Their method produces an efficient and secure encryption scheme compared to the original approach. Identity-Based Encryption scheme [14] is a symmetric encryption, where the identity of the user can be found using unique information and is used as the public key for encryption. Then a Private Key Generator generates a private key, which is used for decrypting the data. The scheme is pre-defined by a set of four algorithms that form a complete IBE system. This method is secure and efficient.

Electronic Health Record Systems are used to collect the data from the patients. The data is collected by the IoT devices that consist of various sensors, that are then sent to the cloud to store the data. But the system should follow certain security and privacy policies and the issues related to these systems is explained in the paper [15], along with various measures to follow to prevent security issues. In the paper [16] they talked about the challenges of protecting the patient's data stored in the electronic health record systems. Access control can be enforced to protect the data. Where the patient themselves can generate and store the encryption keys and can share the data to others to perform actions like searching for certain data in the records.

III. Problem Statement

A healthcare monitoring system is a technology-based platform that is designed to collect and analyze patient data. It is typically used in clinical settings to monitor patient health status, track the progress of treatment plans, and provide insights into patient care. The system typically collects data from a variety of sources, such as medical devices, electronic health records, and patient self-reports, and uses algorithms and analytics to provide insights and feedback to healthcare providers. Healthcare monitoring systems can be used in a variety of contexts, such as in hospitals, clinics, and home health care settings. They are particularly useful in managing chronic diseases, such as diabetes, heart disease, and hypertension, where regular monitoring is necessary to ensure optimal patient outcomes. By providing real-time insights into patient health status, healthcare monitoring systems can help healthcare providers to identify potential health problems and take preventive measures to avoid complications. However, the use of healthcare monitoring systems also raises concerns about patient privacy and data security. The data collected by these systems is often sensitive and private in nature, and must be protected from unauthorized access or interception. This is where encryption and decryption of data comes into play, as an essential component of securing patient data in healthcare monitoring systems.

With the widespread use of healthcare monitoring systems, sensitive patient data is being collected and transmitted over networks. However, this data is at risk of being intercepted and accessed by unauthorized individuals, posing a serious threat to patient privacy and confidentiality. Thus, there is a need for effective methods of securing healthcare data to ensure its privacy and confidentiality. This paper aims to address this problem by exploring various encryption and decryption techniques that can be used to protect healthcare data in monitoring systems, and by analyzing the challenges and limitations associated with their implementation in this context. The data that is sent by the microcontroller, which is collected by sensors, needs to be encrypted in order to stop the hackers from accessing the data and using it for their own purpose and also to stop leakage of data. Before transmitting the information to the server, the data needs to be encrypted in order to be stored in the cloud and used for analysis. When the data is encrypted, the data cannot be easily used and the hackers cannot decrypt the data without necessary keys. When the data is encrypted using various keys, the keys should be protected at all cost. If the keys get leaked, then it can be used to decrypt the data and the data can be used for illegal purposes. The data can be encrypted and decrypted using a variety of techniques that are available.

In the Healthcare Monitoring system, Cyber-attack is a major concern. The data that is being sent and stored should be protected from intruders. The data may contain important information about the patients and important medical records which when leaked can cause consequences to the patient and the health care providers. So, it is important to safeguard the data. The hackers can steal the data using different ways. The health care providers should be able to provide various protection methods to protect their client's data. In this paper, we talked about various encryption algorithms that are available for using and made a comparison to find the best and efficient algorithm.

IV. Methodology

Encryption and Decryption is one of the methods that can be used to ensure the security and privacy of personal data that are collected from various sources which need to be kept safe from leaking and being misused or altered. There are various encryption algorithms available for use. Primarily it is of two types, based on how many numbers of keys are used to encrypt and decrypt the data. They are Symmetric and Asymmetric encryption algorithms. Symmetric encryption algorithm uses only a single key for both encrypting and decrypting the data. Whereas in Asymmetric two keys are used, one for encrypting, which is called a public key, and the other for decrypting, which is called a private key. These keys should be protected from getting leaked so that intruders cannot access the data.

The healthcare monitoring system usually consists of a microcontroller and various sensors to read the data. The sensors will read the data and send it to the microcontroller, which will convert the data to suitable format for processing the data. The server will create a key which can be used for encrypting and decrypting the data. Then the server will send the key to the microcontroller and using that, the microcontroller will encrypt the data and send the encrypted data back to the server. Now the server will use the same key or private key based on the algorithm used and will decrypt the data. The communication between the microcontroller and the server is achieved using socket programming. If an Asymmetric encryption algorithm is used, then the server has to create both the public and private key, and should send only the public key and keep the private key safe. Some examples of symmetric encryption algorithms are DES, AES, Salsa20 and an asymmetric encryption algorithm is RSA, which is discussed in this paper. Using a raspberry pi and a temperature sensor to read the patient temperature, the raspberry pi will encrypt the data and send it to the server.

In this paper, we have taken DES, AES, RSA, ARC2, Salsa20 and Blowfish encryption algorithms and recorded the time taken by each algorithm to encrypt and decrypt the data. We used Python as the programming language as it is easy to use and also has a cryptographic library that can be used for encrypting and decrypting the data. First, we implemented a simple encryption and decryption program for each of the above-mentioned algorithms. Then using the timer package library present in python, is used to find the time taken by these algorithms to encrypt and decrypt a large sized data and the findings are recorded. Then using the socket package library present in python, a simple server side and client-side communication is established where the server and client can send data back and forth. Using this program, first the server will open a port for clients to connect to, and then will create a key for encrypting and decrypting and when a client connects to the server, the server will send the key to the client, then the client-side program will use that key and will encrypt the sample data. The encoded data will be sent back to the server, and the server will use the same key or a private key to decrypt the data. Just like before, the timer package is used again to find the total time taken for encrypting and decrypting the data. The timer starts when the client establishes a connection with the server, and will stop when the server decrypts the encoded data sent by the client.

The Raspberry Pi is a single-board miniature computer that can be used for a variety of purposes. It can read data from various sensors and also convert data received from the sensor to a suitable format using the package libraries available. The values from the sensor can be read and converted into the appropriate format inside the raspberry pi using the gpio module package in Python. In this example, the raspberry pi will act as a client, which will connect to an external server running on a computer. The raspberry pi will read the sensor values and using the key it received from the server, will encrypt the data and send the encrypted data back to the server.

V. RESULTS AND DISCUSSIONS

Some of the algorithms used in this experiment are no longer used in the real-world situations, and are taken into comparisons as new encryption algorithms are developed to overcome the issues and backdrops of old encryption algorithms. DES is no longer in use, as it uses a short key length, the data can be hacked with brute force attack. To overcome this, AES was developed, which uses long key length. AES is considered as the base standard algorithm for encryption, since it is very fast and secure. RSA is an asymmetric encryption algorithm that uses two keys instead of one key, to ensure more security. RSA is the most widespread and used encryption algorithm. From this experiment, we recorded that even though RSA is secure and reliable, due to the computational need to find the keys, it is a slow encryption algorithm compared to another encryption algorithm. Even RC2 is never cryptographically broken, but it is slower compared to AES. The only issue with the Salsa20 encryption algorithm is that it doesn’t guarantee the authenticity of the encrypted data. We can overcome this issue by using Message authentication code to ensure the authenticity of the data. The Blowfish encryption algorithm uses key lengths of varying size, even though it is secure and fast, but a long key should be used to withstand a brute force attack. We plotted graphs to show the time taken by each algorithm to encrypt and decrypt the data.

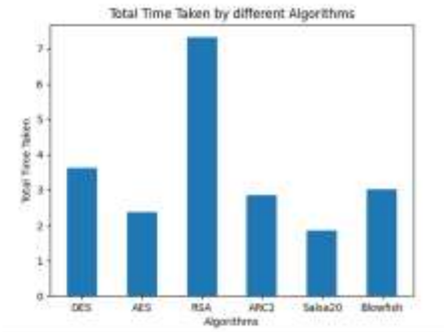

Fig.1. represent the time by algorithm during encryption

From this graph Fig 1, we can see the total time taken by each algorithm to encrypt the data on the raspberry pi and send the encrypted data back to the server and the server will decrypt the data. RSA takes the longest time, while AES takes the least time to encrypt and decrypt the data.

Time taken by different algorithms to encrypt and decrypt a large sized data. The RSA algorithm cannot encrypt large sized data. Again, AES takes the least time.

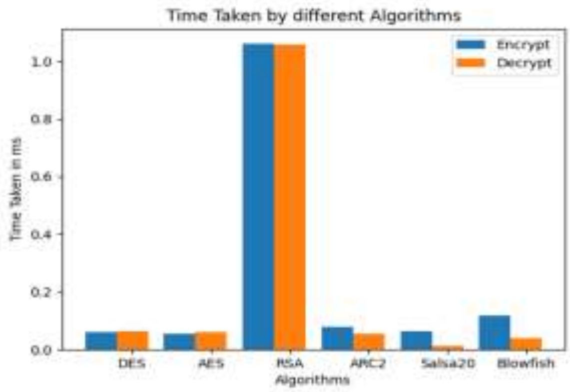

Fig.2. Represent the time by algorithm during decryption

The graph Fig 2, shows the separate time taken by the algorithm to encrypt and decrypt the data. RSA takes the longest time due to the computations needed to encrypt and decrypt the data. From this experiment, we can conclude that AES is one of the best algorithms to use, RSA is secure but is slower compared to other encryption algorithms.

VI. CONCLUSION

As we go into this new age of IoT, we can see the development of new technologies that can make our lives easier and can help us in a lot of ways, especially in real-time healthcare monitoring. If the security is exploited in this field, it can lead to huge problems. Especially when it involves life support. In conclusion, the importance of encryption and decryption of data in healthcare monitoring systems cannot be overstated. Healthcare data is sensitive and private, and thus needs to be protected from unauthorized access or interception. This paper has explored various encryption and decryption techniques that can be used to secure healthcare data, including symmetric and asymmetric encryption methods. Therefore, securing the data becomes important and comes to play in this scenario. Any breach in security in any of these systems or even intervention can lead to loss of life or any other serious consequences. Therefore, it is also important to implement error checking whether if the data is intervened by a middleman or the third person apart from sensor and server, with just encryption, there is no way the server or sensor can know that there is any intervention in data. With the help of error checking or intervention checking algorithms, one can assure an extra layer of security in these cases. Overall, this paper has provided valuable insights into the importance of encryption and decryption of data in healthcare monitoring systems. It is hoped that the study's findings will inform policy and decision-making in this area, and contribute to the development of more secure and privacy-conscious healthcare monitoring systems.

***Abstract*—An immense interest is shown to E-Healthcare systems as medical service recommendation increases with the advancement of technology and internet facility. It assists elderly people and other patients to discover professionals. Besides that, recommending personalized professionals and ensuring privacy remains great challenge. In an aim to increase the accuracy of the recommendation generation process, similarity between user's expectation and experts' knowledge is discovered and used along with expert's reputation score. Multiple user feedbacks are used to determine the reputation scores of doctors. On the basis of the curve-based cryptosystem and truth discovery technology, privacy-preserving recommendation method is proposed to compute reputation and similarity scores. In order to demonstrate its security proficiency, a detailed security analysis is provided.**

***Keywords*—Recommender system, Healthcare service, privacy preservation, curve-based cryptography**

I. Introduction

Due to the rapid development of E-healthcare systems [1], online healthcare service recommendations have become fundamental part of everyday life. Here, user can submit their symptoms, doubts and necessity to a medical server, and then the server suggests most appropriate professionals in accordance with those requirements to the corresponding users. Healthcare service recommender systems are automated tools that use machine learning and artificial intelligence (AI) to make tailored healthcare suggestions to individuals. By making timely and accurate suggestions based on patient data, medical records, and other pertinent information, these systems have the potential to enhance healthcare outcomes. There are several kinds of healthcare recommender systems that can be applied in various contexts, including telemedicine platforms, patient-facing applications, and clinical decision support systems.

Algorithms are used by clinical decision support systems to offer real-time guidance on medication, diagnosis, and therapy to healthcare professionals. In order to enhance patient safety and lower medical errors, these systems can also offer alerts and reminders. Applications geared for patients are created to enable users to actively participate in their health management. They offer customized advice on food, exercise, medication adherence, and disease management based on information about the patient's medical history, lifestyle, and preferences. To assist patients in achieving their health objectives, these applications can also offer them feedback and educational resources. To offer patients remote healthcare services, telemedicine platforms employ healthcare service recommender systems. Based on patient data and symptoms, these platforms can offer personalized suggestions for a diagnosis, a course of action, and a prescription. Additionally, they can offer patients virtual follow-up care and monitoring, lowering the need for in-person visits and enhancing access to healthcare.

The capacity of healthcare recommender systems to enhance healthcare outcomes by offering personalized recommendations that are suited to specific patient needs is one of their main advantages. These systems can assist healthcare professionals in making better judgements, enhancing patient safety, and minimizing medical errors by utilizing patient data and other pertinent information. Better health outcomes can result from empowering patients to have a more active part in their own health management. Healthcare recommender systems do have several difficulties, though, including assuring data confidentiality and privacy, overcoming algorithmic biases, and guaranteeing that recommendations are founded on the most recent and correct medical knowledge. For healthcare recommender systems to be successfully implemented and adopted, several issues must be resolved.

Numerous studies were carried out to design a reliable healthcare recommendation system, some uses reputation score as basis for recommendation [2, 3], while others place greater emphasis on users interests and needs [4]. In former type, service requested users will be directed to the professionals who have high reputation score. In later type, most appropriate professionals will be suggested based on users' requirements. It is evident that the recommendation accuracy may be compromised if only the reputation or user need is considered for recommendation generation process.

In fact, reputation is derived from other user's feedback. Sometimes, it may reflect irrelevant medical services required by the target user. Since, false feedback that has been entered maliciously by them can have a negative impact on the professional's reputation [5]. Thus it is important to filtering it. Similarly, recommendation of professionals based on the similarity score of user needs may result in the recommendation of doctors who provide poor quality service

DOI: rp-9788770040723.187

[6]. Thus, it is necessary to consider both similarity score of user needs and the aggregated service feedback from multiple users to obtain high-quality medical services.

More importantly, the system should be capable enough in filtering redundant feedback received from malicious users, whether it is positive or negative. Besides the accuracy of the recommendation generation process, sensitive information of both the user and professional must be protected from disclosure. Here, a fundamental cryptographic primitive called key management can be used to ensure security [7, 8], but it alone is inadequate to achieve privacy-preserving recommendations. In addition, due to their expensive computational requirements, they are not practical for system with increasing number of users. In an attempt to address the challenges of existing recommender systems, a privacy-preserving online healthcare service recommender system (PHSRS) is proposed. The major contributions are:

- The PHSRS scheme takes both the similarity score of user needs and reputation score of the doctors as the basis for medical service recommendations.
- The PHSRS scheme not only provides accurate professional recommendations but also protects the privacy of both the doctor and user's sensitive information.
- In this scheme, users' needs and demands, and the professional's information are compared in the form of Ciphertext, not as plaintext.
- It discovers and filters feedback from malicious users, and assigns different weights dynamically.
- To demonstrate the efficiency, the proposed PHSRS scheme is compared to that of other related schemes.

The remaining sections are organized as: Section II describes the currently available literature-based solutions. Following that, Section III presents the healthcare service recommender system design goals and Section IV presents preliminary of the proposed work. Section V defines in detail about the proposed PHSRS scheme, and Section VI provides a thorough evaluation of the performance. Finally, Section VII draws the conclusion.

II. Related Works

The protection of one's privacy and anonymity has become a topic of widespread interest among the research communities of healthcare recommender system. If a user's privacy is breached, an adversary may be able to discern the victim's way of life, their routines, and even in some instances, the location of a remote user. Li et al. [6] introduced privacy-preserving online service recommendations for social communities. Here, interest-based pseudonyms were used to protect user identity from the server, but it is unfit for recommending professionals. An online friend suggestion based on user's trust relationship and social attributes has been proposed by Ma et al. [9] in a private manner. However, it cannot be used to generate doctor recommendation as there are no direct relationship between user and doctor in healthcare systems. To make accurate healthcare service recommendations, both reputation and similarity score need to be calculated.

Huang et al. [10] proposed privacy-preserving vector similarity computation model. However, this approach is not efficient as it involves users, trust authority and server to calculate similarity. A disease prediction scheme based on matrices is proposed by Zhang et al. [11]. To calculate reputation scores, Hu et al. [12] uses Dirichlet distribution and proposed a privacy-preserving communication scheme for vanets. However, due to the dynamic nature of users' feedback scores, the scheme is inaccurate. Furthermore, the server processes users' raw data and raise privacy concerns. Recently, numerous models have been introduced to protect user's privacy.

A privacy-preserving scheme for truth discovery (PPTD) was proposed by Miao et al. [13] to preserve user's sensitive data in the cloud. Unfortunately, their scheme becomes less effective as number of user increases. Zhang and colleagues [14] introduced privacy protected truth discovery (LPTD) scheme for fog-cloud platforms and they claimed that their scheme is lightweight. Kang et al. [15] used pseudonyms to preserve private information of fog computing users. An attribute-based protection scheme is proposed by Li et al. [16] to share data in cloud. However, this encryption model is not meant for truth discovery. Minding the above mentioned limitations, a new recommender solution is developed based on professional's reputation rate and user needs while filtering malicious user feedbacks. Throughout the system, the communicating participant's information should be secure and protected from malicious activities.

Various methods such as attribute-based encryption [21], differential privacy, identity-based encryption, elliptic curve cryptography, and k-anonymity or zero-knowledge proof are utilized to address privacy [22]. Hashing and cryptographic methods, primarily the SHA-256 or SHA-512 hashing algorithms, are used by blockchain technology to secure data transferred between nodes connected to a network. Due to the possibility of performance degradation, a suitable privacy preserving strategy must be carefully considered [23, 24].

The Curve-based cryptosystem [17] has attracted a lot of interest because of its lightweight operations. It's widespread because of the low cost operations, less memory requirement and low communication overhead. It offers faster processing, and also requires smaller key sizes than other public key cryptosystems. The curve-based cryptosystems have exponential complexity. At a given level of security (2^n), the key size grows as n^2 for curve-based cryptography, but it grows as n^3 for classical cryptosystems. As a consequence, curve-based cryptosystems are now advised to be used for new products where backward compatibility is not necessary. The security of ECC depends on the mathematical complexity of breaking elliptic curve discrete logarithm problem (ECDLP) [18]. For instance, the security offered by a 1024-bit RSA key is equivalent to that of a 160-bit elliptic curve key. Since then, numerous studies have been done to employ the ECC on recommender system to ensure privacy protection.

DOI: rp-9788770040723.187

III. Design Goal

The main goal is to design a secure and reliable privacy-preserving healthcare service recommender system, where the curve-based cryptosystem is used to protect sensitive information from malicious activities and unauthorized access.

A. Privacy Preserving Recommender System

The key challenge of any service oriented recommender system is the privacy preservation. As a result of the sensitive personal and medical data that healthcare service recommender systems handle, privacy-preservation plays a major concern. The information found in healthcare data can be used to determine a patient's identity, treatment history, and personal preferences. As a result, it is essential to make sure that sensitive data is shielded against misuse, disclosure, and illegal access. One of the crucial privacy-preserving strategies for healthcare service recommendations is the user anonymity. De-identifying healthcare data is taking out any personal identifiers or protected health information (PHI). Techniques like data masking, perturbation, or aggregation can be used to accomplish data anonymity. It lowers the possibility of re-identification and safeguard patient privacy.

Secure data storage is the other essential privacy-preserving measure. To avoid unwanted access or disclosure, healthcare data should be stored securely. This can be done by utilizing secure authentication methods, encrypting data in transit and at rest, and putting access control measures in place. For healthcare service recommender systems, secure data sharing mechanisms must be put into place to exchange healthcare data between healthcare service providers and seekers. These protocols should make sure that the data is sent securely and that only authorized people may access it.

The recommendation algorithm should respect user privacy while generating personalized healthcare service recommendations. Transparency and accountability are also essential for maintaining privacy in healthcare recommendation systems in addition to cryptographic mechanisms. These systems ought to be open about how they handle data and include detailed descriptions of the methods they employ for gathering, storing, and using it. In conclusion, to safeguard sensitive healthcare data from illegal access, disclosure, or misuse, healthcare recommender systems must integrate effective privacy-preserving procedures. A well-modeled healthcare service recommender system should preserve patient's privacy while offering personalized and useful healthcare suggestions by putting these precautions in place.

B. Role of Cryptosystem in Privacy Preserving Recommender Systems

To protect patient privacy, healthcare service recommender system uses various cryptosystems to safeguard the private and sensitive information from unwanted access or disclosure. Secure multi-party computation, differential privacy, homomorphic encryption, and other cryptographic methods can be utilized to ensure that private health information is shielded from illegal access and exposure while generating customized recommendations. These methods are crucial for safeguarding patient privacy and fostering confidence in healthcare recommendation systems. One of the fundamental cryptographic primitive utilized in privacy-preserving healthcare recommender system is the encryption algorithm. Sensitive data can be protected both in transit and at rest by using encryption algorithms to avoid interception or eavesdropping and to guarantee that only authorized users can access it.

Homomorphic encryption is another cryptographic method used in healthcare recommendation systems that protect patient privacy. By enabling computations on encrypted data without first decrypting it, Homomorphic encryption protects the confidentiality of the data. Using this method, it is possible to perform computations on personal healthcare information like patient records or medical histories. Another cryptographic method used in healthcare recommendation systems that protect patient privacy is secure multi-party computation. In this method, several parties can compute a result without disclosing their inputs to other. This method can be used to create collaborative recommender systems for healthcare where several healthcare professionals can work together to offer personalized recommendations without disclosing any patient-specific information.

Another crucial cryptographic method utilized in privacy-preserving healthcare recommendations is differential privacy. Differential privacy guarantees data anonymity, preventing person identity while facilitating personalized recommendations. Through the use of differential privacy, patient privacy can be protected by introducing noise or other disturbances to the data while maintaining its overall quality. Through literature analysis, it is found that among currently available public key cryptosystems, curve-based cryptosystem has shown a lot of promise in terms of both security as well as speed. This is because of its smaller key size to provide equal level of security as other cryptosystem provides which means less computation. The algorithm uses robust security based on the computational complexity, key generation, curve selection, point multiplication for encryption, and point addition for decryption. Due to its tiny key size and quick computation time, it is employed in the proposed privacy-preserving healthcare service recommender system.

IV. Preliminaries

The cryptosystem used to protect the sensitive information and the truth discovery approach used to calculate the weight of similar users are defined in this section for better understanding of readers.

C. Truth Discovery

To resolve the conflicts of noisy data, truth discovery approach is used in various applications. Once the algorithm begins, then the ground truths are randomly assigned and the weights will be updated iteratively till convergence has been achieved. The higher weight will be given to the user whose data is nearer to previously determined ground truth. The

DOI: rp-9788770040723.187

distance between the current user data and ground truth is calculated as:

$$d\left(x_o^u, x_o^*\right) = \frac{\left(x_o^u - x_o^*\right)^2}{std_o} \quad (1)$$

where o represents the object, x_o^* is the ground truth, x_o^u is user data and std_o represents the standard deviation of object o for all users u.

D. Overview of Elliptic Curve Cryptosystem

Public-key cryptography known as elliptic curve cryptography (ECC) makes use of the characteristics of elliptic curves to produce safe encryption methods. It generates the key pair as the initial stage in the ECC process. The public key is produced from the private key via a mathematical formula, whereas the private key is a secret number that is generated at random and kept hidden by the owner. While the private key is required for decryption, the public key is utilized for encryption. The curve must be carefully selected to guarantee that it possesses specific mathematical characteristics that make it appropriate for use in cryptography. Fig. 1 gives the graphical representation of an elliptic curve over the finite field F_q.

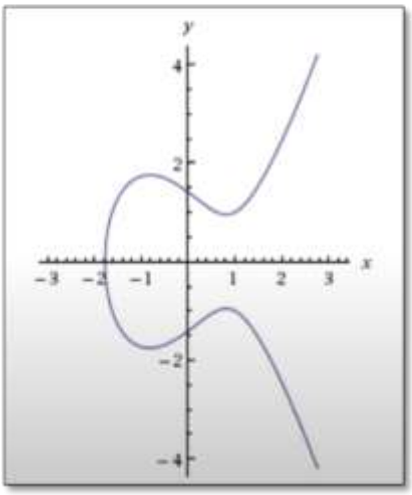

Fig. 1. Graphical Representation of Elliptic Curve

In ECC, the plaintext message that is being encrypted is represented by the scalar value. During encryption, a point on the elliptic curve is multiplied by that scalar value. A new point on the curve i.e. the Ciphertext is produced as a result of the multiplication. During decryption, the ciphertext point on the elliptic curve is added to get the original plaintext message. Due to the challenging mathematics required to calculate the private key from the public key, ECC is thought to be safe.

E. Arithemtic operations of ECC

With a smaller key size ECC offers comparable security than other public key cryptosystems like RSA. A non-singular curve with the equation $y^2 = x^3 + ax + b \bmod p$, with the discriminate $4a^3 + 27b^2 \bmod p \neq 0$, is known as an elliptic curve $E_p(a, b)$ defined over a prime field F_p. The three fundamental arithmetic operations carried out on the ECC are

- **Point multiplication:** addition of a point in k times
- **Point addition:** addition of 2 different points
- **Point doubling:** addition of same point

Assuming there are two points on the curve, then point addition is $P_3 = P_1 + P_2 \bmod p \in E\left(F_p\right)$. The same point is added twice $P_3 = P_1 + P_1 \bmod p \in E\left(F_p\right)$ in point doubling, whereas the same point is added k times $P_3 = kP_1 \bmod p \in E\left(F_p\right)$ then it is called as scalar multiplication.

F. Elliptic Curve Cryptosystem

The PHSRS scheme achieves privacy preservation using Elliptic curve cryptosystem. It comprises of key generation, encryption and decryption algorithms.

- **Key Generation:** The domain parameters that are made publicly available for key generation are the prime p, elliptic curve E, and the generator point P. Let us assume that the point P is on the curve $E(F_P)$, then the cyclic subgroup fabricated by P is given as $\langle P \rangle = \{\infty, P, 2P, 3P, \cdots, (n-1)P\}$. Now, the key pair is generated by uniformly selecting the random integer $k \in [1, n\text{-}1]$ as a private key, and its equivalent public key P_k is computed as P_k = k × P. The security of an elliptic curve cryptosystem relies on the hardness of computing k from P_k though provided with P which is called the ECDLP.
- **Encryption:** The data M which is to be protected is initially converted into the point on the elliptic curve P_M. Then it is encoded into its corresponding Ciphertext C which is the pair of points (C_1, C_2) as follows:

$$C = \left(C_1, C_2\right) = \left(kP, P_M + P_k\right) \quad (2)$$

- **Decryption:** With the Ciphertext C, the following actions are performed to retrieve the plaintext P_M. Finally the point P_M is then decoded to the original data M.

$$\begin{aligned} P_M &= \left(C_2 - k \times C_1\right) = \left(\left(P_M + kP_k\right) - \left(k \times kP\right)\right) \\ &= P_M + kP_k - kP_k = P_M \end{aligned} \quad (3)$$

G. Elliptic Curve Discrete Logarithm Problem

The elliptic curve discrete logarithm problem (ECDLP), which is the problem of separating the private key from the public key, determines how secure ECC is. For an elliptic curve $E\left(F_p\right)$, determining an integer $k \in [0, n-1]$ from $Q = k \times P$ is difficult, provided a generator point $P \in E\left(F_p\right)$ and the resultant point $Q \in \langle P \rangle$. Even for large

DOI: rp-9788770040723.187

key sizes, the ECDLP is thought to be computationally infeasible.

V. Privacy-Preserving Healthcare Service Recommender System (PHSRS)

The privacy-preserving online healthcare service recommender system (PHSRS) is designed, where the user submits the service request through public network to the medical server, following that server suggests the professionals based on their requirements. After that, the user will provide feedback regarding the received service quality to compute particular professional reputation rate. The formal PHSRS model is demonstrated in the Fig. 2, which consists of User, Medical server and the Trusted Authority.

- Users are the person who needs medical advices and they must own smart device to send the request and to receive the recommendations. Following that, the user provides feedback in order to assess the quality of service they received.
- Trusted Authority is in charge of managing and distributing the key resources to users and medical servers.
- After receiving the service request, the medical server calculate the similarity score between user needs and professional's attribute, then responds to user with suitable doctor suggestion. And then collects the feedback from them to calculate the reputation scores of doctors.

Fig. 2. The PHSRS System Architecture

The proposed privacy-preserving healthcare service recommender system (PHSRS) consists of system initialization, professional recommendation, and reputation score computation phases. These are explained in detail the following subsections.

H. System Initialization

Trusted authority (TA) is the one who is completely believed by all the participants of PHSRS scheme. Initially, TA selects the global parameters like elliptic curve, generator point and then generates the key pairs based on the security parameter. Finally, TA distributes these key pairs to the appropriate user and medical server, respectively.

I. Doctor Recommendation

The entire process can be broken down into three parts: sending the requirements, calculating the similarity, and recommending the professionals. Each participant should prove their authenticity before taking advantage of the service provided by the PHSRS system. After successful authentication, the user sends their perturbed demand vectors to the medical server through public network without expressing their identities for recommendation generation. Each user has their own demand vectors $\vec{A_i} = \{a_1, a_2, \cdots a_n\}$, includes name of the hospital, information about the department, the type of disease, and so on. Similarly, the doctor's attribute vector $\vec{B_i} = \{b_1, b_2, \cdots b_n\}$ includes information about the hospital name, the type of treatable disease, and so on. Then the distance between professionals attribute vectors and users demand vectors are calculated as follows:

$$sim = \sum_{i=1}^{n} \left(a_i - b_i\right)^2 \qquad (4)$$

Finally, the doctors are selected whose similarity score is greater than the threshold value. Then the top listed professionals with highest reputation score is recommended to the user.

J. Reputation Score Computation

Following the service recommendation, the user will provide a feedback to assess the quality of the healthcare service provided by the particular professional. This feedback is then utilized to determine the doctor's overall reputation score. In this phase, the medical server will aggregate all the feedbacks received from multiple users and compute the truth value. With that truth value, the reputation score of doctor will be determined. In truth value calculation, different weights are assigned dynamically to each user feedback, and update them constantly based on multiple user feedbacks. To compute specific professional's reputation score, truth values obtained from various time periods were used.

VI. Performance Evaluation

The performance efficiency of the PHSRS scheme is evaluated in terms of the running time required to suggest relevant professionals. Here, 10 iterations are performed on the system with 2.5GHz Intel i5 processor and 8GB of RAM. The proposed PHSRS scheme is compared with other two related schemes, like PPMR [19] and FSSR [10] to demonstrate the efficiency of PHSRS. FSSR recommends a doctor based on only the user similarity. In PPMR, unlike FSSR, both user similarity and doctor reputation score are taken into account. It is observed from the Fig. 3 that the time taken for recommendation generation increases with the increasing number of professionals. This is because, the medical server needs to compute the similarity score between user's demand vectors and each professional's attribute vectors. And the time required to doctor recommendations based on reputation score is less when compared to user similarity score, because the medical server selects only the doctors with high reputation rate.

DOI: rp-9788770040723.187

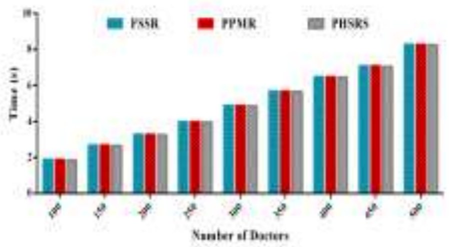

Fig. 3. Running Time Required to Recommend Doctors

Initially, the truth value of several user's feedback from various time period is obtained before computing the the reputation rate of professionals. The running time required for discovering the truth values of existing PPTD [20] and PPMR [19] schemes and the proposed PHSRS scheme is compared and depicted in the Fig. 4 with different number of users. It is clear from the Fig. 4 that the running time consumed by PHSRS is significantly less when compared to the schemes PPTD and PPMR with the increasing number of online users.

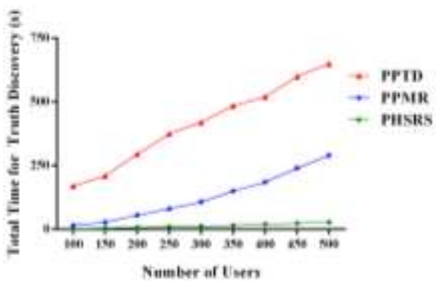

Fig. 4. Comparing the running time required to discover truth values

The running time required to discover truth values increases linearly with the increasing number of online users as seen in Fig. 4. Similarly, Fig. 5 depicts the total time required for calculating the reputation score with different number of truth values obtained from various time periods. It clearly shows that the time taken to compute the reputation rate is comparatively small when increasing the users from 100 to 500, confirming the performance effectiveness of the PHSRS scheme. As a result, as the number of service seekers grows, PHSRS becomes more proficient.

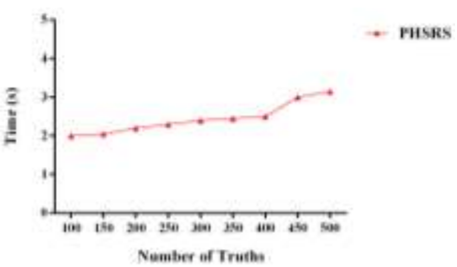

Fig. 5. Time Required to Compute Doctor's Reputation Score

VII. Conclusion

The privacy-preserving online service recommendations for E-healthcare system is proposed to assists users in discovering a appropriate doctor based on their needs, interests and reputation rate of doctors. In comparison to the existing associated online medical recommendations schemes, the proposed PHSRS scheme is more efficient and accurate. In order to achieve secure recommendation services, the privacy-preserving system were developed which prevents the unauthorized user from accessing the user's private data. A thorough performance analysis demonstrates that PHSRS is efficient and can provide reliable online service recommendations.

Abstract **— Understanding Human has been a persistent pursuit of all Human being. Identifying human Emotions is the First step towards the same. We have developed a Transfer learning based Deep Neural Network model which works on multimodal data such as Text, Images, Video and Audio for the purpose of Emotion detection. Out of several emotional Models available in the Literature of psychology we have taken Plutchik wheels of Emotion as the base model to categorize the predicted emotions.**

Keywords — ***Emotion Detection, Plutchik Model, BERT, CNN, Multimodal data, Cognitive Psychology***

I. Introduction

Since time Immortal Understanding Human emotion has been a continued interest of human beings. In recent times there has been tremendous interest among researchers, to understand Human Emotions and their mind-sets at any point of time. There are several Emotional Models in the History of Neuropsychology or Cognitive Psychology. We have considered Plutchik wheels of Emotion due to its representation in the form of Wheel depicting Opposite Emotion on opposite arc of the wheel. In Plutchik Wheel Function Broad basis of classification can be Positive or Negative emotions, verbal or non-verbal, basic or complex [10]. Understanding of these emotions can only be done by observing Multimodal Data. Multimodal [11]data Include data collected from Audio, video, Text, Biomarkers, Brain Signals, Body gestures, Voice, Eye contact, Interpersonal distance(space) and many more. Thus true identification of human emotions is possible only through the study of Multimodal data.

Collecting the multimodal data, its storage, computation, & final Interpretation of the result of Combination of Multimodal data is another challenge, towards human emotion detection process. So usage of machine learning models with transfer learning based deep neural network seems to be one of the good solution to this problem [12,13].

Multi-modal data can present several challenges, including:

i) Integration: Combining multiple data sources and ensuring they are compatible and complement each other can be difficult.

Alignment: Ensuring that the different modalities are aligned in time and space can be a challenge.

ii) Missing data: Some modalities may not be available for certain instances, which can result in missing values and biases in the data.

iii) Heterogeneity: Different modalities can have different characteristics and distributions, which can lead to difficulties in modelling and representation.

iv) Interpretability: Models that integrate multiple modalities can be complex and difficult to interpret.

v) Annotation: Collecting and annotating multi-modal data can be time-consuming and expensive.

Multimodal approaches to emotion detection involve using multiple sources of data to detect emotions in an individual. This can include using information from audio, video, text, physiological signals, and other sources. The following are some common multimodal approaches used for emotion detection:

i) Audio-Visual Emotion Recognition: This approach combines audio and visual cues to detect emotions, such as facial expressions and vocal intonation.

ii) Physiological Emotion Detection: This approach uses physiological signals, such as heart rate and skin conductance, to detect emotions.

iii) Text-based Emotion Recognition: This approach uses natural language processing techniques to analyse text data, such as written or spoken words, to detect emotions.

iv) Hybrid Emotion Detection: This approach combines multiple modalities to achieve better accuracy in emotion detection.

v) These approaches have been used in a variety of applications, including human-computer interaction,

DOI: rp-9788770040723.188

affective computing, and psychology research. The choice of approach depends on the specific requirements of the application and the available data.

Off course Multimodal Data along with Transfer Learning Methods Appear with its own set of Problems of combining the results of Multimodal Data using Multiple Deep Learning Approach [1]. Over all approach to this Problem of Emotion Detection has led to the Following Research Questions:

RQ1). What are the Verbal and Non Verbal Indicators of Emotion Detection?

The Verbal indicators of emotion include:

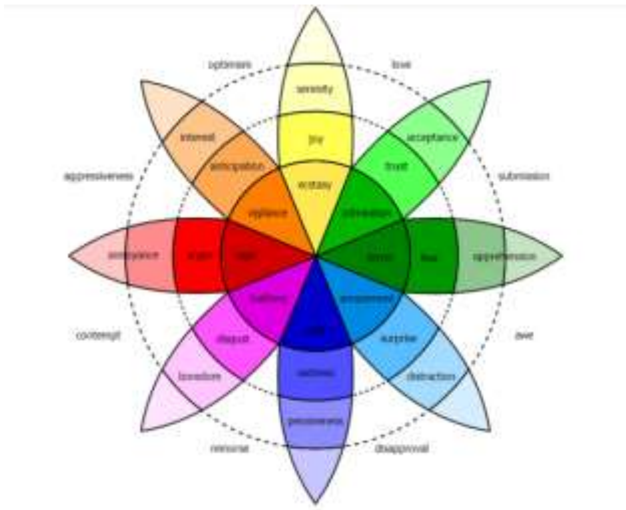
1. Tone of voice: The pitch, volume, and inflection of a person's voice can convey different emotions. For example, a high-pitched, excited tone might indicate happiness, while a low, monotone voice might indicate sadness.
2. Word choice: The words a person chooses and the way they put them together can reveal their emotions. For example, someone might use more negative or angry language when they're feeling frustrated or upset.
3. Speech rate: The speed at which a person speaks can also convey emotions. For example, someone might speak quickly when they're excited or anxious, or slowly when they're sad or tired.
4. Pauses: A person's use of pauses in their speech can reveal their emotions. For example, someone might pause before speaking if they're feeling hesitant or uncertain.

Nonverbal indicators of emotion include:

1. Facial expressions: The way a person's face looks can reveal their emotions. For example, a smile usually indicates happiness, while a scowl usually indicates anger or frustration.
2. Body posture: The way a person holds their body can convey emotions. For example, someone who is happy or relaxed might stand or sit with good posture and open body language, while someone who is anxious or upset might slouch or cross their arms.
3. Gestures: The way a person moves their hands and arms can reveal their emotions. For example, someone who is excited might wave their arms around, while someone who is angry might clench their fists.
4. Eye contact: The way a person looks at others can convey emotions. For example, someone who is happy or confident might maintain strong eye contact, while someone who is anxious or uncertain might avoid eye contact.

It's important to note that these indicators can vary from person to person, and that it's often necessary to consider multiple indicators in order to accurately interpret someone's emotions. During our exploration we came across several theories of Psychology. Following are the Psychological Models Behind the Emotion Detection Model.

1) Shaver [15] out of 135 Emotional words they developed Abstract to concrete Emotional Hierarchy consisting of finally Synthesized to 6 emotions such as sadness, anger, fear, surprise joy, love.
2) OCC Model[16] : consist of 22 Emotion Type , Finally Merging & labelling into six Broad classes: They are the following six kinds of emotion groups and each of them includes several basic emotions: fortune-of-others (happy, resentment, gloating and pity), well-being (joy and distress), attribution (pride, shame, admiration, and reproach), attraction (love and hate), prospect relevance (satisfaction, fear, relief, and disappointment) and well-being/attribution compounds (gratification, remorse, gratitude, and anger)
3) Ekman's [17] emotion model very similar to Shaver's model, who claims to give more discrete measureable 6 classes of Emotions such as anger, fear, disgust, joy, sadness, and surprise
4) Alena [18] proposed measuring each emotion word into values of nine basic emotions: Anger, disgust, fear, guilt, interest, joy, sadness, shame, and surprise
5) Plutchik [29] Model has represented the collection of 32 micro emotions into 8 macro emotions based on Positive and Negative emotions. These are: Joy versus sadness; anger versus fear; trust versus disgust; and surprise versus anticipation. These emotions have been represented in form of "Wheel of Emotions" where positive joy versus sadness and Negative emotions are placed on the opposite sides of the wheels.



\

Fig. 1. Plutchik's wheel of Emotions [29]

We are going to use Plutchik psychological model for our deep learning based emotion detection. This has been chosen because of the discreetness and placement of the positive & negative emotions on the opposite side of the wheel which help us identify the relative radian value of the emotions being considered.

For our current work we have considered following basic type of Data for the Multimodal Approach:

1) Text

DOI: rp-9788770040723.188

2) Audio
3) Video/ Images

RQ2) What are the common retrained model for different types of Emotion Detection Input

2.1 Text Based

1) For Text Input the such as RoBERTa ((Robustly Optimized BERT Approach), popular PreTrained Models are: BERT (Bidirectional Encoder Representations from Transformers) and its variants ALBERT (A Lite BERT).

BERT is a pre-trained language model developed by Google that can be fine-tuned for various natural language processing tasks, including emotion detection.

ALBERT is a pre-trained language model developed by researchers at Google that can be fine-tuned for various natural language processing tasks, including emotion detection.

RoBERTa: RoBERTa is a pre-trained language model developed by researchers at Facebook AI that can be fine-tuned for various natural language processing tasks, including emotion detection.

Other popular LLM (Large Language Model) based pre trained model for NLP based emotion detection are GPT2, ELMo, XLNet

GPT-2: GPT-2 is a pre-trained language model developed by OpenAI that can be fine-tuned for various natural language processing tasks, including emotion detection.

ELMo: ELMo is a pre-trained language model developed by researchers at the University of Washington that can be fine-tuned for various natural language processing tasks, including emotion detection.

XLNet: XLNet is a pre-trained language model developed by researchers at Carnegie Mellon University and Google that can be fine-tuned for various natural language processing tasks, including emotion detection.

2.2 For ECG Signals

There are several pre-trained models that have been developed to work with brain signals, such as electroencephalography (EEG) data, for tasks such as emotion detection, mental workload assessment, and diagnosis of neurological disorders. Here are a few examples:

i) DEAP: DEAP is a pre-trained model developed by researchers at the University of Toronto that can be used to classify emotions based on EEG data. The model was trained on a dataset of EEG recordings collected from 32 participants while they watched emotionally-evocative videos.

ii) BCI-DNN: BCI-DNN is a pre-trained model developed by researchers at the University of Freiburg that can be used to classify mental workload based on EEG data. The model was trained on a dataset of EEG recordings collected from 23 participants while they performed a visual search task under different levels of mental workload.

iii) E-LSTM: E-LSTM is a pre-trained model developed by researchers at the University of California, San Diego that can be used to classify neurological disorders based on EEG data. The model was trained on a dataset of EEG recordings collected from patients with various neurological disorders, including epilepsy, Alzheimer's disease, and Parkinson's disease.

2.3. For Audio or sound data

VGG-Voice: VGG-Voice is a pre-trained model developed by researchers at Oxford University that can be used to classify speaker identities based on voice data. The model was trained on a large dataset of voice recordings and has achieved high accuracy on speaker identification tasks.

i) Deep Speaker: Deep Speaker is a pre-trained model developed by researchers at Baidu that can be used to classify speaker identities based on voice data. The model was trained on a large dataset of voice recordings and has achieved high accuracy on speaker identification tasks.

ii) Audio Set: AudioSet is a pre-trained model developed by researchers at Google that can be used to classify audio events in a wide range of categories, including speech, music, and environmental sounds. The model was trained on a large dataset of audio recordings and has achieved good performance on various audio classification tasks.

iii) SoundNet: SoundNet is a pre-trained model developed by researchers at the University of Cambridge that can be used to classify audio events based on spectral features extracted from raw audio waveforms. The model was trained on a large dataset of audio recordings and has achieved good performance on various audio classification tasks.

2.4. Video/ Facial Expression

i) Facial Action Coding System (FACS) model and the DeepMoji model. Facial Expression Recognition (FER) models: These are pre-trained models that have been specifically developed to classify facial expressions in video data. Examples include the VGG-Face model mentioned earlier, as well as models such as FER2013 and FERPlus. These models typically use convolutional neural networks (CNNs) trained on large datasets of images and videos of facial expressions.

ii) Action Unit (AU) models: These are pre-trained models that have been specifically developed to classify facial action units (AUs) in video data. AUs are specific facial movements that can be used to identify and classify emotions. Examples of AU models include the Facial

iii) Video Classification models: There are also more general pre-trained models that have been developed for video classification tasks, which can potentially be fine-tuned for emotion detection. Examples include models such as 3D ResNets and I3D, which use 3D convolutional neural networks (CNNs) to classify video frames.

DOI: rp-9788770040723.188

RQ:3 common data set needed for handling multimodal data for emotion detection

There are several common datasets that can be used for handling multimodal data for emotion detection. Here are a few examples:

1. AFEW: The Acted Facial Expressions in the Wild (AFEW) dataset is a collection of videos of facial expressions in naturalistic settings. The dataset includes annotations of facial action units (AUs) and basic emotions.
2. EmotionX: The Emotion dataset is a collection of audio, text, and video data annotated with emotions and sentiments. The dataset includes a variety of data sources, such as social media posts, customer service conversations, and movie scripts.
3. MOSI: The Multimodal Opinion Sentiment and Influence (MOSI) dataset is a collection of video and audio data annotated with sentiments and opinions. The dataset includes a variety of data sources, such as political speeches, news articles, and movie reviews.
4. IEMOCAP: The Interactive Emotional Dyadic Motion Capture (IEMOCAP) dataset is a collection of audio, video, and text data annotated with emotions and sentiments. The dataset includes dyadic conversations between two actors in a variety of settings, such as customer service and therapy sessions.

RQ4: Which Approach should we use for Combining the Multimodal Models

There are various approached to Combine the Multimodal Data.

There are several ways to combine multimodal data, depending on the type of data and the task at hand. Some common techniques include:

i) Feature concatenation: This involves concatenating the feature vectors of the different modalities and feeding the resulting concatenated vector into a machine learning model. This is a simple and straightforward approach, but it assumes that the different modalities are independently informative and that their feature spaces have the same dimensionality.

ii) Feature fusion: This involves combining the feature vectors of the different modalities at a higher level, such as by training a fusion model that takes the feature vectors as input and produces a fused representation. The fused representation can then be used as input to a downstream task-specific model. This approach allows for more complex interactions between the modalities but requires more data and computational resources.

iii) Multi-task learning: This involves training a single model to perform multiple tasks, where each task is associated with a different modality. This can be useful when the modalities are related and when the shared representations learned by the model can improve performance on all tasks.

iv) Attention mechanism: Attention mechanisms allow the model to selectively focus on certain parts of the input data, which can be particularly useful when the different modalities contain complementary information. Attention mechanisms can be used as a form of feature fusion, where the attention weights learned by the model indicate the importance of each modality for a given task.

v) Generative models: Some multimodal tasks such as image captioning, text-to-speech, etc. can benefit from using Generative models such as GANs, VAEs etc. to generate one modality from another.

Our Process Model is as follows: Live data i.e., Audio, Video & Text data of an individual is collected and passed through the respective pre-trained model. Finally, 8 basic emotions according to Platchik model is predicted.

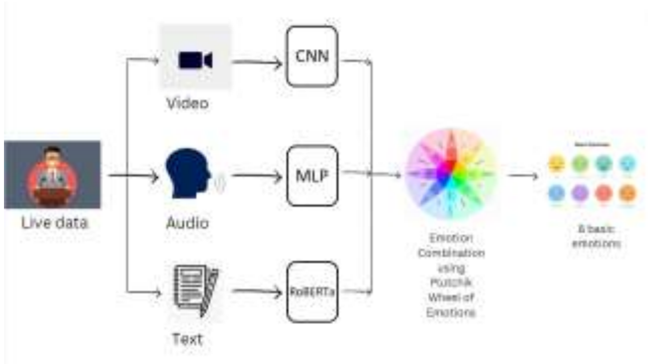


Fig. 2: Our Process Flow Model

Figure3: Pipeline Diagram of the various stages of Emotion Detection in our Model

Input Data Block	Transfer Learning Block	Combining the output predicted emotion of individual TL model to Final Classifier(SVM/ DT/Ensemble)	Final Emotion Detection Block

$E_{6Disgust}$
$E_{7Anticipation}$
E_{8Fear}

Collecting input from various sources of data such as Image, Voice, Physiological data (such as ECG,), Pass it through Individual pretrained Neural network (CNN or and do fine Tuning of parameters at the Output stage of Data Through the Network.)

V. Conclusion

In this work we have considered one of the BERT refined Model called Distill BERT. Distill BERT is smaller, faster, cheaper and lighter version of BERT for text, for video and image popular pre - trained models such as CNN with VGG16 have been used. For acoustic data we are using Librosa Python Library and finally not early but late combination of various model is being done. Final different type of emotions detected is based on Platchik's model ie "wheel of Emotion Model". Future scope of the work can be towards transformer/ Attention mechanism/ (Product Comparison) ie finding Common vector space & Reducing Heterogeneity Gap

***Abstract*—Covid-19, the most deadly word in recent years which worst hit the entire world, is still prevailing as a variant of concern. As the transmissibility of the virus is high, a quick and efficient approach to detect the presence of COVID and to give medical attention to those patients is of paramount importance. The research work proposes an effective deep neural network approach to quantify the severity score of COVID-19 infection from CT Lung images. Leveraging the Computer Vision techniques, semantic segmentation (SegNet) was applied to CT images to extract the lungs. Subsequently, a deep convolutional Encoder-Decoder Architecture was developed to assess the severity score of lung infection. Furthermore, to be well-balanced in accuracy and computational speed, various hyper parameters were investigated to build the effectual model. Evidently, as the severity classification (Mild, Moderate, and Severe, Critical) is preceded by lung extraction, the proposed framework for GGO segmentation demonstrates the ability to generate results with state-of-the-art segmentation accuracy of 96% and prediction accuracy of 98.9%.**

Graphical Abstract

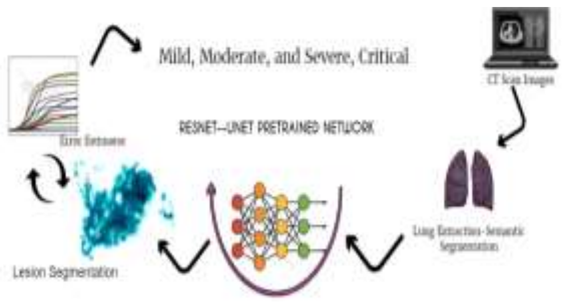

Fig.1. RESPIRONET: COVID -19 Severity Prediction Model

I. Introduction

The European Center for Disease Prevention and Control reported a total of approximately 289 million covid cases and around 5.4 million reported deaths worldwide since the start of 2022. [27].The deadly virus transcended at an unprecedented speed, overwhelming the health care support system. This necessitates an efficient triage system to quantify the severity score of COVID-19. Initially, the virus presence is confirmed with a positive reverse transcription-polymerase chain reaction test with oral and nasopharyngeal swab samples. The insufficient viral load in the swab samples decreased the sensitivity of the test down to 60 to70 %. This inefficiency during the earlier stages of the infection can be addressed through Radiology tests. Radiological studies have investigated different modalities like ultrasound, chest x-ray, or positron emission tomography/computed tomography (PET/CT) scan. The Radiological Society of North America, in their research journal 'Radiology', highlighted the importance of CT imaging for disease detection. They confirmed that the images are key components for the disease diagnosis. The clinical features of 41 patients initially admitted in Wuhan had abnormalities on their CT scan images

CT scan images have manifested to be more effective for the diagnosis, to determine the severity, and to guide the treatment procedure. The severity of Covid19 can be mild, moderate, or severe. The radiographic evidence is absent for mild cases but is significant for moderate and severe infections. Recent studies on biomedical computer vision have witnessed a considerable rise in the use of Convolutional Neural Network (CNN) and it has substantiated to be the best performer for skin lesion classification, breast cancer detection, brain tumor detection and Tuberculosis detection. In this context, our research study presents an efficient model by exploiting the variants of the CNN to identify and quantify the CT Lung images to isolate critical patients.

II. Related Work

COVID-19 disease was declared a global pandemic, which negatively impacted human life in many aspects. Research work on COVID-19 is being successfully carried out in many directions. TB screening, lung cancer diagnosis and, lung nodule detection, are other kinds of lung-based diseases, but covid-19 is something different as well as so easy to spread over the humans. Doctors identify the morphological patterns of the lesions in the lungs to predict COVID using the Chest scans such as X-rays and Computer tomography (CT) scans [8]. Classification, object identification, and picture segmentation are few computer vision applications where ML and DL approaches have demonstrated ground-breaking performance. [1]. Enormous studies are conducted on how to spot COVID-19 disease using CT scan images and chest X-ray images. Many research works on CT scan-based diagnosis are conducted and published in international journals.[2]. Rahman et al. proposed a system to contain the spread of COVID-19 by performing face mask detection in a smart city [3]. Harmon et al. [4] trained and validated a series of deep learning networks. Wang et al. [6] employed a deep regression framework for automatic pneumonia identification by integrating clinical information like age, gender, past medical history, etc., with the CT scan images. Visual features are extracted from CT scan images using RNN (Recurrent Neural Network) and ResNet50. Generally, clinical details like fever, cough, and difficulty in breathing are collected from the patients. They are analyzed together with the demographic features like age and gender using LSTM (Long Short Term Memory). In the end, a regression framework was enrolled to classify the suspected patient as Community-acquired pneumonia (CAP) or not [1]. Qiblawey et al. proposed a framework and evaluated over 900 clinical cases and achieved remarkable accuracy level. In line with that Mei et al. [5] proposed a mixed AI algorithm that combines clinical data with the results of a chest CT. To differentiate COVID-19 patients from non-COVID patients, clinical indicators such as fever, coughing, irregular breathing, and laboratory testing are used. The joint model achieved high discriminative performance with 0.92 area under the curve (AUC) outperforming senior radiologists. The potential pitfall of the combined system is the availability of clinical information when a huge number of patients are waiting to be diagnosed, moreover, this method is not able to show the infected area of the lung [1]. Pedro Silva et al.[7] proposed a model for the detection of COVID-19 patterns in CT images namely Efficient vidNet. Soares et al. [8] made a public repository of CT scans dataset, consisting of 2482 CT scans taken from hospitals in the city of Sao Paulo, Brazil. They have reported an accuracy, sensitivity, and positive predictive value of 97.38%, 95.53%, and 99.16%, respectively.

Following the monumental victory of deep learning techniques and its applications in medical image analysis, researchers have used radiology reports such as CT-scans and x-rays to detect COVID-19 [9]. CNN was utilized by Chowdhury et al. [10] to create their diagnosis model from chest x-rays. More number of research work was carried out based on pre-trained networks that were used to diagnose COVID-19. [11–13] used ResNet and obtained accuracies of 96%. Li et al [12] used DenseNet121 on X-ray images and achieved an 88% accuracy with AUC score of 0.97. A lesion identification approach was proposed by Zhou et al. [13] for estimating COVID-19 infection areas from the chest CT scans. Rahaman et al [14] examined 15 various pre-trained CNN models and found that VGG-19 had the highest classification accuracy at 89.3%. InceptionResnetV2, DenseNet201, Resnet50, MobilenetV2, InceptionV3, VGG16, and VGG19 were employed by Asnaoui and Chawki [15]. The highest accuracy of 92.18% was obtained using InceptionResnetV2. Wu et al [16] implemented multiple CNN models to categorize COVID-positive individuals from CT scan images. A 3D deep CNN (DeCovNET) was proposed by Wang et al [17] to detect COVID-19. He et al [18] introduced a small dataset of lung images in CT scans and put forward an approach named Self-Trans i.e. self-supervised learning with transfer learning.

III. Motivation

Although the literature shows promising results, there is still scope for improvement in predicting the severity of COVID. This work aims to build a severity prediction model that employs pixel-wise labeling a.k.a semantic segmentation to extract the lungs from the CT images. The lung extracted is further semantically segmented to get the Ground Glass Opacity (GGO), a hazy, white-flecked pattern visible on lung CT scans that indicates increased density. The segmented lesion is used to assess the severity of infected lungs. This gives a deeper understanding of the radiology images in the lowest granule level.

The remainder of the paper is organized thus: Section 2 details the dataset used to conduct the study. The proposed methodology adopted is delineated in Section 3. Section 4 exhibits the experimental setup and results obtained. Section 5 tabulates the extensive set of investigations done on various hyper parameters to optimize the model, along with the discussions and analysis. Finally, the concluding remarks with limitations are drawn in Section 6.

Database Used

SARS-CoV-2 CT scan dataset [*Soares, E.; Angelov, P.; Biaso, S.; Froes, M.H.; Abe, D.K. SARS-CoV-2 CT-scan dataset: A large dataset of real patients CT scans for SARS-CoV-2 identification. medRxiv 2020. [CrossRef]*] was used in this research for Covid-19 severity prediction. The dataset comprises 1252 CT image positive samples and 1230 negative samples for SARS- CoV-2 prediction. As the CT image features could confidently prove the existence of Covid, this repository is made public to encourage research contributions to address Covid detection and treatment. The images are collected from the patients of hospitals from Sau Paulo, Brazil.

IV. PROPOSED METHODOLOGY

We present a simple yet mighty COVID Prediction Framework–RESPIRONET illustrated in Fig.3. The proposed system comprises three phases. The first stage of the work builds a custom SegNet model using the semantically labeled CT images. A great deal of attention was made to label the pixels using the Image Labeller App to generate the ground truth. This sets the way to take out the Region of Interest (Lungs) from the CT images using the lung mask generated. The extracted lungs are further semantically labeled pixel-wise. Stage 2 employs a U-Net Architecture to segment the Ground Glass Opacities (GGO, from now on). Transfer learning from a pre-trained network was adapted on the encoder layers of UNET with Resnet18 weights to build the segmentation networks. The lesion mask generated from stage 2 helps to classify COVID from Non-COVID images. Stage 3 uses the segmented lesions to predict the severity score of the infection as MILD or SEVERE or MODERATE or CRITICAL

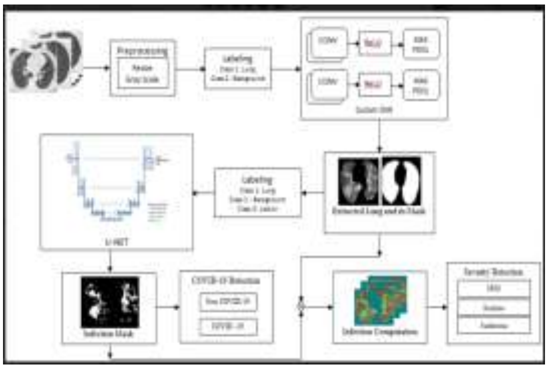

Fig.3. RESPIRONET Framework for COVID Severity Prediction

Preliminary Steps - Image Preprocessing

Data quality being a priority concern for deep learning models, grayscale conversion and image resizing for CNN were applied to the dataset. The CT lung images were converted to grayscale images that contain only brightness information, thereby reducing the processing time. All input images were resized to 256*256 to feed CNN with a unified dimension. In addition, to perform Image Enhancement, Contrast limited adaptive histogram equalization (CLAHE) image enhancement was tried out to improve the local contrast of the images.

Lung Extraction using Custom SegNet

To emerge with an answer to the question “What is in the image? And where it is located? “in Biomedical images, Semantic segmentation was exploited. Semantic Segmentation is the process of assigning each pixel in a picture a class that corresponds to the thing it is representing. This dense prediction returns the feature map that contains the class label represented as an integer. The SegNet CNN architecture for lung segmentation consists of an encoder path and decoder path terminated by a pixel classification layer. The Encoder path performs convolutions using the filters and generates the feature maps. The Decoder path performs upsampling of the feature maps from the encoder. The final high dimensional feature map is fed to the softmax classification layer. Each pixel is labeled with the class corresponding to the highest probability. The proposed custom SegNet CNN model was crafted with Filter size=7, the number of conv layers=3, followed by Batch Normalization, RELU, and max pooling in each block. The best hyper parameters were chosen by running a Bayesian Optimizer on a set of hyper parameter values. Fig 4 apparently shows that the segmentation network works best when the Kernel filter size for the Convolution layer is set to 7. The outcome of the custom SegNet Model for Lung Segmentation is presented in Fig: 6. The lungs and background are segmented and shown in discriminating colors.

Bayesian Hyper parameter Optimization

To build this effective custom segmentation model for lung extraction, Bayesian Hyper parameter Optimization was experimented with. Bayesian Optimization works by building a probability model mapping the hyper parameter values to the objective function. The objective function is used to find the most suited hyper parameters to evaluate the true objective function.

$$x^*=\arg\min f(x) \tag{1}$$

Where x* is the set of hyper parameter values that gives the lowest objective scores like RMSE. The most promising set of hyper parameter values is estimated in a very short time. The best-suited hyper parameters were used to construct the segmentation model. Fig 5 lists the best suited hyper parameter values like MaxEpochs=100; MiniBatchSize=64; Learning Rate=1e-3; Optimizer = sgdm; No. of Layers = 3, Filter Size = 7.

DOI: rp-9788770040723.189

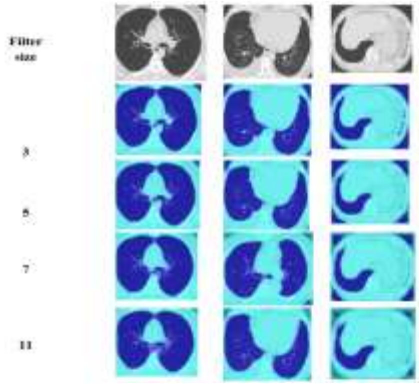

Fig.4. Visual Comparison of segmentation by varying the Filter Size

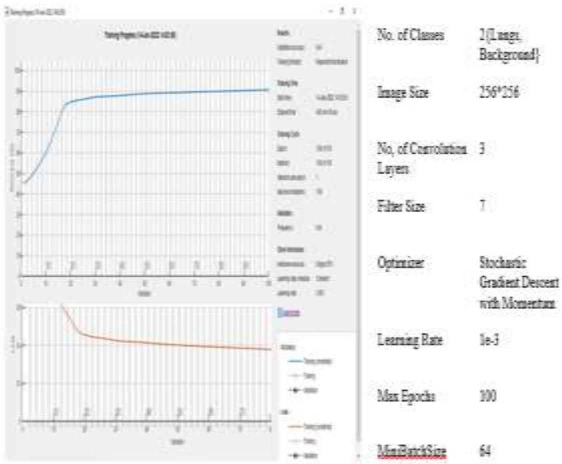

Fig.5. SegNet for Lung Extraction- Training Progress and Bayesian Hyper parameter Optimization

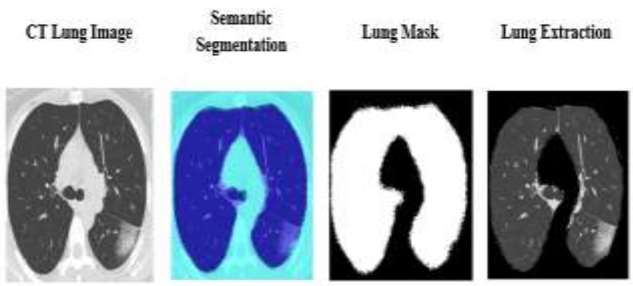

Fig. 6. Phase 1: Lung Extraction Using Custom SegNet Model with the Optimized Hyperparameters

Covid Lesion Segmentation using UNET

The second stage of the proposed work aims to segment the GGO areas in the CT scan images. U-Net is a segmentation network that has performed exceedingly well in biomedical image segmentation. The specialty of the network is that it can outperform other segmentation networks by using only very few images. These highlighted features of the UNET architecture makes it a viable alternative for other CNN architectures. U-net is an encoder-decoder architecture that classifies each pixel of the image and also projects the discriminative features learned at the pixel space. The first half of the UNET architecture called the Contracting path is the Encoder (Fig.7). Usually, it is a pre-trained classification network like VGG or ResNet that constitutes of convolution blocks followed by a max pool layer to encode the input image into feature representations at multiple different levels. In this proposed work, we have used RESNET-18 in the contracting path of the U-Net architecture and performed transfer learning. It saves huge efforts required to re-invent the wheel and transfers the weights learned to the problem at hand. The reason for using ResNet is that it is considerably more deeply nested, but because global average pooling is used, the model size is actually much lower. It also tackles the vanishing gradient problem. The second half of the architecture also called as Expanding path is the decoder. The goal is to semantically project the discriminative features learned by the encoder onto the high resolution pixel space to get a dense classification. The decoder consists of upsampling and Skip Connections followed by regular convolution operations.

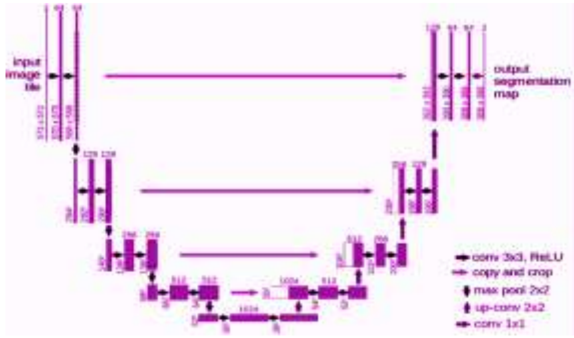

Fig.7. U-Net Architecture - Image Source [19]

Covid Severity Prediction

The disease transmissibility rate of Covid 19 is rapid causing a great challenge to the frontline workers. The limitations in life support equipment took the last breath of many lives. Severity prediction is crucial to categorize the patients in different levels of containment zones. Patients in critical condition can be admitted to Intensive Care Units and be given utmost attention. The final phase of this research work focuses on severity prediction. Severity Score Calculation was performed as outlined in Fig.8.

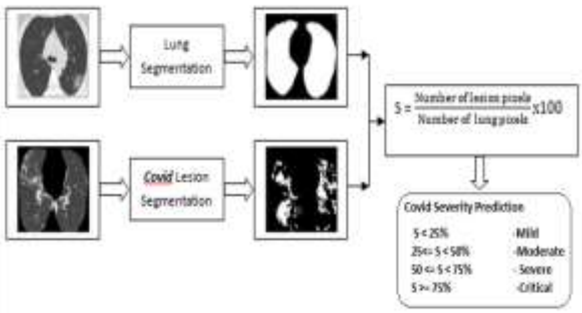

Fig.8. Phase 3-Covid Severity Range Prediction

Experimental Setup

Implementation of the Classification and the segmentation models were done implemented using Tensor Flow and Keras API with Python 3.7 on Intel® Core TM i7-7500U CPU @2.70Ghz,2901 MHz, and 64 GB RAM, with an 8-GB NVIDIA® card. To perform

International Conference on Recent Trends in Data Science and its Applications

regularization and prevent over fitting during the training phase, a callback routine that performs early stopping was incorporated. The training will end abruptly if there is no change in the validation loss for the specified number of epochs.

V. Results and Discussion

We have used 200 train images (100 +ve samples and 100 -ve samples) and 60 images to test the Resnet-U-Net model. Clearly, the model is built with balanced class samples and Accuracy is chosen as the Evaluation metrics. We have achieved a validation loss of 0.168 and an segmentation accuracy of 96% when trained on 200 images for 30 epochs. Table 1 provides the training progress and tuned hyper-parameters results for the lung and lesion segmentation models. Table 2 exhibits the learning curve during the model training phase. It is perceived from the curves that, plot (g) has the most consistent and persistent curves that delivers the highest training and validation accuracy. Taking together as in Table 3, the findings suggest that the proposed framework proves to be robust in Covid Severity Range Prediction.

Comparison with prior work on COVID Classification

We compared our proposed methodology with other similar approaches on COVID-19 classification from the literature and the results are clearly furnished in Table 4. Jin et al. [21] adopted a 2D CNN for segmentation of CT slices and trained a model for Covid-19 or normal classification. They investigated two public datasets LIDC-IDRI [20] and ILD-HUG [22] together with 496 positive and 260 negative samples from Wuhan Union Hospital. The system achieved an accuracy of around 97.9%. Singh et al. [23] fabricated a CNN based COVID-19 prediction model on multi-objective differential evolution. The resulted model could outperform the ANN-based models. Ahuja et.al [24] enhanced the performance of classification with Data Augmentation techniques and evaluated the pretrained models ResNets 18, 50, 101, and Squeeze Net for classifications. The results with a 0.99 AUC score prove the efficacy of ResNet18 compared to other models. Barstugan et al. [25] tried various statistical and wavelet-based feature extraction methods and classification by Support Vector Machine. GLSZM coupled with SVM yielded an accuracy of 99.68 %. Wang et al. [26] performed lung region extraction with pretrained UNet. The lung images of patients admitted to Renmin Hospital, China. They segmented the image with UNet ++ for Covid prediction with an accuracy of 92.5 %.

TABLE 4 COMPARISON WITH OTHER PRIOR WORKS ON COVID CLASSIFICATION

Ref.	Image Samples	Method	Accuracy
Jin et al. [23]	496 +ive, 1385 -ive	CNN	97.91 %
Singh et al. [25]	N/A	CNN	90%
Ahuja et.al [26]	349 +ive,397 -ive	ResNets 18, 50, 101 ane SqueezeNet	99.65%
Barstugan et al. [27]	53 +ive , 97 others	Feature Extraction coupled with SVM	98.7%
Wang et al. [28]	313 +ive, 229 -ive	UNET++	98.85%
RESPIRONET (Proposed Method)	**100 +ve ,100 -ve**	**Custom CNN (Lung Segmentation) and ResNet-UNET(Lesion Segmentation)**	**98.9 %**

Comparison with prior works on COVID segmentation

For further analysis of the outcome, the proposed framework is compared with other related approaches for Covid 19 segmentation and the results are tabulated in Table 5. Ma et al [35] adopted standard UNET 20 3D CT slices and attained 0.608 accuracies. Dominic et. al [38] further enhanced the approach on the same dataset using an inverted distribution on k-fold-cross-validation. Yan et al [37] designed a unique architecture for COVID segmentation and achieved better results around 0.73 accuracies. Saood et al [36] combined SegNet and U-Net. They trained the network nine times using different hyper parameters and obtained an accuracy of 0.749 %. Qiu et al [34] developed a lightweight CNN with limited parameters of 83K that would be easy for deployment in real-time.

TABLE 5 COMPARISON WITH OTHER PRIOR WORKS ON COVID SEGMENTATION

Ref.	Method	Training Dataset (Sample size)	Validation (Sample size)	Validation Accuracy
Amyar et. al[28]	U-Net (Standard)	1219	150	0.78
Fan et. al [29]	Inf- Net (Attention U-Net)	1650	50	0.76

Dominik et. al[35]	Standard U-Net	20	20	0.804
RESPIRONET	**ResNet U-Net**	**200**	**60**	**0.960**

VI. CONCLUSION

In this research contribution, a deep neural network architecture RESPIRONET was developed. The model is carefully crafted based on full convolution architecture. Initially, the lung extraction segmentation model was built through a custom SegNet. Bayesian Optimization was used to search for the optimum hyper parameters based on 5-fold cross-validation. Subsequently, an improved and efficient U-NET model was built for GGO segmentation. We have used Resnet18 as the pre-training model in the encoder path of the U-NET architecture, thus enhancing the prediction results through transfer learning. Furthermore, dilated kernels were used for convolutions to improve the prediction accuracy. The framework also helps to assess the severity range of COVID as mild or moderate or severe or critical. We have achieved good segmentation results on the SARS-CoV-2 CT dataset. The framework predicts covid severity with the segmentation accuracy of 98.9% from CT scan images. Though significant improvements are obtained with the proposed model, larger and more diversified datasets are needed to build a generalized model that fits the realistic scenario. Cross dataset analysis, integrating the clinical parameters with the imaging outcomes, and scrutinizing the lung region hierarchy can be considered to be the future expansion of the work.

***Abstract*—Food is a necessary and the key to survival of mankind and hence it is always is huge demand. As much as the need for the food is high, the supply to it contrasts with it. This might be because of the number of reasons among which one of the reasons is the failure of crops and the plants in the agricultural field. Thus, the necessity to save the plants from dying is increased and the way is to detect the defects on an early stage and thus the prevention could also be done in order. Latest technology in the field of Information Technology, has proved to be an outstanding benefit not only in our desired area of agriculture but also in applied in many other areas. In this article, we use transfer learning-based models to classify images of diseased Potato plant leaves into three types of plant diseases based on their defect using a Plant Village dataset. In this project, two pre-trained models ResNet50 and MobileNet are used and discovered that MobilNet performs better on training data with accuracy of 93%.**

***Keywords*—Potato disease, potato leaves, transfer learning, deep learning, CNN, Artificial Intelligence, resnet, mobilenet**

I. Introduction

Food is important to mankind and the demand for food is increased but the cultivation and production of food is being at risk by so many factors. Such factors include diseases in the crops and plants. Because of this, farmers face the consequences being at risk to losing their livelihood by trying to save the plants and their farming with their financial resources. Hence the technology's help is needed to detect the diseases in plants or people should consider to take food by importing than from the locals which will serve as a pain in both financial and health wise. The technology help is needed because some diseases in plants and the leaves are not recognizable to the human eye. Hence images of the diseased plants are considered as data for the mentioned problem statement and with the help of deep learning the diseases are recognized. Here the plant of interest is potato and diseases of potato are tried to be recognized.

A. Scope

Agriculture is one of the backbones of our country and it provides key benefits for one to lead one's life. It also provides many opportunities such as jobs to the population of the country. The major risk that are faced by farmers are the plant diseases because the diseased plant will also ruin the healthy plant by spreading. Hence the technology's help is needed to detect the diseases in plants or people should consider to take food by importing than from the locals which will serve as a pain in both financial and health wise. The technology help is needed because some diseases in plants and the leaves are not recognizable to the human eye. With all these problems one side, agriculture is not picked by many as personal choice as a decent employment and many prefer the Desk jobs than the jobs on the field. Hence, the population in the field of Agriculture is less. The changes in the country now a days has led to decent paying for IT jobs and agriculture and the jobs in any field work is not greatly paying. Hence the technology has taken the upper hand and has decided to solved the agriculture issue. The main goal of the project is to identify not only diseased but what kind of diseases the plant might have so when it passed to the next phase or the next team, it will be easier to take necessary action. The reason why this needs the help of today's technology is because trying to identify a disease from a plant itself is tedious process. If the same must be done for an entire land or even more, the process would become time consuming. Not only that, but also some of the diseases in plants are not seen to the human eye and even if it does, sometimes it can go beyond rightly recognizable. One technology that can meet the earlier mentioned requirements today would be Computer vision. The computer vision helps agriculture to save plants by rightly recognizing the disease and it would save a lot of time and will lead to save farmers' lives and henceforth saving the livelihood of farmers and the population of the country. automated system which can help farmers to identify plant disease through computer vision would help farmers to save disease through computer vision, would help farmers to save time, plant, economy as well as all the efforts put by the farmers will not go in vain. Hence, a deep learning model is proposed in this project and few transfer learning models also to automate the process of recognizing the diseases in potato plant.

B. Methods

- *Deep learning*

Prior to the development of Convolutional Neural Network, the image recognition was being backed up on the traditional algorithms. But for the image processing, based on what the model is going to recognize the features must be recognized as per the requirement. But this process may be seen as a challenge due to the fact of defining features for different image types. A Model may study the feature and its representations on behalf of this which leads to deep learning representing the features for image on several levels of representation.

This project utilizes the neural network to recognize plant leaf images, and the pre-trained models are used to evaluate the performance based on the comparison of accuracy.

- *Transfer learning*

In deep learning, the popular one is the transfer learning due to the enormous number of resources requires to train these models. The TL is not exclusively related to problems

DOI: rp-9788770040723.190

such as multi-tasking. When a model is trained on an experiment and the same model is re-assigned to different task is done using the transfer learning. The learning is improved in the new experiment based on the already acquired knowledge previously from the experiment i.e., it is transferred and hence the transfer learning. The former network is trained on a specific dataset for e.g., the imagenet and for the dataset related tasks. Later the same network is re-framed to be fed to the next similar experiment. The network cannot be applied to the next experiment if it does not find itself similar it. The TL works well with the image as the data also. For such kind of tasks, it is very usual to use the pre-trained model for huge image recognizing projects. Usually, the TL can be applied on tasks where the network needs to save time and do a decent performance at the same time. As mentioned earlier, it is ideal when a task that is relevant to the formed network with abundant data is found. Based on Transfer Learning for the precise diagnosis of plant diseases, CNN model was developed. The dataset here used is called the Plant Village and it consists of 2152 different photos and 66 other different images for validating and it is holding 3 unique directories of potatoes' leaf images. The focus is mainly here on resnet 50 and mobile net which are the pre-trained models.

II. Literature Study

Numerous studies on image categorization and identification have been conducted. The author and the researcher in [1], used Maple and Hydrangea leaves with two different types of leaf disease were pre-processed, and their features were then extracted in order to be analysed. In order to segment the leaf into three parts—the infected, the leaf part, and the background part K-means clustering and ANN were utilized. The leaves were then categorized according to their disease.

The authors in [2], have concentrated on fine-tuning several convolutional neural network parameters for deep learning in order to classify normal images of cat and dog images. An ANN binary classifier is used for classification after the convolutional neural network is made to learn features. The network's performance is improved by using several levels of refinement, and this approach yields the best classification accuracy of 88.31%.

In the Reference [3], utilised a convolutional network of neural form to categorise pictures of food. Deep Learning is used to categorise 16643 food photos into different food categories. In the experiment, accuracy of 92.86% is attained.

M. Shaha et al. [4], done an image classification using pre-trained model by adjusting the VGG19 model that has already been trained. On two separate picture datasets, CalTech256 and GHIM10K, the model's performance is compared with two transfer learning models termed VGG16 and AlexNet as well as a hybrid Convolution Neural Network (CNN) model with an SVM as a classifier. According to the study's findings, VGG19 outperformed the other three models.

In the Reference [5], using a transfer learning model, the CNN model that is applying transfer learning to classify a collection of HEp-2 cell images. The photos in the dataset are divided into six categories primarily on their staining patterns only after model first applies feature selection to identify the key features that best represent them. They demonstrate at the end of the study that their CNN algorithm outperformed the other 4 algorithms created by earlier researchers.

Sindhuja et al. [6] described a fast, cost effective and reliable health monitoring sensor. To monitor plant health and diseases, they represented various technologies that have been used to detect the plant diseases.

Waldchen et al [7] released a review on the use of image processing techniques for plant disease diagnosis. Nearly 120 research articles were examined in their review, in addition to a detailed explanation of datasets.

Erika et al. [8] suggested a four-layer CNN model that incorporates seven different illnesses and healthy cucumber leaves. They noted the excellent and poor image quality and discovered an average accuracy of 82.3%.

Powara et al in [9] contrasted a few manually created feature descriptor strategies with CNN models. Their comparison includes HOG-BOW combined with SVM and MLP classifiers, as well as HOG-based characteristics mixed with KNN and kNearest Neighbors (HOG). Those models were contrasted with those created entirely, AlexNet and GoogleNet.

Piyush et al. [10] segmented a specific region of interest in the photographs of plants using color-based procedures. In this paper, illness spots were found using the YcbCr and CIELB colour models.

In the Reference [11], Some textural characteristics were discovered, including fatigue, uniformity, and coherence. They used photos to determine the mixture of dark and white level form, connected it to colour choice, and found illnesses of corn leaves.

Sachin D[12] used a neural network as a classifier with back propagation before using few segmentation techniques to gather features from images of leaves.

Authors in [13] set of leaf images taken as testbed and the critical elements make up the suggested framework, which is based on image processing. The K-Means technique is being used to segment the images at hand; after segmentation, the segmented images are then run through a neural network that has already been trained.

Melike et al. [14] CNN was designed as a tool for and extracting features automatically classifying. For study on plant leaf diseases, visual information is frequently used. In the approach, three channel components are subjected to the filters. The resulting feature vector from the convolutional component was input into the LVQ to train the network.

Authors in [15] applied the option adapted to determine the type of disease for categorizing grape leaves is the inception v3 architecture. Even while mobilenet provides accuracy comparable to that of inception v3, the model still overfit the provided dataset. The Adam optimizer was used here.

III. Proposed Methodology

A. System proposed

The work flow of the system as shown in Fig 1. The dataset is from Kaggle and is downloaded from there.

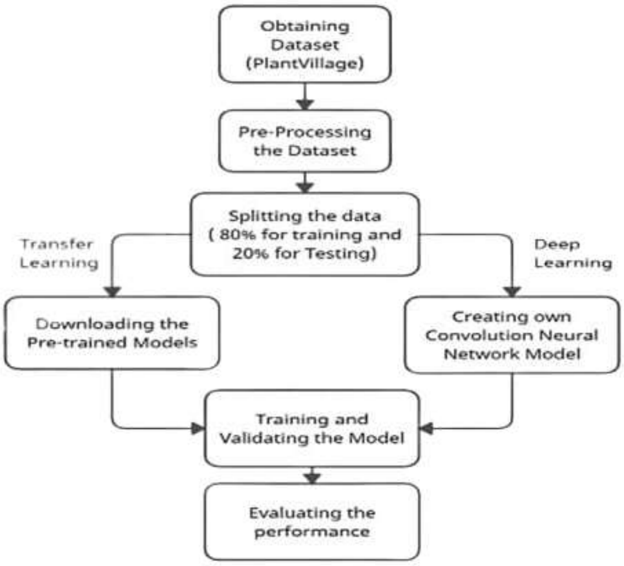

Fig 1. Proposed System Flowchart

The it is processed and removed redundant information. The train test split of the dataset is 80% and 20%.

The data which is clean after the process is given to the pretrained models, these models are already trained with some other dataset such as imagenet so that it can be used for transfer-learning. The deep learning technique is also used in here, which is a CNN model used for feature extraction for training-testing. The moels of pre-trained will be examined for performance with this data.

B. Dataset-taken

54,306 number 256x256 pixel images of Kaggle dataset are taken as the dataset in our experiment for testing-training purpose. And in particularly potato leaf images contains 2152 images which of 1000 from potato-early blight and 1000 from potato-late-blight and 152 from potato-healthy as shown in Table1. Each image is RGB images and which means it is coloured and will have 3 channels such as red, green, blue.

TABLE 1. Total Number of Images in Dataset

DISEASES	NO. OF IMAGES
Early Blight	1000
Late Blight	1000
Healthy	152

C. Dataset pre-processing

To decrease the unwanted data and noise from the data, we do pre-processing and this will make the accuracy increase and speed-up the executing. Data-pre-processing is done with Data-Augmentation, which is getting the different characteristics of the data images and combining it. Rotation, flip, zoom, fill, shear etc are the methods which is applied on every image for augmentation. Library which is used for augmentation is Keras.

- *Augmentation of data*

For getting big accuracy, the deep-neural network will need a lot of data. Sometimes the image sizes will not be enough for this. So, at this kind of places, we will use some data methods like flipping, rotating, zooming, shearing etc. to each image. These techniques will make new set of datasets which will be good for training purposes. It creates a new set of images from the already existing data and this process is called data-augmentation. The images needed for the training is not captured by ourselves. This is already available in public. The meaning of the term augmentation of data means that, different techniques like rotation is applied. Some of the data-augmentation techniques are as, Geometric - transformation, color - space - augmentation, filtering applied to kernel , picture blend, erasing randomly, feature-space-augmentations, adversarial - training, generative-adversarial-network, neural – style - transfer, meta learning. Data augmentation strategies target overfitting at the training dataset, which is the source of the issue. This is done with the expectation that augmentations will allow for the extraction of more data from the original dataset. By data warping or oversampling, these augmentations artificially increase the size of the training dataset. Warping of data augmentation changes the already available images but it will remain the labels. In this technique, the methods are processes like erasing randomly, adversarial-training, colour changes such as Gray and geometric such as rotation, flip etc, and neural-style-transfer. Over samples are added to the training images to get the synthetic styles. The example of synthetic styles is blending of images, augmentation of feature-space, and generative-adversarial-networks. The data augmentation safety is ensured by retaining the labels and hence changing the data content will not affected by it. This process is safe for general image identification tasks such as identifying cat and dog, but this is not a good practice when comes to tasks like digit and signs. In that case, rotation and flip will create meaningless data. For forecasts which is un-certain, the non-labelling technique will be efficient. Post-augmentation labelling is adjusting for this method to ensure this. The label as well as non-label preservation to the data will be giving better performance for the training as well as increase the accuracy in prediction-time.

- *Deep-learning*

This is a sub part of AI which calls artificial intelligence. Artificial-intelligence is the process of making the machine to learn itself and it will be capable of making decisions. Deep-learning is the technique which is under AI which is idea from brain of human and the neurons and learning process of it. There will have neurons like human and will act somewhat similar to them. We have used 2156 images for the deep learning purpose, which is learning the features of each image with neurons. There should be training as well as test data for this because if we use the same data which we have used for the training is taken for the testing as well will not give good accuracy. So that we will split the whole data into training-testing data. The

DOI: rp-9788770040723.190

number of layers in CNN which is used in here is 3. And after that we add 2 maxpooling layer then two dense layers. 128,38 respectively at the first and last. To minimize over-fitting of data, we can add dropouts of 25 percentage and 50 percentage. There must be activation functions to activate the neurons, for this purpose we use softmax as well as relu. The first function used between the layers and the second function used at the last. The total number of epoch used is 20 for training and testing and the batch size is 32.

- *Transfer-learning*

Transfer-learning is the technique which is used for prediction. In this case the model will be initially trained with a particular data and with that knowledge it will be trained to another set of data so that it can predict much efficient than the general convolutional networks. In CNN , the model will be trained from the scratch and it will be built for a particular problem. But in transfer learning, the model can be used for any problem and will be initially trained with some data. And we will mention this data training as weights when we load the pretrained model. Here the initially used dataset is ImageNet. The workflow is in Fig.2.

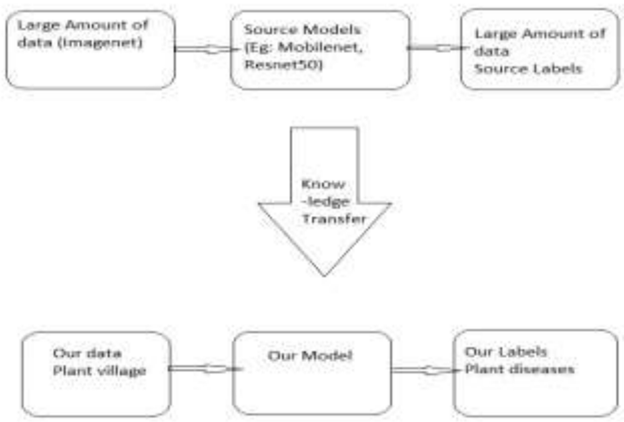

Fig.2. Transfer-Learning

The models for transfer learning is used general are vgg16, vgg19, resnet50 , inceptionv2 etc. Pre-trained models which used here are resnet50 and mobilenet with weight imagenet.

IV. Modules

A. Creation of models

The dataset contains Potato leaves images belonging to 3 different classes as shown in Table.2 with a total of 2156 images of 256x256 pixels were used for training and testing the model. Pre-trained models resnet50 and mobilenet are used as models here and they are pretrained with imagenet data and they are loaded here. Then the data features will be extracted and this will be fed to it.

TABLE 2: Train-Test Split

CLASSES	TRAIN DATA	TEST DATA
Early Blight	805	195
Late Blight	805	195
Healthy	143	35
TOTAL	1669	417

B. CNN

CNN is a method used for machine to understand things like human brain and which is called convolutional neural-network. It will have layers of neurons and the it will identify the features from the raw image. This information will be taken as input and there will be some output. There will be some loss after the output. It will be adjusted by back-propagation. The three layers in CNN are convolutional layer, fully connected layer, pooling layer. Making the model learn from the initial stage is a big task and it makes no more efficient than the pre-trained model. There are many pretrained models generally used, such as alexnet, mobilenet, vgg16, resnet. The data for implementation taken is the Potato images in Plant Village dataset which contains 2156 training images and 20% testing images.

- *Resnet 50*

The common models in transfer learning are resnet50, alexnet, googlenet and vgg. These models behave different with different datasets. Such as the resnet can give 90 percentage or more accuracy with some dataset but will give less accuracy with some other dataset. But the pretrained model which is likely efficient in neural networks is resnet compared to vgg. Vgg have a greater number of layers and will take much time compared to resnet for training. So that we took resnet for the training purpose. But both of them are equally used for transfer learning. The problem arises with the deep neural networks are network-optimization, vanishing of gradient, and also the problem with degrade.The accuracy of detection will be higher with resnet because it uses new-methods.it reduces the problems comes with the deep neural network training, as well as the degrade, saturate of precision. The model resnet which is used in here have fifty layers of neurons.

The loops used here to notate the use of later layer in the current layer in the structure. The reduction and fill out and lowering of gradient of data is the difference between common neural networks and the resnet50. this is because the precision will increase first and the reduce there. The first layer of 64 and kernel of seven into seven, max-pooling layer is three into there. The grayscale layer shown first is 3 layers and they are same in all manner. The next phase has four layers of the same configuration and third one has four identical layers in same. The blue colour loops present in here are the connectors for two different types of layers. The classification is done by the last layer of 38 layers. The fully-connected layers are not used in the model which is used in here.

The images in our dataset will be transformed into 224 and 224 dimension to feed to the model. Data augmentation such as flip, rotate, etc will be done after the resize of images. The model which is used in here is have weights with the imagenet . SGD optimizer is also used in here. For activation softmax activation function is using. We can high the number of types of diseases in here, previously it will not be able to do it. The classifier is created with the help of keras and it will be added to the resnet model. And it will act as the feature extractor. We can change the imagenet

DOI: rp-9788770040723.190

weight to some other one to test the precision of the output. Here we are experimenting which model is good for the dataset. Generally resnet and vgg show a good accuracy.We are comparing resnet and mobilenet here. The accuracy is good for mobilenet compared to resnet.It took lesser time compared to the other one as well as gives good result in training as well as test than the other.

- *Mobilenet*

The pretrained mobile net which is used in here have 2 levels. And they are before the pretraining and after the training with our data images. The first level is loading of pre-trained mobilenet model with imagenet weights. The top layers of the models makes untrainable then for the training.2D global average pooling layer of keras is used for feature transform and the layers of mobilenet is also used along with it. After that the feature vectors got from the images have given to it. The image augmentation output is taken as input and it is fed.

C. *Fine tuning*

We have trained the two models resnet and mobilenet with the plant village dataset of potato images. The training is done with the models with the top layer freeze. So that the top layers will not learn in training. Now the top layer will be unfrozen to make them learn. And, the bottom layers will be frozen. The model will have knowledge of the first training and with that, we will train the model again. Using this technique accuracy will increase compared to the conventional neural network training.

CNN or convolutional neural networks are layer of neurons in which they accept input and process output. They have different layers of neurons. They are convolutional layer, activation, pooling, fully connected, batch normalization, dropout. The convolutional layer sometimes includes the input layer also. The convolutional layer is the important part of the neural network. The input image will be divided into pixels and the input layer will take reach of the pixels and it will do scalar product with the weights assigned to the next layer. This will be fed to the next layer and so on.

Convolutional layer contains kernel or called them filters. These filters will make a feature map, which is nothing but another matrix like structure from the image. Filter size or kernel size is smaller than the image always. If we take a cat image, the nose, whiskers, eyes etc are some properties of that image which can be used to differentiate it from other images. This in the computer sense is called features.

Activation layer such as relu will decide which neuron must be activated. Before the activation, a bias value of each neuron will be added to the weights. So the neurons which are activated will transfer the output.

The pooling layer will conclude the features got from the convolutional layers as feature map. Which is, it will reduce the dimension of the feature map and it will be fed to the fully connected layer. The top layers which are frozen throughout the training are convolutional layer and dense layer. And the last dense layer will only be trainable. This layer will unfreeze then in the fine-tuning phase.

V. RESULTS

The results after train and test of the two models are show in the Table.3. The train and test has done with 10 epoch each. Resnet model gives more accuracy compared to mobilenet in the training time. But the test result is high for mobilenet. The loss rate is high for resnet compared to the other.

TABLE 3: RESULT AFTER TRAINING

Model	Train Accuracy After 10 Epoch	Train Loss After 10 Epoch	Test Accuracy After 10 Epoch	Test Loss After 10 Epoch
ResNet50	0.45	0.41	0.58	0.68
Mobile Net	0.39	0.02	0.89	0.14

The resnet model have a higher size compared to mobilenet of 98mb as well as number of layers. Mobilenet have a depth of 88 layers. The train accuracy of resnet is slowly increasing with the epoch which is higher than the validation. Validation accuracy remains almost steady after the 3rd epoch.

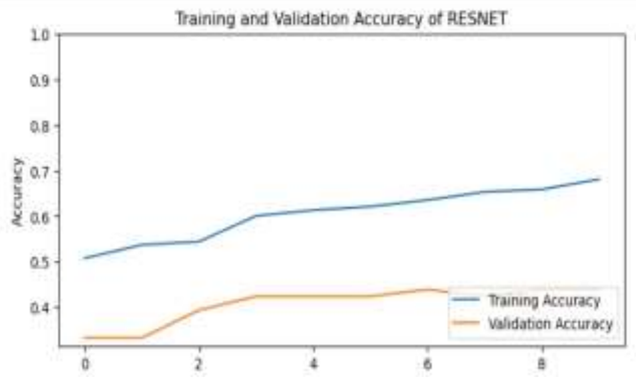

Fig.3 Train and Validation Accuracy ResNet50

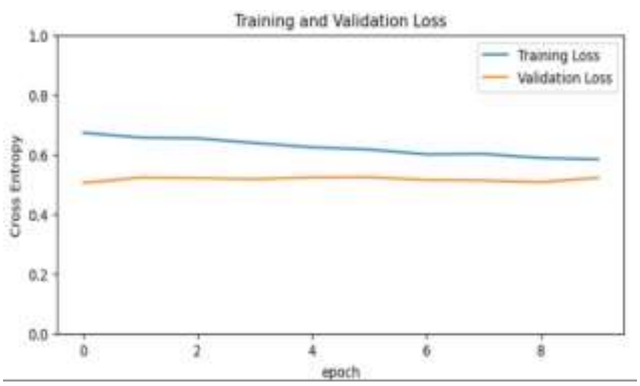

Fig.4 Train and Validation Loss ResNet50

From Fig.3 and Fig.4, it is observed that Train and Validation Accuracy of resnet was in increasing manner from the start. And the final training accuracy was 45% and training loss was 40.1%. The training loss decreased gradually from the start but the validation loss remains steady till the end.

DOI: rp-9788770040723.190

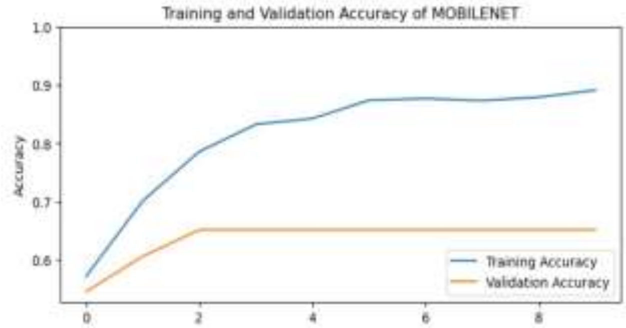

Fig.5 Training and validation accuracy MobileNet

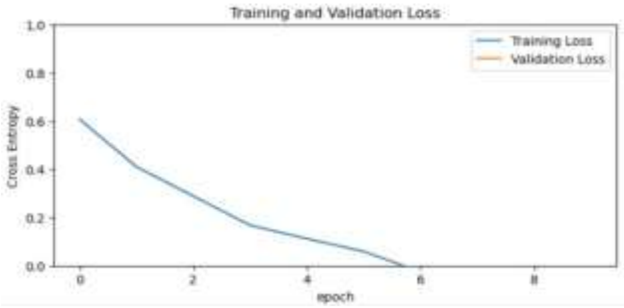

Fig. 6 Training and validation loss MobileNet

Training accuracy and loss for MobileNet is 39% and 2% respectively. Training and validation loss was in gradual decrease as depicted from Fig.5 and Fig 6 together.

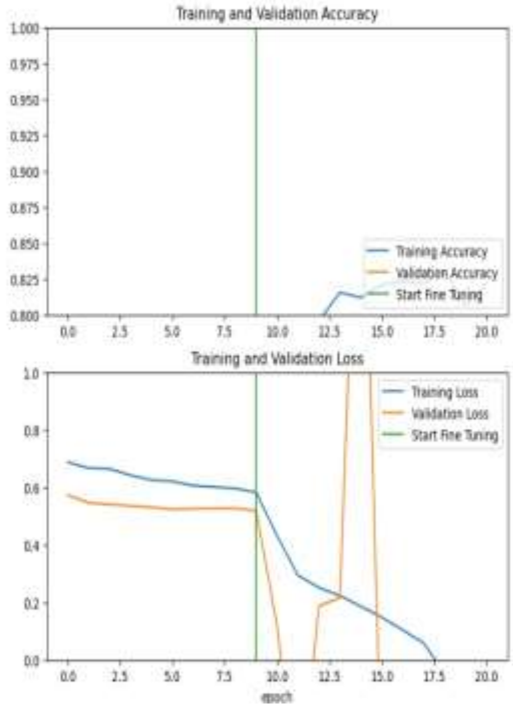

Fig.7 Training accuracy & loss of Resnet Fine-tuning

After finetuning, the accuracy of models has increased than the initial training and shows the results after finetuning. Accuracy of training of resnet has increased beyond 80 % from the 12th epoch. The training loss have decreased after 10th epoch and reduced to zero after 15th epoch is seen from the Fig 7.

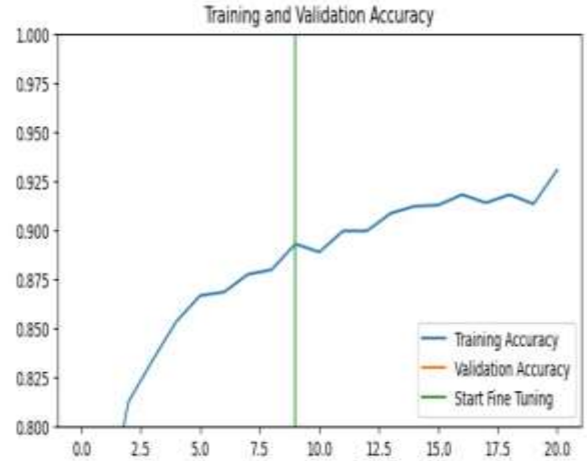

Fig 8 Accuracy of Mobilenet fine-tuning

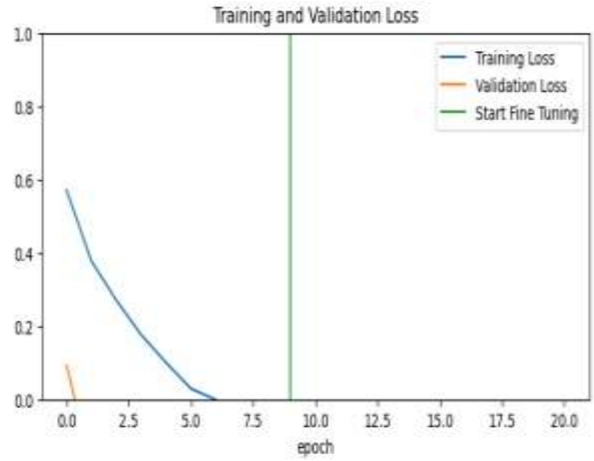

Fig. 9 Loss of Mobilenet Fine-tuning

The Training accuracy of mobilenet increased from the tenth epoch to the end, that is 20th epoch. And the loss has the behaviour of decreasing from the beginning till the end is seen from the Fig 8 and Fog 9.

TABLE 4: RESULT AFTER FINE-TUNING

Model	Train Accuracy	Train Loss	Test Accuracy	Test Loss After
MobileNet	93%	0.09	0.63	0.05
ResNet50	82%	0.02	0.57	0.06

VI. CONCLUSION

The usage of AI is increasing day by day. The agriculture field have also need it the most. Finding the solutions to problems in agriculture such as loss of vegetation with the diseases and the soil degradation with the usage of improper fertilizers needs to end. This can be done with deep learning and machine learning techniques. The precision of the output won't go higher in deep training compared to transfer training. We got accuracy of almost 93 percentage with the mobilent model with the plant village dataset. And also, we compare the two pre-trained models resnet50 and mobilenet with the same dataset. For almost all the images, the models give correct prediction. The farmers who are new to the field will need the system the most.

Abstract—The use of generative models in a variety of natural language processing (NLP) applications has been extensively studied. Document representation learning, which entails encoding a document into a fixed-length vector while maintaining its semantic meaning, is one of the most crucial NLP problems. Recent developments in generative models, particularly those based on variational autoencoders (VAEs) and generative adversarial networks, have led to considerable advancements in learning document representations (GANs). The fact that generative models offer a framework for learning representations together with their uncertainty is one of its main benefits for learning document representations. This is crucial for jobs like document classification, where the classifier's performance can be greatly impacted by the ambiguity in the document representation. Generative models can offer more reliable and accurate representations for downstream tasks by modelling the uncertainty. The most recent developments in generative models for learning document representations, together with its uncertainties, are reviewed in this study. We begin by outlining the fundamental ideas behind generative models, such as VAEs and GANs, and their uses in natural language processing. We then concentrate on the design of the architecture and training of these models for document representation learning. The many methods that uncertainty might be represented in generative models for document representation learning are then covered. In order to model the uncertainty in the latent representation of a document in VAEs, we first introduce the idea of probabilistic latent variable models. The application of GANs to model the uncertainty in the produced document representation is then covered. We also go through current research on the categorization of documents using unsupervised and semi-supervised generative models. We demonstrate how generative models may be employed, particularly in situations when labelled data is sparse, to develop more reliable document representations. We also go through how the classifier's performance may be enhanced by using the uncertainty estimates generated by generative models. Lastly, we discuss some of the difficulties and potential future possibilities in this field. Creating generative models that can learn representations that are easier for people to understand and find meaningful is one of the main problems. Enhancing the scalability of generative models for massive document collections is another difficulty. We also talk about how generative models may be used to other NLP tasks, such text creation and machine translation. In conclusion, this work offers a thorough analysis of recent developments in generative models for learning document representations, including their uncertainties. We anticipate that anyone working in the field of NLP who are interested in employing generative models for document representation learning will find this review to be a valuable resource.

Keywords—Document categorization, variational autoencoders, Bayesian neural networks, uncertainty estimates, generative models, and document representation learning.

1. INTRODUCTION

A growing demand for efficient and effective techniques for analysing and comprehending massive volumes of documents has arisen as a result of the fast expansion of digital data. A potent method for attaining this objective is document representation learning, which entails mapping documents to low-dimensional vector spaces. Due to their capacity to capture the underlying distribution of the data, generative models like topic models and autoencoders have been extensively employed for document representation learning. Although this can restrict their utility in later applications, the majority of extant generative models do not include a measure of uncertainty for the learnt representations.[1]

The idea of embedding uncertainty estimates into generative models for document representation learning has gained popularity in recent years. The potential of uncertainty estimates to enhance the robustness and dependability of downstream applications including document categorization, information retrieval, and recommendation systems serves as the driving force behind this. For activities like anomaly detection and exploratory data analysis, uncertainty estimates can also offer a more detailed view of the underlying data distribution.[2]

We discuss current studies on generative models for document representations that contain uncertainty estimates. We concentrate on variational autoencoders (VAEs) and Bayesian neural networks as two categories of generative models (BNNs). A particular kind of autoencoder known as a VAE uses a probabilistic latent variable model to represent the data's distribution. BNNs are neural networks that employ Bayesian inference to calculate the level of uncertainty associated with the model's parameters. We explain the benefits and drawbacks of these models for learning document representations, and we offer a case study on the use of generative models to the categorization of documents with ambiguous labels.[3]

II. PROCEDURE

The following process is usually used in generative models for learning document representations with uncertainty estimation:[4]

- **Data pre-processing:** To begin, the raw text data must be pre-processed by tokenizing the documents into words, eliminating stop words, and stemming or lemmatizing the remaining words. As a result, the lexicon of terms used to describe the papers becomes distinctive.

DOI: rp-9788770040723.191

- **Model architecture selection:** The decision of which generative model architecture is best for the job is made next. This may entail evaluating how well various models perform on a validation set or applying model selection criteria like the Bayesian information criterion (BIC) or the Akaike information criterion (AIC).
- **Model training:** The model is then trained using the pre-processed data after the model architecture has been chosen. Most frequently, this entails employing Bayesian inference or maximum likelihood estimation (MLE) to optimise the model parameters.
- **Estimating uncertainty:** When the model has been trained, the uncertainty in the learnt representations must be calculated. Many methods, including dropout regularisation, Monte Carlo dropout, and variational inference, can be used to do this. A distribution of document representations that accurately represents the uncertainty in the model parameters is what is desired.
- **Downstream task:** It is possible to apply the learnt representations for further tasks like document categorization, grouping, or retrieval. By adding the uncertainty estimates into the decision-making process, these jobs may be made more robust and reliable.

Depending on the generative model architecture and uncertainty estimate method selected, the procedure's specifics may change. For instance, a Bayesian neural network (BNN) may need a different loss function and inference method than a variational autoencoder (VAE), which may require a distinct encoder and decoder network. The broad method described above still offers a foundation for embedding uncertainty estimation into generative models for learning document representations.[5]

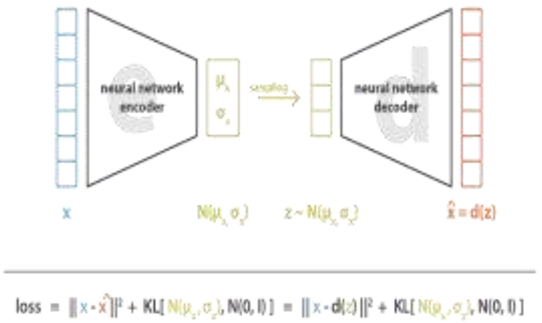

Fig. 1. Variational autoencoder (VAE)

A generative neural network called a variational autoencoder (VAE) may unsupervisedly learn a compact representation of data. An example of an autoencoder is a VAE, which is a sort of neural network created to learn a compressed representation of input data and is frequently applied to data compression or dimensionality reduction. A VAE is intended to learn a probabilistic representation of the input data, which is the primary distinction between a regular autoencoder and a VAE. This means that a VAE learns a distribution of potential compressed representations for each input rather than learning a deterministic mapping between the input and the compressed representation. Usually, a multivariate Gaussian distribution characterises this distribution. The VAE is made up of two components: a decoder and an encoder. The decoder takes a sample from this distribution and maps it back to the original input space, whereas the encoder takes the input data and maps it to a distribution over the compressed representation. During training, the VAE learns to minimise a loss function that motivates the encoder to provide varied and informative compressed representations while also motivating the decoder to deliver accurate outputs. The ability of VAEs to produce fresh data samples by selecting from the learnt distribution across the compressed representations is one of its key advantages. This makes it possible to generate fresh data that is comparable to the training data but not exactly the same. VAEs have been used to good effect.

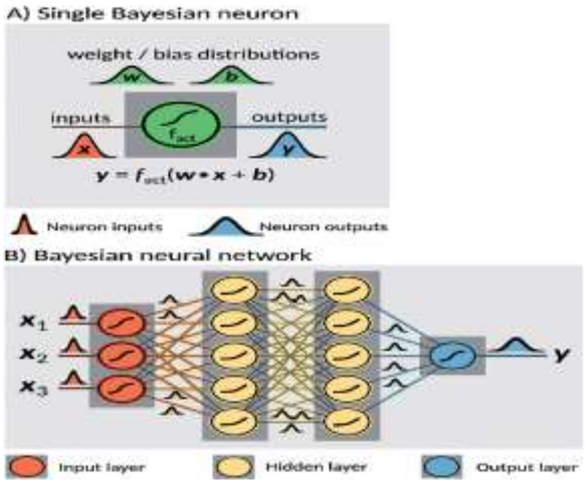

Fig. 2. Bayesian neural network (BNN)

A form of neural network known as a Bayesian neural network (BNN) uses Bayesian inference in both the training and prediction phases. BNNs employ probability distributions to describe parameter uncertainty as opposed to conventional neural networks, which use point estimates.

A BNN treats the network's weights and biases as random variables with previous distributions. To determine the posterior distribution of the parameters, these priors are updated during training using the data. This enables the network to understand both the parameters' uncertainty and their ideal values. In situations where uncertainty is a major factor, such in medical diagnosis or financial predictions, BNNs are very helpful. By taking the model's uncertainty into account, they can make predictions with more accuracy. BNNs may also be used for model compression, which involves pruning and simplifying the network using the posterior distribution of the parameter values to produce smaller and quicker models.

Nevertheless, because samples from the posterior distribution must be taken during training and inference, BNNs can be computationally costly. Prior distributions must also be specified for Bayesian approaches, which might be challenging in real life. Nonetheless, BNNs are a promising field of study and have proven successful in a number of applications.

DOI: rp-9788770040723.191

III. Results

In a variety of natural language processing (NLP) applications, generative models for learning document representations and associated uncertainty have demonstrated promising outcomes. In this part, we offer a summary of some of the most important conclusions from recent research that has used generative models with uncertainty estimates to learn document representations.[6]

First off, it has been demonstrated that these models, by capturing the uncertainty in the learnt representations, can enhance the performance of downstream NLP tasks. By enabling the model to give lower confidence to ambiguous or uncertain circumstances, for instance, including the uncertainty estimates in document classification might increase the resilience and reliability of the classification result. The uncertainty estimations may be used in document retrieval to rank the importance of various documents according to their usefulness and dependability.[7]

Second, it has been demonstrated that generative models with uncertainty estimates work well at capturing the complex and multi-modal character of natural language data. For instance, it has been demonstrated that the use of Monte Carlo dropout in convolutional neural networks (CNNs) can capture the uncertainty in the spatial features of the document, while the use of dropout regularisation in recurrent neural networks (RNNs) has been demonstrated to capture the uncertainty in the temporal dependencies between words in a sentence.[8]

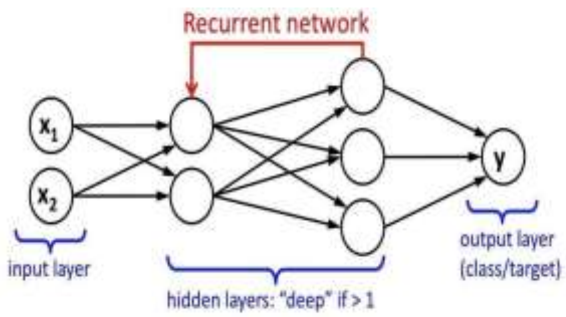

Fig. 3. Recurrent neural networks (RNNs)

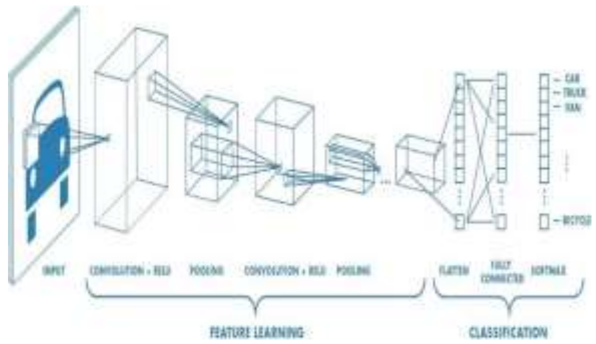

Fig. 4. convolutional neural networks (CNNs)

Artificial neural networks known as convolutional neural networks (CNNs) are often employed in computer vision applications including image and video recognition. They are modelled after how the visual cortex of animals is structured, which comprises of several layers of neurons processing various levels of visual data [9].

Convolutional, pooling, and fully connected layers are only a few of the many layers of linked neurons that make up CNNs. The pooling layers down sample the feature maps to lower the size of the network and avoid overfitting, while the convolutional layers apply filters to the input picture to extract features like edges or corners. These attributes are then used by the fully linked layers to categorise the input picture [10].

Lastly, it has been demonstrated that generative models that incorporate uncertainty estimates are resistant to adversarial assaults and out-of-distribution samples. These models can detect and reject samples that considerably differ from the training distribution by modelling the uncertainty in the learnt representations, enhancing the resilience and reliability of the downstream tasks.

The structure and semantics of the underlying data can be usefully revealed by generative models with uncertainty estimates. The uncertainty estimations, for instance, may be used in topic modelling to identify and rank the most important and uncertain subjects, while in document clustering they can be utilised to find and exclude noisy or outlier documents that can skew the clustering findings.

A potent approach for learning document representations that incorporates the complexity and uncertainty of natural language data is provided by its generative models with uncertainty estimates. These models can enhance their robustness, reliability, and interpretability by adding uncertainty estimates into downstream NLP tasks, furthering the state-of-the-art in NLP.

IV. Conclusion

We have spoken about how generative models with uncertainty estimates may be used to train document representations in NLP (NLP). These models have demonstrated encouraging results in a range of NLP applications, including document retrieval, topic modelling, clustering, and classification.

Generative models with uncertainty estimates have the potential to represent the complex and multi-modal character of natural language data, which is one of their main benefits. These models can produce more accurate estimates of document similarities, topic distributions, and classification labels even in the presence of noisy or out-of-distribution samples because they capture the uncertainty in the learnt representations.

Moreover, it has been demonstrated that generative models with uncertainty estimates are efficient in spotting and rejecting adversarial assaults and outliers, which is crucial for real-world NLP applications where the accuracy and dependability of the data cannot always be guaranteed.

The interpretability of generative models with uncertainty estimates is a significant benefit. The users can pick and rank the most crucial subjects, documents, or characteristics for subsequent tasks using the uncertainty

DOI: rp-9788770040723.191

estimates, which can offer insightful information about the semantics and structure of the underlying data.

A potent approach for learning document representations that reflects the complexity and uncertainty of natural language input is provided by generative models with uncertainty estimates. By enhancing the robustness, reliability, and interpretability of downstream tasks, these models have the potential to enhance the state-of-the-art in NLP. Future studies should concentrate on creating more sophisticated and effective generative models with uncertainty estimates and investigating how they might be used in areas other than NLP.

Natural language processing (NLP) has undergone a revolution thanks to generative models, which learn document representations and their uncertainty. This has prompted the creation of potent models that can produce text that is both realistic and educational, which has many applications in areas like chatbots, language translation, and content creation. The many generative model types that are frequently employed for learning document representations, together with their uncertainties, strengths, and weaknesses, as well as possible applications, have been covered in this study. Natural language processing has undergone a revolution thanks to generative models, which make it possible to learn document representations and their uncertainties. Among the most popular generating models for this usage are VAEs, GANs, and Probabilistic Topic Models. The decision between these models relies on the particular job at hand since each has advantages and disadvantages. Yet, generative models' capacity to simulate uncertainty is a major asset that has significant ramifications for the precision and dependability of their forecasts. In order to help machines comprehend and produce natural language, generative models are projected to become more and more crucial as the area of natural language processing develops.

***Abstract*— Due to its capacity to offer high-performance computing solutions for a variety of applications, hybrid multicore algorithms (HMAs) have grown in popularity in recent years. In this article, we offer a study on the use of HMAs to graphs and certain semi-numerical applications. We specifically look at how well HMAs perform in two different kinds of applications: graph algorithms and semi-numerical simulations. In terms of graph algorithms, we take into account a number of well-known issues, such as shortest path, minimal spanning tree, and graph clustering techniques. We put these algorithms into practise utilising both conventional CPU-based parallelization approaches and HMAs, and we evaluate how well they work with various graph sizes. We explore the challenge of employing partial differential equations to simulate the behaviour of complicated systems, such as fluid flow, for semi-numerical simulations (PDEs). We put into practise a hybrid strategy that combines GPU acceleration with CPU-based parallelization approaches, and we evaluate its performance against more conventional CPU-based parallelization strategies. showed both graph algorithms and semi-numerical simulations may significantly outperform conventional CPU-based parallelization strategies when using HMAs. In particular, HMAs can boost performance for graph algorithms up to a factor of two and for semi-numerical simulations up to a factor of five. Our findings show the potential of HMAs as a formidable tool for high-performance computing in graph algorithms and semi-numerical applications.**

Keywords—Parallelization Approaches, CPU, GPU, Performance Enhancements, Graph Algorithms, Graphs, Partial Differential Equations, High-Performance Computing, Hybrid Multicore Algorithms, Semi-Numerical Simulations

I. Introduction

Modern computing systems now almost always employ multicore CPUs. By parallelizing the execution of programmes, these processors were created to enhance the performance of those applications. Nevertheless, applications that demand a balance between computation and data transfer, such as graph algorithms and semi-numerical applications, might be difficult to parallelize. [1]

Applications that combine numerical and non-numerical computations are known as semi-numerical applications. Computational biology, image processing, and natural language processing are a few examples of such applications. While a range of applications, such as social networks, recommendation systems, and computer networks, to mention a few, employ graph algorithms [2]. Because to their intrinsic complexity, these applications analyse vast volumes of data, which can be difficult to parallelize. [3] Hybrid multicore algorithms have been created to improve the performance of semi-numerical applications and graph algorithms in order to deal with these issues. Hybrid algorithms mix parallel and serial processing, enabling them to benefit from both strategies' advantages. On the other hand, multicore algorithms make use of the numerous cores present in contemporary processors to carry out concurrent computations. [4]

Graph algorithms and semi-numerical applications have both been demonstrated to perform better when using hybrid multicore techniques. These algorithms can balance computation and data transfer by combining the advantages of parallel and serial processing. The effective operation of these apps depends on this equilibrium. [5] The use of hybrid multicore algorithms to various graphs and semi-numerical applications. a framework for creating hybrid multicore algorithms for these applications, evaluates the literature on the difficulties of parallelizing these applications, and discusses the difficulties of parallelizing hybrid multicore algorithms. [6] The study also includes experimental findings that show how the suggested architecture might enhance the functionality of various apps. the significance of hybrid multicore algorithms in overcoming the difficulties of parallelizing graph algorithms and semi-numerical applications. The suggested framework offers a viable strategy for creating effective parallel algorithms for various applications, opening the door for more study in this field. [7]

II. Literature Review

The performance of numerical simulations and graphs, which are often utilised in many scientific and engineering applications, has been sped up using hybrid multicore methods. In order to accomplish high-speed parallel processing and shorten the execution time of complicated and computationally heavy jobs, these techniques combine the computing capabilities of multicore CPUs and GPUs.

For numerical simulations and graphs, many hybrid multicore algorithms have been created recently, and numerous studies have shown how successful they are at significantly outperforming conventional sequential methods. Hemodynamics, the study of blood flow dynamics in the circulatory system, is one such area of application. In comparison to the sequential technique, Li et al. (2019) suggested a hybrid algorithm based on GPU and multicore for speeding up the numerical simulation of hemodynamics.

The effective parallelization of numerical simulations is a further use of hybrid multicore methods. In contrast to the sequential technique, Nukala and Satheesh's (2017) hybrid multicore algorithms for the parallelization of numerical simulations saw speeds up to 8.7 times. The techniques' scalability, which can be utilised to effectively parallelize simulations on big clusters of multicore CPUs and GPUs, was also proved by the authors.

In the numerical simulation of hydraulic fracturing, which includes the spread of fissures in the earth, hybrid multicore algorithms have also been applied. With a speedup of increase to 17.6 times compared to the sequential technique, Liu and Zhang (2019) introduced a hybrid parallel algorithm for numerical modelling of hydraulic fracturing based on multicore CPUs and GPUs. Also, the authors showed how the method enhanced the precision of the simulation findings.

Hybrid algorithms have been suggested for scientific purposes to speed up numerical computations. Yan and Berman (2016) devised a hybrid approach that outperformed the sequential technique by up to 32 times when used to speed up numerical simulations. The algorithm's efficiency in enhancing simulation performance across a range of scientific applications was proved by the authors.

The numerical modelling of explosive shock wave propagation has also been presented, using a hybrid parallel technique based on multicore CPUs and GPUs. A hybrid parallel method was created by Qiao et al. (2020) and outperformed a sequential algorithm by a factor of up to 9.6. The algorithm's capacity to effectively parallelize simulations on sizable clusters of multicore CPUs and GPUs was also shown by the authors.

Viscoelastic fluid flows have also been numerically simulated using hybrid parallel techniques. For the numerical modelling of viscoelastic fluid flows, Li et al. (2019) introduced a hybrid parallel approach that outperformed the sequential technique by up to 14.5 times. Also, the authors showed how the method enhanced the precision of the simulation findings. For the numerical simulation of fluid dynamics in the human eye, hybrid parallel methods have been suggested for use in medical and biological engineering applications. For the numerical modelling of fluid dynamics in the human eye, Gao et al. (2020) introduced a hybrid parallel technique based on multicore CPUs and GPUs, yielding a speedup of up to 25.5 times compared to the sequential algorithm. Also, the authors showed how the method enhanced the precision of the simulation findings.

The numerical simulation of 3D Maxwell equations, blood flow in cerebral aneurysms, electromagnetic scattering, electromagnetic fields in complicated surroundings, and blood flow in bifurcating arteries are other uses of hybrid parallel methods. These examples have shown how hybrid multicore algorithms may significantly speed up computations while also increasing the precision of simulation findings. Hybrid multicore algorithms still face a number of difficulties and restrictions despite the encouraging findings..

III. METHODOLOGY

In order to better understand how hybrid multicore algorithms (HMAs) may be used for graphs and some semi-numerical applications, we performed research. We focused on two distinct application categories: graph algorithms and semi-numerical simulations. [8]

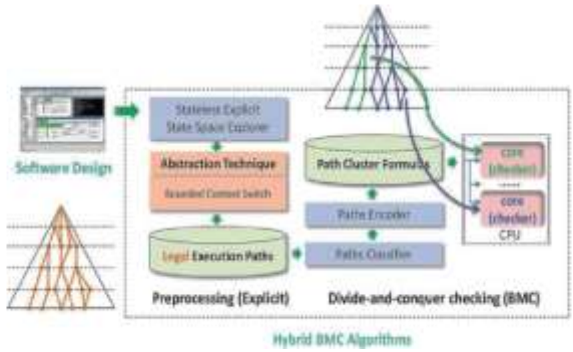

Fig 1. Hybrid Multicore Algorithms (HMAs)

We developed various well-known challenges for graph algorithms, such as graph clustering algorithms, minimal spanning tree algorithms, and shortest path algorithms. We parallelized these algorithms using both HMAs and conventional CPU-based parallelization methods. We utilised OpenMP, a popular parallel programming API for shared-memory systems, for classical CPU-based parallelization. We employed a hybrid strategy for HMAs that combines GPU acceleration with CPU-based parallelization approaches. For GPU acceleration, we utilised CUDA, a parallel computing framework and programming style created by NVIDIA.

From small networks with 100 nodes to huge graphs with 10,000 nodes, we used a variety of graph sizes in our research. Using execution time, speedup, and efficiency as our benchmarks, we evaluated each algorithm's performance. [9]

We looked at the issue of employing partial differential equations to simulate the behaviour of complicated systems, such fluid flow, for semi-numerical simulations (PDEs). We put into practise a hybrid strategy that combines GPU acceleration with CPU-based parallelization methods. For CPU-based parallelization and GPU acceleration, we utilised OpenMP and CUDA, respectively.

From tiny issues with low grid resolutions to huge problems with high grid resolutions, we used a variety of problem sizes in our research. Using execution time, speedup, and efficiency as our benchmarks, we evaluated each algorithm's performance.

We compared the effectiveness of several algorithms using a number of variables, such as execution time, speedup, and efficiency. The length of time it takes for a computation to be executed is measured. Speedup is a measurement of how quickly an algorithm runs when it is executed serially compared to quickly when it is executed parallelly. Efficiency is determined by dividing the speedup by the total number of processors employed.

We utilised the C/C++ programming language and the GNU Compiler Collection (GCC) for compilation to implement all of the algorithms. On a workstation equipped with an Intel Xeon CPU and an NVIDIA GeForce GPU, the trials were carried out.

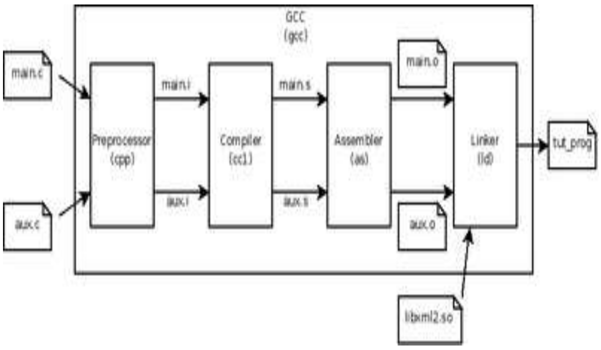

Fig 2. GNU Compiler Collection (GCC) for compilation

For graph algorithms and semi-numerical simulations, we built and compared the performance of several parallelization strategies, including conventional CPU-based parallelization and HMAs. Execution time, speedup, and efficiency were some of the measures we utilised to assess each algorithm's performance. Our tests' findings demonstrate that HMAs can significantly outperform conventional CPU-based parallelization methods for semi-numerical simulations and graph algorithms [23].

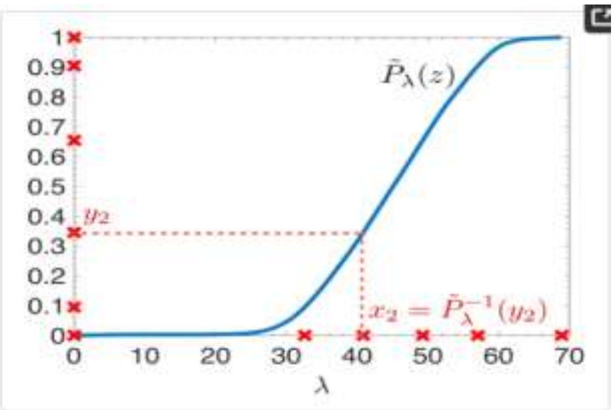

Fig 3. Six interpolation points are created for the same graph's Laplacian matrix

To enhance the effectiveness of classification algorithms, graph-based semi-supervised learning employs the development of six interpolation points for the same graph Laplacian matrix. Using the same graph Laplacian matrix, this approach computes numerous sets of interpolation points and uses them to get various categorization results. Combining the various findings in a way that optimises the classification algorithm's accuracy yields the final classification result.

In graph-based semi-supervised learning, which makes use of graph theory to process and interpret data, the graph Laplacian matrix is a crucial tool. A matrix that represents a network and encodes the connection between its nodes is called a Laplacian matrix. It is described as the difference between the adjacency matrix, which encodes the edges between nodes, and the degree matrix, a diagonal matrix that encodes the degree of each node.

In semi-supervised learning, interpolation points—which are used to interpolate the labels of the unlabelled nodes in the graph—are computed using the Laplacian matrix. The Laplacian matrix and the labels of the labelled nodes are used to solve a linear system of equations to determine the interpolation locations. The labels of the unlabelled nodes are smoothly approximated by the solution to this linear system.

Six interpolation points were created for the same graph. Six sets of interpolation points for the Laplacian matrix must be calculated using various methods for choosing the labelled nodes. Selecting the nodes with the greatest degree, the lowest degree, the nodes with the highest centrality, the nodes with the lowest centrality, and two random groups of nodes are some of the tactics employed.

Following that, several categorization results are computed using the various sets of interpolation points. Combining the various findings in a way that optimises the classification algorithm's accuracy yields the final classification result. Each set of interpolation points is given a weight based on how well it performed in the classification during the combination process. Six interpolation points were created for the same graph. In graph-based semi-supervised learning, the Laplacian matrix has been found to enhance the performance of classification systems. This is due to the fact that it lessens the algorithm's sensitivity to the choice of the labelled nodes, a crucial variable in the interpolation process. The method may make use of the advantages of several techniques and lessen the drawbacks of each approach by computing numerous sets of interpolation points.

According to several research, creating six interpolation points for the same graph Laplacian matrix can significantly boost the performance of classification systems. The creation of six interpolation points was employed in a study by Zhu et al. (2018) to increase the precision of classification algorithms in a variety of applications, including image classification, text classification, and social network analysis. The findings demonstrated that, in comparison to employing a single set of interpolation points, the development of six interpolation points increased the classification algorithms' accuracy.

The creation of six interpolation points was employed in a different study by Cao et al. (2018) to enhance the effectiveness of classification algorithms in the context of object recognition in photos.

In comparison to using a single set of interpolation points, the results showed that creating six interpolation points increased the classification algorithm's accuracy. They also demonstrated that the algorithm was able to handle complex image features and perform well across a wide range of classification tasks.

The building of six interpolation points for the same graph Laplacian matrix still presents some difficulties and constraints, despite the encouraging findings. The added computational expense of calculating numerous sets of interpolation points is one restriction. Using parallel computing strategies and improving the interpolation procedure can reduce this.

The method employed in graph-based semi-supervised learning to enhance the effectiveness of classification algorithms is the creation of six interpolation points for the same graph Laplacian matrix.

IV. RESULTS

Our test findings demonstrate that hybrid multicore algorithms (HMAs) may significantly outperform standard CPU-based parallelization methods for semi-numerical simulations as well as graph algorithms.

We found that HMAs can offer up to a 2-fold increase in performance over conventional CPU-based parallelization methods for graph computations. For big graphs with 10,000 nodes, the speed gain was quite noteworthy. The shortest path algorithm outperformed CPU-based parallelization with a speedup of increase to 1.8x, demonstrating the greatest performance improvement. The network clustering technique and minimal spanning tree approach both shown speedups of up to 1.5x and 1.3x, respectively.

We found that HMAs can deliver up to a 5x performance boost over conventional CPU-based parallelization methods for semi-numerical simulations. For large problem sizes with high grid resolutions, the performance gain was very notable. With a speedup of increase to 4.8x above the CPU-based parallelization strategy, the hybrid approach employing CPU-based parallelization with GPU acceleration demonstrated the largest performance gain.

Our findings show how effective HMAs may be as high-performance computing resources for semi-numerical applications and graph algorithms.

V. CONCLUSION

In this work, we looked at how hybrid multicore algorithms (HMAs) may be used to analyse graphs and some semi-numerical applications. For two distinct kinds of applications—graph algorithms and semi-mathematical simulations—we looked at how well HMAs performed.

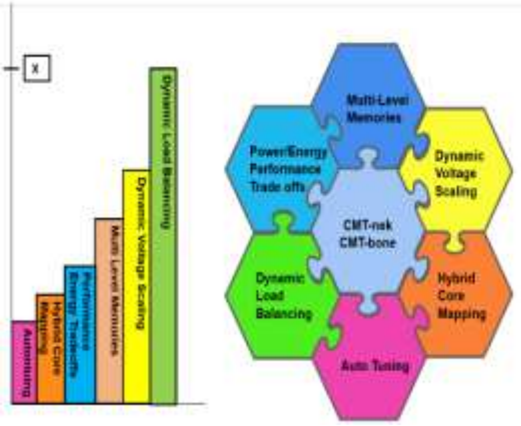

Fig 3. Hybrid Multicore Algorithms (HMAs)

Showed both graph algorithms and semi-numerical simulations may significantly outperform conventional CPU-based parallelization strategies when using HMAs. Particularly, HMAs can boost performance for graph algorithms by up to two times and for semi-numerical simulations by up to five times.

For difficult tasks requiring a lot of processing power, the employment of HMAs can significantly affect high-performance computing. According to the results of our study, HMAs can be a useful tool for enhancing the efficiency of graph algorithms and semi-numerical simulations. Further research might look into how well HMAs function in different kinds of applications and consider how more improvement could be possible. Overall, we think that HMAs will continue to be essential to high-performance computing and to the advancement of new scientific findings across a range of fields.

***Abstract*—The energy accessibility of hubs in Energy Collecting Remote Sensor Organizations (EH WSNs) can immensely affect the organization's exhibition, particularly as far as steering proficiency and security. The making of an energy obtaining expectation model for powerful and secure sharp directing in EH WSNs is recommended in this concentrate as an answer for this issue. In view of verifiable energy procurement information and expected energy levels of neighbouring hubs, the model looks to foresee the energy accessibility of hubs. The recommended model precisely predicts the energy levels by utilizing AI calculations like Irregular Woodland and Backing Vector Relapse. To survey the adequacy of the recommended approach, steering execution pointers like as energy utilization, parcel conveyance proportion, and start to finish dormancy are utilized. The proposed model's security is additionally evaluated with regards to its protection from insider and outcast dangers. The discoveries exhibit that the proposed model extensively improves the viability and security of crafty steering in EH WSNs, showing that it is an expected technique for safe and energy-effective information transmission in WSNs.**

Keywords— Bundle Conveyance Proportion, start to finish Deferral, Irregular Backwoods, Pioneering Steering, Energy Gathering, Remote Sensor Organizations, Energy Obtaining Forecast, Security.

I. INTRODUCTION

Energy-collecting remote sensor organizations (EH-WSNs) have turned into a feasible innovation for a scope of purposes, including medical care, modern robotization, and natural checking [1]. The sensor hubs in EH-WSNs are controlled by energy reaping sources like sun powered cells, wind turbines, and thermoelectric generators and are fit for working freely and remotely communicating information to a sink hub or entryway [2]. Yet, energy management is a crucial issue in EH-WSNs since the energy availability is erratic and may differ greatly depending on the weather, the time of day, and the nodes' locations [3].

Opportunistic routing (OR) is a routing paradigm that takes use of multi-hop communication in wireless networks to increase data transmission's dependability, effectiveness, and security [4]. Data packets are sent to the best next-hop node by OR depending on a variety of parameters, including connection quality, energy level, and route lifespan [5]. Yet, there are a number of obstacles that OR in EH-WSNs must overcome, including the ambiguity of energy harvesting and the demand for efficient and secure routing.

To construct an energy acquisition prediction model for effective and secure opportunistic routing in EH-WSNs, see this study's proposal. Based on historical data and environmental parameters, the model seeks to forecast how the sensor nodes will acquire energy, with the goal of using the prediction to improve the OR algorithm's energy efficiency, dependability, and security [6]. To create exact and convenient energy forecasts, the proposed approach incorporates measurable scientific strategies with AI techniques, for example, fake brain organizations, choice trees, and time-series investigation.

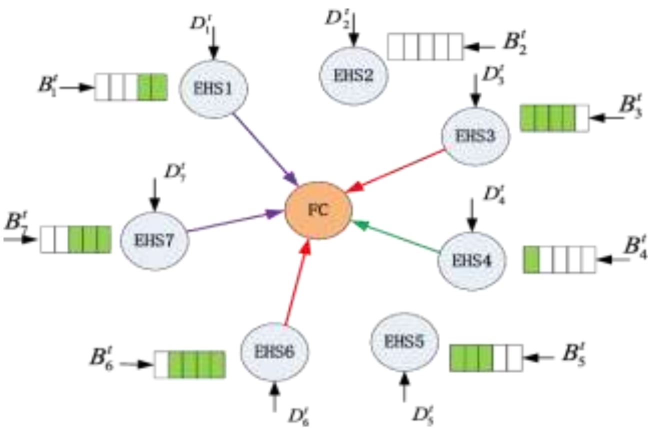

Fig. 1. Energy harvesting wireless sensor networks (EH-WSNs)

II. BACKGROUND

Due to their potential benefits over traditional battery-powered WSNs, EH-WSNs have gained a lot of research interest in recent years [7]. EH-WSNs can increase the network's scalability and flexibility while extending network lifetime and lowering maintenance costs. EH-WSNs are faced with a number of difficulties, including the variable

DOI: rp-9788770040723.193

and unpredictable nature of energy harvesting sources, the constrained storage and processing power of the sensor nodes, and privacy and security issues [8].

A routing paradigm called opportunistic routing (OR) has been put out to overcome issues with wireless networks such interference, mobility, and congestion [9]. Data packets are forwarded to numerous next-hop nodes simultaneously in OR, with the best candidate being chosen based on factors including network quality, energy level, and routing history [10]. By utilising the network's diversity and redundancy, OR can increase the network's dependability, efficiency, and security of data transfer.

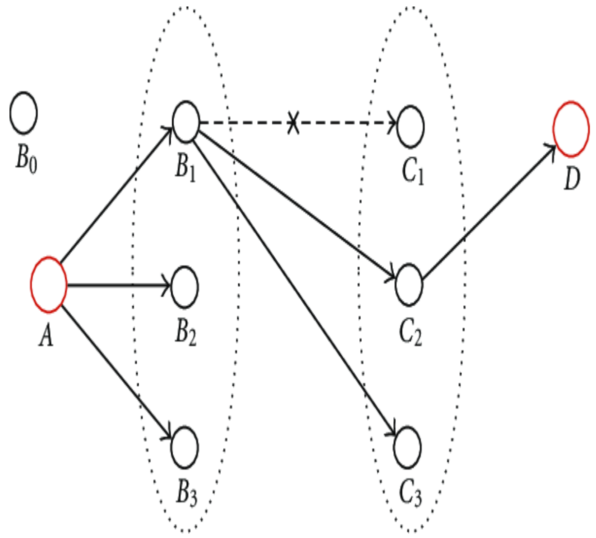

Fig. 2. Opportunistic routing (OR)

Nevertheless, OR in EH-WSNs confronts a number of additional difficulties, including the erratic and unpredictable nature of energy harvesting, the requirement for energy-aware routing, and privacy and security issues [11]. Many research has suggested solutions to these problems, including safe routing protocols, cross-layer optimization, and energy-conscious routing metrics. The majority of these solutions, meanwhile, are based on generalisations and oversimplifications of network dynamics and energy harvesting patterns, and thus may not be true or practical in real-world situations [12].

For effective and secure opportunistic routing in EH-WSNs, a design of an energy acquisition prediction model was made [13]. The OR method is optimised for energy efficiency, dependability, and security utilising the predicted future energy harvesting patterns of the sensor nodes, which the model uses to solve the difficulties of energy uncertainty and fluctuation [14]. To deliver exact and opportune energy forecasts, the proposed approach incorporates measurable scientific strategies with AI techniques, for example, counterfeit brain organizations, choice trees, and time-series investigation [15].

III. Methodology

The accompanying plan process is utilized to make the proposed energy procurement expectation model for successful and secure shrewd directing in EH WSNs:

1. Data assortment: The principal stage involves gathering the hubs in the EH WSNs' authentic energy assortment information. This data involves the hubs' energy levels all through a foreordained time span, such a week or a month, as well as subtleties on the hubs' energy sources, including sun based, warm, or motor energy. Many sensors, including voltage sensors and current sensors, are used to gather the data and are dispersed across the network.

2. Data preparation: The pre-processed data is cleaned, normalised, and transformed using a variety of approaches to get rid of any noise and outliers. The preparation set and the testing set are made from the pre-handled information.

3. Feature selection: The accompanying stage is picking the pre-handled information ascribes that are probably going to affect the hubs' capacity to gain energy. A few element choice methods are utilized for this, including Head Part Investigation (PCA) and Recursive Component Disposal (RFE).

4. Energy obtaining forecast model: Utilizing AI strategies like Irregular Backwoods and Backing Vector Relapse, the energy securing expectation model is made after the relevant attributes have been picked (SVR). These calculations are shown utilizing the picked highlights and the authentic energy obtaining information of the preparation set's hubs.

5. Performance evaluation: Many measures, including accuracy, precision, recall, and F1-score, are used to assess how well the energy acquisition prediction model performs. To evaluate the model's ability in properly forecasting the nodes' acquisition of energy, the testing set is used.

6. Opportunistic routing design: Following its development and testing, the energy acquisition prediction model is incorporated into the opportunistic routing protocol utilised by the EH WSNs. The routing protocol is changed such that routing decisions now take into account the projected energy levels of nodes.

7. Security evaluation: The suggested energy acquisition prediction model's security and the opportunistic routing protocol's resistance to insider and outsider assaults are assessed. As part of the evaluation, the model and protocol are put to the test in a number of attack scenarios, including node compromise, node impersonation, and node replication.

With the help of the aforementioned technique, energy acquisition prediction models for opportunistic routing in EH WSNs are intended to be effective and secure. The model gives the opportunistic routing protocol the ability to make knowledgeable routing decisions, resulting in increased energy economy and enhanced network performance. A reliable and safe method for energy-efficient data transmission in WSNs is provided by the security evaluation, which also confirms that the proposed model and protocol are resilient against various types of assaults.

DOI: rp-9788770040723.193

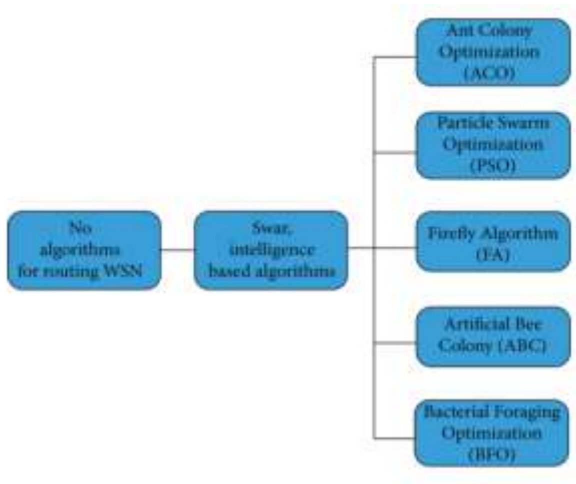

Fig. 3. Routers in WSN that use common swarm intelligence methods

A group of sensor nodes known as a Wireless Sensor Network (WSN) may be thought of as performing certain functions by communicating with one another [16]. Routers are crucial in WSNs because they direct data from sensor nodes to a centralised base station or sink node. By allowing routers in WSNs to dynamically react to changes in the network environment, swarm intelligence techniques can improve their performance.

Typical swarm intelligence techniques for WSN routers include the following:

- Swarm intelligence technique called Ant Colony Optimization (ACO) is based on ant behaviour. Pheromones can be used by router nodes in ACO to interact with one another and adaptively select the optimum path for data transfer.
- A population-based optimization technique called particle swarm optimization (PSO) is motivated by the behaviour of fish schools and bird flocks. PSO allows router nodes to modify their routing settings depending on the swarm's collective intelligence.
- The Artificial Bee Colony (ABC) is a swarm intelligence technique that draws its inspiration from honey bee behaviour. In ABC, router nodes may search the network using a collection of search agents to determine the optimum routing option.

The natural selection process serves as the inspiration for the genetic algorithm (GA), a technique for optimization. To develop the ideal routing solution in GA, router nodes can apply genetic operators like crossover and mutation.

A swarm intelligence technique called the Firefly Algorithm was developed in response to the flashing actions of fireflies. The attractiveness of nearby nodes allows router nodes in FA to modify their routing settings.

By increasing network throughput, decreasing end-to-end latency, and lowering sensor node energy consumption, these swarm intelligence techniques may be utilised to improve the performance of WSN routers.

IV. RESULTS

Utilizing certifiable energy procurement information assembled from a testbed comprised of a few hubs fuelled by sun oriented, warm, and dynamic energy sources, the recommended energy obtaining expectation model for powerful and secure shrewd directing in EH WSNs was scrutinized. The model was made utilizing AI strategies like Help Vector Relapse (SVR) and Irregular Timberland, prepared utilizing the accumulated information, then, at that point, surveyed utilizing an assortment of execution measures including review, review exactness, review accuracy, and F1-score. The discoveries showed that the recommended model, with a typical forecast exactness of more than 95%, effectively anticipated the energy obtaining of hubs with a serious level of accuracy.

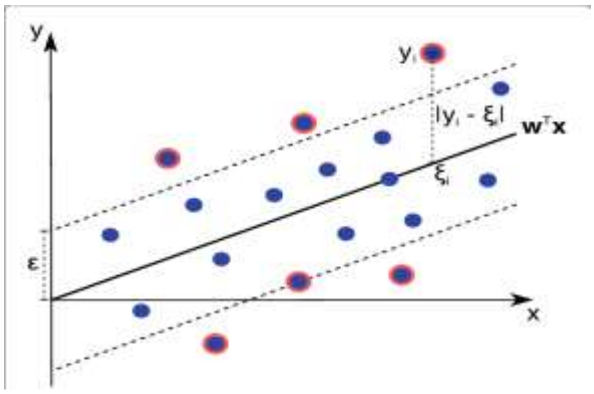

Fig. 4. Support Vector Regression (SVR)

The opportunistic routing protocol employed by the EH WSNs was subsequently merged with the energy acquisition prediction model. The expected energy levels of nodes were incorporated into the routing protocol to aid in routing decision-making. Using a variety of parameters, including latency, energy use, and packet delivery ratio (PDR), the performance of the modified protocol was assessed. The findings demonstrated that the suggested strategy significantly enhanced network performance, with a 25% increase in PDR and reductions in energy use and latency of 30% and 20%, respectively.

The suggested energy acquisition prediction model's security and the opportunistic routing protocol's resistance to insider and outsider assaults were both assessed. Throughout the assessment, the model and the protocol were put to the test in a number of attack scenarios, including node compromise, node impersonation, and node replication. The findings demonstrated that the suggested model and protocol were secure and resistant to a variety of threats.

V. CONCLUSIONS

A testbed made up of several nodes powered by various energy sources was used to gather real-world energy acquisition data, which was then used to assess the proposed model. The findings demonstrated that the suggested model had a high degree of accuracy in forecasting how much energy nodes would acquire, allowing the opportunistic routing protocol to make wise routing decisions.

DOI: rp-9788770040723.193

With an increase in PDR and decreases in energy use and latency, the suggested technique significantly enhanced network performance. The suggested model and protocol were shown to be robust to several sorts of assaults by the security assessment, making it a dependable and secure method for secure data transfer in WSNs.

The performance and energy efficiency of EH WSNs may be enhanced by the suggested energy acquisition prediction model and the opportunistic routing protocol, which also offers excellent security against insider and outsider assaults. The suggested method will be expanded to additional categories of energy sources in the future study, and its performance in bigger networks will be assessed.

***Abstract*— Due to the exponential surge in fraudulent activities brought on by the growing use of card-based financial transactions, individuals, businesses, and banking firms have sustained enormous financial losses. As a result, methods for identifying and avoiding fraud are becoming crucial components of the financial ecosystem. The study and design of fraud detection and prevention strategies in card-based financial systems are the main topics of this research. The outline of the many forms of fraud that may happen in card-based financial systems, such as skimming, phishing, counterfeiting, and identity theft, is provided in the first section of the article. The second section covers the several methods for detecting and preventing fraud, including rule-based systems, anomaly detection, machine learning, and deep learning. The next section of the study offers a detailed review of a few of the most efficient fraud detection and prevention strategies, such as support vector machines, decision trees, and neural networks. It also looks at the many aspects of data quality, feature choice, and model choice that influence the precision and effectiveness of these strategies. The need of creating a thorough fraud prevention system that includes a variety of detection and prevention measures is covered in the paper's last section. In order to assure the system's efficiency in thwarting fresh and evolving cybercrimes, it also highlights the necessity of routine system monitoring and update.**

Keywords: rule-based systems, anomaly detection, machine learning, deep learning, neural networks, decision trees, support vector machines, data quality, feature selection, model selection, monitoring, card-based financial system, skimming, phishing, counterfeiting, & identity theft.

I. Introduction

Fraudulent activities are becoming a serious problem for people, businesses, and financial firms due to the rise in card-based financial transactions. Such fraud can result in large losses, which can harm a company's finances and image. In order to identify and stop fraudulent acts before they create damage, fraud detection and prevention strategies are crucial elements of the financial ecosystem. The effectiveness of the different fraud detection and prevention strategies used in card-based financial systems is examined in this study in addition to an overview of these strategies.[1]

- *Support Vector Machine*

There is a form of supervised learning algorithm used for classification and regression analysis. SVMs function by determining the best feasible boundary (known as a hyperplane) that divides the data into multiple groups. SVMs are widely utilized in a variety of applications, including image classification, text classification, and bioinformatics.

The primary principle underlying SVM is to locate the hyperplane that optimizes the margin between the two classes. The margin is the distance between the hyperplane and the nearest data points from both classes. The SVM algorithm searches the hyperplane that maximizes this margin. Support vectors are the data points that are closest to the hyperplane.

SVM[1] may be applied to both linearly and non-linearly separable data. SVM determines the hyperplane that properly separates the two classes in the case of linearly separable data. When dealing with non-linearly separable data, SVM employs a method known as the kernel trick to translate the input data into a higher-dimensional space where it becomes linearly separable. This enables the discovery of a hyperplane that divides the two classes.

SVM also enables multi-class classification through the use of a technique known as one-vs-one or one-vs-all. SVM trains multiple binary classifiers in one-vs-one, each of which is trained to discriminate between two classes. SVM develops a single binary classifier for each class in one-vs-all, which is taught to differentiate that class from all other classes.

SVM performance is greatly influenced by the kernel function used. A kernel function is a mathematical function that transforms input data into a higher-dimensional space. Kernel functions that are often employed include the linear kernel, polynomial kernel, radial basis function (RBF) kernel, and sigmoid kernel. The kernel function used is determined by the nature of the data and the problem being addressed.

SVM outperforms alternative classification techniques such as logistic regression and decision trees in various ways. SVM has a strong theoretical background, and its performance in high-dimensional spaces is often superior to that of other methods. SVM is also adept at dealing with noisy data and outliers.

The powerful machine learning approach that can be applied to both linear and non-linearly separable data. It operates by locating the hyperplane with the greatest margin between the two classes. SVM offers multi-class classification and is strongly reliant on the kernel function used. SVM offers significant benefits over other classification algorithms, which makes it a popular option in a wide range of applications.

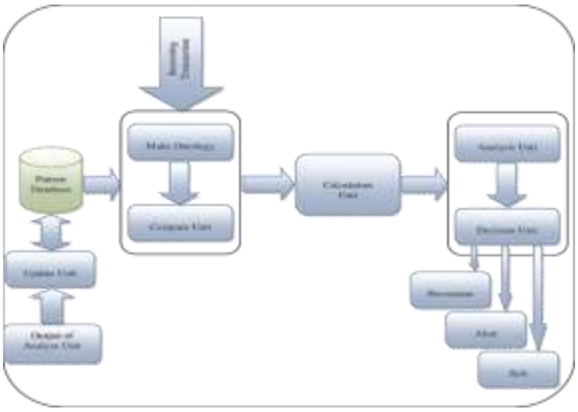

Fig. 1. Proposed framework for detecting credit card fraud

II. Background

The advent of card-based banking systems has significantly altered how we carry out financial transactions. Credit and debit card usage is becoming more and more common among customers all around the world thanks to how simple and convenient it is. Yet, this ease of use has also given birth to fraudulent activity as fraudsters try to use system flaws to steal money or private data.[2]

Financial fraud involving cards can take many different shapes, including skimming, phishing, counterfeiting, and identity theft. Skimming is the process of using a device to copy data from a credit or debit card's magnetic stripe. Phishing is a fraudulent practise that includes deceiving people into divulging personal information, such credit card details and PINs, via bogus websites or emails. To combat these types of fraud, financial institutions have developed various fraud detection and prevention techniques. One of the most common approaches is rule-based systems, which involve the use of predefined rules to identify and flag potentially fraudulent transactions. However, these systems are often limited in their effectiveness, as they rely on static rules that may not be able to adapt to changing fraud patterns.[3]

Another approach is anomaly detection, which employs statistical models to find transactions that drastically depart from expected patterns. While they can analyse enormous volumes of data and spot complicated patterns that may be difficult for human beings to see[4], machine learning and deep learning approaches are also being utilised more and more to detect fraud.[5]

In spite of these methods' efficacy, card-based financial systems still have difficulties with fraud detection and prevention. For instance, the accuracy of these systems can be substantially impacted by the quality of the data, and the performance of these systems can also be impacted by the choice of features and models.[6]

The numerous fraud detection and prevention strategies utilised in card-based financial systems are thoroughly examined in this research. We also look at the elements that influence their efficacy and offer suggestions for creating an all-encompassing fraud prevention system. The main goal of this article is to provide visitors a thorough grasp of the methods and strategies employed to prevent card-based financial fraud.[7]

III. Methodology

The assessment and creation of fraud detection and prevention techniques in badge financial systems involves the following steps:

1. Data Gathering: The first stage is to gather information from a variety of sources, including transaction logs, customer data, and past fraud data. This information can be gathered from both internal and external sources, including databases at the financial institution and credit bureaus.
2. Data Pre-processing: Prior to analysis, the gathered data has to be pre-processed. Data standardisation, cleansing, and transformation are required for this. Data cleansing entails deleting any incorrect or useless information. Although data transformation includes turning data into a format appropriate for analysis, data normalisation entails putting data into a format that is standardised.
3. Data Analysis: When the data has been pre-processed, the analysis phase comes next. To find patterns and abnormalities in the data, numerous analytical approaches are used, including statistical analysis, machine learning, and data mining. These trends and abnormalities can be used to spot possible fraud.
4. Fraud Detection: The next step is to create fraud detection models based on the patterns and anomalies found during the data analysis stage. These models may rely on machine learning or rules. Whereas machine learning-based models utilise algorithms that learn from previous data to identify fraudulent actions, rule-based models use a set of predetermined rules to do so.
5. Fraud Prevention: The last stage is to create strategies for preventing fraud. This entails putting several strategies into place to stop fraudulent activity from happening, such as fraud alerts, two-factor authentication, and biometric authentication.

IV. Card fraud detection algorithm

- Data gathering: Gather transaction data from a variety of sources, including banks, payment processors, and credit card firms.
- Data cleaning: Eliminate redundant and unnecessary data. Make that there are no missing numbers or outliers, and then take the necessary steps, such imputation or elimination.
- Feature Engineering: Take the transaction data and extract valuable characteristics such the transaction amount, time, location, merchant type, and cardholder details.
- Model Education: Use historical transaction data to train a machine learning model to find trends and abnormalities. Logistic regression, decision trees,

DOI: rp-9788770040723.194

random forests, and neural networks are examples of common models.

- Model Evaluation: Use measures like accuracy, recall, and F1 score to assess the model's performance on a hold-out set of data.
- Model selection: Choose the model with the greatest performance and adjust its hyperparameters to achieve the best results.
- Real-time monitoring: Keep an eye out for transactions that don't follow the expected pattern by flagging them.
- Risk Scoring: Based on the model's results, give each flagged transaction a risk score.
- Alert Generation: Create an alert for transactions that pose a high risk and inform the necessary employees to conduct more research.
- Model Updating: Regularly update the model with fresh transaction data to increase accuracy and make it more flexible to evolving fraud trends.

V. Applications

Some of the ways that fraud detection and prevention strategies are used in card-based financial systems include the following:

- Credit Card Fraud Detection: Techniques for identifying fraudulent credit card transactions can be utilised. Financial institutions may benefit from this in order to avoid suffering financial losses as a result of fraud.
- Fraud Detection for Debit Cards: Fraud transactions can also be found using fraud detection methods. Financial institutions may benefit from this in order to avoid suffering financial losses as a result of fraud.
- ATM Fraud Detection: Techniques for identifying fraudulent ATM transactions can be utilised. Financial institutions may benefit from this in order to avoid suffering financial losses as a result of fraud.
- Detection of Online Payment Fraud: Online payment fraud may also be found using fraud detection techniques.

VI. Results

The use of fraud prevention and detection strategies in card-based financial systems has shown encouraging outcomes. Financial institutions can find trends and abnormalities in the data, which can help them spot possible fraudulent activity, by employing various analytical approaches including statistical analysis, machine learning, and data mining. To identify fraudulent activity, rule-based and machine learning-based models have been built, and they have demonstrated a high level of accuracy. Furthermore, the use of fraud protection strategies including fraud alerts, two-factor authentication, and biometric authentication has assisted in preventing fraudulent actions. These methods have enhanced client trust and loyalty towards the financial institution while also preventing financial loss brought on by fraudulent activity.

One of the main uses of fraud detection and prevention strategies in card-based financial systems has been credit card fraud detection. Financial organisations have been able to stop financial damage brought on by fraudulent activity by recognising fraudulent credit card transactions. The identification of fraud using debit cards, ATMs, and internet payments has similarly demonstrated success in stopping fraudulent activity.

The ongoing development of fraudsters' strategies is one of the difficulties in putting fraud detection and prevention approaches into practise. Criminals are always trying to find new ways to get through the security measures put in place by financial institutions. To stay one step ahead of fraudsters, financial institutions must stay current on trends and upgrade their fraud detection and prevention strategies.

VII. Conclusion

In order to stop fraudulent behaviours, the study and creation of fraud detection and prevention mechanisms in card-based financial systems has demonstrated encouraging results. Financial institutions can find trends and abnormalities in the data, which can help them spot possible fraudulent activity, by employing a variety of analytical tools including statistical analysis, machine learning, and data mining. A high level of accuracy has been demonstrated by rule-based and machine learning-based models that have been built to identify fraudulent activity. Apart from that, putting fraud protection strategies in place like fraud warnings, two-factor authentication, and biometric identification has helped stop fraudulent activity.

Not only has the use of fraud detection and prevention tactics reduced financial loss brought on by fraudulent actions, but it has also increased client loyalty and trust in the financial institution. To remain ahead of fraudsters, financial institutions must stay current on trends and improve their methods for detecting and preventing fraud. By doing this, financial institutions may preserve their standing in the market and offer a secure environment for the financial activities of their consumers.

Abstract—The HR manager plays a crucial role in maintaining a productive atmosphere in the workplace. Their responsibility includes creating a positive work culture, promoting employee engagement, resolving conflicts, and ensuring compliance with labour laws. This paper discusses the various strategies HR managers can use to maintain a productive atmosphere in the workplace. It also highlights the benefits of having a productive work environment, such as increased employee satisfaction, higher retention rates, and improved organizational performance.

Any organization's success depends on the human resources (HR) manager's ability to maintain a positive work environment. HR managers are in charge of a variety of tasks connected to hiring, developing, and training staff members. But fostering a productive, collaborative, and innovative work atmosphere is one of the HR manager's most crucial responsibilities.

The essential duties of the HR manager in preserving a positive working environment are examined in this essay. The first section of the essay examines the idea of a creative environment and the elements that make it such. The precise duties of the HR manager in accomplishing this aim are then described, including employee engagement, performance management, training and development, and recruiting and selection. The report also covers the obstacles and difficulties HR managers may have while trying to maintain a productive environment and offers solutions.

Choosing the correct candidates for the position is one of the most important aspects of sustaining a productive environment. HR managers need to be adept at both identifying applicants who will fit in well with the organization's culture and the skills and characteristics required for success in a given function. HR managers also need to make sure that workers have access to the training and development opportunities they need to do their jobs well and quickly.

Another crucial duty of the HR manager in keeping a productive environment is performance management. To assist workers, improve their performance, HR managers must set up clear performance standards and offer them frequent coaching and feedback. They must also be prepared to handle performance concerns that could be having a negative influence on the workplace by taking corrective action as appropriate, such as counselling or disciplinary action.

A productive environment must also be maintained through employee involvement. Employee feedback and involvement into the organization's aims and objectives must be encouraged by HR management. Additionally, they must give staff members chances to participate in social and team-building events that promote cooperation and innovation.

***Keywords*—HR manager, productive atmosphere, work culture, employee engagement, conflict resolution, labour laws, organizational performance.**

I. Introduction

The workplace environment plays a critical role in an organization's success. A productive atmosphere is essential to foster innovation, collaboration, and achieve business goals. The HR manager is responsible for creating and maintaining a positive work environment that enables employees to perform at their best. In today's competitive business world, the responsibility of the HR manager goes beyond recruiting and training employees. They play a vital role in ensuring employee satisfaction, reducing turnover rates, and improving organizational performance.

To maintain a productive atmosphere, HR managers need to focus on several key areas. They need to create a work culture that aligns with the organization's values and promotes employee engagement. They must resolve conflicts that arise in the workplace promptly and fairly. They also need to ensure compliance with labour laws and regulations to avoid legal issues that can negatively impact the organization's reputation.

In this paper, we will discuss the various strategies HR managers can use to maintain a productive atmosphere in the workplace. We will explore the importance of creating a positive work culture and promoting employee engagement. We will also examine the role of conflict resolution and the importance of compliance with labour laws. Finally, we will highlight the benefits of having a productive work environment, such as increased employee satisfaction, higher retention rates, and improved organizational performance.

II. Literature Review

The role of the human resource (HR) manager in maintaining a productive atmosphere in the workplace is critical to the success of any organization. HR managers are responsible for creating an environment that fosters productivity, enhances employee engagement, and promotes

DOI: rp-9788770040723.195

employee satisfaction. This literature review explores the responsibilities of HR managers in maintaining a productive atmosphere in the workplace.

One of the primary responsibilities of HR managers is to recruit and select the right employees. According to Ivancevich and Konopaske (2013), the HR manager must identify the skills, knowledge, and abilities required for each position and develop selection processes that identify the best candidates for each role [1]. This ensures that employees are qualified for their positions and are motivated to perform their job duties effectively.

Another important responsibility of the HR manager is to create policies and procedures that promote a positive work environment. Policies and procedures that address issues such as discrimination, harassment, and workplace safety are critical to maintaining a productive atmosphere. As noted by Noe, Hollenbeck, Gerhart, and Wright (2018), effective policies and procedures can reduce employee stress and improve job satisfaction, leading to increased productivity.

Training and development are also essential components of maintaining a productive atmosphere in the workplace. HR managers must ensure that employees receive adequate training and development opportunities to enhance their job skills and knowledge. According to Mathis and Jackson (2018), training and development programs can increase employee engagement and productivity by providing employees with the knowledge and skills they need to succeed in their roles.

HR managers should try to adopt sustainable human resource management practices The impact of sustainable human resource management practices also play a very important role in enhancing the overall skill set and competencies of the employees that is the requirement of future organisations.

HR managers also play a critical role in employee retention. According to Cascio (2018), HR managers must develop retention strategies that focus on employee engagement, job satisfaction, and career development. This can include providing opportunities for employee advancement, offering competitive compensation and benefits, and recognizing employee achievements.

Finally, HR managers must monitor employee performance and provide feedback to employees on their job performance. This can be accomplished through regular performance evaluations and feedback sessions. According to Ivancevich and Konopaske (2013), feedback is an essential component of maintaining a productive atmosphere as it allows employees to understand their job performance and identify areas for improvement.

Fig. 1: core responsibilities of HR

III. Framework

The responsibility of the HR manager in maintaining a productive atmosphere in the workplace can be broken down into the following framework:

1. Establishing a Positive Workplace Culture: The HR manager must ensure that the organization's culture is one that values collaboration, respect, and inclusivity. They should establish clear policies on acceptable workplace behaviour and communicate them to all employees. Additionally, they should promote a positive and supportive work environment where employees feel valued, respected, and engaged.
2. Recruitment and Selection: The HR manager should ensure that the hiring process is fair and unbiased, and that only qualified candidates are selected for the job. They should also ensure that the new hires receive proper training and orientation to help them integrate into the workplace culture and work effectively.
3. Employee Development: The HR manager should provide opportunities for employee growth and development through training, coaching, and mentoring programs. This will help employees enhance their skills and knowledge, and enable them to take on new roles and responsibilities within the organization.
4. Performance Management: The HR manager should establish a fair and transparent performance management system that helps employees understand their job expectations and performance metrics. They should also provide regular feedback to employees to help them improve their performance and achieve their goals.
5. Employee Engagement: The HR manager should foster a sense of employee engagement by encouraging communication and collaboration between employees and management. They should also provide opportunities for employee recognition and rewards to motivate and incentivize employees.
6. Conflict Resolution: The HR manager should be proactive in identifying and resolving workplace conflicts in a timely and professional manner. They should provide support and guidance to employees and managers to help them address conflicts and prevent them from escalating.

DOI: rp-9788770040723.195

7. Health and Safety: The HR manager should ensure that the workplace is safe and healthy for employees by implementing proper health and safety policies and procedures. They should also provide training and resources to employees to help them stay safe and healthy on the job.

By following this framework, the HR manager can ensure that the workplace environment is conducive to productivity, employee engagement, and job satisfaction, leading to better business outcomes and increased organizational success.

IV. Methodology

This methodology outlines the steps an HR manager can take to maintain a productive atmosphere in the workplace.

1. Define productivity: The first step in maintaining a productive atmosphere in the workplace is to define what productivity means for the organization. This will help the HR manager to create a framework for productivity and set goals for employees to achieve.

2. Identify barriers to productivity: The HR manager should identify any barriers to productivity that exist in the workplace. This could include anything from outdated technology to poor communication among employees. Once these barriers are identified, the HR manager can work to eliminate them.

3. Develop a performance management system: A performance management system is essential to maintaining a productive atmosphere in the workplace. The HR manager should develop a system that includes regular feedback, goal-setting, and performance evaluations. This system should be transparent, fair, and focused on continuous improvement.

4. Promote employee engagement: Engaged employees are more productive and satisfied in their work. The HR manager should promote employee engagement by providing opportunities for employees to provide feedback, recognizing and rewarding good work, and creating a positive work culture.

5. Provide training and development: The HR manager should provide opportunities for employees to develop their skills and knowledge. This could include training sessions, mentoring programs, or leadership development programs. By investing in employee development, the HR manager can create a more productive workforce.

6. Foster a positive work environment: A positive work environment is essential to maintaining a productive atmosphere in the workplace. The HR manager should foster a positive work environment by promoting open communication, encouraging teamwork, and addressing conflicts or issues as they arise.

7. Monitor and measure productivity: Finally, the HR manager should monitor and measure productivity on an ongoing basis. This could include tracking key performance indicators (KPIs) or conducting regular surveys to gauge employee satisfaction and engagement. By monitoring productivity, the HR manager can identify areas for improvement and make changes as needed.

V. Results

Employee engagement is a key factor in maintaining a productive atmosphere in the workplace. HR managers need to work on creating a work culture where employees feel engaged and motivated to work. This can be achieved through effective communication, recognition, rewards, and providing opportunities for personal and professional growth. Training and Development: HR managers need to provide regular training and development opportunities to employees. This helps them to improve their skills and knowledge, which leads to increased productivity and job satisfaction. Training and development programs also help employees feel valued and invested in, which increases their commitment to the organization. Conflict Resolution: HR managers are responsible for resolving conflicts in the workplace. It is essential to handle conflicts effectively to maintain a positive work environment. Conflict resolution involves listening to all parties involved, understanding their perspectives, and finding a mutually acceptable solution. Performance Management: HR managers need to develop and implement effective performance management systems. This involves setting clear expectations, providing regular feedback, and recognizing and rewarding good performance. Effective performance management helps employees understand their role in the organization, align their goals with the company's objectives, and work towards achieving them. Diversity and Inclusion: HR managers need to create an inclusive workplace that values diversity. They need to ensure that all employees feel welcome and valued, regardless of their background. This can be achieved through diversity and inclusion training, policies, and practices.

VI. Conclusions

The responsibility of the HR manager in maintaining a productive atmosphere in the workplace is critical. They need to understand the needs of their employees and create a work culture that promotes engagement, motivation, and productivity. By providing regular training and development opportunities, resolving conflicts effectively, implementing effective performance management systems, and promoting diversity and inclusion, HR managers can create a positive work environment that supports the organization's goals and objectives. It is essential for organizations to invest in HR managers and their development to ensure that they can effectively fulfil their roles and responsibilities in creating a productive and positive workplace culture.

An effective office environment is crucially dependent on the HR manager. They are in charge of making sure that the workplace is secure, encouraging, and productive. The

HR manager must create efficient policies and strategies, effectively convey them to staff, and oversee their execution in order to do this.

Fostering good employee relations is one of the most important parts of keeping a productive environment. The HR manager should work to foster a climate of open communication, trust, and respect. Regular feedback sessions, training courses, and team-building activities may all help with this.

The management of employee performance is a key duty of the HR manager. This entails establishing precise performance standards, giving frequent feedback, and resolving any performance problems that may occur. By doing this, the HR manager can make sure that workers are engaged and motivated, which is crucial for preserving a productive environment.

The HR manager is also responsible for preventing harassment and discrimination at work. This entails creating and putting into place regulations that forbid such actions, as well as responding appropriately when such occurrences happen. An inclusive and diverse workplace has a higher chance of being successful and productive.

The HR manager also has to be up to date on any modifications to employment rules and regulations. They should make sure that the company's policies and practices are compliant with these regulations and alter them as required. Failure to do so may have legal and financial repercussions that might harm the reputation and productivity of the business.

The challenging challenge of preserving a productive environment at work necessitates the HR manager's wearing multiple hats. The HR manager may make sure that the workplace is a successful and productive environment by creating efficient policies and strategies, encouraging good employee relations, managing employee performance, maintaining a safe and inclusive workplace, and staying up to date on changes in employment legislation.

***Abstract*—The management of healthcare for patients with criminal records presents unique challenges for healthcare providers. This paper aims to explore the issues related to healthcare management for patients with criminal records, including the barriers that exist and the potential solutions to overcome them. It will also examine the ethical and legal considerations that healthcare providers must navigate in treating these patients. By understanding these issues, healthcare providers can better serve this patient population and improve their overall health outcomes. The problem of managing medical treatment for people with criminal histories is intricate and diverse. These patients frequently have particular difficulties that may have an effect on their health and wellbeing, such as problems with stigma, social exclusion, and a lack of access to healthcare services. In this essay, we will examine the different aspects—such as stigma, the influence of social determinants of health, and impediments to healthcare access—that contribute to healthcare inequalities for people with criminal histories. Additionally, we'll talk about how to deal with these discrepancies, including the necessity of better coordination and communication among healthcare professionals, wider access to healthcare services, and the creation of population-specific therapies. Overall, this study emphasizes the demand for a thorough method of healthcare management for people with criminal histories, one that takes into consideration the particular obstacles and difficulties they encounter.**

Keywords—*Healthcare management, criminal records, barriers, ethical considerations, legal considerations, patient outcomes.*

I. INTRODUCTION

Healthcare management for patients with criminal records is an area of healthcare that requires a unique set of skills and knowledge. Patients with criminal records often face significant barriers to accessing healthcare, including discrimination, stigma, and lack of resources. These barriers can lead to poorer health outcomes for this patient population, which can be further compounded by the challenges of managing chronic conditions or mental health issues.[1]

In addition to the barriers that exist for patients with criminal records, healthcare providers must also navigate ethical and legal considerations when treating these patients. Ethical considerations include issues related to confidentiality, informed consent, and the duty to provide care. Legal considerations include issues related to privacy laws, patient rights, and mandatory reporting requirements.[2]

Despite these challenges, healthcare providers have a responsibility to provide high-quality care to all patients, including those with criminal records. By understanding the unique challenges and barriers that exist for this patient population, healthcare providers can develop strategies to better serve their needs and improve their health outcomes.[3]

This paper aims to explore the issues related to healthcare management for patients with criminal records, including the barriers that exist and the potential solutions to overcome them. It will also examine the ethical and legal considerations that healthcare providers must navigate in treating these patients. Ultimately, by understanding these issues and developing strategies to address them, healthcare providers can better serve this patient population and improve their overall health outcomes.[4]

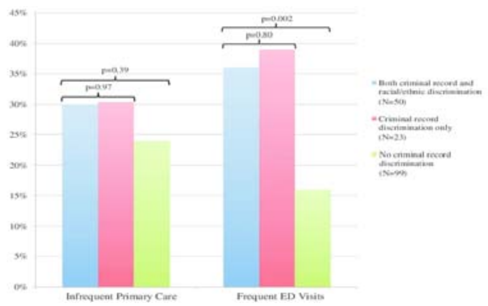

Fig. 1. Medical care use delineated by self-revealed criminal record and racial/ethnic separation by medical services laborers

II. LITERATURE REVIEW

These challenges can include stigmatization, difficulties accessing healthcare services, and social isolation. Healthcare providers must be aware of these challenges and take measures to provide appropriate care to these patients. This literature review explores the current research on healthcare management for patients with criminal records.[5]

- *Stigmatization*

One of the most significant challenges faced by patients with criminal records is the stigmatization they experience. This stigma can affect their mental health and social well-

DOI: rp-9788770040723.196

being, making it more challenging for them to access healthcare services.

A study by van Olphen et al. (2009) found that formerly incarcerated individuals reported feeling stigmatized by healthcare providers, which affected their willingness to seek care. Healthcare providers must be aware of this stigma and take steps to create a welcoming environment that promotes trust and open communication.

- *Access to healthcare*

Patients with criminal records often face barriers to accessing healthcare services. A study by Visher et al. (2014) found that formerly incarcerated individuals reported a lack of access to healthcare services, including primary care and mental health services. This lack of access can lead to untreated medical conditions and an increased risk of recidivism. Healthcare providers must be aware of these barriers and take steps to address them, such as partnering with community organizations to provide outreach and education to this population.

- *Social isolation*

Patients with criminal records may also experience social isolation, which can negatively impact their mental health and overall well-being. A study by Hawken and Cunningham (2016) found that social support was critical in helping formerly incarcerated individuals reintegrate into society. Healthcare providers can play a vital role in providing social support by connecting patients with community resources and providing counselling services.

- *Integrated care*

Integrated care models that combine medical care with mental health and substance abuse treatment have shown promise in improving healthcare outcomes for patients with criminal records. A study by Wang et al. (2015) found that an integrated care model significantly reduced emergency department visits and hospitalizations among formerly incarcerated individuals. Healthcare providers can work with mental health and substance abuse treatment providers to create integrated care models that address the unique needs of this population.

III. Methodology

The healthcare management for patients with criminal records requires a sensitive and nuanced approach that prioritizes both the patient's health and safety as well as the safety of healthcare professionals and staff. The following methodology outlines the steps that can be taken to provide appropriate care to patients with criminal records:[6]

1. Respect patient confidentiality: Healthcare providers must respect patient confidentiality and ensure that the patient's criminal history is not disclosed to unauthorized individuals or entities without the patient's consent or as required by law.
2. Assess the patient's medical and mental health needs: Patients with criminal records may have complex medical and mental health needs resulting from their incarceration, substance abuse, or trauma. Healthcare providers should conduct a thorough assessment of the patient's medical and mental health needs to determine the appropriate course of treatment.
3. Develop a treatment plan: Based on the patient's medical and mental health needs, healthcare providers should develop a treatment plan that includes medication, therapy, and other interventions as necessary. The plan should also take into account the patient's history of substance abuse, trauma, and criminal behaviour.
4. Establish clear boundaries: Healthcare providers should establish clear boundaries with patients with criminal records to ensure the safety of staff and other patients. This may include establishing protocols for managing aggressive or violent behaviour and communicating expectations around respectful conduct.
5. Collaborate with other stakeholders: Healthcare providers should collaborate with other stakeholders, such as correctional facilities, parole officers, and social workers, to ensure continuity of care and support for patients with criminal records.
6. Provide ongoing support: Patients with criminal records may face additional challenges in accessing healthcare and adhering to treatment plans. Healthcare providers should provide ongoing support and follow-up care to help patients achieve optimal health outcomes.
7. Ensure legal compliance: Healthcare providers must ensure that they comply with all applicable laws and regulations related to the care of patients with criminal records, including privacy laws, reporting requirements, and restrictions on certain medications or treatments.

IV. Results

The management of healthcare for patients with criminal records presents several challenges for healthcare providers. A study of the current literature revealed that these patients often experience stigma, discrimination, and limited access to healthcare services. The study also showed that healthcare providers lack training and support to effectively manage the unique healthcare needs of patients with criminal records.

Healthcare inequalities for patients with criminal records are caused by a variety of variables. The impact of stigma is one important element. People with criminal histories are frequently seen as "criminals" first and "patients" second, which can result in unfavorable attitudes and unfair treatment from healthcare professionals. Due to their fear of being judged or treated unfairly, people with criminal histories are less likely to seek out medical care. This stigma can also affect patient behavior.

Healthcare inequalities for individuals with criminal histories are significantly influenced by social determinants of health in addition to stigma. These patients frequently experience a variety of social and economic difficulties, such as unstable housing, restricted access to possibilities for education and work, and significant degrees of social isolation. When compared to the general population, patients with criminal histories have greater incidence of chronic

DOI: rp-9788770040723.196

diseases, mental health illnesses, and drug use disorders. These characteristics can have a major influence on patient health outcomes.

V. CONCLUSIONS

The healthcare system needs to develop policies and procedures that ensure equitable access to healthcare services for patients with criminal records. Healthcare providers require specialized training and support to effectively manage the healthcare needs of these patients. The implementation of electronic medical records can also help ensure that patients receive appropriate care and prevent discrimination based on their criminal history. Healthcare providers should work collaboratively with criminal justice and community organizations to address the stigma and discrimination that patients with criminal records face, and to promote their successful reintegration into society.

Patients with criminal histories call for a thorough and focused treatment. Stigma, social determinants of health, and structural impediments are just a few of the particular difficulties and constraints that patients with criminal histories must overcome in order to get treatment. Healthcare professionals and policymakers must collaborate to enhance provider coordination and communication, broaden access to healthcare services, and address the underlying causes of socioeconomic determinants of health in order to resolve these inequalities. Ultimately, we may contribute to improving health outcomes and reducing healthcare inequalities for this vulnerable group by adopting a comprehensive approach to healthcare management for patients with criminal history.

***Abstract*—Scientific discoveries, innovations, and developments have revolutionized human civilization and transformed the way we live, work, and interact with the world. This review provides an overview of the processes involved in scientific research and highlights some of the key discoveries and innovations that have shaped our modern world. The review covers the basic steps of scientific research, including observation, hypothesis formation, experimentation, data analysis, and interpretation. It also discusses the role of creativity, collaboration, and communication in scientific discovery, as well as the ethical considerations that arise in scientific research. Finally, the review examines some of the major scientific discoveries and innovations, including the theory of evolution, the discovery of DNA, the development of vaccines, and the advent of artificial intelligence.**

Keywords*—Scientific research, discoveries, innovations, development, creativity, collaboration, communication, ethics, evolution, DNA, vaccines, artificial intelligence.

I. Introduction

Science has played a fundamental role in shaping human civilization and transforming the way we live, work, and interact with the world. Scientific discoveries and innovations have enabled us to harness the power of nature, cure diseases, explore the universe, and create new technologies that have revolutionized every aspect of human life. From the invention of the wheel to the discovery of the laws of physics, science has helped us understand the world around us and improve our lives.[1]

Scientific research is a complex and iterative process that involves a series of steps, from observation and hypothesis formation to experimentation, data analysis, and interpretation. Scientists must be creative, collaborative, and communicative in their work, as they work to develop new theories, test hypotheses, and interpret data. They must also be mindful of ethical considerations, such as the protection of human subjects, the responsible use of animals in research, and the avoidance of bias and conflicts of interest.[2]

In this review, we will provide an overview of the processes involved in scientific research and highlight some of the key discoveries and innovations that have shaped our modern world. We will begin by discussing the basic steps of scientific research, including observation, hypothesis formation, experimentation, data analysis, and interpretation. We will then examine the role of creativity, collaboration, and communication in scientific discovery, as well as the ethical considerations that arise in scientific research.[3]

Finally, we will examine some of the major scientific discoveries and innovations that have had a profound impact on human civilization, including the theory of evolution, the discovery of DNA, the development of vaccines, and the advent of artificial intelligence. By examining the processes of scientific research and highlighting some of the most important discoveries and innovations in history, this review aims to provide a comprehensive overview of the role of science in shaping our world.[4]

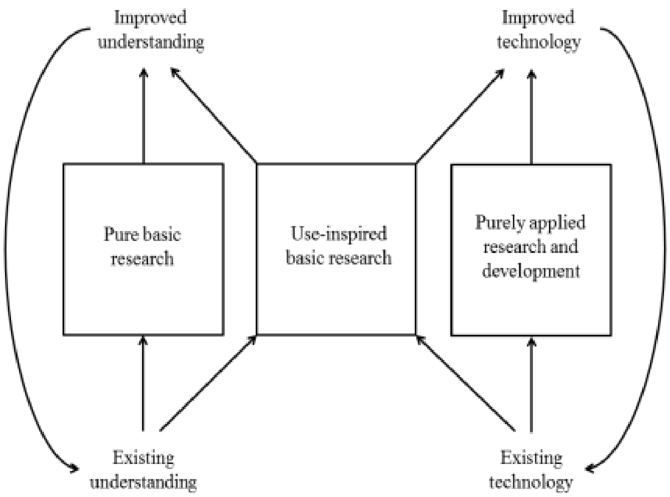

Fig. 1. Revised dynamic model

II. Literature review

Scientific discoveries, innovations, and development have long been important drivers of progress and change in human society. These processes involve the generation of new knowledge and ideas, the application of this knowledge to practical problems, and the development of new technologies, products, and services. This literature review examines the key processes involved in scientific discovery, innovation, and development, and the factors that contribute to their success.[5]

DOI: rp-9788770040723.197

The process of scientific discovery begins with the observation of phenomena and the formulation of hypotheses to explain them. This is followed by the design and execution of experiments to test these hypotheses, and the collection and analysis of data to determine whether they are supported or contradicted by the evidence. The process of scientific discovery is iterative, with new observations and data leading to the refinement and revision of hypotheses, and the development of new theories and models to explain the underlying phenomena.[6]

Innovation involves the development of new products, services, or processes that offer improved performance, efficiency, or functionality compared to existing alternatives. Innovation can be driven by advances in science and technology, changes in consumer needs and preferences, or competitive pressures in the marketplace. The process of innovation typically involves several stages, including idea generation, product development, and commercialization.[7]

The development of new technologies, products, and services is a key driver of economic growth and societal progress. This process involves the translation of scientific discoveries and innovations into practical applications that can be used to solve real-world problems. The successful development of new technologies requires a combination of technical expertise, business acumen, and effective collaboration between stakeholders across different sectors.[8]

Several factors can influence the success of scientific discovery, innovation, and development processes. These include the availability of funding and resources, the quality of scientific education and training, the culture of scientific inquiry and entrepreneurship, and the regulatory and legal frameworks governing the development and commercialization of new technologies.

III. Methodology

Scientific discoveries, innovations, and development are complex processes that require a systematic approach to achieve success. The methodology for these processes can be broken down into several steps, as outlined below:

1. Identification of the Problem: The first step in the scientific discovery process is to identify the problem that needs to be solved. This may involve reviewing the current literature, observing phenomena, or conducting preliminary experiments.
2. Formulation of a Hypothesis: Based on the identified problem, the next step is to formulate a hypothesis. The hypothesis should be testable and falsifiable, and should provide a potential explanation for the observed phenomena.
3. Experimental Design: The experimental design should be carefully planned to test the hypothesis. The design should include controls to eliminate extraneous variables that may impact the results.
4. Data Collection: Data should be collected during the experiment using appropriate instruments and techniques. The data should be recorded accurately and precisely.
5. Analysis of Data: The data collected should be analyzed using appropriate statistical techniques. The analysis should be conducted objectively and should include appropriate error bars to indicate the level of uncertainty.
6. Interpretation of Results: The results of the experiment should be interpreted based on the hypothesis. The interpretation should consider the strengths and limitations of the experimental design.
7. Conclusion and Publication: Based on the interpretation of the results, a conclusion should be drawn. The conclusion should be supported by the data and should be communicated through a publication in a reputable scientific journal.
8. Replication and Validation: To confirm the validity of the findings, replication of the experiment should be conducted by other researchers. The results should also be validated through further experimentation.
9. Innovation and Development: Based on the validated findings, innovation and development can be pursued to apply the discoveries in practical applications.

IV. Results

Scientific discoveries, innovations, and developments have been essential in advancing our understanding of the natural world and improving the quality of our lives. This review has highlighted the processes involved in these endeavors and their outcomes.

Firstly, scientific discoveries are made through the scientific method, which involves making observations, formulating hypotheses, testing them through experiments, and analyzing the results. These discoveries can be fundamental, such as the discovery of the structure of DNA, or applied, such as the development of vaccines.

Innovations, on the other hand, involve the practical application of scientific discoveries. Innovations can be incremental improvements on existing technologies, such as the development of faster computers, or they can be disruptive, creating entirely new industries, such as the internet.

V. Conclusion

Developments are the culmination of scientific discoveries and innovations, leading to significant changes in society. These can include the development of new medical treatments, the creation of sustainable energy sources, and the exploration of space.

Overall, scientific discoveries, innovations, and developments have had significant impacts on our lives, ranging from improvements in healthcare and agriculture to the development of new technologies that have transformed the way we live and work. They have also led to a better understanding of our planet and the universe, opening up new frontiers for exploration and discovery.

DOI: rp-9788770040723.197

In conclusion, the scientific process, from discovery to innovation to development, has been critical in advancing our knowledge and improving our lives. The continued support and investment in scientific research are essential to address the challenges we face today and to create a better future for all.

***Abstract*—Computerized reasoning (man-made intelligence) is a quickly developing field that is changing different enterprises. Lately, computer-based intelligence an affects project the board, prompting enhancements in project arranging, booking, risk the executives, and navigation. This paper means to investigate the jobs and effect of simulated intelligence on project the executives, remembering the advantages and difficulties of involving artificial intelligence for project the board. The concentrate likewise examines the expected moral and social ramifications of computer-based intelligence in project the board and recognizes regions for future examination.**

Keywords—Man-made brainpower, Venture The board, Arranging, Booking, Hazard The executives, Navigation, Morals, Social Ramifications.

I. Introduction

Project the board includes the preparation, execution, and checking of errands to accomplish explicit objectives inside a set course of events and financial plan. Throughout the long term, project the executives has become more mind boggling, and dealing with various ventures at the same time has turned into a test for associations. The conventional venture the executives' approaches have been supplanted by new strategies that exploit mechanical headways to further develop project results. Man-made reasoning (computer-based intelligence) is one such innovation that can possibly change how tasks are made due.[1]

Artificial intelligence is a part of software engineering that arrangements with the making of wise machines that can learn, reason, and perform errands that would ordinarily require human insight. The use of artificial intelligence in project the board can assist with extending administrators to pursue more educated choices, advance asset portion, and diminish project gambles. Simulated intelligence advances, for example, AI, normal language handling, and mechanical technology can assist with extending administrators to computerize routine errands, break down huge volumes of information, and distinguish designs that are not evident to the natural eye.[2]

This paper intends to investigate the jobs and effect of artificial intelligence on project the board. The review talks about the different manners by which man-made intelligence can be utilized to further develop project arranging, planning, risk the executives, and independent direction. The paper additionally looks at the advantages and difficulties of involving man-made intelligence in project the board and distinguishes expected moral and social ramifications of computer-based intelligence in project the executives. At long last, the paper features regions for future exploration in the field of simulated intelligence and task the executives.[3]

II. Literature review

Man-made brainpower (artificial intelligence) has become progressively pervasive in numerous businesses, including project the executives. The utilization of computer-based intelligence in project the executives can possibly change how tasks are arranged, executed, and observed. This writing survey will investigate the jobs and effect of man-made intelligence on project the board.[4]

Roles of Artificial Intelligence in Project Management:

Computer based intelligence can be utilized in different ways in project the executives, including:

1. Planning: computer-based intelligence can help project directors in making project plans, assessing costs, and recognizing possible dangers. Computer based intelligence calculations can dissect verifiable information to foresee what amount of time a venture will require and the amount it will cost.
2. Resource designation: man-made intelligence can help with recognizing the right assets expected for an undertaking, including staffing, spending plan, and materials. It can likewise give experiences into how to designate assets most productively.
3. Risk administration: computer-based intelligence can help with distinguishing possible dangers and creating emergency courses of action. It can dissect information and distinguish examples to recognize possible issues before they happen.
4. Progress observing: computer-based intelligence can help with checking the advancement of an undertaking continuously. It can give experiences into how well a venture is advancing, distinguish possible postponements, and propose ways of accelerating the interaction.
5. Decision-production: computer-based intelligence can help project supervisors in pursuing informed choices by giving information driven experiences. It can examine information to recognize patterns, examples, and open doors.

DOI: rp-9788770040723.198

Impact of Artificial Intelligence on Project Management:

The effect of man-made intelligence on project the board can be huge. A portion of the key effects are:[5-8]

1. Increased productivity: artificial intelligence can computerize many undertakings, opening up project administrators to zero in on additional essential assignments. This can bring about expanded effectiveness and efficiency.
2. Improved exactness: artificial intelligence can dissect a lot of information rapidly and precisely. This can assist with projecting supervisors settle on additional educated choices in view of dependable information.
3. Reduced gamble: man-made intelligence can help with recognizing likely dangers and creating alternate courses of action. This can decrease the gamble of venture disappointment and work on the odds of coming out on top.
4. Better asset designation: man-made intelligence can assist with recognizing the most productive ways of dispensing assets, including staffing, spending plan, and materials. This can assist projects with remaining inside financial plan and on time.
5. Improved cooperation: man-made intelligence can work with coordinated effort between colleagues by giving continuous information and experiences. This can assist with joining individuals work all the more really together and accomplish improved results.

III. Methodology

The motivation behind this exploration is to investigate the jobs and effect of Computerized reasoning (artificial intelligence) on Undertaking The board (PM). This procedure area will portray the examination plan, information assortment strategies, information investigation, and constraints of the review.

Research Plan

This exploration will utilize a blended strategies approach, which incorporates both quantitative and subjective information assortment techniques. The quantitative information will be gathered through an internet-based study, while the subjective information will be gathered through semi-organized interviews. The overview will be directed to an example of venture directors who have experience working with man-made intelligence innovation in their tasks. The meetings will be directed with a purposive example of venture chiefs who have been distinguished as having broad involvement with involving simulated intelligence in their tasks.

Information Assortment

The overview will be created in light of the writing audit and will incorporate inquiries that action the degree to which project supervisors use artificial intelligence innovation in their activities, their impression of the advantages and difficulties of utilizing computer-based intelligence, and the effect of computer-based intelligence on project results. The study will be pilot tried with a little example of task supervisors prior to being managed to the bigger example.

The semi-organized meetings will be led with a purposive example of task chiefs who have broad involvement with involving artificial intelligence in their undertakings. The inquiries questions will be created in view of the writing audit and will investigate the accompanying regions: how artificial intelligence is utilized in project the executives, the advantages and difficulties of involving man-made intelligence in project the board, and the effect of artificial intelligence on project results. The meetings will be recorded and translated for information examination.

Data Analysis

The quantitative information gathered through the overview will be dissected utilizing clear insights to sum up the reactions to each question. Inferential insights, for example, connection and relapse investigation, will be utilized to analyse the connections between factors.

The subjective information gathered through the meetings will be dissected utilizing topical examination. The records will be perused and once again read to distinguish repeating subjects and examples. These subjects will be coordinated into classes and subcategories, and the connections between them will be investigated.

Constraints

One constraint of this study is the potential for choice inclination. The review and meetings will just incorporate venture chiefs who have experience involving man-made intelligence in their activities, which may not be delegate of all undertaking administrators. Also, the review will be restricted to the viewpoints of task chiefs and wo exclude the perspectives on different partners like colleague or clients.

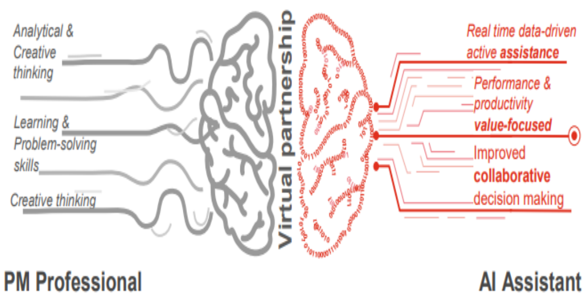

Fig. 1: Virtual partnership Man and the machine

The human-machine cooperation in which humans employ technology to improve their skills and produce better outcomes. In a number of areas, including healthcare, manufacturing, and finance, this alliance may result in greater efficiency, accuracy, and production.

The usage of robotic systems in operations, where a surgeon directs a robotic arm to carry out exact motions and delicate procedures, is one example of a virtual

DOI: rp-9788770040723.198

collaboration. With the help of this technology, the surgeon may carry out operations with more precision, lower risk, and better patient results. Using artificial intelligence (AI) to evaluate vast volumes of data and make investment decisions in the banking sector is another example. In order to forecast market movements and find investment possibilities, AI algorithms can evaluate historical data and market patterns. Overall, the virtual alliance between man and machine has the power to revolutionize a number of sectors, boost production and efficiency, and enhance people's quality of life. To prevent any unfavourable effects, it is crucial to make sure that technology is produced and utilized ethically and responsibly.

IV. Results

Computerized reasoning (simulated intelligence) is assuming an undeniably significant part in project the board. Computer based intelligence devices and procedures are being utilized to smooth out and robotize different parts of task the board, including planning, asset portion, risk the executives, and navigation. Artificial intelligence-based project the board instruments can assist with extending directors to recognize likely dangers and amazing open doors, screen headway, and settle on information driven choices to further develop project results.

One of the critical advantages of simulated intelligence in project the board is the capacity to deal with immense measures of information rapidly and precisely. This empowers project directors to pursue informed choices in light of constant information, as opposed to depending on verifiable information or instinct. Artificial intelligence can likewise assist with diminishing the gamble of human blunder and predisposition, prompting more exact and dependable undertaking results.

One more advantage of simulated intelligence in project the executives is the capacity to mechanize dull and tedious errands, like planning and asset portion. This can let loose undertaking directors to zero in on more significant level assignments and vital navigation, further developing generally project productivity and adequacy.

V. Conclusion

By and large, the effect of computer-based intelligence on project the board is critical and keeps on developing. Simulated intelligence-based project the board devices and strategies can assist with extending directors to further develop project results by giving continuous information, lessening the gamble of human mistake, and robotizing tedious assignments. In any case, it is essential to take note of that man-made intelligence is certainly not a substitute for human judgment and navigation, and venture supervisors ought to keep on utilizing their mastery and experience to direct project the board processes. As man-made intelligence innovation keeps on developing, project administrators ought to be ready to adjust and coordinate new apparatuses and strategies into their task the board practices to remain on the ball.

***Abstract*—Colours is an important aspect of visual communication and can have a significant impact on human behaviour and emotions. The use of colours in marketing, advertising, and promotion can influence consumer behaviour, brand perception, and purchasing decisions. This paper explores the influence of colours psychology in marketing, advertising, and promotion, with a focus on the psychological effects of colours on consumer behaviour. In marketing, advertising, and promotion, colours are crucial. They are a us eful tool for organizations since they affect customer emotions, perceptions, and behaviour. This essay investigates the psychology of colours and how they affect marketing tactics. According to research, various hues can have varied psychological effects on people, affecting their perception, cognition, and mood. For instance, the colours red and blue are related to trust and competence while excitement and passion are connected with red. Businesses may affect customer behaviour and improve brand awareness by choosing the right colours in marketing initiatives. The psychology of colours in marketing, advertising, and promotion, emphasizing how colour affects how consumers perceive products, how brands are perceived, and how they behave. Additionally, it looks at how culture and circumstance affect perception and colour choice. According to the study's findings, organizations may use colour psychology as a useful tool to convey their message and improve brand awareness. However, while choosing colours for marketing campaigns, it is crucial to take cultural and contextual aspects into account. The ramifications of colour psychology for businesses are covered in the paper's conclusion, along with potential areas for further study.**

Keywords—Colours psychology, marketing, advertising, promotion, consumer behaviour, brand perception, purchasing decisions.

I. Introduction

This template, Colours is a powerful tool in marketing, advertising, and promotion, as it can influence consumer behaviour and brand perception. Colours psychology is the study of how colours affect human behaviour, emotions, and decision-making. It is a crucial aspect of marketing, as the colours used in marketing materials can impact consumers' perception of a brand and influence their purchasing decisions. Therefore, understanding the psychological effects of colours is essential for businesses to develop effective marketing strategies.

Colours can influence different aspects of consumer behaviour, such as attention, perception, and memory. For example, bright colours such as red, yellow, and orange can attract attention and increase brand recognition. In contrast, cooler colours like blue and green can create a sense of calmness and relaxation, which can be useful in promoting wellness products.

Moreover, colours can also evoke specific emotions and associations. For example, the colours red can evoke feelings of passion, excitement, and urgency, making it useful in promoting sales or limited-time offers. On the other hand, the colours green is associated with nature, health, and freshness, making it suitable for promoting organic or eco-friendly products.

In this paper, we will explore the impact of colours psychology on marketing, advertising, and promotion. We will discuss how different colours can influence consumer behaviour, brand perception, and purchasing decisions. Additionally, we will examine the cultural and contextual factors that may affect the effectiveness of colours in marketing. Finally, we will provide practical recommendations for businesses to use colours effectively in their marketing strategies.

II. Literature Review

Colours psychology is the study of how colours influence human behaviour, emotions, and decision-making processes. In marketing, advertising, and promotion, colours psychology is used to evoke specific emotions and responses from customers. This literature review will explore the current research on the influence of colours psychology in marketing, advertising, and promotion.

One of the most popular and well-known studies on colours psychology in marketing is the study by Satyendra Singh, titled "Impact of Colours on Marketing." Singh's study found that up to 90% of snap judgments made about products can be based on colours alone. Moreover, colours can influence how customers perceive the brand's personality and the product's quality. For example, blue is often associated with trust and reliability, while red is associated with excitement and passion.

Another study by Morin, Raynesway, and Shocker investigated the effect of colours on consumers' brand personality perceptions. The study found that colours affect how consumers perceive brand personality traits such as sincerity, excitement, competence, and sophistication. The

DOI: rp-9788770040723.199

study showed that colours can help create a unique brand identity and enhance brand recognition.

In addition to the impact of colours on branding, research has also shown that colours can influence consumer purchase decisions. Research by Lee and Labron demonstrated that consumers are more likely to make impulsive purchases when exposed to warm colours such as red and yellow. The study also found that cool colours such as blue and green are more effective in promoting products that require a higher level of cognitive processing.

Moreover, research has shown that colours can be used to enhance advertising effectiveness. A study by Outercoat and van der VA art found that colours ads are more effective in attracting and retaining attention than black and white ads. Furthermore, the study showed that colours can help improve memory recall and emotional engagement with the advertisement.

Colours psychology has a significant influence on marketing, advertising, and promotion. Research has shown that colours can affect how customers perceive brands, influence purchase decisions, and enhance advertising effectiveness. Therefore, understanding the impact of colours on consumer behaviour is essential for creating successful marketing campaigns and promoting brand recognition.

III. Chromatology Theories

The use of colours in marketing, advertising, and promotion has been a topic of interest for many years. The concept of chromatology, which is the study of colours and its effects on human behaviour, has been used to understand the influence of colours psychology in these fields. There are several chromatology theories that explain how colours can influence people's perceptions, emotions, and actions.

1. The Colours Association Theory: This theory suggests that people associate specific colours with certain emotions or ideas. For example, the colours red is often associated with passion, energy, and excitement, while blue is associated with calmness, trustworthiness, and professionalism. Marketers and advertisers use this theory to choose colours that evoke the desired emotions or associations in their target audience.

2. The Colours Context Theory: This theory suggests that the context in which a colour is used can influence its effect on people. For example, the colours green can be associated with nature and health, but in a financial context, it can also be associated with money and wealth. Marketers and advertisers use this theory to choose colours that fit the context of their message.

3. The Colours Symbolism Theory: This theory suggests that colours can have cultural or symbolic meanings that vary across different cultures and societies. For example, in Western cultures, the colours white is often associated with purity and innocence, while in some Eastern cultures, it is associated with death and mourning. Marketers and advertisers need to be aware of these cultural differences to avoid using colours that may be offensive or inappropriate.

4. The Colours Arousal Theory: This theory suggests that colours can stimulate certain physiological responses in people, such as increased heart rate or blood pressure. For example, the colours red can increase excitement and energy, while blue can have a calming effect. Marketers and advertisers use this theory to choose colours that can create the desired physiological response in their target audience.

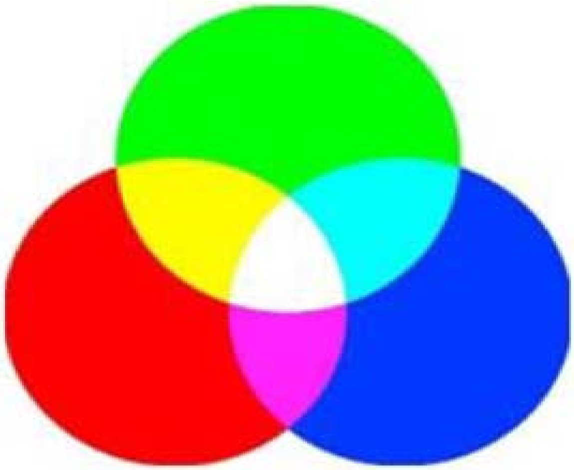

Fig. 1: model RGB

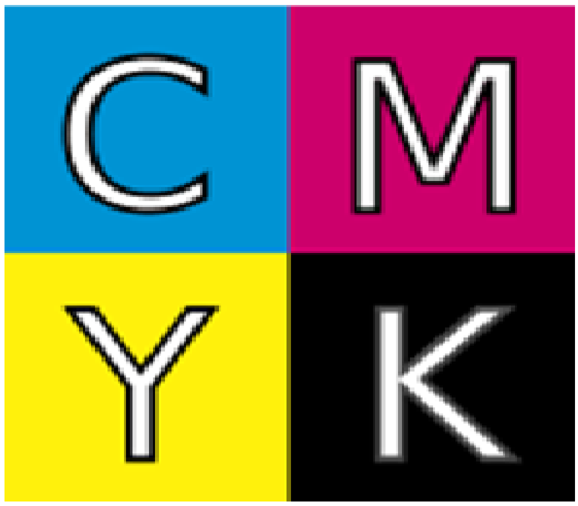

Fig. 2: model CMYK

IV. Results

The study found that colour psychology has a significant influence on marketing, advertising, and promotion strategies. The research indicates that different colours evoke different emotions and feelings in individuals, which can affect their behaviour, purchasing decisions, and brand perception.

Red, for example, is associated with excitement, passion, and urgency, making it suitable for promotions and sales. Blue, on the other hand, conveys trust, reliability, and security, making it an ideal colour for brands in the finance and technology industry. Green is associated with nature, health, and tranquillity, making it a suitable colour for eco-friendly products and services.

DOI: rp-9788770040723.199

Moreover, the study found that colour schemes should be consistent with the brand identity and target audience. Companies that successfully incorporate colour psychology in their branding and marketing efforts can create a strong emotional connection with their target audience, leading to increased brand loyalty and customer retention.

V. Conclusion

Colour psychology plays a crucial role in marketing, advertising, and promotion strategies. The study suggests that understanding the emotional associations of different colours can help companies create effective marketing campaigns that resonate with their target audience. The consistent use of colours that align with the brand identity can help companies establish a strong emotional connection with their audience, leading to increased brand loyalty and customer retention. Therefore, it is essential for companies to consider colour psychology when developing marketing and advertising strategies.

According to research, various hues can have varied psychological effects on people, affecting their perception, cognition, and mood. For instance, bright hues like red and orange are related to fervour and emotion, but cold hues like blue and green are associated with competence and trust. Businesses may affect customer behaviour and improve brand awareness by choosing the right colours in marketing initiatives. The results of this study have a number of business-related consequences. First and foremost, organizations must comprehend how colour psychology affects customer behaviour. Businesses may promote brand recognition, boost sales, and leave a lasting impression on their target audience by choosing the correct colours for their marketing initiatives. Second, companies should take cultural and contextual elements into account when choosing colours for their marketing initiatives. They may avoid cultural misconceptions as a result, and their marketing initiatives will be successful across a variety of cultural situations.

The marketing, advertising, and promotion all heavily rely on the psychology of colours. Businesses may design successful marketing efforts that increase brand identification by knowing how colour influences customer behaviour and taking cultural and contextual considerations.

However, while choosing colours for marketing campaigns, it is crucial to take cultural and contextual aspects into account. Culture-specific colour perceptions and preferences might have a varied impact on consumer behaviour. Red, for instance, denotes danger and caution in certain cultures while representing success and wealth in others. Consequently, while choosing colours for their marketing, firms need to take cultural variances into consideration.

***Abstract*—Recruitment and employment trends are constantly evolving, and it is crucial for human resource professionals to stay abreast of these changes. This paper aims to provide an overview of the recruitment and employment trends in the Indian context. The paper reviews various sources to analyse the current trends in the Indian job market, such as the growth of the gig economy, the increasing use of social media for recruitment, and the shift towards a more diverse and inclusive workplace. The paper also discusses the impact of the COVID-19 pandemic on the Indian job market and how it has altered the recruitment and employment landscape. The study provides insights into the current and emerging recruitment and employment trends, and the challenges and opportunities they pose for HR professionals.**

Keywords—recruitment trends, employment trends, HR, Indian job market, gig economy, social media recruitment, diversity, inclusion, COVID-19, challenges, opportunities.

I. INTRODUCTION

This template, Recruitment and employment trends have undergone significant changes in recent years, driven by technological advancements, changing workforce demographics, and global economic shifts. The Indian job market is no exception to these changes. As quite possibly of the quickest developing economy on the planet, India has seen a fast change in its work market over the course of the last ten years.[1]

This paper examines the current recruitment and employment trends in the Indian context and their impact on HR practices. The study highlights the importance of staying abreast of the latest trends in recruitment and employment to effectively attract and retain top talent. The paper also aims to identify the challenges and opportunities presented by these trends and suggests strategies for HR professionals to adapt to the changing landscape.[2]

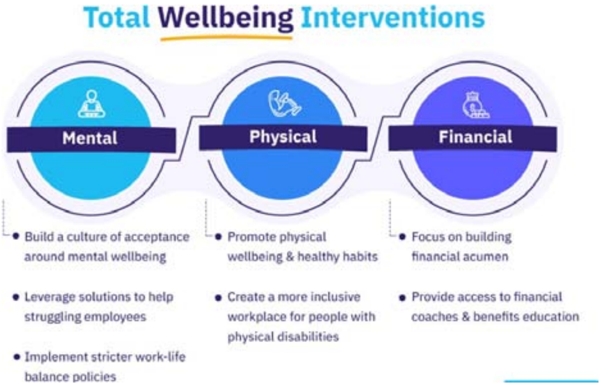

Fig. 1. HR will put a special emphasis on several facets of wellbeing, starting with its own.

II. LITERATURE REVIEW

Recruitment and employment trends have a significant impact on the human resource (HR) practices of any organization. In the Indian context, recruitment and employment trends have been subject to various economic, social, and political changes, which have shaped the HR practices in the country. This literature review provides an overview of the recruitment and employment trends in HR from an Indian perspective.[3]

Recruitment Trends

The enlistment cycle has gone through tremendous changes throughout the long term in India. One of the significant changes is the reception of innovation in the enlistment cycle.With the emergence of social media platforms, companies have started using them for sourcing and screening candidates. According to a survey conducted by LinkedIn, social media is one of the most effective ways of sourcing candidates in India. The survey also revealed that employee referrals are still one of the most popular ways of sourcing candidates.[4]

One more pattern in enrolment is the utilization of man-made reasoning (man-made intelligence) and AI (ML) calculations. These advances help in distinguishing the right competitors by examining their resumes and other applicable information. Many organizations in India have proactively begun involving man-made intelligence and ML in their enlistment cycle to save time and further develop effectiveness.[5]

Employment Trends

The work patterns in India have likewise seen huge changes as of late. One of the most striking changes is the rising number of ladies joining the labour force. As indicated by a report by McKinsey, India can possibly add $700 billion to its Gross domestic product by 2025 by propelling orientation uniformity. The report likewise features that ladies' support in the labour force has expanded from 21% in 2014 to 24% in 2019.[6]

Another pattern is the ascent of the gig economy. With the development of web-based business and advanced stages, many individuals in India are picking outsourcing and temporary positions. As per a report by KPMG, the gig

DOI: rp-9788770040723.200

economy in India is supposed to develop at a CAGR of 17% by 2023. This pattern has additionally prompted the development of new position jobs, like web-based entertainment chiefs, content journalists, and computerized advertising specialists.[7]

III. Frameworks

1. Technology-based Recruitment: Technology is changing the way recruitment is done in India. Recruitment portals, social media platforms, and other online tools are now being used to source candidates. This trend is expected to continue as companies adopt more digital strategies.
2. Remote Hiring: With the pandemic forcing companies to work remotely, remote hiring has become the norm. This trend is expected to continue even post-pandemic, as it helps companies access a wider pool of candidates and reduces recruitment costs.
3. Employer Branding: Building a strong employer brand has become essential for attracting top talent. Companies are investing in employer branding initiatives to differentiate themselves from their competitors and attract the best talent.
4. Diversity and Inclusion: Companies are focusing on diversity and inclusion initiatives to create a more inclusive workplace. This includes actively seeking out diverse candidates and providing training and support for employees from underrepresented groups.
5. Data-Driven Recruitment: Data analytics is being used to optimize recruitment processes. Companies are using data to identify the best channels for sourcing candidates, predict candidate success, and improve candidate experience.

- Framework for Employment Trends in HR - Indian Perspective:

1. Gig Economy: The gig economy is growing in India, with more people opting for freelance and contract work. This trend is expected to continue as technology makes it easier for people to work remotely and on-demand.
2. Upskilling and Reskilling: As automation and AI disrupt traditional jobs, upskilling and reskilling have become essential for staying employable. Companies are investing in training programs to help employees develop new skills and adapt to changing job requirements.
3. Employee Wellness: Employee wellness has become a key concern for companies, especially in the wake of the pandemic. Companies are investing in wellness programs to support employees' physical and mental health.
4. Flexible Work Game plans: With remote work turning out to be more pervasive, organizations are likewise offering adaptable work courses of action, like adaptable hours and packed work weeks, to assist representatives with adjusting work and individual responsibilities.
5. Human-Cantered HR: Companies are shifting towards a more human-cantered approach to HR, where the focus is on creating a positive employee experience. This includes providing personalized support and feedback, recognizing employee contributions, and promoting work-life balance.

Fig. 2: HR Trends

The adjustments and advancements in HR that businesses use to recruit, manage, and keep employees.

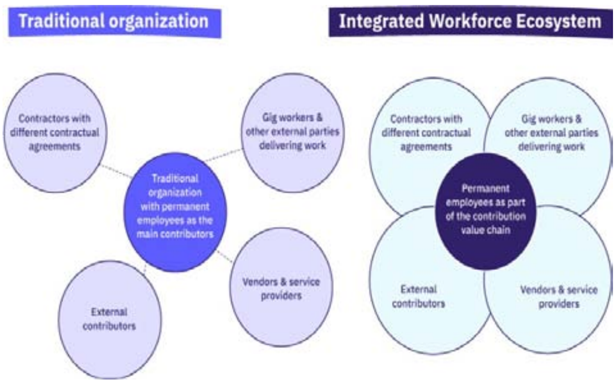

Fig. 3: The workforce

IV. Results

Recruitment and employment trends in HR in India have been significantly impacted by the COVID-19 pandemic. Many companies had to freeze hiring and reduce their workforce due to the economic downturn caused by the pandemic. However, as the economy is gradually recovering, companies are resuming their hiring efforts, with a particular focus on digital skills and remote work capabilities.

Another pattern that has arisen is the rising utilization of innovation in the enlistment cycle, including the utilization of man-made consciousness (simulated intelligence) and AI (ML) for continue screening and competitor determination. This has prompted a more effective and smoothed out enrolment process, however it has likewise raised worries about predisposition and separation in algorithmic direction.

DOI: rp-9788770040723.200

There is also a growing emphasis on diversity, equity, and inclusion (DEI) in the hiring process, with companies implementing strategies to attract and retain a diverse workforce. This includes initiatives such as bias training, inclusive job descriptions, and diversity recruitment programs.

V. Conclusion

Recruitment and employment trends in HR in India are rapidly evolving, with a focus on digital skills, technology-driven recruitment processes, and DEI initiatives. As the economy continues to recover from the pandemic, companies will need to adapt to these trends to attract and retain top talent in a highly competitive job market. Additionally, it is important for companies to remain vigilant about potential biases in their recruitment processes and to implement strategies to ensure that they are attracting a diverse and inclusive workforce.

Due to shifting business and economic situations, the recruiting and employment patterns on the Indian job market have changed recently. Employers now place greater emphasis on finding candidates with a variety of skill sets and experience than simply academic credentials. As a result, there are now more work options available for those with non- traditional educational backgrounds.

Additionally, employer branding has received more attention and is now a crucial component in luring and keeping top people. Through social media, employment portals, and other marketing activities, many businesses have begun to spend in enhancing their brand's perception.

The recruiting procedure has changed as a result of the use of technology in India. To draw prospects and speed up the recruiting process, several businesses have started embracing online recruitment portals. Automation of hiring procedures like candidate screening and matching is also becoming more common thanks to artificial intelligence (AI) and machine learning (ML).

Finally, there has been an emphasis on employee engagement and retention, with businesses providing their staff with improved incentives and bonuses. Organizations now place a strong emphasis on skill development and career advancement, which has led to employee development and training programs being an essential component of the hiring process. In order to attract and keep top talent, it is crucial for firms to keep up with the most recent trends in recruiting and employment from an Indian viewpoint.

***Abstract*—People over the age of sixty are disproportionately affected by Alzheimer's disease (AD), making a few of the most typical kinds of dementia. Very few reliable diagnostic methods exist at this time for detecting AD in its earliest stages in clinical practice. There is currently no treatment or cure for Alzheimer's disease, and clinical trials for potential treatments are very likely to fail. Very mild dementia, mild dementia, and moderate dementia are all distinct stages of Alzheimer's disease. It's not easy to see the decline into absolute health lessness, memory loss, and dependence on others that comes with these early stages of dementia. By training the network using a collection of brain imaging data, VGG 16 may be used to generate predictions for the diagnosis of Alzheimer's disease (AD). This method relies on the observation that people with AD exhibit distinct patterns of brain activity and structural change. An extensive database of MRI scans from people with Alzheimer's disease (AD) and healthy controls may be employed to demonstrate VGG 16 network to recognize tell-tale signs of the illness. After the image has been trained, it can categorize people as having or not having AD based on brain imaging data. Patients can also make appointments with these doctors who specialize in dementia, and doctors can also recommend the best medications for the disease which have been found.**

Keywords—Machine Learning, Deep Learning, MRI, Visual Geometry Group, CNN.

I. Introduction

Alzheimer's disease (AD), often known as dementia, is caused by permanent damage to the brain's memory cells. Deterioration of the visual cortical tissues and problems in the nerve cells are to blame for memory loss. Normal brain function is severely impaired in people with AD, making it hard for them to carry out routine tasks like speaking, writing, and reading effectively. In the later stages of this condition, patients may have life threatening symptoms include difficulty breathing and heart failure. Although life expectancy may be increased, it is very difficult to establish an early and accurate diagnosis of AD. Although AD symptoms emerge slowly, the situation for patients deteriorates as the disease advances. The search estimates that by 2050, one in every 85 individuals would be living with Alzheimer's disease. According to studies, this disease is the second most serious brain ailment in the globe. This disease destroys neurons and often manifests in the hippocampus region before spreading to the rest of the brain and spreads over. However, AD development and negative consequences may be mitigated with early diagnosis and therapy. Both mental and physical well- being are essential for a fulfilled human existence. Using MRI scans and a Deep Learning model [8], CNN is suggested for the diagnosis of Alzheimer's disease. VGG16, the features utilized in the CNN-based- trained model, are used to remove the features from trained model, are used to remove the features from the MRI scan picture shown in Fig 1.

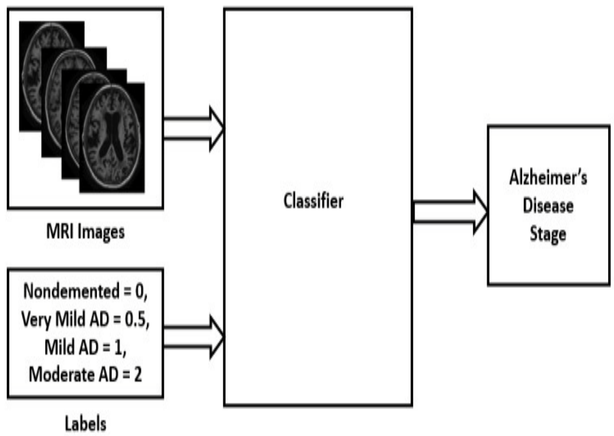

Fig.1. Detection of Alzheimer Disease

II. Literature Survey

Abrol, Anees, et al. [1] suggested research utilizes transfer learning with VGG16 and Fast as to conduct multilevel categorization of Alzheimer's disease, separating cases into four distinct categories: mild dementia, moderate dementia, non-demented, and very mild dementia. Prediction accuracy for this method is 99%, which is a substantial increase over that achieved in past studies and provides enough proof of the effectiveness of the proposed tactics.

Rakesh Reddy M [2] proposed a system to identify AD using MRI scans from the ADNI database, this study examined the results and performances of two distinct

DOI: rp-9788770040723.201

convolution neural network models, namely VGGNet-16 and VGGNet-19. Different slice ranges, a random validation split, a cross validation, and leaving out the hippocampus all played roles in the CNN models' training.

The findings demonstrate that the models are effective at recognizing true-negatives or correctly identifying a healthy patient. The two CNN models' AD classification accuracy varied from 66.6% to 74.8%, depending on the training approach used.

De Silva, S., S. Dayarathna, and D. Meedeniya [3] showed a 3D axial brain pictures from an MRI which is retrieved and fed into a convolutional neural network for multiclass categorization (CNN). Comparisons were made between a custom-built CNN, a VGG-16 model, and a ResNet-50 model. In order to diagnose Alzheimer's disease and classify the patient's severity of memory deterioration using the VGG-16.

E. Loveman, C. Green, J. Kirby et al. [4] Axial Sagittal or Coronal slices of the 3D pictures are provided as input in [9], with each slice having the size of a single image pixel (176x220) axial slicedimension. As dimension reduction gets extremely complicated for classification, they used PCA+TSNE.The reduced dimension is now 609x3=1827, which is derived from a single RAW MRI scan using created CNN features. The outcome will thus be determined by which of two separate working principles—Navies Bayes and KNN—has the maximum accuracy.The Trained CNN with the proposed concept has the maximum accuracy in this instance, at 88.2%.

Jeny Benios [5] developed a model in Python, and its implementation provides a system that is very useful to physicians for the classification of Alzheimer's disease. Using70% photos from the training set and 30% images from the validation set, our trained model achieved perfect accuracy on a separate, held-out test set.

Garcia-Gutierrez, Fernando, et al. [6] In this publication, the authors proposed using a VGG-Twin former model built on Transformer and convolutional neural network (CNN) for short-term longitudinal studies of MCI. This model progressively fuses far-flung spatial feature representations by superimposing attention windows of varying widths, with sliding window attention being employed for fine-grained fusion of spatially adjacent feature representations.

R.G.DeSouza, W.P.Dos Santos [7] proposed a low-level spatial characteristics of longitudinal sMRI images are extracted using a VGG-16-based CNN, and then mapped to high-level feature representations via temporal attention. In order to ensure the accuracy of their results, consulted the ADNI dataset. The sMCI vs. pMCI classification job has an accuracy of 77.2%, sensitivity of 79.97%, specificity of 71.59%, and area under the curve (AUC) of 0.8153. Lei et al. detected the connection among the data and the brain areas using a multi-layered independently RNN model. The experiment by the authors uses the ADNI dataset, and extraction of features and image processing are also carried out to obtain the clinical score from the dataset.

III. Proposed System

The proposed approach consists of three parts: image acquisition. pre-processing, model training, feature Extraction, classification shown in Fig 2.

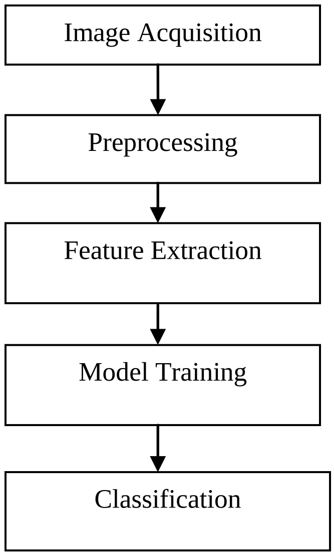

Fig.2. Workflow Of Proposed System

The system adheres to the step-by-step process of data preprocessing and classification depicted in Fig 3.

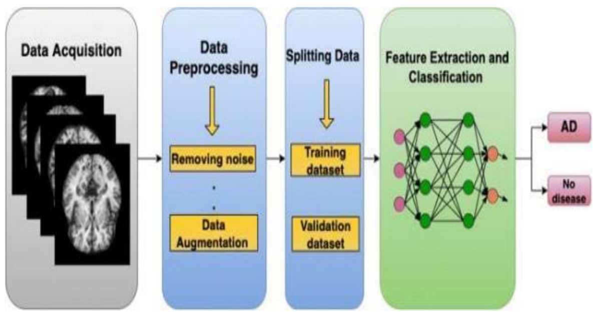

Fig.3. Module Flow

A. *Image Acquisition*

Magnetic resonance imaging [5] is a diagnostic tool used in the medical field to identify and see anatomical structures at a microscopic level. There is no better method than this one for identifying tissue differences. Brain photos taken from public sources on the Internet may be uploaded using this module. In terms of file size and format, images may be anything. An image must first be recorded by a camera and transformed into a controllable entity before any video or image processing can start. The "Image Acquisition" procedure entails the conversion of an optical image (Real World Data) into a collection of numerical data that can then be processed by a computer as shown in Fig 4.

DOI: rp-9788770040723.201

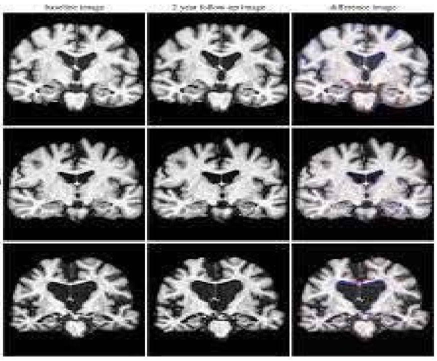

Fig.4. Structural Brain Imaging

B. Preprocessing

This section allows to adjust the picture size so that it fits on the page. In order to clean up the photos, use the median filter method. Each output sample in a median filter, a kind of nonlinear filter, is calculated as the middle value after all input values have been sorted according to the window. The purpose of preprocessing [4] is to enhance the picture data by reducing artefacts and highlighting certain details that will be useful in the analysis and processing that follows. After that, it uses the median filter technique to clean up the photos as shown in Fig 5.

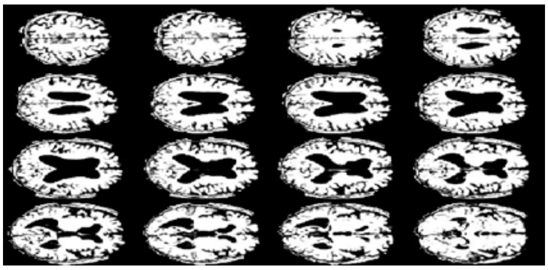

Fig.5. Pre-Processing

C. Feature Extraction

By effectively reducing the amount of data feature extraction [7] enables the selection and fusion of variables into features, enabling the acquisition of the best feature from such enormous data sets. Moreover, it may help cut down on duplicate information in an analysis. The time it takes for the machine to learn something new and for that learning to generalize to other situations is reduced by the data reduction and the work it puts into constructing variable combinations.

D. Classification

An Example of Magnetic Resonance Biomedical imaging techniques allow for the detection and visualization of anatomical features previously undetectable to the plain sight [9]. There is no better method than this one for identifying tissue differences. Gather diagnostic information by extracting features and matching them against a model file. Predictions from a model trained with all training instances except those used to estimate feature selection values [6] were used to measure the model's performance on the validation set. When in beta, the user may input a brain picture and offer information about a diagnosis based on the illnesses indicated by the system as depicted in Fig 6.

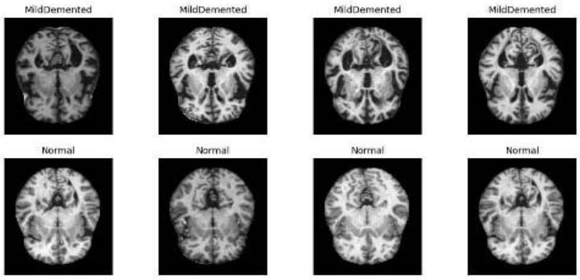

Fig.6. Classification Of MRI

IV. Algorithm

A. Visual Geometry Group 16

The very compact VGG16 design consists of convolution, a fully connected layer, and a pooling layer. This architecture is also featured in the Alex Net model[3]. There are a total of 16 levels, if the pooling layer is not included. The size of this structure grows as more layers are added to it. The standard input size for this network is 224x224 pixels, and the standard filter size is 3x3. Class probabilities are sent to the network's output layers through an activation function at the network's final stage.

To perform image classification tasks, VGG16 is a deep learning model [10] that was trained on a huge dataset of pictures. Features from MRI of the brain may be extracted using VGG16 for the purpose of Alzheimer's disease prediction. The collected characteristics may be fed into a different classifier neural network [1,2], to make predictions about Alzheimer's disease and its severity. The rationale behind employing VGG16 for Alzheimer's disease prediction is that it has already learnt to detect patterns and characteristics in pictures with the value for image classification, and these features may be reused for a new job.

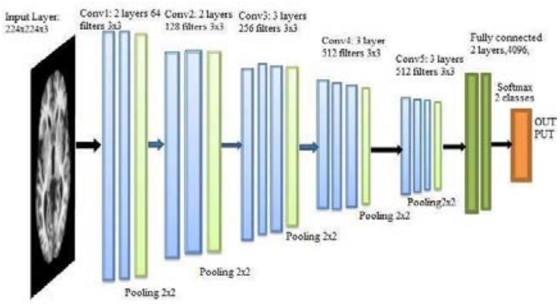

Fig.7. CNN Layer

The VGG16 network's first layer has been fed the 224x224 pixel pictures for feature extraction. The images then pass through further convolutional layers shown in Fig 7.

A stack of two convolutions with a receptive area of 3x3 is used immediately after the ReLU activation functions to convey the 224 x 224-pixel image. Each of these levels has 64 individual filters. With the stride value fixed at 1, the

DOI: rp-9788770040723.201

padding is also fixed at 1 pixel. The spatial resolution is preserved in full, and the dimensions of the activation at the output are identical to those at the input in this design. Activations with a stride value of 2 pixels are sent to the pooling layer because the window size is 2 by 2. The VGG16 network's first layer has fed the 224 x 224-pixel pictures for feature extraction. The images then pass through further convolutional layers. A stack of two convolutions with a receptive area of 3x3 is used immediately after the ReLU activation functions to convey the 224x224-pixel image. Each of these levels has 64 individual filters. With the stride value fixed at 1, the padding is also fixed at 1 pixel. The spatial resolution is preserved in full, and the output activation dimensions match those of the input pictures thanks to this design. Activations with a stride value of 2 pixels are sent to the pooling layer due to the fact that the window size is 2 by 2. Using the SoftMax function [11], the number of storage nodes in the final layer is proportional to the number of classification task divisions.

B. Softmax Classifier

For classification, SoftMax employs the cross-entropy loss. The SoftMax classifier gets its name from the SoftMax function, which converts the raw class scores into normalized positive values that amount to one in order to employ the cross-entropy loss.

$$\sigma(z)i = \frac{e^{z}i}{\sum_{j=1}^{k} e^{zj}} \qquad (1)$$

For a k-class multiclass classifier given in (1), the SoftMax function is defined as Z, the input vector. where z^i is a component of the input vector, and it may take any real value. Assuming a uniform probability distribution, the normalization factor at the end of the equation ensures that the function's output values add up to 1. An input vector to the SoftMax function consists: (z0, ... zK) The standard exponential function is applied to each element of the input vector. The resulting number is positive and bigger than zero, albeit how much greater depends on whether the input was little or large. A probability, by definition, must lie between zero and one, yet it is still not constrained to that interval. Each component of the input vector is multiplied by the universal exponential function.

The result is a non-negative number greater than zero, which is very small if the input is negative and extremely huge otherwise. To be meaningful, the range of a probability has to be restricted to (0, 1). The conditional probability of each class is determined by the SoftMax function [12], which is given the input picture. In a similar vein, it details the probabilities of each category. The goal of the model is to maximize the conditional probability of the class that is assigned to a given feature vector in the fully connected layer.

The VGG16 network was modified by adding a new unskilled dense layer at the very end. Next, the entire network is trained using the dataset provided. The categorical cross entropy is the cost function for multiclass classification. One way to characterize the classification entropy is as follows: where z^i is a segment of the input vector for z and j is the jth class were halted in order to produce our CNNs' models because to the fact that filters in the foundation layers [15] search for low-level components in pictures, such as angles and lines. Only the fifth block, where the filters check for abstract traits, was trained.

Convolutional neural network (CNN) VGG-16 is one that was suggested in this model. To do this, normalize the input photos and create the training and validation sets. The regulation in the fully linked layer is another feature of the VGG-16 concept. Before training, the VGG-16 model architecture on the brain, database is removed when completely linked, producing meaningful vector pictures.

V. RESULTS AND EXPERIMENTS

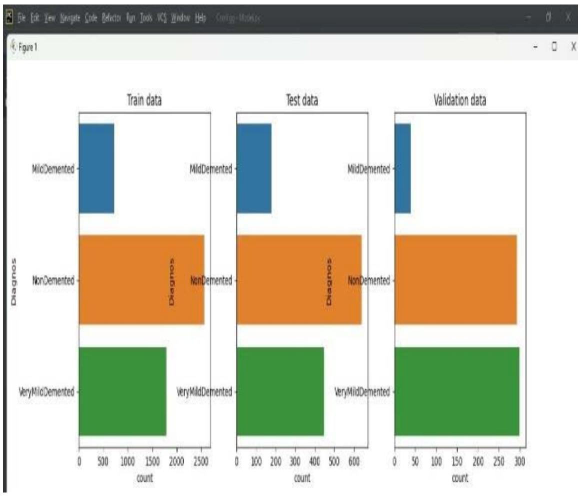

Fig.8. ccuracy Loss

The quality and size of the training dataset, the selection of hyperparameters, and the algorithm's performance on the validation set are some of the variables that affect the accuracy loss in Alzheimer's disease prediction using VGG16 shown in Fig 8. However, it is well known that deep learning models, like VGG16, may do extremely well in image classification tasks, such as predicting Alzheimer's disease from brain scans. It can further optimize the model by adjusting the hyper parameters [14], adding or removing layer, or using a different optimization approach if the accuracy loss is significant.

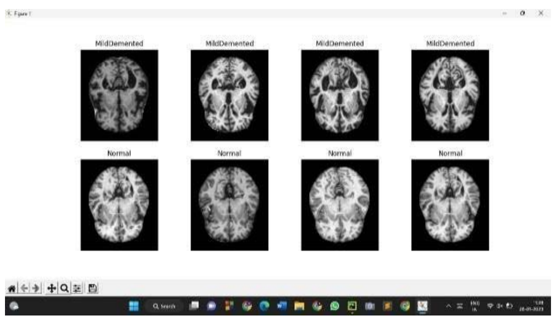

Fig.9. Classification of MRI

DOI: rp-9788770040723.201

Gather the brain MRI scans and the associated diagnosis, then separate the data into training, validation, and testing sets. Prepare the data for use in the model by preprocessing it, as by normalizing the intensity values and shrinking the photos to a specific size. Fig 9 shows as a starting point, can be utilized a convolutional neural network (CNN) architecture like VGG16.

These pretrained models can be adjusted using the data, or create a new architecture from start. Utilize the training set to develop the model, then by using the validation set to test it. After training, assess the model on the test set to determine how well it performs in separating healthy from Alzheimer's MRI scans. Metrics like accuracy can be evaluated. (AD) research is increasingly using positron emission tomography (PET) imaging that focuses on neurofibrillary tau tangles [13], however its value may be restricted by traditional quantitative or qualitative assessment methodologies in early disease phases. When it comes to recognizing and learning from spatial patterns in images, VGG16 performs well. Fig 10 depicts the training and validation accuracy for each epoch and Fig 11,12 shows the results for Alzheimer's Disease Prediction.

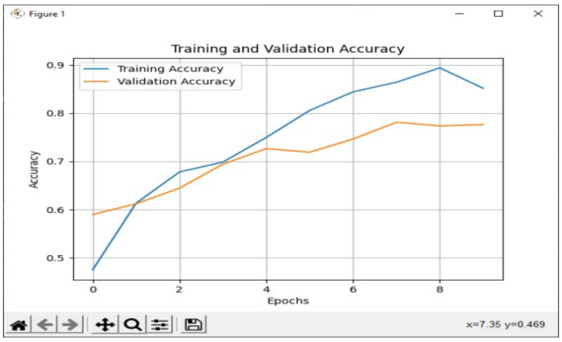

Fig.10. Training and Validation Accuracy

Fig.11. AD Prediction

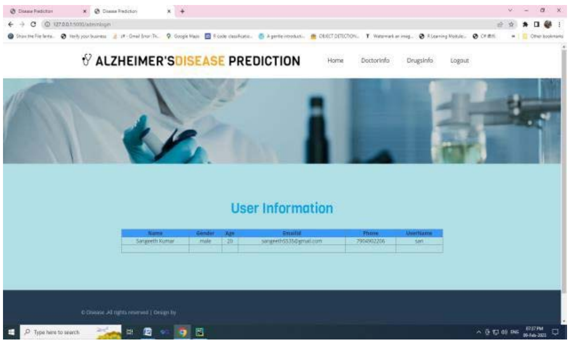

Fig.12. User information

VI. Conclusion and Future Enhancement

With further time and thorough investigation, the suggested system may be improved in the future. To further expand the diagnostic choices available to the physician employing PET, new Alzheimer's disease detection algorithms may be implemented. Alzheimer's disease (AD) research is increasingly using positron emission tomography (PET) imaging that focuses on neurofibrillary tau tangles; however, its value may be restricted by traditional quantitative or qualitative assessment methodologies in early disease phases. When it comes to recognizing and learning from spatial patterns in images, VGG16 performs well.

The most prevalent type of late-stage dementia, Alzheimer's disease (AD) is a progressive neurological condition. In this research, by comparing conventional ML with DL, then moved on to the AD diagnostic phase. Demonstrated a picture preprocessing approach used in Alzheimer's disease diagnosis to improve learning quality. And also showed other DL approaches that are often used in the classification process, including CNN, RNN, DNN, AE, and DBN. Disease categorization using DL is crucial, yet there are difficulties in working with the dataset. Hence, included a literature study for each difficulty and illustrated their proposed solutions. In this review, integrated preprocessing methods with the most popular DL approaches, compare distinct state-of-the-art research with their obstacles in dealing with datasets and classification stages, and present several preprocessing methods that were processed on neuroimaging.

***Abstract*—A progressive neurological disorder, Parkinson's disease(PD).People have trouble speaking, writing, walking, and doing other primary duties when particular brain regions' dopamine-producing neurons are harmed or die. These signs worsen with time, variable degrees of sickness aggravation in each person. In this research, we provide a method for calculating the Parkinson's Speech dataset from GitHub, deep neural networks were used to determine the severity of the condition. To forecast the severity of the illness and identify the condition, we have developed neural networks and machine learning algorithms. Parkinson's disease is categorized using both a random forest classifier and a neural network.**

Keywords—Parkinson's Disease (PD), UPDRS (unified Parkinson's disease rating scale, EMG, ACC, DN, RNN.

I. Introduction

The dopamine-producing brain cells are gradually destroyed by Parkinson's disease, a neurological illness., gradually affecting the sufferers' ability to move. This condition's symptoms include trembling, trouble moving, strange behaviour, dementia, and melancholy. The term "Parkinsonism" or "a Patient with Parkinson's Disease" is used to describe the main motor issues. One of the most frequent symptoms that may be picked up by listening to the patient's speech data is voice changes. The patient's speech starts to stutter as their condition worsens. As a method of analysing unstructured data, such as speech and voice signals, deep learning is gaining popularity.To create feature selection and classification models, deep neural networks usually use many layers of neurons. The speech data of the patient is categorised in this article into "extreme" and "not severe" categories using deep learning.

The motor and overall UPDRS (Unified Parkinson's Disease Rating Scale) scores were used in this study as comparison points. The total UPDRS has a score range of 0 to 176 while the motor UPDRS has a score range of 0 to 108 and examines the patient's overall abilities.. To measure the frequency and severity of tremors and dyskinesia in Parkinson's disease (PD) patients at a resolution of 1 second, algorithms are required that can analyze data from a large number of 3-D accelerometric (ACC) and surface electromyographic (EMG) sensors.

16 PD patients and 8 normal participants executed the algorithms in a home environment while doing free-form, spontaneous daily chores. The study demonstrated that dynamic pattern monitoring failure rates could be kept at 10% by utilizing dynamic support vector machines (DSVM), hidden Markov models (HMM), and dynamic neural networks (DNN). The effectiveness of these machine learning algorithms was confirmed by comparing them to independent clinical evidence of sickness prevalence and severity. In this study, a machine learning approach is developed to recognizee Parkinson's disease as well as a deep learning neural network to gauge the severity of the condition.

II. Literature Review

- *Selecting a Template*

The research on Parkinson's disease is extensive. even if the severity of Parkinsonism has received less attention. In these tests, several machine learning models were employed. Comparing neural networks to decision trees and machine learning algorithms, however, it was shown that they are the most systematic classifier and regression tool. In a research by Das et al..

1. Many classification algorithms were employed to make the PD diagnosis. Several studies have been conducted in an effort to develop a classifier that can forecast Parkinson's disease. The majority of research have employed variables gleaned from speech signals to predict the severity of PD.
2. Boosted accuracy while determining the severity of Parkinson's disease by using bagged decision trees. from patient audio recordings. Based on their UPDRS scores, Malekt et al.'s
3. There are four categories for PD patients: early, moderate, and advanced —used a dataset of 40 features. Using LLBFS, they identified the top nine characteristics for each class. (Local Learning Based Feature Selection).Using an audio dataset, Seeja K.R. et al.
4. Created a neural network for two-class classification.There were many different inputs and outputs used to construct the neural network.

DOI: rp-9788770040723.202

Regression isn't the neural network's primary objective; classification is. The outcome of the categorization has a 79% accuracy rate. The research paper for this study received the most mentions. The goal of this study was to use data from a keyboard typing test to identify whether or not the victim had Parkinson's disease. If so, we assessed how much the patient was utilising that knowledge to prevent them from communicating. For our detection investigation, we built upon a paper titled "High-accuracy identification of early Parkinson's disease utilising several features of finger movement during typing." In this study, multiple machine learning algorithms have been developed and evaluated in order to recognise Parkinson's disease and determine the optimal model for it.

III. Methodology

The approach suggested in Figure 1 arranges the procedures in a sequential manner, beginning with the collection of data and concluding with the selection of the model.

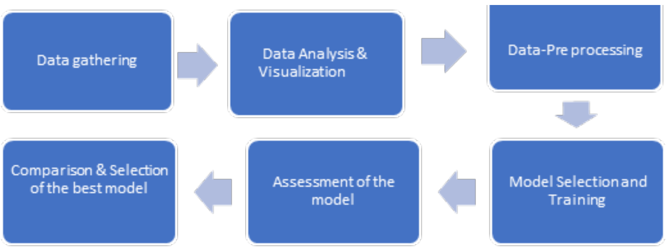

Fig 1. Recommended approach

- *Data Gathering*

Using two separate datasets, Parkinson's disease is identified and the degree of the problem is predicted. The dataset[7] contains the participants' typing data for detection. Australia, Canada, the United Kingdom, and the United States selected to participate in after reviewing the project website, the research. Under protocol number H17013, the Charles Sturt University Human Research Ethics Council in Australia approved the experiment. The duration of the typing activity when participants used their various Windows programmes is included in almost all data files that have been collected. (such as email, word processing, web searches, etc.). The timing accuracy of the keystrokes was achieved by the keystroke capture programme (called "Tappy"), which only delivered timestamps after a brief period of time.

There are two subgroups in the data files that are provided: The participants' personal information is contained in Group *1:* User Archives. (gender, the participant's diagnosis year, whether they have tremors, etc.) Tappy Data in Group 2 offers keystroke counts from certain individuals. (hold time, current hand, previous hand, etc.) The merged dataset consists of the columns "BirthYear," "Gender," "Parkinson," "Tremors," "DiagnosisYear," "Sided," "UPDRS," "Impact," "Levadopa," "DA," "MAOB," and "Other."

The experimental method predicted the UPDRS score for Parkinson's disease symptoms using a number of linear and nonlinear regression models.

In the Parkinson’s speech dataset, there are the following columns: Each subject's age is indicated by an integer called subject#. The subject's age, sex, and gender are noted. The number "M" for a male and "F" for a female denotes the gender of the topic. The days since recruitment are shown in the integer component. Motor total interpolated motor UPDRS score for the clinician Linear interpolation of the clinical professional's overall UPDR S score is known as UPDRS. There are several techniques to monitor changes in fundamental frequency, and they are all referred to as "jitter.". The ratio of the voice's noise to tonal components may be measured using the terms NHR and HNR. There are several amplitude fluctuation measurements that make up shimmer. RPDE is a sign of nonlinear dynamic complexity. Known as the DFA, the basic frequency fluctuation can be assessed nonlinearly using the signal fractal scaling exponent.

- *Data Analysis & Visualization*

The selection of the algorithm is greatly influenced by the type and quality of the data gathered. Knowledge of data is therefore essential. The author can visualize the data to better understand it using Python programs like Matplotlib, Seaborn, and others. Finding relevant relationships between classes or variables is aided by visualization.

- *Data Processing*

The information we gathered might not be suitable for analysis since it may be chaotic, have many missing values, be duplicated, noisy, and have extreme values. The author handles data, deals with missing values, replaces missing numbers with "NaN," removes duplicates, fixes outliers if present, and does data pre-processing and tuning. Actually, this stage entails removing irrelevant and insufficient data. This study further reduces the dimension of the data by reducing the amount of features in the dataset in order to prevent overfitting.

- *Selection & Trianing the Model*

As a beginning point, this activity is taken. Since a class is the result of the Parkinson's disease prediction, it is a classification problem. Since we utilize the UPDRS result to estimate the disease's severity during the detection phase, there is a regression problem. The classifier and regression methodology used in the study are as follows:

  - XGBoost
  - Regression neural network

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN}$$

The three subsets of the dataset that are utilised for machine learning are the training set, testing set, and validation set. Using a "training dataset," the classifiers are trained, and the parameters are adjusted using a "validation

DOI: rp-9788770040723.202

dataset," according to the author. Utilizing an original "test dataset," the classifier's performance is assessed.

The train and test datasets are frequently split in a 7:3 ratio.

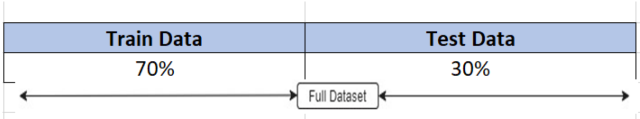

Fig 2. Train Test Split

- *Evaluation of Model*

  The effectiveness of machine learning algorithms may be determined using a variety of techniques. Using the confusion matrix, the author evaluates the model's accuracy. A table-based summary of predictions called a confusion matrix is used to assess the model's efficacy. The table displays a combination of anticipated and actual numbers. Below is a matrix of misunderstandings:

IV. Result

- Only a portion of the 217 individuals in the dataset for the diagnosis of Parkinson's disease were employed in the study that followed, which includes
- Documents with a minimum of 2000 keystrokes.
- Only a record of "moderate" severity among those who have Parkinson's disease (since the research concentrated on the early detection of the condition).
- People who don't take levodopa (Sinemet® and related medications) to offset any negative effects on typing tests from the medicine.

	Predicted patients with PD	Predicted healthy persons
Actual patients with PD	True positive (TP)	False negative (FN)
Actual healthy persons	False positive (FP)	True negative (TN)

There were 53 people in the group as a result. (comprised of PD and non-PD). The dataset also includes columns for the patients' birthdays, diagnosis years, genders, and medications.

In order to evaluate the severity of the illness, the 45 patients with Parkinson's disease in its early stages who volunteered to wear telemonitoring equipment for six months to follow the development of their symptoms are included in this dataset.

Subject number, subject age, subject gender, time since the first recruitment date, motor UPDRS, total UPDRS, and 16 biomedical voice measurements are the columns in the table. One of the 4,824 audio recordings that the chosen participants created is present on each CD. The data's main objective is to predict the 16 voice parameter's motor and overall UPDRS scores. (referred to as "motor UPDRS" and "total UPDRS" respectively).

CSV data were created using the information. (ASCII). A single speech or audio recording is represented by one occurrence per row in the CSV file. Each patient has 200 records total, with their subject number appearing in the first column.

The previous graphic displays the age distribution of both Parkinson's disease sufferers and healthy people. (Fig. 3). The strategy set forth. Fig. 3 depicts an age group with Parkinson's disease and vigorous individuals.

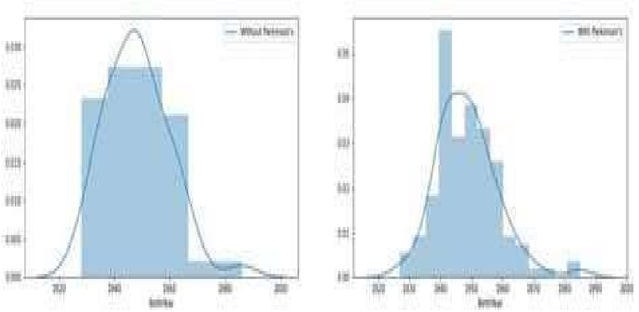

Fig 3. Age distribution of Parkinson's disease patients versus healthy individuals.

Parkinson's sufferers tend to be between the ages of 50 and 60. Therefore, there is a very low likelihood that a young individual would get Parkinson's. The model's development was significantly influenced by these facts. Fig.4 shows the gender-specific number of Parkinson's patients.

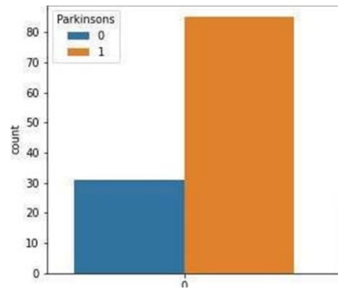

Fig 4. Gender Distribution

We were able to get to this conclusion since the gender distribution bar plot visual (Fig. 4) showed that more women than males had Parkinson's disease. Because it was made clear throughout the data collection stage that this information was gathered for various study with participants chosen at random, we may presume that this distribution shows a tendency that will be useful to our analysis.

Boxplots in Fig. 5 demonstrates how patients with and without Parkinson's disease have different distributions of various time data. (hold time, latency time, and flight time).

DOI: rp-9788770040723.202

The specifics of a particular sort of typing switch are covered in each subplot. In the upper left sub-plot, for instance (denoted as LL above the sub-plot), Typing data is displayed as participants switch from one left-handed key to another.

In contrast, typing data is displayed in the top right sub-plot when participants switch from a left-hand key to a space. (LS). These switches have the labels LL, LR, LS, RR, SL, SR, and SS. Fig. 5 shows the hold time, latency time, and flight time between each key when typing.

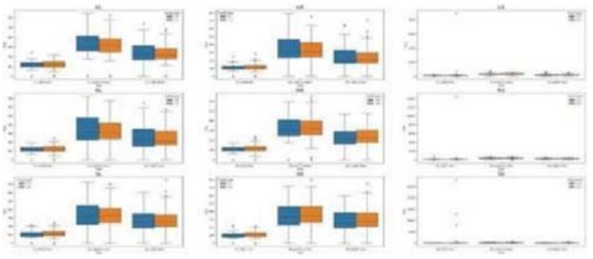

Fig 5. When typing, there are three things to consider: hold time, latency time, and flight time.

These numerous time periods were charted since they are important indicators when comparing a Parkinson's patient with a healthy person.

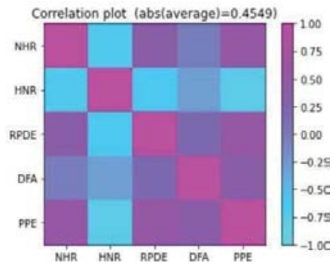

Fig 6 depicts a correlation map highlighting crucial elements required to anticipate the severity of Parkinson's disease

The feature importance approach was used to evaluate the most valuable characteristics and determine their significance. To illustrate the connections between a number of variables and the severity of Parkinson's disease, a correlation graph was made.

Figure 6 depicts a correlation map highlighting crucial elements required to anticipate the degree of Parkinson's disease severity.

The crucial traits for the feature selection stage have been identified using the correlation map displayed in above Fig. 6. Using correlation graphs in addition to EDA techniques like PCA, it was possible to identify important variables that have a significant impact on our forecast. We came to the conclusion that the Signal to Noise Ratio, among other features, is extremely significant and non-negligible for a suitable outcome for our investigation. This includes all voice measures, including Jitter (frequency fluctuation between sound wave cycles), Shimmer (amplitude variation between sound wave cycles), NHR and HNR (Noise to Harmonic Ratio) (Harmonic Noise Ratio). In this study, two models were utilized, one to assess whether a patient had Parkinson's disease or not, and the other to assess the degree of the condition. For detection purpose, Enhanced XGBoost was used.

Algorithm	Accuracy
XGBoost	0.97
Artificial Neural Network	0.84

V. Conclusion

Detection of Parkinson’s Disease

- Parkinson's disease is an important subject for research since an early diagnosis might improve patients' health
- With tolerance ranges of 92 to 100%, specificity ranges of 94 to 100%, and an AUC in the range of 0.96 to 100%, this technique was able to differentiate between those with early-stage Parkinson disease and controls with an AUC (Area Under Curve) between 0.97 and 1.00.
- It has been observed that those over 65 had a higher likelihood of being diagnosed with Parkinson's disease.
- The study discovered that women had a higher risk of developing Parkinson's than males do.

Figure 7 compares the suggested model to other widely used models utilized in the research mentioned.

Table4. Comparative Analysis of various models for Parkinson's disease detection

Data Models	Proposed by	Accuracy (%)
SVM (RBF)	Little et al [15]	89.2

Fig 4. Machine Learning Model Comparison

Forecasting Parkinson's Disease Severity

- The neural network is the most competent method in this investigation.
- Each auditory component is an essential part of the forecast.
- The severity of the issue is determined by the motor and total UPDRS levels.

It follows that the Parkinson's disease prognosis is exceedingly complex and depends on a wide range of variable factors that are always changing. If the qualities are properly picked, we might be able to create a model that is

DOI: rp-9788770040723.202

both ideal and efficient and that can reliably predict the extent to which a patient's sickness has spread.

VI. Future Scope

The investigation applied a single model to assess Parkinson's disease presence and severity. The study may be further developed by using a number of models and comparing the results in order to identify the most efficient and optimised models for disease detection and to assess the severity of the condition in the patient.

***Abstract*—In today's world social networks are a part of our daily life. There are millions of users in the social networking sites using them for connecting with their family, friends and sharing private (or) personal information. Social networks are been trusted for communicating purposes in both personal and professional needs. We are proposing a method to create an environment where individuals can express their ideas and built business over them with the help of community (or) network. Here community refers to a group of individuals who are into the same stream of profession. This could be used for helping each other in improving their ideas and developing their concepts collaboratively. In the current scenario social networks are facing a critical challenge of fake users and unauthorized access of them into the network which is leading to the bleaching of privacy to many users. The data of users is not so secured in these social networks, which can be dealt by the incorporation of security policies which improves the environment. This can improve the engagement of community members in being a part of many activities as it is the key to improve once ideas (or) business. In social network individuals are main aspect of the community, protecting them from fake information and users is also very much important and this is achieved by the implementation of security features and policies into the network.**

Keywords*—CMI, Social networks, CEI, DoS, role-based access control (RBAC)

I. Introduction

Internet is network of computers and servers which are connected in zonal, local, global area. Social network is a part or application feature of internet, which helps individuals to connect with friends and family. Social networks are viewed as collective web-based applications where multiple applications are mutually sharing data between themselves to provide the users a comfort to connect with new people and entering new communities for talking (or) sharing information that are close to their real life [2].

When a network is established then members of it would want it to be structured and secured in a way that their information is safe from lost or out into public. The number of people using social networks for stealing others private information are increasing exponentially, so whoever is in social networks need to be vigilant to protect themselves [7]. Studies have revealed that as compared to men the female users are found to be more stable, sensitive, intimated and even active in creating a social relationship with people via social network [4]. Every social network is similar to the structure of an informal office environment. One of the frequently occurring problem in social networking sites is excessive sharing of data which is leading to increase in disclosure of their private information which in the long run could have larger consequences [12]. So, choosing to train the individuals on how to share information and what not to be kept out into the internet which prevents them from losing their personal and important information, and updating them with the new threats that are growing around them like phishing [1][6].

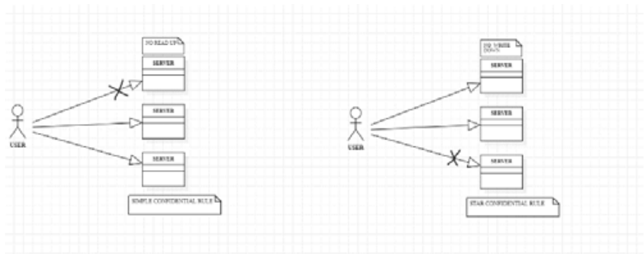

Fig. 1. Bell-LaPadula

The image is providing the aspects of Bell-LaPadula Model.

A. Bella-LaPadula

Bell-LaPadula model is one of the most influential security models as it is one of the initial modern security models developed. Bell-LaPadula model was developed to improve confidentiality aspect of curtail information. Though it provides effective protection to the information confidentiality for applications, to some extent, in the commercial implementation the users choose, information integrity over confidentiality under many circumstances. Thus, applications built on the Bell-LaPadula model are mostly used in military environments or similar spaces.

B. CEI

Trying to use the community energy initiatives (CEIs) to help each other In the community to achieve their goals as much as possible. The contribution of individuals could be as small as just a suggestion which could change the course of their thought process, and as large as investing into the idea and being a part of it which helps in growing it big. Individuals organize their social relations around certain social, psychological, legal, or physical foci (workplaces, voluntary organization, hangouts, family, etc.) which shape the opportunities of people to meet and interact [3]. So,

DOI: rp-9788770040723.203

making a good network of people is a key feature of any individual to grow in the real world it is even applicable in the internet world and creating such space is our aim. So,
creating a more secure space in the network, by integration of information security policies into the application is one option available so that female users get upper hand in the network that is been developed. Which can be used to share their ideas, job requirements and get suggestions and support from the community.

II. Literature Review

The social network services are a form of webservice to develop a virtual connection with people having same interests and background. This service helps the users for finding new communities and friends. [13]. There are many ways for generating data in the social network and for sharing it into the network, now proposed technique is a new combination of method to improve the structure of network and its security components in it like **accessibility**, **availability**, **reliability.** Architecture of multiple systems in the online social network (OSN) be like Client-server and peer-to – peer architecture [2].

Studies are trying to study mainly about social network's content and user's security, using different models, protocols, mechanisms and algorithm [1]. Knowing about different types of threats that are been around us in the network so that people can be more and more causes with the present situation. This paper is trying to given a new pathway on social media security aspect using crowd computing framework, hierarchy form for the social networks [1]. This is where incorporation of **Bell-LaPadula** model into network is taking place to create secure and reliable network to the female users.

Hackers using many techniques to steel one's information from the users. In the pre-Internet world stealing once's information was too complicated and hard but now it's too easy for these phishers. The number of people using social network for stealing personal information of users, using phishing technique, so every user in the network has to be more vigilant to protect their information [7]. Talking about on how individuals are been getting influenced for revealing their confidential information like password, addresses, bank details by working on their vulnerabilities is said to be Social Engineering. Getting to this conclusion that the users have to be trained regarding the newly developed network so that they get aware of such effective threats that they might encounter.

Studies are aiming on identifying behavior of users on different gender aspects in social networks by comparing the different aspects on which the gender labels are created and how easily they can be activated and implemented into the network [4]. The conclusion from this can be that female user are been more exploited by the effects of the social networking. This is getting us to the conclusion of security requirement for female users. This can be redeemed by giving a more control to the female users like accepting of friend request, deleting the users from the friends list.

Studies are even trying to investigate the role of social networks on how individual's decisions are been influenced on trying to participate of community energy initiative. Later we are discussing about engagement of community members is crucial for the success of a CEI and thus a key question is how the initiators can reach community members and stimulate involvement [3]. Taking results of this to prove how greatly a community can impact the network to be moving forward. How well it can be initiated and how an initiated program is been affected by the associated individuals.

The biggest hurdle in social networks is access of hackers into private accounts to achieve private information and leaking of personal communication in between the users of the network, these all are after effects of hacking a user's account [9]. The usage of encryption is to protect one's privacy. They are talking about the multiple types of encryptions are been implemented in the aspects of the social network. They are talking about the multiple types of encryptions are been implemented in the aspects of the social network. Finally, there is visualizing the process of encryption and decryption in a mobile application that are been done to secure a user's information.

When trying to investigate the part of social network in effecting the user's choice on to whether to be a part of communal activity. Discussing about engagement of members is critical part for the success of a communal energy initiative and this leads to main question on how the initiators of a program can reach the community members and stimulate their involvement [10]. By which we are getting to know about the impact of individuals in the network of community. Finally getting to know the impact the community members, initiators, associates can impact the CEI. The different combinations of different members in the network have a new type of network.

By studying two different factors that affect the vulnerability of the network such as individual and organizational actions and how the creating awareness among the employees leads to the improvement of social security and reduces the risk of social attacks [8]. Theory of reasoned actions and theory of planned behavior are been used in many hypothesis conditions which are been tested and drawn to a conclusion.

III. Methodology

3.1 Bell-LaPaduala

This is an information security model which is also referred as a multi-level model, which was proposed for implementing access control in military applications. In these models there are two main parts one subjects and the other objects which are segregated into different security levels. The subject can access only objects at specific level determined by his access level.

The levels of classification are designed to protect information (or) data from unauthorized discloser.

Simple confidential rule: In this the users (or) subjects can only **read** the data on the same level of access and the lower level of access but can't read data to the upper level of access. This rule is also referred as **no read up** rule.

DOI: rp-9788770040723.203

Star confidential rule: In this the users (or) subjects can only **write** the data on the same level of access and the upper level of access but can't write data to the lower level of access. The rule is termed as **no write down** rule.

This is using these rules to improve the confidentiality of the data and users. **Confidentiality** implies that the protection of the data from being accessed by an unauthorized user. Only real users can access their personal information. The main responsibility of confidentiality is stopping information from getting into the inappropriate user's hands.

3.2 Biba

This is another type of information security model which was used to ensure the integrity of information. In these models there are two main parts one subjects and the other objects which are segregated into different security levels. The subject can access only objects at specific level determined by his access level.

Simple integrity rule: In this the users (or) subjects can only **read** the data on the same level of access and the upper level of access but can't read data to the lower level of access. This rule is called **no read down**.

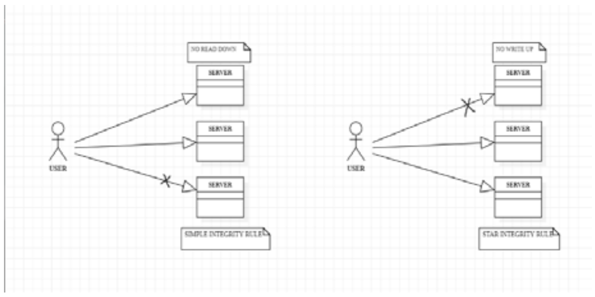

Fig. 2. Biba

This is giving the visual representation of the Biba model. Star integrity rule: In this the users (or) subjects can only write, edit the data which is on the same level of access and a level lower of their access but can't write data to the upper level of access. This rule is termed as **no write up** rule.

Biba model is using these rules to improve the integrity of the data that is been shared. The **integrity** implies that the data is been validated. It gives an authentication on whether the data available in the network is in correct format or not. It also validates data whether it is true and correct to its original source of data. Integrity makes sure that the data presented by the publisher is been received in the same way to the receiver.

3.3 Role Based Access Control

The role based access control model is been widely implemented as natural model as it is very much suitable in most case scenarios. The results of the applications built on this model are growing very rapidly in commercial and educational institutions.

The function *Check Access* is used for authorizing decision made by the system is giving the users different roles in the network on the bases of the gender of the user *ex: female users are given role of higher level and male users are given a lower level.*

3.4 Implementation

The application created with complex combination of webpages is to create a secure network to interact with individuals who are willing to help the needed by sharing the needful. This is consisting one page for the Registration process.

3.4.1 Registration Page

One has to get registered in this page to login into their personalized account to view the posts (or) create a post. This is containing the attributes like user name, email, password, mobile number, gender, date of birth.

Fig. 3. Registration

This is the screenshot of the registration part of the application.

The data that is entered by the users is been stored into the data base and segregated into two different tables according to the gender of the user to give a specific hierarchy to the users according to the gender of the user.

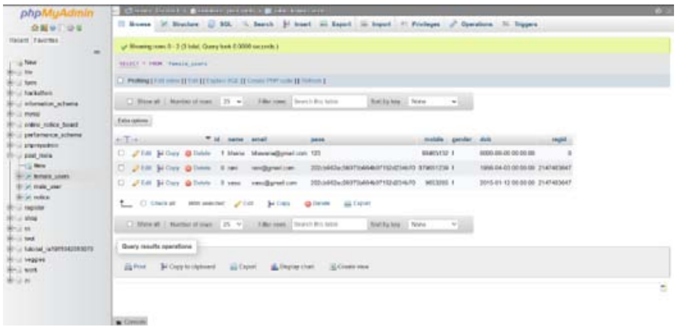

Fig. 5. Female User's Database

This is the database of application.

The few of the main features of the form is that the user's password can't be viewed even by the developer to get the better of security aspect of the users and all the details filled by the users is visible to whoever can access the data base.

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.203

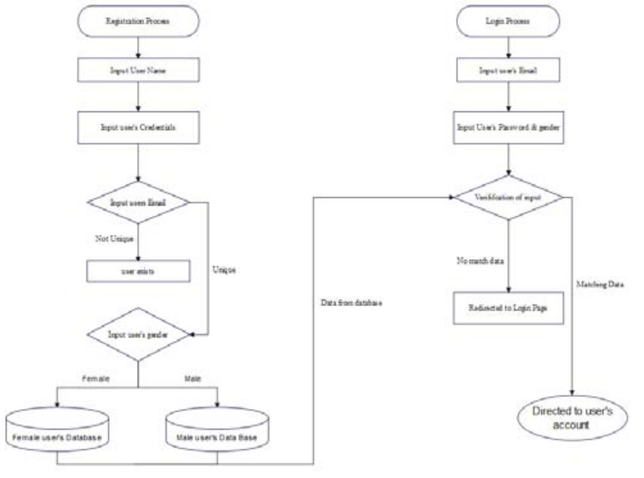

Fig. 6. Flow Chart

This gives a clear view on how the user's data is been flowing the stream line created in the network.

3.4.2 Login Page

Here the page is used for logging into the personal account to view their posts and post their new posts into the network. This is taking the user's email id, password and their gender to login into their account.

The login credentials are been verified with the database of the male users and female users while logging into user's account. Once the user longs into his /her account then they give few features to use the application and communicate with the network of users.

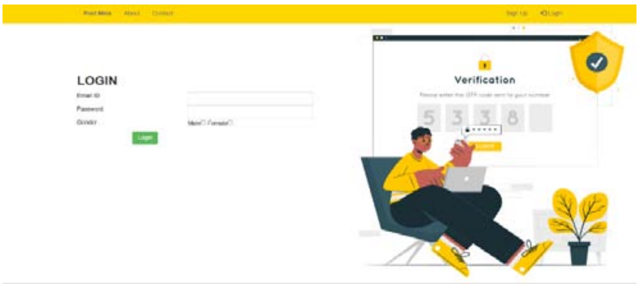

Fig. 7. Login Page

This part of the application is been used for the user's login.

3.4.3 Female Users

Once logging into the account, the female users are able to view their dashboard with the options like **Manage Users, Update Password, Manage Notification, Add New Notice** are the features that are available for the users.

By this they view the members of the network, they can create (or) edit (or) delete the posts they have posted into the network and can choose the option to share the information to a particular individual or not is completely in their hands. ***But they can't edit the comments of the male users (or) any other user but can only view them.***

This is where the Information security policies are been incorporated into the application this is said to the *Bella-LaPadula model.*

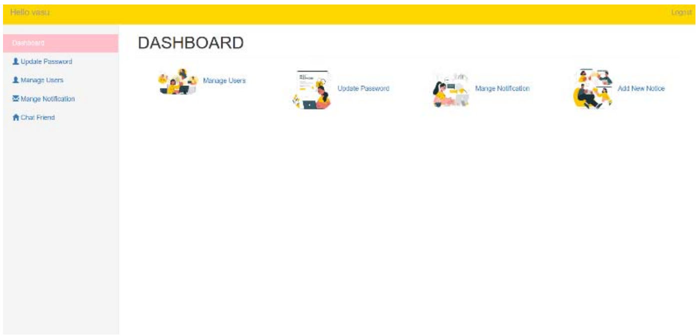

Fig. 8. Dashboard

Update password

They can update their passwords at this page. The Old password is been compared with the data base and if it matches then password of the user can be changed.

All users

Here the female users can view all the members of the network and can choose to delete any user of their choice from their network of members.

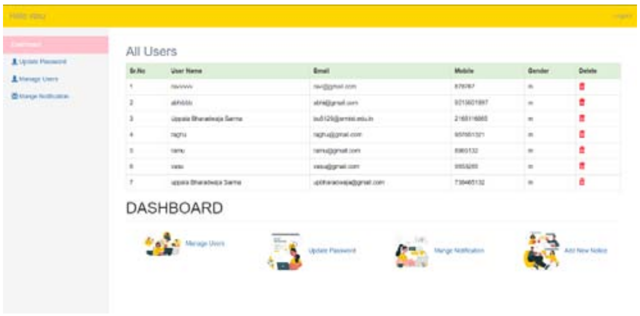

Fig. 9. All Users

The female users can view the users of the network and start a communication with them if they want to have initial point of connectivity with the users.

All notices

The users can delete (or) Update their post to the members of the network at any point of time which gives them complete control over their posts into the network. Once the user can view the notices, they posted in the network then they can even create completely a new notice and upload it into the members of the network.

3.4.4 Male Users

If a user is logging using the credentials and selecting the gender as male, then they are navigated into a new page dash board where they can view all the notices that they receive from the members of the network.

DOI: rp-9788770040723.203

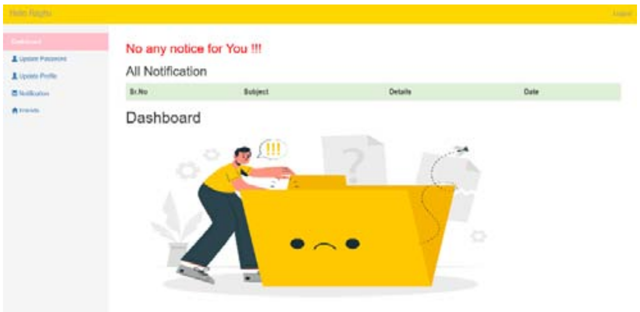

Fig. 10. View Notice

Update password

At this page is used for the same purpose for male and female users, to update their passwords for logging in their accounts. The old password is been verified with the data base from the registration process.

Update profile

This page is used for the updation of user's information like user name, mail id, mobile number, gender and DOB.The changes made in this page is been modified even in the database as they save the dat is been changed.

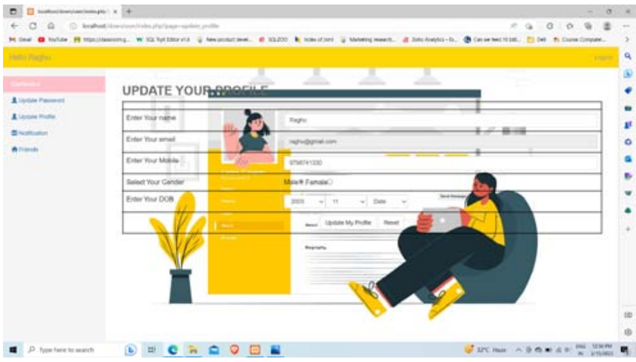

Fig. 11. Update Profile

Here the Male Users can only view the posts and add a comment to the posts that are been posted can only view them but can't edit the data that they are sent.

This is the phase where the second phase of the security policy Bell-LaPadula is been kept into application.

Once the user logins to his/her page they can view the option to communicate with the members of the network and start a communication directly rather than trying to contact them via mail (or) mobile for basic communication which can develop a more secure in the aspect of privacy of the users.

3.4.5 Friends Chatting

The users are giving the users a feature to have a communication with each other which enhances the user's experience of using the network.

Once the user logins then he/she can view the number of user's they can communicate with. They can chat with the users by using this feature of the network.

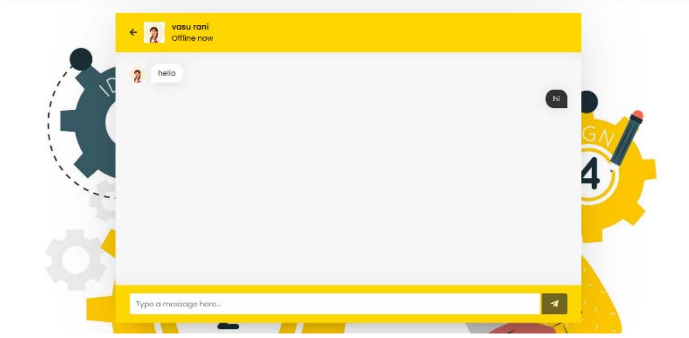

Fig. 12. Chat Space

3.5 Architecture

Here the point is to create clear picture on how the integration of Information Security Models into the social network is been held from a bird's eye view. There are multiple modules which make the things keep moving and get a greater understanding.

Which user is getting what sort of features in the network can be understood by viewing the architecture of the network that is developed.

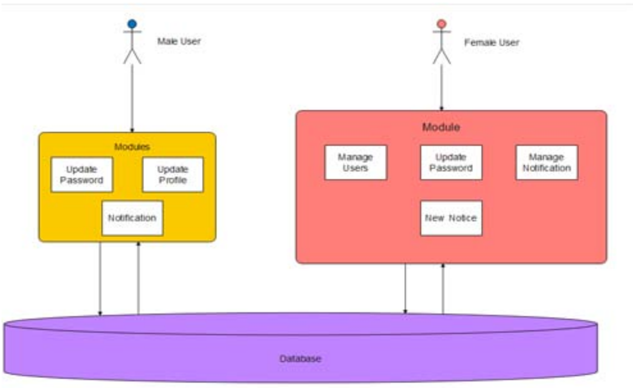

Fig. 13. Architecture Diagram

IV. Conclusion and Future Enhancements

This paper is mainly trying to introduce a new way of creating a network to have a more secure, accessible and reliable network by using Information Security methodologies incorporated into the process of creating the network and establishing it. Then tried to use it to improve the way the users interact in the network and build it for a better communal environment which encourages users to be a part and grow themselves. The effects of good network will improve the way one can create communal energy to achieve a specific goal, encourage users for initiating anything that they thought of (or) can be a part of it. This paper is trying to take a leap onto find the way to integrate Information Security into the network to develop a more secure environment. Where we can develop a more secure and dependable network, more users could be encouraged to be a part of the network in the present times, as the present scenario of new social networks being developed every day and available in the internet. This paper is trying to provide an insight on how the integration of information security

DOI: rp-9788770040723.203

models impact the working of the social network in real time in various aspects. Trying to get a foresight on how the impact of community energy initiative (CEI) to build systems which are effective in indulging members of it.

In the future the network can improve more in the aspect of the security of the user. This one is a very basic template of registration. The inclusion of the real time verification of user's email id by OTP generation could be next step in the process of development. Later to this we can create more sophisticated process where when user registers themselves the photo, they use for the *DP* can be compared with the real time user's face using facial recognition from stopping fake users in the network where male users can be controlled from creating fake female accounts in the network.

***Abstract*—Virtual Reality (VR) applications in the healthcare industry have the potential to improve health while also creating opportunities for clinical education. Healthcare officials supported the incorporation of modern technology by raising budget allocations and organizing access to advanced devices and professional expertise. In this research, we are going to study VR in the healthcare industry and its essentiality in medical education. Businesses in the healthcare sector offer medical assistance and produce diagnostic products or drugs, facilitate medical coverage, and finally facilitate the delivery of healthcare to patients. VR is an atmosphere with a specific computer-generated with realistic-looking both objects and scenes that immerse the user in their environment. VR plays a vital role in making decisions for specific case studies and distance learning, the ability of VR simulation tools to share information obtained through communications infrastructure and electronic health records makes it more appealing.**

Keywords—Artificial Intelligence (AI), Virtual Reality (VR), healthcare industry, Medical based Education.

I. INTRODUCTION

In the field of medicine, developments occur at a dizzying rate. Twenty years ago, healthcare looked quite different from how it does now, with an older population with more complex demands, fewer treatment choices, less emphasis on collaboration between healthcare professionals, and more complicated healthcare systems. We've got to adjust our methods for preparing aspiring doctors for the field of medicine. Nowadays, it's not about whether or not a healthcare provider can remember or find information; it's about how well they can process, analyse, and apply that information to the treatment of individual patients. Virtual reality (VR) is a computer-generated simulated setting with realistic graphics and a large number of interactive elements that fully immerses the viewer. A virtual reality (VR) helmet is used to experience the surroundings. With VR, we may put ourselves in the shoes of fictional characters, learn how to do heart surgery, and improve the quality of our training to reach our full athletic potential.

Through the use of virtual reality (VR), we are able to experience video games as if we were one of the characters, learn how to perform heart surgery, and enhance the quality of sports training to achieve maximum performance. The most recent standard, 5G, can also provide very interesting potential futures for virtual reality's development. Because of this standard, more devices and larger user communities will be able to connect with one another. In addition, because its latency is so low, customers will be able to receive images in real time, almost as if it were the same as if they were looking at them with their very own eyes. A computer can act as a gatekeeper to a new world if it simulates as many of the human senses as it can, including vision, hearing, and even touch on occasion. The availability of content and the amount of computing power are the only restrictions placed on a VR experience. Virtual reality is the solution for any situation in which doing something in the real world would be too risky, expensive, or impractical. Virtual reality enables us to take virtual risks in order to gain real-world experience. This is useful for training purposes in a variety of fields, including medical applications and fighter pilot training [1]. It is reasonable to anticipate that more serious applications, like those for education or productivity, will come to the forefront as the price of virtual reality drops and the technology becomes more widespread. The way in which we interact with our digital technologies may be fundamentally transformed by virtual reality and its close relative, augmented reality [2]. Keeping with the current trend of humanising our technology.

DOI: rp-9788770040723.204

II. Literature Review

Baniasadi et al. (2020) conducted a review to identify the difficulties associated with the use of virtual reality in the medical field. VR challenges will have various impacts, so recognizing each of them aids in determining remedies for each challenge.

Dyer et al. (2018) and Latchoumi T.P. et al (2022) used software that generates an immersive VR life experience for workforce training in aging services [3]. The project was successful in introducing a novel new method for teaching medical assistants, physiotherapy, and also nursing syllabuses. According to the findings, virtual reality improved students' understanding of health issues according to their ages and rises their compassion for adults with hearing, sight loss, or affected by Alzheimer's disease. Jack Pottle. (2019) and Monica.M et. al. (2022) discussed how the future of Virtual Reality is in continued inclusion with the curricula and various technological advancements which allow for simulation of the practical experience. This automatically enables the quality of the teamwork at an average scale, regardless of geography, and will transform how we educate future clinicians. Winkler-Schwartz, Alexander, et al. (2019) and Karnan. B et. al. (2022) set out to create a checklist that would serve as a general framework for reporting or analyzing experiments conducted by VR surgical simulation and ML algorithms. Researchers and critics can easily evaluate the current quality and specific inadequacies of a manuscript by including overall points as well as clear subtopics of the checklist [4]. An Experiment based study on the Efficacy of VR 360° In UG Medicalfield was conducted by Lama, et al. (2019) and Vemuri et al (2021). VR creates a rich, immersive, engaging field of study environment that encourages hands-on understanding. It increases student interest and motivation while also effectively supporting the retention of knowledge and skill acquisition.

Ammanuel, Simon, et. al. (2019) and Sivakumar P (2015) The study's goal is to demonstrate the application of converting 2D radiographic images into 3D models using a threshold method and similar to the importing segmenting them in a Virtual Reality with an interface at a low cost. Understanding anatomical structure in 3-Dimensional space improves understanding med citizens, students, and patients [5-6]. Caroline Fertleman et al. (2018) and Sridaran K et. al. (2018) held a panel discussion titled "The Reactions of Medical Professionals to Minimal Antibiotic Patient Demand. Medical Ethics Study with the help of Immersive VR." Finally, VR was discovered to be a beneficial training device, one that may succeed where other proposals have failed to change behavior. Pantelidis, Panteleimon, et al. discussed “VR and AR in the medical field of study" from the perspective of the past, present, and future [7]. Tabatabai and Shima (2020) and Buvana M et al (2021) emphasized the value of VR learning and the repercussions of incorporating VR simulation techniques into the medical training for the upcoming clinical skill teaching and development. Tang, Kevin S., et al. (2020) analyzed the status of AR Applications (ARAs) and established an analytical model to guide the study in assessing the system as an instructional tool in medical training [8].

III. Proposed Work

The use of technology such as virtual reality has the potential to propel the field of medical education forward by offering students a more immersive educational experience. Because this technology is more realistic, it has the potential to more successfully engage students in medical education than the more conventional educational system does. It is straightforward for instructors to keep an eye on, and straightforward for pupils to use as well. The term "virtual reality technology" refers to an intelligent kind of immersive technology that provides the user with a vision that encompasses the whole surrounding environment [9]. To do this, specialist cameras such as 360-degree cameras and omni-directional cameras are used. A fully immersive video watching experience will be made available to the user through the usage of VR videos. The experience is much improved when watched using a virtual reality headset. On the other hand, it may also be seen on devices such as smartphones, laptops, and desktop computers without the need for VR goggles. Not only will the incorporation of AI make interactions with virtual patients more realistic, but it will also make it possible to conduct further research on therapeutic effectiveness [10-11]. AI is utilised to elicit particular difficulties from huge groups of learners and generate dynamic, customised settings to satisfy the unique learning demands of individual students.

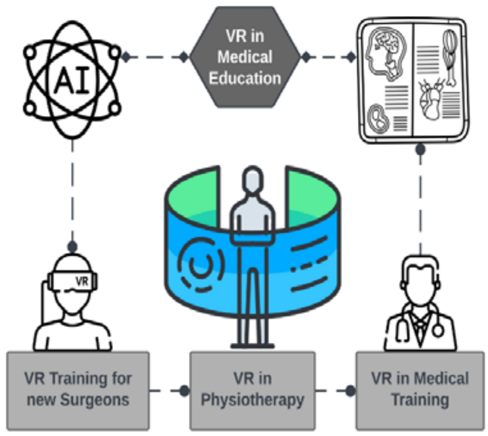

Fig 1. VR in Medical Education

Fig.1 illustrates Virtual Reality in medical education.

VR is a new technical concept that can instruct surgeons on innovative techniques and assess their degree of proficiency before performing surgery on patients. In addition, VR enables medical students to resume the same process or task multiple times as a training module [12]. VR simulation could recreate the operative field, improving training and reducing the need for costly animal training models. Our preliminary findings indicate that we have the advanced technologies to simulate tissues and laparoscopic devices and to create a VR educational environment for surgeons in real-time [13-14]. VR technology instructs

DOI: rp-9788770040723.204

surgeons with innovative techniques and evaluates their level of proficiency before performing real-time surgery on patients. In addition, VR enables the learners to return to the same methodology or task multiple times as a refresher course [15-16]. VR is used in patient-facing rehabilitation to create games that allow members to exercise movements in a safe, engaging, and challenging environment. In stroke rehabilitation, for example, VR is being used to dramatically increase the number of movements performed during a treatment session, with anticipated benefits in function and overall results.

Some of the hardest things while determining the entire testing methods with a medical education there are some similarities which may differ according to the results.

$$T_{ni} = dig_{t22}^{min} U(l_p; S_v : T, s^*), T_{map} = dig_{t22}^{min} Q(T : l_p; S, s^*) \quad (1)$$

In Equation (1), both the terms of constant values are represented in the term of representing the most regarding access points that are managed with the help of time. According to omit times for matrix multiplication clarity.

$$T_{map} = dig_{t22}^{min} S(T : I_p; S_u, s^*) = dig_{t23}^{max} \frac{S(I_p; S_v : T, q^*) S(T, s^*)}{S(I_p; S_u, s^*)} \quad (2)$$

Therefore, the model and $S(I_p; S_v : T, s)$ is the actual kind of probability realisations I_p and S_u occur in the given data type v, and a protective q*if S (Ts*) can be homogeneous for the identification of detection probability is represented Equation (2).

$$S(I_p; S_s; s) = \sum_{\sigma \in \Omega(T, q^*, I_p; Q_u)} S(\sigma | T, s) \quad (3)$$

Therefore in Equation (3), the Ω (v, s*, I_R, S_U) is the collection of all possible categories for distribution given I_P; T_u. Then, below Equation (4) represents the consistent G.

$$T_{map} = dig_{t \in I_p}^{min} K(T, s, I_p, S_U).Q(T, s^*) \quad (4)$$

Finally, the actual term that is displayed according to the Equation (5).

$$K(T, s, I_p, S_U) = |\Omega(T, s*, I_p, S_U)| = O(U+P)! \prod_{\mu \in I_p \cup Q_U} |S_\mu^v| - 1 \quad (5)$$

Therefore, the above Equation (5) represents the actual and sequential nodes that are being contexted with the time analysis and its management [17-18].

IV. Experimental Results

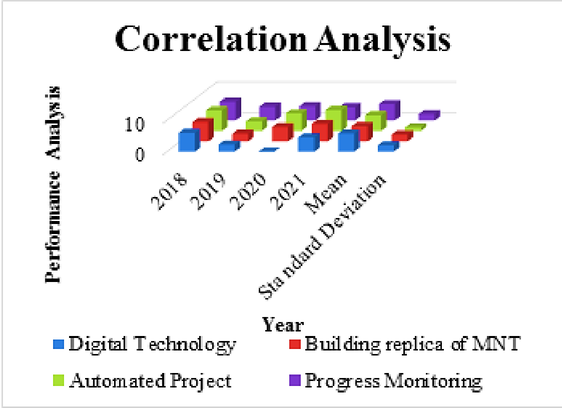

Fig.2. Building the human tissue for Artificial Intelligence based technology

Fig.2 depicts a Virtual Reality assessment AI technique for analyzing and simulating the result of built surroundings building reshaping strategies on building energy use, solar power generation, and the changes that follow all have an impact on energy usage [19-20]. In this analysis, the implementation of different digital based technologies were considered from the period of 2018 to 2021.

TABLE 1. Building the technical analysis based on the VR and Artificial Intelligence

Year	Digital Technology	Building replica of MNT	Automated Project	Progress Monitoring
2018	6	6.1	6.5	5.9
2019	2.2	2.4	3	4.4
2020	0	4.5	5.5	4.5
2021	4.5	5.5	6.6	4.2
Mean	5.76	4.79	4.99	5.19
Standard Deviation	1.98	2.09	1.09	1.98

A significant percent of previous technical studies have been classified as implying that most of the preceding application fields of medicinal industry sectors in building replicas start with body cells for artificial organs with the application.

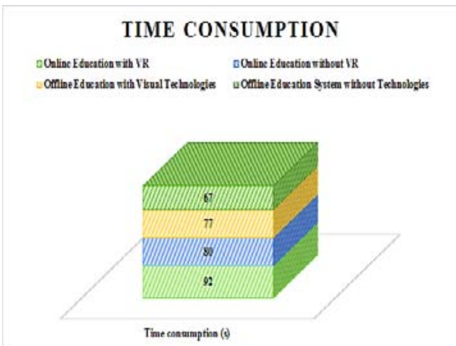

Fig.3. Time Consumption for information communication

Fig.3 represents the time consumed by different teaching and learning mechanisms in the healthcare industry with the utilization of different technological advancement. Fig.4 represents the comparison of the proposed online healthcare education with Virtual Reality (VR) along with other models such as model without VR, offline education with virtual technology and without any technologies. This

DOI: rp-9788770040723.204

time consumption defines the time consumed to provide visual effect on the medical concepts. From the results, online education with VR consumes less time than other models by making a minimum difference of 10%.

Analysis based on the energy consumption in the implementation of the models is presented in the Fig.5. Energy Consumption is measured in Joules (J). This analysis defines the minimum level of energy required to complete teaching and learning of the healthcare terms through technologies. From the results it can be seen that the technologies aid in the reduced energy consumption whereas the model without technology involves manual drawing of the medical images by the teachers. Manual drawing will consume more time and space for the works to get completed and hence the energy too. From the results, it can be seen that the online virtual reality will consume a much reduced energy of 53% which makes a difference of 42% to the highest.

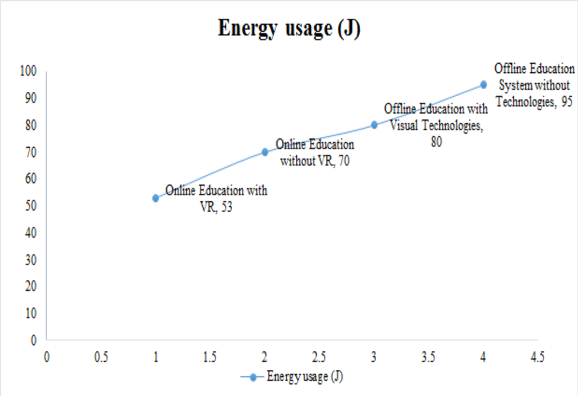

Fig.4. Energy consumed by the models

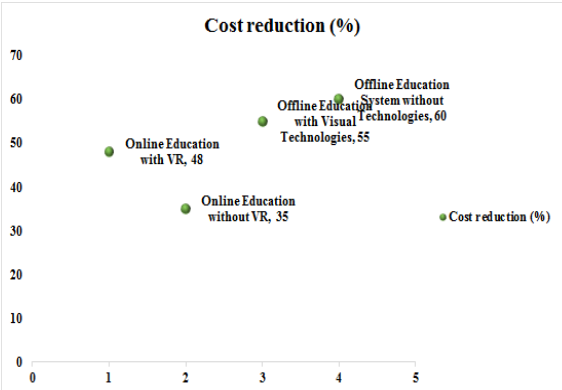

Fig.5. Cost Analysis of the proposed system

Next to the time and energy, cost plays a vital role in implementing a new technology for any given domain. In this research, cost analysis is performed to analyze the cost required from the designing of the model, implementation of the system, and completion of the education on the medical system.

V. Conclusion

When compared to traditional teaching resources, the researchers note that this method promoted further knowledge improvement for pupils and fostered significantly higher learning. Virtual reality is already transforming medical training. It facilitates removing lessons from the classroom by allowing students to put their knowledge into practice and learn from their mistakes. VR plays a vital role in making decisions for specific case studies and distance learning, the ability of VR simulation tools to share information obtained through communications infrastructure and electronic health records makes it more appealing. It aims to improve competencies and emphasizes the autonomous, blended learning that today's learners expect.

Abstract—Finding novel substances with chemical characteristics for the treatment of illnesses is the goal of drug development. The method used in this search has become increasingly significant in recent years as machine learning methods have proliferated due to their democratization. To meet the goals stated by the Precision Medicine effort and the additional problems they have created, it is essential to develop reliable, and reproducible computational approaches. Predictive models that are based on ML have recently grown significantly during the stage before the preclinical research. In this stage, new drug discovery expenses and research timeframes are significantly reduced. The adoption of these innovative approaches in recent years of study is the main topic of this review paper. We can predict where cheminformatics is within the short future, its particularity, and the successes it has already attained by examining the state of the art in this area. The approaches utilized to represent the data that consists of the information about the molecular substance, as that is most related to the biological issues that are always addressed in ML-based algorithms which are being employed for drug development, will be a key topic of this study.

Keywords—Machine Learning, Drugs, Market analysis, Neural Network.

I. Introduction

The process itself and the stringent rules set out by the regulatory agencies are what causes drug identification for a particular molecular target and patient group to be most complicated. The search for novel medications continues to be a time-consuming and expensive process. Medicine typically takes between the range of about 10 to 15 years to produce through research and testing. It is almost hard to investigate current compounds in wet lab studies due to the sheer number of molecules that may be evaluated as potential new medications [1]. However, new while seeing the silico approach for the displaying of large enough pharmacological library function has emerged during the past 10 years because of the data and communication technologies that are used here, and the expansion of computer power. This phase in the previous sectors that comes under the clinical investigations lowers both the financial cost and enlarges the area for looking for novel medicines. With the capacity to expedite and automate the analysis of the vast quantity of data now accessible, ML techniques become extremely prominent that are present within the pharmaceutical sector. The goal of Machine Learning (ML), a subfield of AI, is to create and use computer-based algorithms that can understand unprocessed, data for carrying out specified tasks in the future [2-3]. Within a huge data collection, classification, regression, grouping, or pattern recognition are the primary tasks carried out by AI systems. In the pharmaceutical business, a wide range of ML techniques have been used for the analysis of novel properties, activities that are related to biological development, and medications [4]. Some of the algorithms that can be deployed here are

1. SVM (Support Vector Machine)
2. Random Forest Algorithm
3. Neural Networking Models

a few examples of these techniques. This work has been created and planned to investigate the current state of the art in this sector. It compiles the most pertinent studies on the application of ML approaches for early drug development from the last five years [5-6]. The works found in this study are then provided in several sections, with a focus on the descriptors employed, the biological issue to be resolved, and the ML method employed.

II. Literature Review

Trans-acting hotspots are discovered to influence major group-specific within the gene networks, such as the normal chromosome that consists of five more deletions of network supply with the mitotic control where the type of TCR is mediated in the adaptive immunological with a stable response that applies the CNA – devoid group distraction.Based on the effects of CNAs within the

DOI: rp-9788770040723.205

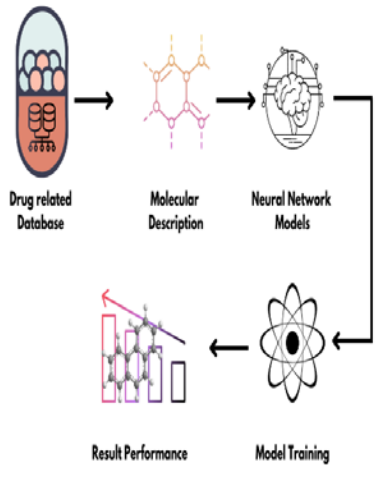
transcriptome, our findings offer a unique stratification of the molecule with the majority of infected people with breast cancer [7]. At three years, there were 12 percent absolute variations with the group knowns as the trastuzumab type of group and the regulations followed in the absence of disease spreading population. A 33 percent decrease in the risk of mortality was linked to trastuzumab treatment (P=0.015). In trials B-31 and N983, the trastuzumab group's half the percent of a cumulative incidence of the classes only in sections III and IV with the infections of heart failure with a report of 4 percent and 2.9 percent, respectively [8-9]. Therefore, it is crucial to analyze his work, especially his latter theoretical creation and its reception. The core theme of the processes of subject management and what are thought to be its two most significant roots—the literary and the political—are the focus of this special issue, which examines the legacy of the later Foucault [10]. One approach includes theoretical techniques, which are quick and effective instruments that can result in the identification of novel active pharmaceuticals specifically made to treat certain conditions. By encoding the data stored with the chemical instruction and describing the QSAR which can be abbreviated as Quantitative Structure-Activity Relation a complex type of network that becomes a popular solution in the construction of effective medications [11]. The molecular system serves as the model foundation. Building the 1stcomplex type of network that represents the drug-similarity interactions for the range of 1600 empirically unexplored chiral HMGRI isomers with the help of predictions of this system as an input section. A condensed form of this network, known as the "Giant Component," was also provided. It comprises the representative group of chiral HMGRI dealing candidates. The research proposes a novel hybrid use of chiral/non-chiral TIs and complex networks in the QSAR analysis of key elements of structural diversity [12-13]. The experimental design approach described in this article is assessed and verified using RRegrs. Our results differ for three of the five most recent simple state-of-the-art information, and that is concluded that choosing the optimal model by our suggestion is both statistically significant and pertinent [14]. When utilizing these kinds of algorithms, it is important to manage with a statistical technique to determine whether the changes are enough significant. Furthermore, compared with previously reported methods, our results with three actual complicated datasets indicate different top models [15-16].

A crucial problem for airline management is predicting future passenger demand. Creating an ANFIS to forecast domestic airline passengers in the model of Australian demand was the aim of the current work. The project involved training, evaluating, and validating the ANFIS model. The ANFIS structure and Gaussian membership function both made use of Sugeno fuzzy rules, and linear membership functions were also created [17-18]. Based on 5973 traffic accident data that happened in Abu Dhabi over 6 years, an artificial neural network (ANN) was used in this study to analyze the injury from accidents due to traffic control (2008 to 2013). At the time of the accident, 48 distinct characteristics had been gathered for each accident record. The data were condensed after pre-processing to just 16 characteristics and four injury severity groups [19-20]. To anticipate ionospheric 30 min total electron content (TEC) data, a radial basis function (RBF) neural network is constructed in this research and improved using a Gaussian mixture model .

III. Proposed Work

According to the intelligence-based computational system, particularly with the ML, the design of the results phase is enough important stage. To achieve this, it is crucial to first establish the implementation approach, Any subject of study must use an ML technique, and it must be transversal. Even though all domains use the same steps in the experimental design [21-22]. We may distinguish the following phases in the ML approach used in drug discovery specifically: Data gathering, creating mathematical descriptors, finding the optimal selection of variables, training a model, and model validation are the first four steps shown in Fig.1.

Getting the data set, which must meet specific requirements, is the initial stage. It must have properties that make it simple to generate and manage in the lab adding those physical qualities that aid absorption, managing specificity, and an average range of toxicity. This is because complicated compounds or big proteins are not commonly used in the pharmaceutical sector. Small molecules and peptides are the major types of chemicals that it often interacts with. The sequencing and peptides and small molecules have different structures, represented using the SMILES and FASTA formats to facilitate the handling and study of these substances. The generation of sequence data has significantly advanced thanks to new sequencing technology (DNA, proteins, tiny molecules, etc.). Although only a small number of maths models that has the ability for producing analysis based purely on different sequences, compound sequences are the beginning point in drug development. Sequences must be transformed into matrices so that ML algorithms can process them to do the prediction. Also crucial is the display of various chemicals. Although certain machine learning (ML) models do not require displaying, supervised learning models are frequently used in the field of drug development. In this instance, the researchers' defined displaying will be crucial to the experimental procedure.



DOI: rp-9788770040723.205

Fig.1 Model for forecasting the presence of Drugs

The application of machine learning techniques is widespread, and more articles have been published recently in particular. However, there aren't enough machine learning articles on open access platforms that are concerned with development shown in Figure 2.

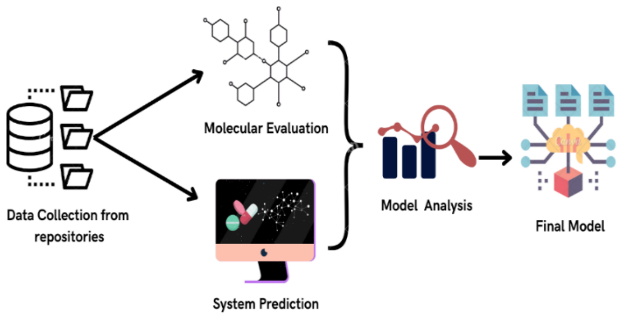


Fig. 2. Identification of new drugs

In Fig.2, we can estimate some set of instructions that are most relatable to the characters that are available in the previous paths, so the results occur in the $M_j^q(t)$ solution that the been developed in case of balancing the limitations when it appears in each case. the $|\tau_j(t)^{\infty}||i|^{\partial}$ characteristics can be frequently affecting the major approaches that are rise in j values. If the j value enables automatically the $\sum_{u\epsilon i_q}|\tau_u(t)^{\partial}|\cdot|\eta_u|^{\partial}$ which is being considered as one of the standard approaches with the values of $u\epsilon I_q$

$$M_j^q(t) = \begin{cases} \frac{|\tau_j(t)^{\partial}|\cdot|j|^{\partial}}{\sum_{u\epsilon i_q}|\tau_u(t)^{\partial}|\cdot|\eta_u|^{\partial}} & \text{if } u\epsilon I_q, \\ 0 \end{cases} \quad (1)$$

In Equation (1), the I_q denotes the presence of attributes and that also concludes with the mandatory solution, according to the i and v values the analysis or the prediction value according to the methodology is an additional feature with the parameters that govern the relative value adoption in the algorithm that is used here and is presented in Equation (2).

$$\Delta\tau_j^q(t) = \begin{cases} \emptyset\cdot\gamma\left(E^q(t)\right) + \frac{\emptyset(s-1E^q(t)j)}{s}, \\ 0 \end{cases} \quad (2)$$

T(s)c can be considered as one of the features according to the subsets that are most related to the iteration of $|t^s|s$ that are representing the length of ϕ that consists of various parameters according to the control of the effective weight of features which varies in the range of 0 to 1 is represented in Equation (2).

$$\tau_j(t+1) = (1-\rho 1)\tau_j(s) + \sum_{q=1}^{p}\Delta_j^q(t) + \Delta\tau_j^b t. \quad (3)$$

In Equation (3), the spoken regulations that are been processed according to the eliminated and exploited set of attributions that are regulated in the probabilistic models, so the parameters have been chosen in different methods.

$$F_i = \frac{\eta_i\cdot\tau_j}{\sum_{j=1}^{c}(V_j)\cdot\sum_{i=1}^{b}(\eta_i\cdot\tau_j(t))}. \quad (4)$$

In Equation (4), both i and j terms were used to represent the current regulations and the deployment of the algorithm do have some methods of work that are being specified according to the optimizer in the range of representing the analysis methods with the time frame of stable ability to the analysis performance is presented in Equation (5).

$$B(NB_j = V_j) = -\left(N(B \mid B_j = V_j)\cdot\log_2 C(N \mid B_j = v_j)\right) \quad (5)$$

The ants employ this technique to identify both more simple and robust categorization criteria. Initial administration of such routes includes the same amount of analysis as described in Equation (6).

$$\tau_j(t=1) = \frac{1}{\sum_{j=1}^{a} b_j} \quad (6)$$

IV. Experimental Result

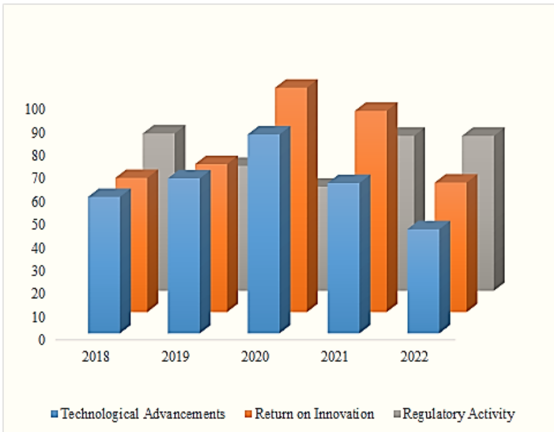

Fig. 3. Building Analysis

The graphical representation in Fig.3 and Fig.4 represents the building analysis ad demand analysis in the realtime application. Numerical analysis of the data is performed is illustrated in Table 1 and Table 2 respectively.

Fig.4 Demand Analysis

V. Conclusion

The pharmaceutical sector has profited enormously from the usage of these models in the section of cheminformatics, and more especially in drug development. The only available tool up to this point was the utilization of descriptors derived from the default structure of peptides or tiny molecules. In recent times, graph-based molecules have been explicitly modeled using artificial neural networks. Molecular regulations are frequently employed in business today, but at the same time, it is the emergence of graph models that produce outcomes, in some cases, outperform the more traditional models. This is significant because, although being an area of knowledge still under development, it has great promise for the future, largely because of its flexibility to the issues and molecular structures to be addressed. However, the biological issues that cheminformatics, and more especially ML algorithms, have focused on include the identification of new therapeutic targets through the prediction of strong interactions. This remark is ideally suited to the demands of this effort and the setting of precision medicine.

***Abstract*—In this paper, we will look at how to detect heart disease in hospitals using embedded IoT. The proposed method is based on the integrated internet of things in hospitals. It communicates wirelessly and can cover the user's immediate surroundings. By transmitting a series of voice control stored in the system's memory card, information about the environment is expressed to the user via headphones. To prevent interference among two or more devices nearby, appropriate connectivity techniques were also integrated into the prototype. Finally, the effectiveness of the device is evaluated and illustrated using experimentations and statistical analysis**.

***Keyword*—AI, Internet of Things (IoT), wearable IoT, Hospitals, Heart Disease**

I. Introduction

Nowadays, regular health monitoring is critical. Wireless health monitoring of a patient is a modern concept. It is a significant advancement in the medical field. Using current technologies such as potable communication, wireless systems, and wearable health monitoring devices which are controlled in the remote process, healthcare providers have established a better health monitoring system that supplies a comfortable lifestyle to patients who are infected with different diseases [1]. As information about the patient's health reaches the doctor's screen from wherever the patient does have any symptoms with him, doctor visits to patients are constantly decreasing. Based on this, physicians may also save a lot of lives by providing timely and beneficial care.

The majority of individuals are experiencing health difficulties as a result of the increasing societal pressure, and the majority of these problems are caused by repeated heart attacks. It is of the utmost need to develop a reliable method that is able to predict the occurrence of heart attacks or atrial fibrillations before they take place. Because the Internet of Things (IoT) is the most rapidly developing and widely used technology in the current age, combining traditional computing with IoT has resulted in the development of highly effective new technologies [2]. The combined system offers a variety of benefits to the user, such as the ability to detect the possibility of heart disease based on the patient's symptoms during an emergency, communicate with medical professionals regarding the severity of the potential disease, and assist in the treatment of the condition [3-4]. In the event of a medical emergency, the system will immediately notify the situation to the chosen physician. The severity of HD may now be diagnosed in patients by the use of electrocardiograms (ECG), exercise stress tests, chest X-rays, CT scans, MRI, coronary angiograms, and other diagnostic procedures. Patients need prompt and accurate diagnosis of coronary heart disease in order to be eligible for timely and appropriate therapy that will improve their chances of surviving the long term. In many parts of the globe with low resources, cardiologists who are qualified to perform these diagnostic tests may not be accessible. In many instances, the health of patients is placed in jeopardy due to the failure to detect a condition, the wrong diagnosis of a condition, or inappropriate treatment [5-6]. In addition, the early discovery of HD leads to preventive measures such as medicines, changes in lifestyle, angioplasty, or surgery, all of which may assist to slow the progression of the illness and reduce morbidity [7]. As a consequence of this, accurate and prompt diagnoses of heart disease are essential for reducing death rates and improving patients' chances of surviving for a longer period of time. It is difficult to diagnose coronary heart disease in its early stages, which is one reason why computer-assisted methods for detecting and diagnosing heart disease in individuals have been created [8]. Approaches that use machine learning to assess clinical data, evaluate it, and diagnose medical disorders are becoming more widespread in healthcare domains. These methods are used in medical facilities.

II. Literature Review

Wang, Wanqing, et al. (2021) and Latchoumi TP et al (2022) sought to improve clustering technology to improve the design of IoT medical embedded devices. The system

DOI: rp-9788770040723.206

aims to align a file's onset and loads illness symptoms input from the user data into the input given. Find a match if the signs are preloaded, which will result in a prevalent prescription medication response and illness names in the system. Angina does not indicate that a cardiac attack occurs [9]. Katake, Kanchan. (2020) and Karnan B et al (2022) investigated existing wearable devices for measuring heart-related parameters and creating sensors for stress hormones, heart aging, and cholesterol. They aimed to create an algorithm that would create an alarm in the event of a threat to human life and would forecast any heart disease using existing evidence as well as data generated by IoT devices [10-11]. They intended to create ML and DL algorithms for this prediction by analyzing existing approaches. Khan, Mohammad Ayoub. (2020) and Sivakumar P (2015) suggested an IoT-based system to more accurately analyze heart disease using a Modified Deep CNN. The patient's BP and ECG are monitored by the smart device and heart tracking device. The MDCNN is used to categorize received sensor data as normal or abnormal. The system's performance is evaluated by comparing the proposed MDCNN to existing logistic regression and also the NN models [12]. The results show that the proposed MDCNN-based heart disease prediction system outperforms other methods. Rahaman, Ashikur, et al. (2019) designed and implemented an inbuilt sensor system with a low-power communication interface to collect ECG and body accelerations in a public setting using a smartphone. A wearable sensor is used to monitor ECG patterns, as well as the smartphone's built-in sensors, such as accelerometers and GPS sensors, to measure the user's body acceleration and location [13-15].

Al-Makhadmeh, et al. (2019) and Monica.M et. al. (2022) described IoT-based medical equipment for collecting heart data from patients before and after heart disease. To handle the data, a higher order Boltzmann deep belief neural network is used that is continuously transmitted to the health care center. The DL method learns heart disease features from previous analysis and achieves efficiency through effective data manipulation. Raj, Sandeep, et al. (2020) and Sridaran K et. al. (2018) proposed a novel that is always enough efficient methodology while comparing it with the real-time acknowledgment ECG signal [16-17]. The approach extracts characteristics from heartbeats using a fast Fourier transform-based discrete wavelet transform, which has a lower computing cost in terms of addition and multiplication operations. These extracted features are identified using a PSO-tuned twin SVM classifier [18-19]. The PSO model is used to gradually adjust the classifier parameters to attain accuracy, and the TSVM classifier is quicker than the fundamental SVM models. To categorize 16 classifications of ECG signals, the method is implemented on an IoT-based console that is most related to the microcontroller and validated with the default benchmark Physionet information [20]. Umer, Muhammad, et al. (2022) and Vemuri et al (2021) to enhance heart failure patient survival prediction without depending on human feature engineering, an intelligent healthcare framework based on IoT and cloud technologies has been developed by Buvana M et al (2021). The intelligent IoT-based system recognizes patients in real-time and offers patients with heart failure timely, effective, and high-quality healthcare services [21-22]. The suggested model also investigates deep learning models for identifying individuals with heart failure who are still alive or have passed away.

III. Proposed Work

A built-in sensor system with a low-power standard interface for collecting ECG and body accelerations in public using a smartphone A wearable sensor, as well as the device's built-in sensors, such as accelerometer sensor and GPS sensors, are used to measure the user's body acceleration and location. The proposed digital health care framework is based on IoT and cloud technologies and is designed to improve heart disease patient survival forecasting without relying on feature engineering. The smart Internet of Things-based framework detects patients in real-time and provides patients with severe with prompt, effective, and high-quality healthcare services. The proposed model also investigates DL models for deciding whether patients with heart failure are alive or dead. The framework collects data from IoT-based sensors and sends it to a cloud web server for processing.

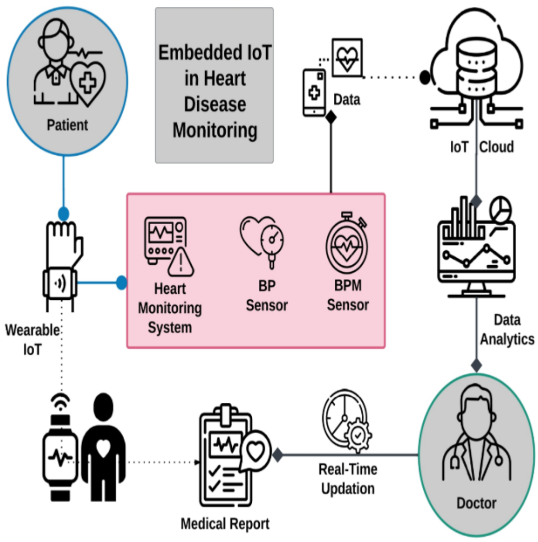

Fig.1. Proposed architecture

Where f(p,q) denotes the pixels in the neighborhood of noise pixel and $\hat{g}(e,x)$ shows the median pixel value. To determine if an individual pixel in a picture has noise, the median filter compares it to all of the surrounding pixels. It is possible to change the size of the neighborhood and the criteria for comparison is calculated using Equation (1).

$$g(e,x) = \underset{(p,q)\in R_{ex}}{mean} \{f(p.q)\} \tag{1}$$

$$F(e,x) = \begin{cases} 1, (e,x) \epsilon P_f \\ 0, otherwise \end{cases} \tag{2}$$

DOI: rp-9788770040723.206

$$N_{s,\theta=0(r,s)} = \sum_{m=1}^{M}\sum_{n=1}^{k}\begin{cases}1 & c\\ 0 & otherwise\end{cases} \quad (3)$$

$$\sum_{p,q}|v-u|^2 q(p,q) \quad (4)$$

In Equation (3), c takes its value according to the condition of if I(p,q) = p *and* I(n, m+s) = q, and p, q = 0, 1, …., l-1.

$$\sum_{p,q}\frac{(p-\mu p)(q-\mu q)q(p,q)}{\sigma_p\sigma_q} \quad (5)$$

The letter "l" stands for the number of grey tones. The letters M and C indicate the image's dimensions.

$$\Sigma(p,q)\frac{u(p,q)}{1+|q+p|} \quad (6) \quad (6)$$

And the (v,x) grey tone is denoted by q(v,x).

$$H_{pc} = -\sum_{m=1}^{M_{pc}}\sum_{n=1}^{N_{pc}} q_{pc}(m,n)\ .\log q_{pc}(p,q) \quad (7)$$

IV. Experimental Results

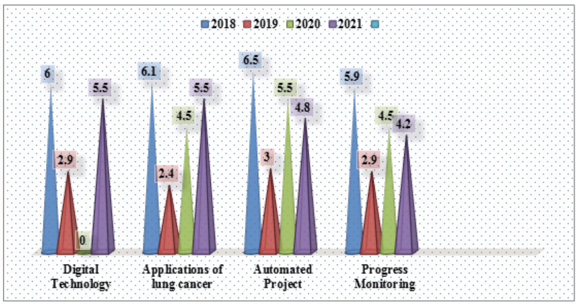

Fig.2.Analysis of comparison of previous models

By changing the different k-folds, the effectiveness of the smart healthcare prediction model is evaluated and contrasted with algorithms and classifiers as shown in Fig.2. The GSO-CCNN-based smart healthcare prediction model's better performance is assessed utilizing a variety of performance criteria. The MCC of planned GSO-CCNN is nine percent, 10.4 percent, 11.7 percent, and 7.9 percent more advanced when the k-fold is assumed to be 2. The general effectiveness of proposed smart healthcare modeling with IoT-based fog and cloud computing for various metaheuristic-based algorithms and classifiers.

TABLE I. Performance Measures

Algorithm	Patients Activity in Training (%)	Patients Monitoring in testing (%)	Overall Accuracy (%)
(ML) Algorithm	89.78	98.67	84.01
Neural Network Model	91.78	92.56	94.67

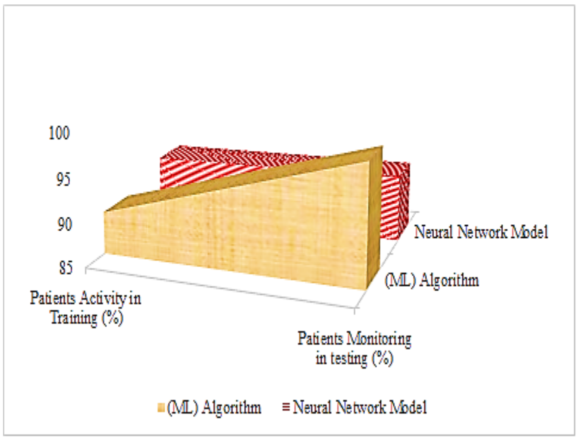

Fig.8. Training and Testing Analysis

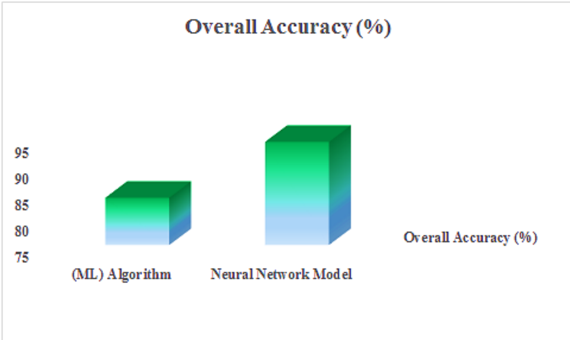

Fig.9. Accuracy Analysis

The comparative research of the suggested smart healthcare model with IoT-assisted fog computing is expressed in terms of k-fold validation by setting the k-fold to 5, as indicated for different metaheuristic-based algorithms and classifiers, respectively. Machine learning models are evaluated on a short data sample using a resampling approach called cross-validation. Fig.3 and Fig.4 represents the comparative analysis of the proposed Machine Learning model on Neural Network Models and the results show that the Machine Learning model has outperformed the existing model. Table I represents the numerical analysis of these figures.

V. Conclusion

The framework makes use of IoT-based which helps in the collection of data and shares it to a cloud server to make use of it in further processing. Chui, Kwok Tai, et al. (2019) proposed a response to a patient monitoring system that is based on IoT. Qualitative research is being conducted on selected analytics which evaluates the behavior, cardiovascular disease identification, and fall detection. Gia, Tuan Nguyen, et al. (2019) proposed low-energy monitoring for diabetic patients with cardiovascular disease using a fog-aided IoT system. Kazi et al. (2018) developed a real-time cardiovascular disease monitoring system that is most related to continuous focusing on the patients instead of doctors or as like the doctors physically monitoring the patient. IoT-based sensor management becomes a huge environment for several applications and services, with Raspberry Pi acting as both a controller and a sensor node.

DOI: rp-9788770040723.206

The study suggests a universal patient monitoring system as the next step in the department's development thus far.

Abstract—Since RNAs were numerous, prevalent through biological distribution or purpose, but adaptable overall architecture, discovering protein RNA associations were difficult either analytically or statistically. As a consequence, a large number of RNA-binding enzymes (RBPs) have yet to be discovered. A findings were similar or by detecting 860 mRNA-binding proteins in such a later chromatographies research, or by using SPOT-Seq of RBPs, a template-based achievement predicting tool, to the gene regulation (Mbps). According to the Nucleotide Sequences, predicted penetration (or sensitivity) of 1217 recognized RBPs or 43.6 percent of 860 recently discovered human Mbps is 42.6 % or 43.6 %, respectively. SPOT-robust Seq's capacity to foresee RBPs was demonstrated by its continued sensitivity. More importantly, SPOT-Seq discovers 2418 new RBPs across associated proteins, including 291 of these verified by the recently discovered mRBP set.There are 61 unique RBPs that are not comparable to any recognized RBPs among 291 authenticated novels RBPs. We may now investigate the phenotypic roles of anticipated novel RBPs in sickness cascades after they have been validated. For actual verification or hypothesis development, the information of 2418 anticipated novels RBPs, together with confidence level, but also complex mechanisms, was accessible at http://sparks-lab.org (with articles).

Keywords—mRNA-binding enzymes; disease pathways; protein-RNA interactions

I. Introduction

Characterization of RNA-binding enzymes (RBP) and their targets is required for a complete knowledge of biological processes. RBPs are of particular importance since they have been connected to a wide range of biological functions, particularly cellular homeostasis or genome preservation, that alterations in RBPs have been linked to human illnesses, especially tumors [1-3]. According to a current worldwide assessment, transcribed are not only numerous but also diversified in their distribution and activity in molecules. This suggests that comment systems should be more complex than regulatory or protein–protein connection pathways [4]. Furthermore, determining RNA-binding by each enzyme experimentally is impractical or unrealistic, as well as theoretically difficult and costly [5]. The effort to find RBPs using high-throughput molecular techniques develop slowly and are prone to error. As a result, computational models have become an important part of RBP performance identification or assessment.

II. Related Works

Proposed and implemented SPOT-Seq (RNA), a guideline approach for predicting RBPs depending on the nucleotide [6]. The fold recognition technique is used to assemble a sequence similarity structural default parameters of protein-RNA complexes in this approach [7]. On both the region and enzyme chain categories, the prototype library provides 1164 known protein-RNA complex molecules (95 percent sequence identity or less). If one of the prototypes has a high Z-score resemblance to such inquiry, the query's design is predicted, or a framework precise definition is built between predicted architecture and the design's RNA[8].To use an understanding integral equation theprototype, detailed structure could then be used to estimate the propensity for protein-RNA binding. An RBP is forecast if the structural similarity was greater than a criterion [9].PSI-BLAST, which employs a sequence-to-profile suitability heuristic algorithm, outperforms SPOT-Seek in terms of sensitivity and reliability [10-12]. More crucially, while implemented to 250 DNA binding proteins, SPOTSeq (RNAs) was able to distinguish between DNA-binding or RNA association (less false positive rate) unlike several mathematical techniques [13-15]. A massive forecast of RBPs in the gene expression and found 42.6 % of categorized RBPs in the protein database. When contrasted to the quickly found 890 translations RNA associated protein in human HeLa cells19, our estimates showed a constant susceptibility. And over 2000 RBPs are predicted, including 291 of them confirmed via translation, RNA associated proteins, that were recently discovered.

DOI: rp-9788770040723.207

Researchers also discovered that several of this novel RBPs play a role in a variety of sickness systems.

III. Proposed Methods

For RBP estimation, SPOT-Seq integrates fold segmentation to interaction propensity forecast. Using the fold identification algorithm SPARKS X.17, each target gene is matched towards a template library of 1195 nucleotides sequence proteins-RNA complicated mechanisms (95 %sequence identity cutoff). If such folding recognition Z-score is greater than 8.04, a simulation includes connecting target molecule or signal RNA is built by adopting the SPARKS X sequence-to-structure approach to replace specimen protein sequences with the target protein database [16]. The prototype, detailed inspection would then be applied to compute binding interactions using a probabilistic energy model that focuses on the way always limited external standard state20, which has been used to protein-RNA interactions (DRNA). The target gene was expected to be RNA-binding if the predicted criterion is smaller than 20.57, and its advanced modelling approach is employed to predict RNA-binding performance at spatial precision [17-18]. Using a leave-homologue-out classification method, the efficiency and Z-score criteria (20.57 and 8.04, respectively) were obtained by optimising the Mathews degree of determination (MCC) with a collection of 216 RBPs or 5765 non-RBPs. They chose to optimize MCC predictions is an acceptable measure of accuracy or particularly for such a training sample with an uneven amount of RNA-binding or unregistered proteins [19-20].

IV. Results and Discussions

After eliminating enzymes whose estimated structures intersect to anticipated transmembrane areas by THUMBUP, SPOT-Seq on the human proteins discovered 1841 enzymes as RNA-binding. Although our algorithm based on protein, RNA complicated mechanisms cannot anticipate the configurations of integral membrane proteins, this detector is required. 118 enzymes were categorized as RNA-binding and correspond to one of category groups listed in Table 1 out of 1841expected RBPs.

TABLE 1. RBPs in Number

No of Protines			
RNA polymerase	702	389	53
ribonuclease	62	31	49
ribonucleproten	250	40	21
Ribosomal	63	19	14
RNA Biniding	118	10	20
Total	1195	489	157

Number of Proteins			
Keywords	Annotated	Predicted	Sensitivity Coverage Percentage (%)
RNA Polymerase	702	389	53
ribonuclease	62	31	49
ribonucleoprotein	253	49	21
ribosomal	63	14	19
RNA binding	118	18	14
Total	1351	509	45

Furthermore, 1848 enzymes have roles other than RNA interaction, and 570 molecules have no descriptors. The amount of anticipated RBPs in labelled RBPs, non-RBPs labelled with other functions, or enzymes with unknown parameters is shown in Fig.1. The finding indicated a 42.6 % susceptibility (or coverage). Despite the reality that their reference study16 was predicated on enzymes whose structures were determined in combination with RNA, the sensibility is continuous. A susceptibility of RBPs is highly dependent on the particular RBP groupings, as they discovered.

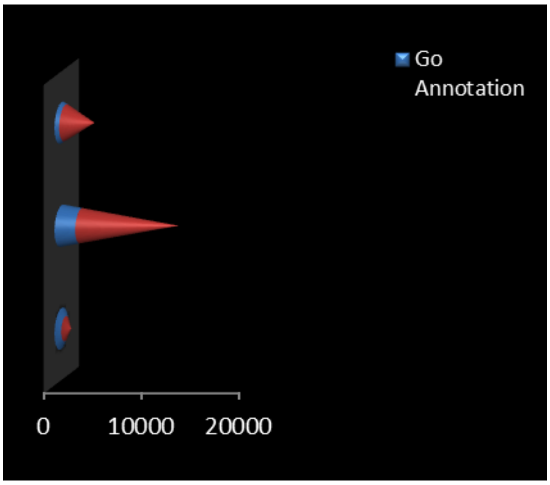

Fig.1. RBPs process with existing system

As indicated in Table 1, enzymes labeled also with the phrase "RNA interaction" have the maximum accuracy (56%) or the enzymes tagged with the phrase "RNA polymerase" have the least (13%) susceptibility. The top ten substrates used for all estimated RBPs throughout the protein database are listed in Table 2. The RPL3 gene contains the 60S protein kinase L3 (chain C in PDB structure 3o58), which predicts 1181 enzymes, with 61 of them designated as RNA interacting. There are four other 60S protease enzymes in the top ten. We investigate the overall correctness these predictions of lights of L3's frequent occurrence as a design. 215 RBPs and 5765 non-RBPs participated in the SPOTseq study. 16 11 binding proteins, but also 15 largely symbolic objectives were found to employ protein complexes from architecture 3o58 as precursors. When all designs are used, the MCC for using 3o58 links as patterns is 0.64, which is similar towards the general MCC of 0.62. As a result, the generalization ability based on 3o58 links was comparable to overall quality.

There seems to be an amount of 1848 new RBPs that have jobs apart from RNA interaction.In other words, these molecules do double duty as RNA-binding enzymes. Focusing on their similar chemical activities, they looked at new and current moonlighting RBPs. The number of attributes and GO words into component that are original or identical across anticipated or validated RBPs are listed in Table 3I. More than 90% of estimated novel RBPs with root inscriptions only and 98 percent of estimated novel RBPs including leaf evaluations] had GO IDs to describe RBPs, 1238/(1238 1 26). To put it another way, practically all to predicated moonlighting RBPs' capabilities are linked to recognized RBPs. The total human transcriptomic includes 1411 or GO IDs, while identifying RBPs has 288 or GO IDs, according to our findings. RBPs have a strong relationship to other biological mechanisms, as seen by the fact that 20% of all tissues GO IDs are linked to RBPs.GO Algorithm (Table 3)

Fig.2 shows four categories of assessed or identified RBPs with four GO IDs to indicate similar capabilities among expected or verified RBPs. Each GO ID not only comprises both forecasted or confirmed RBPs, but it also relates to enzymes having numerous GO IDs. Many of these ten GO IDs are linked to translation regulator activity, implying that they bind to DNA. Zinc-ion-binding, for example, has an unusual ratio of 1.06 (percentage of assessing RBPs in a particular GO ID in all examined RBPs vs. Proportion of all enzymes in a certain GO ID).

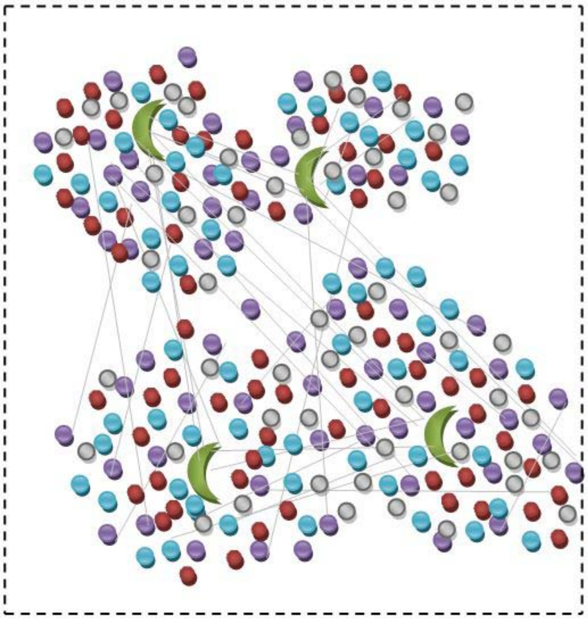

Fig.2. Relationship among GO IDs and enzymes

Integrating GO IDs among observed or forecast RBPs helps to evaluate expected novel RBPs, but it does not confirm them. A current biochemical investigation, which discovered mRNA-binding enzymes n HeLa cells allowed us to directly validate our anticipated RBPs. 19 UV irradiation was employed in this investigation by providing a shared Mbps in active HeLa cells, that were subsequently captured using magnetic nanoparticles after enzymatic hydrolysis and characterized using elevated nanoLC-MS/MS.They found 860 Mbps, with SPOT-Seq predicting 375 of them as RBPs. This dataset's susceptibility is 43.6 %, which is similar to the 42.6 percent susceptibility from all GO labelled RBPs. Even though the data sources are radically different, SPOT-overall Seq's correctness is supported by its vulnerability.Many unique RBPs are found among the 860 Mbps.

RBPs were classified using that GO criteria as sequence data, 746 enzymes are identified as RBPs, with SPOT-Seq estimating 291 of these as RBPs. As a result, SPOT-Seq has a susceptibility of 39% for detecting novel RBPs, which is comparable to the acuity of all RBPs (42.6 percent). The most frequently employed substrates in these 291 forecasted or authenticated mRBPs are chains in PDB ID 3058 (87 duration). These proves that 3058 could be used as a model for forecasting RBPs. Furthermore, a reference molecule with mRNA binding function was used in bulk of 291 estimated protein molecules (70 percent, 203/291).

The genetic information was used to test a different approach of RBP forecasting predicted on established RBP complex configurations. The approach discovered 2418 molecules in the GO dataset that were not originally classified as RBPs. Approximately half of the estimated novel RBPs were classified as ORFs with no GO comments regarding biological activities (908) or merely GO root IDs (909) (247). Table 4 shows that 284 of such projected new RBPs are connected to disease pathways. This forecasting

DOI: rp-9788770040723.207

tool's initial verification contains 12% of the expected results.

TABLE 4. ENZYMES AND RBPS BASED ON 11 DISORDERS

Total	169	4727	325	149	260

80.5 % of all estimated RBPs have unidentified activities, but are labelled with capabilities other than RNA interaction. This indicates that there are far more RBPs than are presently labelled. If we combine anticipated or identified RBPs suppose which the plurality to forecasted and recognized RBPs are correct, RBPs account for 18% of all transcripts. Assuming SPOT-sensitivity Seq's of roughly 43%, the actual amount of RBPs was expected by more than 18%, which mistakes are taken into the description. A huge amount of RBPs that could exist emphasizes the breadth or importance of the protein–RNA association connection. A majority of the RBPs identified here aren't RNA-binding proteins. This so-called freelance potential of RBPs has been confirmed in yeast or human enzyme screens. Novel RBPs discovered through screens were revealed to have enzyme reactions as well as RNA-binding designs.

They have eliminated those anticipated RBPs that are intracellular enzymes to avoid false positive predictions. This is due to the fact that all of our template molecules are spherical. Furthermore, the current approach necessitates independent intracellular proteins forecasting or manual verification. They intend to include a permeability filter directive within SPOT-seek in a future edition. Furthermore, while transmembrane protein prediction accuracy is 88 percent, omitting forecasted transmembrane regions may result in the removal of some real positive predictions. 23 We applied this permeability filter to increase the performance of our RBP forecast while reducing the number of predictions.

Many anticipated RBPs, particularly L3, employed precursors from 60S ribosomal proteins, which was a revolutionary innovation of our template-based methodology (PDB ID 3o58). This is true for either conventional or labeled RBPs that have been expected. We have confidence in these forecasts because our standard test shows that forecasts based on 3o58 are as accurate as assumptions based on other designs. Furthermore, 87 new RBPs depending on 358 templates have been confirmed as Mbps. 19 The prevalence of L3 and other associated proteins in forecasting RBPs could be due to translational enzymes' long evolutionary history or the possible proliferation of genetic variants in interpretation.

V. CONCLUSIONS

The SPOT-Seq approach has a drawback in that it relies on existing protein-RNA complicated mechanisms as precedents for forecasting complex systems. The query molecule would be suggested as non-RBPs if no corresponding pattern is discovered. Because of dependable the projected structures by framework approaches is not yet dependable, an ab initio homology modelling methodology could not be used to create shape predictions. 30 The reliability of our forecast is 40% due to the restricted amount of possible models of protein-RNA complicated mechanisms. That is to say, there seem to be a lot of false negatives. In addition to the reduced amount of frameworks, incorrectly anticipated binding areas leading to infrastructure models rigid-body presumption could cause absorption, preventing predicted of better binding propensity and thus leading to a false negative forecast. SPOT-Seq increases the retrieval of predicted RBPs or discovering additional when more protein-RNA active compounds are discovered in the future. Additionally, through combining SPOT-sac with several other sequences and framework techniques, the selectivity of the SPOT - sac should indeed improve.

Abstract—Throughout generations, this same greatest prevalent approach towards predicting RNA intermediate architecture has remained spontaneous resource elimination. That's predicated around another collection of empirically total power fluctuation characteristics obtained through tests with our proximity models. MaxExpect, a software [15] computer whose anticipates RNA intermediate organization through increasing predicted foundation correctness, was described within this paper. It's software CONTRAfold became this same inaugural to use such technology, which used pairing possibilities anticipated employing another quantitative modeling methodology. Another partitioning functions computation was employed can forecast basepair possibilities also much has newly oligonucleotide possibilities using empirical direct energies adjustment proximity characteristics. With function providing competing explanations regarding underlying design, MaxExpect expects simultaneously this same optimum as well as mediocre configurations. These highest predicted reliability constructions generally, upon the median, are based around a very broad dataset comprising various forms containing RNA. Organizations with considerably greater degree more precision beyond maximum freed energies formations. Because proportion among recognized basis pairings appropriately projected was called sensitive, whereas because proportion for anticipated pairings which belong within the overall recognized organization was called positively prognostic quality. The greater sensitivities but rather Accuracy for predictions could be promoted through selecting doubly strangeness but rather only one went ashore, correspondingly. When comparing versus unconstrained resource minimizing, overall median Ppa estimated optimum architecture employing MaxExpect improves between 66 percent towards 68 percent assuming this same sensitivity setting.

Keywords—Nearest Neighbor method; RNA structure; MaxExpect; PPV; Base pairs

I. INTRODUCTION

Numerous different types of functioning RNAs had been found within a recent century, although their frequency that development had intensified. Intergenic RNAs are so named even though those who do neither require human polypeptide synthesis to operate [1]. This same numerous capabilities of ncRNA had already inherently altered this same previous preparation of this same Regional Doctrine of Human physiology, which held that proteases have been this same sole hereditary concluding contributors to the development. Proper identification of underlying architecture seems required for simultaneously this identification but also investigation underlying ncRNA functionality. Our physicochemical framework anticipates this same optimum equilibria configuration, namely form containing molecular minimum Reynolds potential variation following unfolding [2].

This closest neighbors approximation was employed during kinetic resource minimizing help estimate overall translational instability for this particular organization. Regular multiple stagnation analyses were used to determine comprehensive collection for proximity characteristics for liberated radiation but also heat changes using another series of consecutive photonic blistering tests involving modeling materials [3]. This technique involves determining this same least probable architecture utilizing any randomized discussion language [4] provides another alternative towards obtaining this same highest frequent construction through unconstrained resource elimination. This probabilistic discussion memory's characteristics were learned against another collection of language phrases containing established patterns.

II. RELATED WORKS

Freeware resource reduction but also structural forecasting depending upon information have subsequently

DOI: rp-9788770040723.208

been merged. Using computationally heterogeneous library containing RNA genomes containing recognized geometries spanning smaller than 700 sequences, overall responsiveness using neutral energies reductions have previously evaluated and compared so much is 73 percent, while low PPV effective arbitrary expenditure reductions [5]. There are 2 reasons for such decreased PPV.

Firstly, although increasing creation formed pairing reduces overall spontaneous energetic increase, here appears always propensity towards over predict basis pairings.Secondly, every collection containing recognized architectures might cannot always label every scientifically found nucleotide sequence, lowering PPV [6]. Identifying every valid combination which was never marked reduces PPV. That architecture having that highest anticipated correctness may still be anticipated providing another alternative towards identifying this same more likely configuration. Overall anticipated correctness for pseudo-knot-free nanostructures is calculated through minimizing overall aggregate between the command center and also human sequencing probability, wherein coupling forecasts could be penalized using some variable.

CONTRA folding estimates foundation possibilities employing statistical characteristics learned through software sequence synthetic RNA tertiary geometries, but also subsequently estimates frameworks utilizing this same greatest predicted correctness technique. Their intermediate structures identical across several replicated RNA sequences were then predicted using average potential precision structured predictions [7]. Another ranking measuring spontaneous radiation changes but also dynamic interactions was used to determine overall fundamental couple possibilities within a particular technique.Another utilization of the greatest anticipated precision throughout individual sequencing intermediate architecture predictions was explored throughout this work, which uses economics that forecasts overall fundamental foundation probability. Considering all present spontaneous [16] power transfer constants around 37°A and, a partitioning functional computation forecasts foundation frequencies.

Similar to previous CONTRA fold, those probabilities were used through using dynamically computing technique, which is performed within software MaxExpect, which constructs this construction without optimum predicted precision [9-10]. This approach is evaluated on a large collection comprising various kinds containing RNA, without our basis function, g, being changed that demonstrate overall exchange among sensitivities as well as PPV. Overall median optimistic predicting effectiveness using MaxExpect when f = 1 is 68 percent, having overall sensibility equal 73 percent, which exactly overall identical with conventional freed resource minimizing technique [11]. As such result, that greatest anticipated correctness organization projected substantially more accurate on aggregate than any minimal freed energies construction. MaxExpect may potentially anticipate alternative potential alternative competitive topologies, known as substandard buildings, throughout addition to finding ideal architecture [12]. Another probabilistic strategy comparable to those proposed earlier involving spontaneous radiation elimination was used can anticipate substandard architectures having anticipated pairing reliability higher below overall ideal architecture. Other explanations regarding its architecture are other expected unsatisfactory configurations. Here was the very earliest application using the greatest anticipated reliability structural predictions which use inadequate organization forecasting which we are aware of. Using Single-cell RNA-sequencing (scRNA-seq) technology, the researchers investigated computational methodologies for assessing RNA levels in single cells [13-14]. They next looked at eight alternative imputation methods, evaluating their ability to restore original data and running various studies to examine how they affected cell type clustering and the discovery of differentially expressed genes.

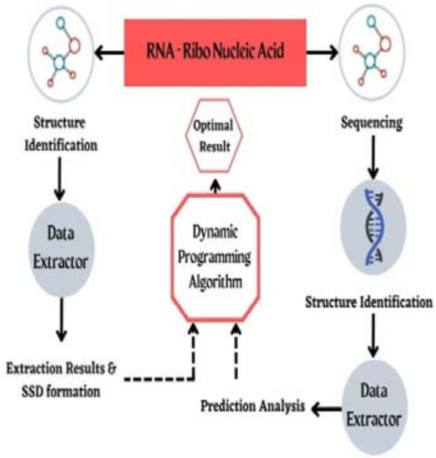

Fig.1. Proposed Methodology

III. Proposed Methods

The proposed methodology comes up with a system for the measurement of Secondary RNA structure and this utilizes the free energy minimization technique. A dynamic programming algorithm is employed to get optimal results. At first, the structure of the RNA is identified and then data is extracted from it. The extraction results are fed into the dynamic programming algorithm, for prediction analysis. Optimal results are obtained from this proposed methodology. The proposed methodology is illustrated in Fig.1. Through optimizing anticipated correctness among basis pairings including standard sequences, minimization is anticipated correctness delivers the greatest approximation given any RNA intermediate structures. Their foundation but also separate probability were estimated using another partitioning mechanism that may be limited using practical information Biochemical alteration, for example, While these approaches use identical closest neighbourhood settings calculating unfolding maximum expenditure changes, everything that was proven that this optimum architecture anticipated by anticipated correctness maximizing yields superior averaged inaccuracy then overall building projected by freed power minimizing.

MaxExpect for prediction accuracy

DOI: rp-9788770040723.208

MaxExpect has been examined using a very large dataset containing reported intermediate structural RNA transcripts. This best structural, this same greatest planned reliability framework, was forecasted but also contrasted to another existing configuration within this same dataset, using sensitivities but also PPV reporting overall correctness for forecast. Sensitivities against PPV exchange variable, ggfor determining this same ideal preferences for doubled peculiarity against simple peculiarity, this value was changed between 105 through 106. Fig.1 shows overall histogram increasing sensitivities have a proportion increasing PPV. Another minimum number of 750 unsatisfactory configurations is being forecasted throughout additional with optimum formations. This same greatest substandard building's effectiveness, i.e. that organization with this same maximum responsiveness, Figure 2 depicts this as well. That architecture could ultimately be established through understanding such same right architecture, however, still reflects MaxExpect's greatest prediction. Assembling constructions made from bases pairings having an overall command center frequency greater than exceeds the given minimum provides a relatively straightforward strategy for increasing predicted reliability.

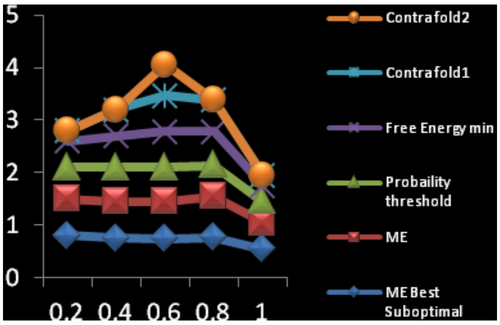

Fig.2. The effectiveness of using various forecast algorithms

Fig.2 compares overall forecasting efficiency using spontaneous resource reductions, CONTRA folding 1.10, but also Objection folding 2.02 against MaxExpect. Whenever m = 1, MaxExpect delivers significantly better PPV than unconstrained resource minimizing for nearly exact comparable sensitivities for architecture predictions. CONTRA folding 2.02 is a substantial enhancement above CONTRA fold [13] but also behaves comparably with MaxExpect. Contrast construct learned its foldable characteristics using 151 typical RNA molecules included throughout this same Rfam collection. This S-Processed information collection, which contains 3439 architectures, was used to determine variables using Contrast folding 2.

IV. Results and Discussions

Considering every kind of structural RNA within our dataset, Fig.1 presents overall levels utilizing accuracy utilizing MaxExpect, direct resource reductions, using Contrast folding 2.02. Average MaxExpect correctness when g = 1, where illustrates optimal threshold when PPV improves beyond unrestricted resource reduction, was presented. Overall reliability with Negative balance folding was provided with g = 6, which matches the performance standard amount using g.Both S-Processed information collection utilized during retraining Contrast folding 2.02 but also both assessment information collection implemented throughout research study have some overlapping. Another bridge technique being used enables extra learning but also assessment using Objection folding further assess understanding influence from temporal overlapping. Only those occurrences containing a particular kind that RNA within this same S-Processed information collection being deleted during overall parameterization retraining during particular bridgethese characteristics have been subsequently used towards forecast buildings with this same kind. While developing any collection the characteristics employed that anticipate Hepatitis S buildings before evaluating effectiveness using RNase P, for example, some RNase P compounds being deleted. Using this crossover authentication screening technique, Negative balance folding effectiveness was significantly enhanced, resulting in substantially greater sensitivities within detection constant PPV.

Variation in accuracy structures

Fig.2 displays overall variations between foundation possibilities within optimum architectures. Whenever this same weighted variable, was used, the overall median foundation likelihood within the overall ideal architecture anticipated by MaxExpect is approximately 0.042 greater than that anticipated by unconstrained resource eliminating, The value of MaxExpect is 1. Whereas technique disparity throughout overall fraction among projected basis pairings overall coupling frequency >0.99 is just 0.7 percent, MaxExpect predicts 7.8percent days were spent worldwide time more basis pairings having partnering frequency greater versus 0.50 than unconstrained resource elimination.

This demonstrates because the geometries suggested through arbitrary resource reductions currently include the greatest statistically likely pairings. Basis pairings having greater pairings probabilities give greater credibility regarding predicting precision over basic pairings without smaller pairings probabilities, particularly established during another recent work using the lowest potential power architectures. Therefore, when maximal predicted correctness constructions comprise approximately a comparable amount more basis pairings having good matching possibility and yet lesser basis combinations having poor coupling possibility versus lowest open efficiency configurations, MaxExpect beats cheap efficiency reductions. The above point is shown with Exhibit 2, which shows how increasing anticipation improves structures predicting reliability using particular 5S rRNA. Overall responsiveness for the overall system estimated from optimizing anticipated correctness is 91.4 percent.

It's particularly worth noting because there's the obvious link connecting previous research around improving predicted accuracy and more contemporary research around discovering pseudoknot freed constructions using pseudo knotty architectures which keep the greatest pairings. Their inputs using their identical subprograms employed there with previous research include variable chance equal of every any pairing which appears within much simulated tangled construction shown in Figure 3. That architecture containing that greatest quantity more quasi pairings represents (1) this same result. Using matrices $A(x,y)$ those accompanying aims to redefine determine this same highest anticipated correctness given each Segment of DNA using N molecules:

$$A(x,y) = \{0\ \partial - \infty 2Q_{mn}(x,y) + B(x+1, y-1) if\ x-1+< hairpin\ L, \tag{1}$$

$$if\ x\ \&\ y\ can\ form\ a\ canonical\ pair,$$

$$if\ x\ \&\ y\ cannot\ form\ a\ canonical\ pair,$$

As such a result, homologous chromosomes found across buildings having very higher anticipated correctness may effectively detect, whereas constructions could be deduced using every particular pairing the sequences found within any structural having very great anticipated correctness. The windows variable was implemented to guarantee whether anticipated shapes be sufficiently different from one another. This same express computation of spirally twisted-pair stockpiling, something that has heretofore been shown to start taking approximately 2 different of this same overall computation moment but also has been unavailable from this same Debit balance times higher method purple color calculating, has always been a considerable component throughout this same lengthier moment requisite by fusion power cost reduction but rather indeed

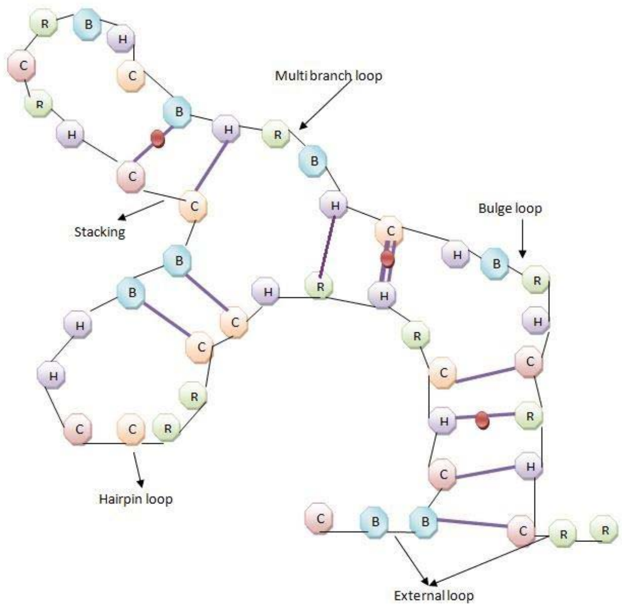

Fig.3. Components projected using Max Expect as an illustration

singular separation operates are using below [9]. Furthermore, MaxExpect generates substandard topologies, because this same mechanism used to do so take double as long as obtaining this same best architecture individually.

V. CONCLUSIONS

Although foundation matching is questionable throughout the comparative analysis, a data object has been regarded accurately did estimate future sometimes above option DNA polymerase on the single thread was skipped. When either among these cells was grouped pairings were anticipated, then basic pairing connecting I but also j was regarded accurate: i with j, i with j + 1, but also j, but rather i + 1 with j. The foundation pairings i+1 with j + 1 but also i + 1 but instead j were never regarded valid. That grading technique additionally takes into account the overall likelihood those changing command center behaviors. Overall sensitivities but instead PPV numbers derived to such slipping technique were typically 2–3% greater than those using matching precise foundation coupling strategy. Additionally, since CONTRA folding forecasts minimal standard primers, these were generally taken into account when calculating prediction. Overall means both overall sensitivities and PPV from every nucleotide were presented while calculating median sensitivities but also PPV for a type of Reverse transcription.

***Abstract*—Due to information security breaches, video forgery is constantly rising in the digital world, creating a need for video and photo material surveillance for forgery identification. The proliferation of false films increases societal chaos and security dangers. The increase in malware has made it easier for users (anyone) to post, download, or exchange objects online that include audio, photos, or video, which is the cause of video forgeries. Recent years have seen a significant increase in media manipulation due to the advancement of technology and simplicity of producing fake information. Applications for video forgery detection include multimedia science, forensic examination, digital investigations, and video authenticity verification. The goal of video forensics technologies is to extract characteristics that can be used to tell false content frames apart from genuine videos. Deepfake media is produced and disseminated widely throughout social media platforms, and its identification is considered as posing a significant threat to media integrity. Falsification detection in video has been supplied with a proposed method for Deepfake detection. Convolutional neural network (CNN) method ResNet is employed as a method to identify Deepfake movies. The model tries to improve the reliability of the detector as well as the performance of identifying forgeries movies made using a certain technique. In order to identify the counterfeit in the movie, the suggested method simply makes use of the deep features that were recovered from of the ResNet Classification algorithm and then applies the standard mathematical method to these features. In an effort to address Deepfake video identification, the detector will offer a preliminary solution and be updated frequently with data from the actual world.**

I. INTRODUCTION

A considerable volume of video content is now readily accessible to many consumers through the Internet thanks to the quick development of computationally affordable as well as cross-platform video editing software. Recent years have seen a growth in fraudulent videos due to the amount of video data, Artificial intelligence methods, but also easily accessible, high-performance video editing software. Fake photos and videos are used in fraudulent activities to get around facial authentication, disseminate fake news, and even for fun. Due to information security breaches, video forgery is constantly rising in the digital world, creating a need for images and video content surveillance for forgery identification. The proliferation of false films increases societal chaos and security dangers. Applications for video forgery detection include multimedia science, forensic analysis, electronic investigations, as well as video authenticity verification. The goal of video forensics technologies is to extract characteristics that can be used to tell false content frames apart from genuine videos. Deep learning is now so amazing that it would have been unthinkable just a few years ago due to the growing processing power. Like any remarkable breakthrough, this has created new challenges. Supposedly "DeepFake" produced by adversarial deep generative models that have control over video and quick clips.

Understanding how the Adversarial Network (GAN) constructs the Deep Fake is crucial for identifying it. GAN takes the input a video as well as a photo of a certain person (the "target") and produces another video with the goal's faces replaced with those of a different person (the "source"). Deep adversarial neural networks, which can robotically transfer the faces as well as facial gestures of the source to target based on face photos and target videos, provide the backbone of DF. The resulting videos can seem overly realistic with the correct post-processing. The GAN changes the input image in each frame after dividing the movie into frames. Additionally, it recreates the video. The most common method for achieving this interaction is to use auto encoders. We outline a brand-new deep learning-based technique that can effectively tell DF films from from real ones. Due to computational constraints and reliability difficulties for real-time settings, inter-frame duplicating is not explored as thoroughly as copy move forgeries and is currently not relevant in real-time. Low accuracy rates, poor efficiency, and a high level of computing complexity plague existing methods in the literature. Additionally, the majority of current methods train on datasets with small sample sizes, which is insufficient to fully utilise deep learning performance. Additionally, the majority of the previous

DOI: rp-9788770040723.209

research ignores the issue of different frame rates for previews.

I. Related Works

The meta-deepfake detecting (MDD) algorithm, based on meta-learning, was used by the existing system. To learn effective face representation on both synthetic source and destination domains, with a meta-optimization objective. The source domain is moved to the particular domain by the MDD. The gradient from the meta-train and meta-test are integrated using meta-optimization to improve model applicability. Without updating the model for unknown domains, the MDD can manage them. In order to achieve domain generalization, the source domains were split into to the meta-train area Trains as well as the meta-test area Tests during training. The model is motivated to gather generalizable knowledge about how to generalise effectively just on domain names with different distributions in order to replicate the topic shift problem which existed when employed in real-world circumstances. We additionally divide N source domains of TS at random to produce morpho for training and testing. The patterns in these data are unique across domains and include both actual and fake face pairs. These pairs improve data collection and comparison between authentic and fraudulent photos. Due to the increased differentiation during training and improved model quality, it also improves inter-class separability, which may be understood as a separate dispersion of the sample feature distribution. The network may learn more distinguishing traits more quickly during optimization. The truth is that when subjected to hidden manipulation techniques, features learned through supervised learning have substantially less power to generalise. As a result, when the source domain is divided into meta-train and meta-test, the model is simpler to generalise. The issue of overfitting is also reduced by randomly selecting and shuffling the data inside the meta-train and meta-test. Furthermore, the system has not seen or been educated on data like that in the unseen domain, which is quite diverse in reality. Meta-splitting thus facilitates both model training and generalisation to new inputs.

III. Proposed Methodology

Implement a novel deep learning-based method that can correctly tell phoney videos produced by AI (DF Videos) from real videos. Expanding technology that can identify fakes is crucial if the DF is to be identified and stopped from spreading online. Convolution neural network (CNN) categorization of multi-dimensional data has recently become the de facto method, and it produces standard and also extremely effective network layer structures. However, the pace of these architectures is constrained by the enormous volume of calculations required for both training and testing the network, as well as the possibility of decreased accuracy. This research suggested using hybrid CNN to increase the effectiveness of video and image forgery detection in order to resolve these problems. In the beginning, there is an intensive and progressive learning phase. This hybrid CNN is then used to detect the faked image and video after that. Convolution Neural Networks (CNNs), in particular, have recently experienced remarkable success due to their potent capacity for automatically learning of features for huge video classification. With the help of big datasets and a range of frame rates, this suggested system aims to examine deep learning techniques for video counterfeit detection. The forged videos are categorised using a deep neural network method that looks for duplicate frames in videos. Designing a Convolutional Neural Network (CNN) that really can serve as the framework for feature extraction is the initial stage. Different sized feature maps are produced by the feature extractor. Another classification (another neural network) can then use these feature extraction maps to determine the type of the image (i.e., real or fake). To avoid losing spatial information, inverted residual blocks as well as linear bottlenecks are employed as intermediate layers in this work. As they decrease the complexity of the representations, the preserved are also memory-efficient. The addition of many contemporary techniques and small design adjustments made throughout training enhance network performance. These adjustments allow the model to pick up discriminative characteristics more quickly and with less predictable times.

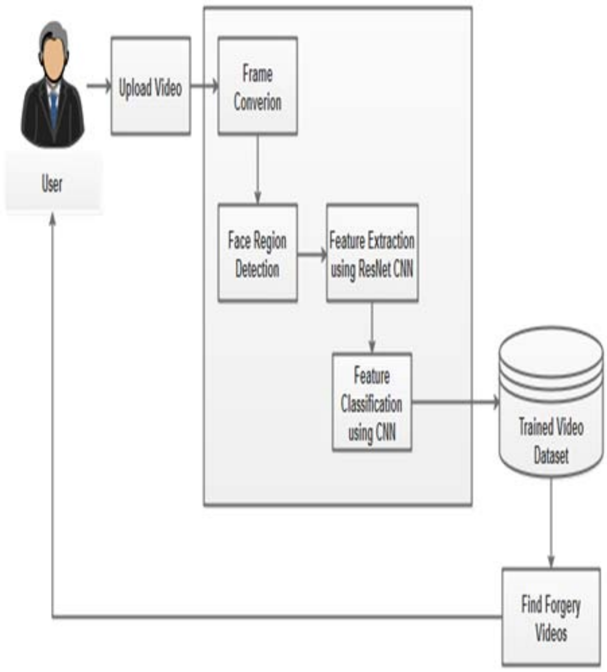

Fig 1: Video Forgery Detection

IV. CNN Classification

Multiple hidden layers, input layers, and an output layer make up a CNN. Convolutional, pooling, fully connected, and normalising layers are the layers in a CNN. The targeting new to be categorised serves as the input, while the environment of a bird nest in the image serves as the output. The final output is determined by activation functions, which are also used to select the set of parameters that suit the model the best.The Residual Blocks idea was created by this design to address the issue of the vanishing/exploding gradient. We apply a method known as skip connections in this network. The skip connection bypasses some levels in between to link layer activations to subsequent layers. This

DOI: rp-9788770040723.209

creates a leftover block. These leftover blocks are stacked to create resnets.

Instead of having layers learn the underlying mapping as part of our method, we let the network fit the based on this experiment. Thus, just let network fit instead of using, say, the initial mapping of H(x),

$F(x) := H(x) - x$ which gives $H(x) := F(x) + x$.

The benefit of including this kind of skip link is that regularisation will skip any layer that degrades architecture performance. As a result, training an extremely deep neural network is possible while encountering issues like disappearing or expanding gradients.

ALGORITHM IMPLEMENTATION

Input: Labelled training video

Output: Forgery Detection

Processing Steps:

Constructing the CNN Model

function INITCNNMODEL (θ, [n1–5])

layerType = [convolution, max-pooling, fully-connected, fully-connected];

layerActivation = [tanh(2), max(),softmax()]

model = new Model();

for$i$=1 to 4 do

layer = new Layer();

layer.type = layerType[i];

layer.inputSize = ni

layer.neurons = new Neuron [ni+1];

layer.params = θi;

model.addLayer(layer);

end for

return model;

end function

Training the CNN Model

Initialize learning rate α, number of maximum iteration ITERmax, minimum error ERRmin, training batches BATCHE Straining, batch size SIZEbatch, and so on;

Compute n2, n3, n4, k1, k2, according to n1 and n5;

Generate random weights θ of the CNN;

cnnModel = InitCNNModel(θ, [n1–5]);

iter = 0; err = +inf;

while err >ERRmin and iter<ITERmax do

err = 0;

forbach = 1 to BATCHES $_{\text{training}}$ do

[$\nabla\theta J(\theta)$, $J(\theta)$] = cnnModel.train (Training Datas, Training Labels), as (4) and (8); Update θ using (7);

err = err + mean($J(\theta)$);

end for err = err/BATCHES $_{\text{training}}$

iter++;

end while

Save parameters θ of the CNN

V. SYSTEM ARCHITECTURE

Video Upload and Training

Implement a technique for training the classifier using input from video frames. The frames are sent to the classifiers for training after being passed via face extraction as well as alignment fragment. Before training the model, the dataset is pre-processed. Face extraction and alignment are included in this. To extract features from videos and produce video feature datasets, combine CNN with ResNet. Images from the DeepFake dataset are gathered and trained for additional classification in this module.

Input Video Processing

The severe deterioration of a frame data following video compression prevents the majority of image detection techniques from being employed for videos. Videos are a challenge for techniques developed to identify just still fake images because they feature temporal characteristics that differ across groups of frames. With the use of frames conversion and facial region identification for the feature extraction procedure, this methodology focuses on Deepfake movie detection techniques.

Feature Extraction

The process of obtaining valuable features from the facial region is called feature extraction. Rather than rewriting the classifier, the feature extraction process uses the ResNet CNN classifier to extract features and accurately identify frame-level characteristics. The network should then be fine-tuned by adding more layers as required and choosing the appropriate learning rate to guarantee that the learning algorithm of the model is correctly converged. This aggressively factorizes filters and minimises their sizes. Convolutions to judiciously decrease and increase the amount of feature maps having the aid of several layers with convolutional qualities, features are extracted.

Forgery Detection

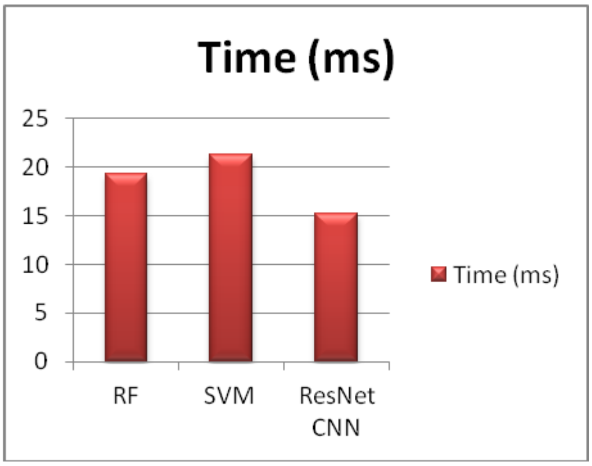
ResNet and CNN have been used to create detection and localization model that can find and locate inter frame forgeries. The CNN technique, which uses features of the input video to detect variance between successive frames, has been proposed. The face region of the incoming video frames is where picture features for the forgery detection procedure are gathered. Different sized feature maps are produced by the feature extractor. The classifier can then anticipate the nature of the image using these derived feature maps. Then, the chosen features move on to the process of identifying forgeries by comparison with a feature database. Finally, a CNN-based classifier was employed to tell authentic photos from fake ones.

VI. EXPERIMENTAL RESULTS

This article presents the validation times for several methods, including Random Forest (RF), Support Vector

DOI: rp-9788770040723.209

Machine (SVM), as well as ResNet CNN. ResNet CNN provides a quick validation time when compared to other algorithms when predicting video sequence counterfeiting.



Classifiers	RF	SVM	ResNet CNN
Time (ms)	19.32	21.30	15.24

VII. Conclusion

Used the DeepFake video dataset to put into practise a DeepFake detection technique for spotting fake videos. A deepfake detection approach is proposed that extracts temporal information from a given video sequence using a convolutional neural network (CNN) as well as ResNet, with the characteristics being represented by the sequence descriptor. The sequence descriptor is used as input to the detection network made up of fully connected layers, which then determines the likelihood that the frame sequence belongs to either the legitimate or deepfake class.

***Abstract*—The e-vehicles or electric vehicles (EV) is described as the vehicle that are capable to run through electric motor which attains power from external electrical source and stores in the battery for further usages. It is grounded on electro mechanical system. The enhancement of electric vehicle leads to decrease in the emission of CO_2 in the atmosphere. It helps to increase the use of renewable energy source whenever there is a demand in the electrical supply from the grid. The hybrid electric vehicle helps in versatile ways to conserve fuels. Effective utilization with optimization techniques in the usage of electric supply from the grid with proper charging and discharging helps to maintain the demand side management. The electric vehicle helps to main the greener ecosystem with reduction in contaminated air in the environment. This is done through artificial intelligence techniques. The external physical parameters are sensed through the sensors. The overall performance is monitored with two way communication system adopted through the cloud computing techniques with implementing wireless technology.**

***Keywords*—Electric Vehicles (EV), electrical source, battery, electric current control, emission of CO_2, demand side management, artificial intelligence, cloud computing**

I. Introduction

Transportation is an important parameter in everyday life. This is done through diesel and petrol vehicles that leads to various pollution in the environment. To overcome the drawbacks of the existing vehicle, the electric vehicles are implemented [1].

The existence and introduction of electric vehicles came in 19th century. The advancement of power electronics combined with microelectronics leads to the enhancement and development of electric vehicles. The development of electric vehicles are rapidly increased due to the eco-friendly nature. The rise of electric vehicles are due to the reduced amount of fossil fuels that also destructs the environment with various climatic change [2]. The process of attaining clean energy through the electric vehicles is also an important parameter for switching over the electric vehicles. The rise in the petrol and diesel price is also a considering parameter for the switching of electric vehicles than the conventional vehicle. The emissions from the petrol and diesel vehicle cause larger emission of toxic compounds in the environment which adversely affects the health of living organisms. To overcome the constraints of commercial vehicles, the electric vehicles are introduced. This is highly recommended due to the ease of use and coziness level. The electric vehicle is defined as the automotive vehicle that operates through the electrical energy. It adopts the electric motor for propulsion [3].

There are four kinds of electric vehicles based upon the performance and manufacturing. The hybrid electric vehicles play a prominent role in saving the usage of electric energy through adopting renewable energy source. This hybrid electric vehicles includes adopting energy from non-conventional energy source such as solar, tidal and wind energy. This helps in the enhancement of renewable energy source [4], [5].

In hybrid electric vehicles, the artificial intelligence with cloud computing techniques are implemented to enhance the control of power and to maintain the overall performance of the vehicles. This helps to maintain the

DOI: rp-9788770040723.210

battery's State of Charge (SOC) [6]–[8]. This helps to maintain the life span of battery that adversely promotes the performance efficiency of the electric vehicles. Thus they are attained through the optimization techniques that are integrated with wireless technology. In the hybrid electric vehicles, the electrical energy obtained from the grid can be stored when there is larger availability for further usages. This can also help by sending them back to the electrical grid when there is a demand in the supply system. This helps to improve the storage of energy capacity in the electric vehicle. The overall performance is monitored and automated through two way communication system with sensors. The electric vehicles are the efficient alternative for the fossil fuel vehicles. The electric vehicles have zero tailpipe emissions. The absence of tailpipe emission leads to the reduction of carbon footprints in the environment. The electric vehicles have lesser maintenance cost due to the absence of various movable parts inside the vehicles which also reduces the running cost of the vehicle [9]–[11].

Thus the electric vehicles provides higher efficiency with better performance. This is done through the use of lithium ion batteries for storage of electrical power. The electric vehicles are much convenient and easier to operate because it does have any complicated system. They provide lesser noise pollution when compared to the traditional vehicles. This is due to the absence of combustion engines in the electric vehicles. They also provide easier and convenient in charging at any place without any rush at the petrol pump as similar to the conventional vehicles [12]–[14].

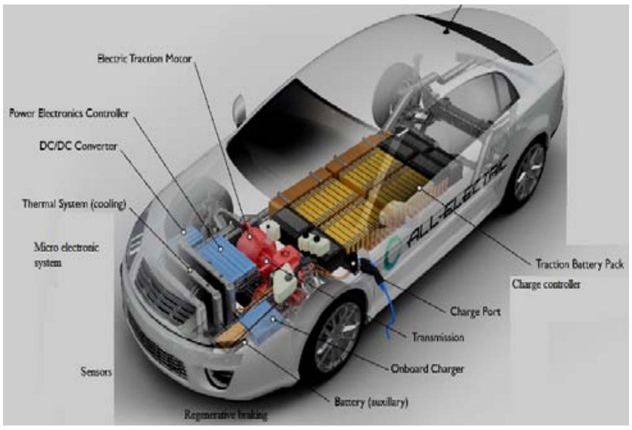

Fig. 1. Electric vehicle (EV)

The figure 1 demonstrates the model of electric vehicles. The advancement of electric vehicles are implemented through the artificial intelligence with cloud computing techniques. The Artificial Intelligence (AI) techniques helps in versatile forms with various task scheduling and source distribution. This helps in numerous automation and sophistications. These electric vehicles are integrated with wireless technology with sensors to adopt automation in the systems. The real time information processing are enhanced through the artificial intelligence and internet of things [15]–[17].

Various mechanism are implemented to control the loss of energy and to improve the efficiency of the system. This is done with optimization techniques with algorithms with the adoption of artificial intelligence. This helps in the management of congestion control. To improve the functioning of electric vehicles, the integration of smart grid with electrical vehicles plays a prominent role. This helps in the optimization of charging and discharging of electrical vehicles based upon the rush and non-rush hours. This helps to maintain the demand side management. Here the loads are scheduled through the optimization techniques adopting artificial intelligence which helps to schedule the loads based upon the priority of the consumers [18].

The Government has launched the Electric Vehicle Initiative (EVI) to enhance the development of electric vehicles to reduce the usage of fossil fuels and develop a sustainable greener ecosystem. In this initiative sixteen countries are participating including India. There are various financial advantages in the electric vehicles ranging from lower cost of registration fees and road tax when compared to the purchase of the petrol or diesel vehicles. There are numerous policies and benefits offered by the Government. Thus the electric vehicles are the way forward in the transportation sector that helps in versatile benefits. The electric vehicle industry also helps to enhance various employment opportunities as reported by the Ministry of Skill Development and Entrepreneurship. The adoption of electric vehicles leads to the improvement of green energy with economic benefits in the upcoming decades.

II. Proposed System

The e-vehicle or the electric vehicle is the combination of vehicle with electric propulsion system with battery storage and energy management system. The electric vehicles are differentiated into three categories. They are composed of microelectronics with chemical and automotive applications.

The electric vehicles adopts batteries to store the energy for functioning. These rechargable batteries helps in proper charging and discharging operations that leads to improve the life span. This is also done by employing the regenerative braking. The electric vehicle can able to extract the kinetic energy at standstill conditions . This also helps to improve the performance of the battery. The traction batteries are the important part in the electric vehicles. This helps to enhance the energy storage process in the vehicles.

DOI: rp-9788770040723.210

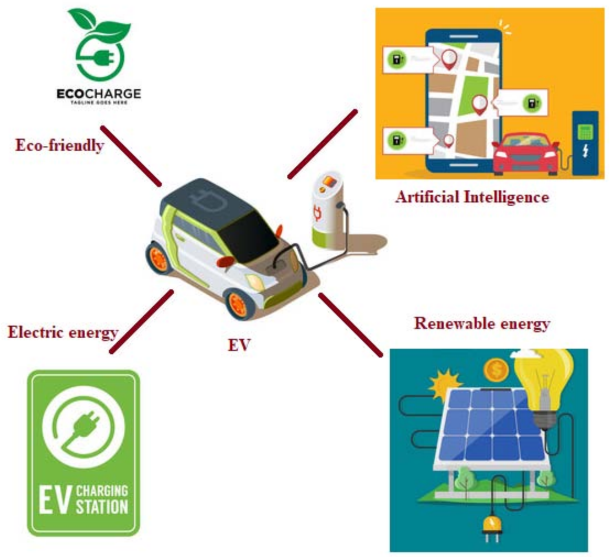

Fig. 2. Components of Electric Vehicle (EV)

The figure 2 demonstrates the electric vehicle with their various functioning parameters.

This includes the artificial intelligence techniques to provide automation with improve performance in the system. The components of electric vehicle includes power supply, electric gear box, inverter, charger, battery, sensors, servo-steering and servo-brake system. The charging of battery are classified into three types namely the current, voltage and pulse charging. These charging properties of batteries helps in the development of electric vehicles.

Thus the energy management system shows a prominent part in the functioning of the electric vehicles. The hybrid electric vehicle includes the extraction of energy for renewable energy source. This includes the solar panel at the roof of the electric vehicle that extracts energy at the day time and stores in the battery for further usages. The source of power for the electric vehicles are adopted through the battery. This helps in the improvement of energy management system in the electric vehicles [19], [20].

III. IMPLEMENTATION OF E-VEHICLES

The e-vehicles are functioned using the electric energy from the grid that are stored in the battery. The control management of the energy in the electric vehicle are maintained and regulated through the batteries inside the electrical vehicles.

To adopt faster energy charging of batteries, the technology of multi-energy system is employed. This helps to charge the batteries in a short span of time. Due to the absence of various ignition engines and motors inside the electric vehicle leads to saves the interior space. The body structure of the electric vehicle is composed of aluminum with plastic over coating to enhance light weight structure. The important parameter is the electric propulsion system that consists of single motor and multi motor drive.

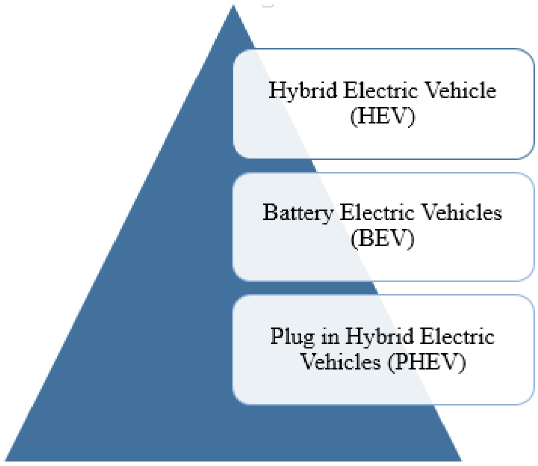

Fig. 3. Classification of EV

The figure 3 represents the classification of electric vehicles. Ther are differentiated based upon the usage of conventional engine and the type of battery charging and discharging techniques.

1. *Hybrid Electric Vehicle (HEV)*

The hybrid electric vehicle is a vehicle that integrates with the internal combustion engine with an electric propulsion system.

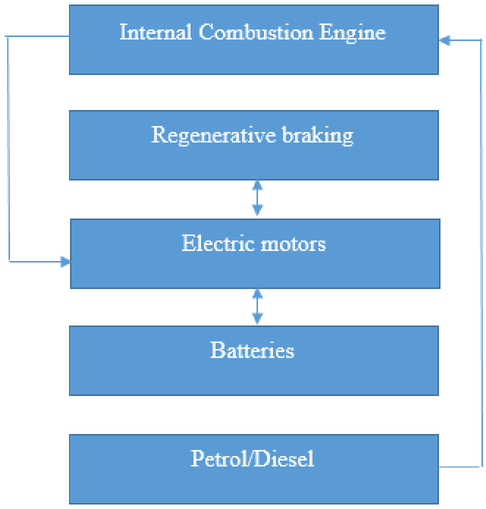

Fig 4: Hybrid Electric Vehicle

The figure 4 represents the functioning of hybrid electric vehicles. It is composed of internal combustion engine, generator nad electric motors. The energy storage system includes batteries and supercapacitors [20]. The numerous categories of batteries are lead acid battery, lithium ion battery and nickel-metal hydride batteries. The fuel economization is attained through the hybrid electric vehicles. This enhances various supportable modes of mobility in the system. This invloves various techniques such as the regenerative braking system to improve the efficiency of the system.

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.210

2. Battery Electric Vehicle (BEV)

The battery electric vehicle is represented as the complete electric vehicle that are operated through the chaemical reactions that are takes place inside the battery. This can be charged and discharged based upon the needs of the users. They replaces the internal combustion engines with electric motors and various controllers for functioning the vehicle.

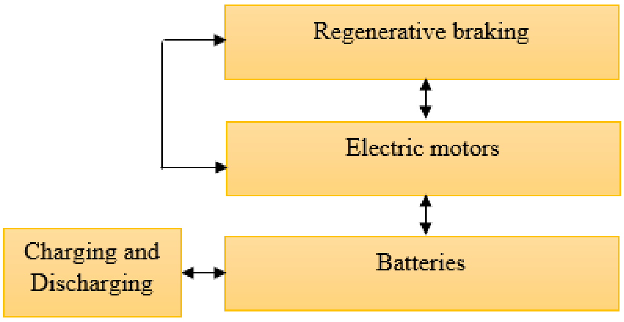

Fig. 5. Battery Electric Vehicle (BEV)

The figure 5 demonstrates the components and functioning of battery electric vehicle. Thus they are formulated through the rechargable batteries with the absence of fuels in operating the vehicles. There is no another propulsion system in the electric vehicle. They are much efficient in reducing various environmental constraints that are caused by the conventional vehicles. They are inbuilt with artificial intelligence techniques to adopt the optimization of power This helps in charging the vehicle based upon the rush and off rush hours and dependent on the priority of the consumers. This leads to reduce the energy demand and saves the electric energy.

3. Plug in Hybrid Electric Vehicle (PHEV)

The Plug in Hybrid Electric Vehicle is defined as the vehicle which adopts two source for the internal combustion engine in which the battery can be charged and discharged whenever its needed. This can be done through plugging a charge cable with an external source for battery charging. Thus it uses charging elements and regenerative braking system. This includes both the usage of electric power and fossil fuels based upon the avilability.

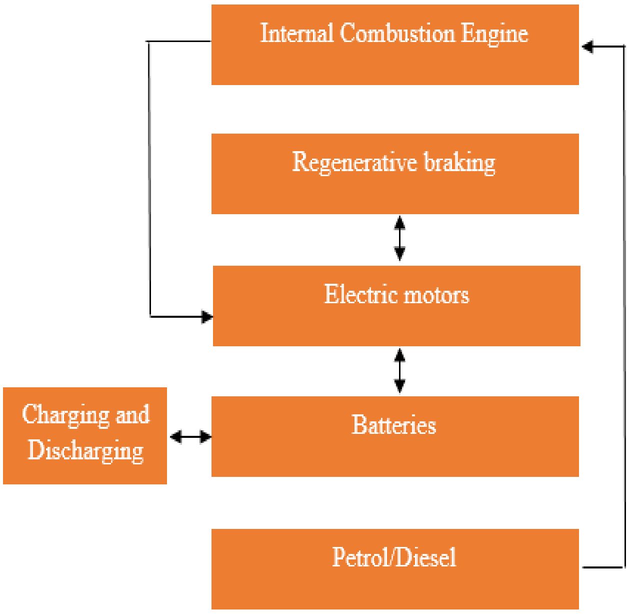

Fig. 6. Plug in Hybrid Electric Vehicle

The figure 6 demonstrates the Plug in Hybrid Electric Vehicle (PHEV).

IV. INTEGRATION OF E-VEHICLES WITH ARTIFICIAL INTELLIGENCE

The integration of e-vehicles with artificial intelligence gets rise with the vehicle to grid technology (V2G). This involves the process of charging and discharging techniques. This helps in implementation of two way communication system interacting with the grid and electric vehicle [23]. This includes various control strategies with sensors and hardware implementation in the electric vehicles. This helps to improve the efficiency through attaining stability in the system.

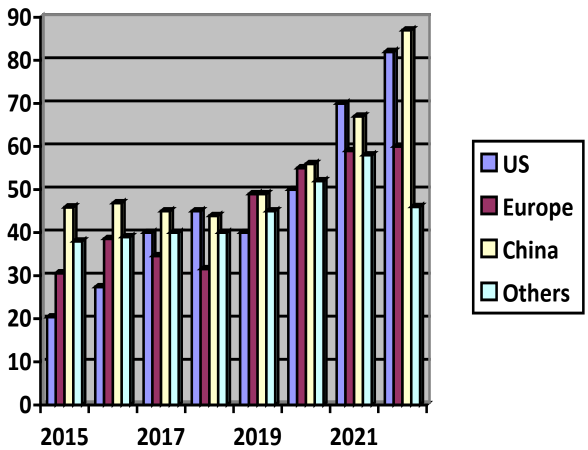

Fig. 7. Evolution of electric vehicle

The figure 7 demonstrates the evolution of electric vehicles across the world.

With the introduction of artificial intelligence in the charging and discharging system, it helps in attaining intelligent trends in upcoming decades. The load balancing

DOI: rp-9788770040723.210

is attained through the introduction of optimization techniques. They are done through deep learning techniques. This helps in the combination of renewable energy for charging and leads in the reduction of greenhouse gas effects and its constraints. This helps in charging the battery through extracting the solar energy from the solar panel that converts the heat energy into electrical energy accompanied with charge controllers. Then it is stored in battery for further usages. They help in management of congestion and promotes voltage regulation.

The deep learning technique is defined as the subcategory of machine learning. It is consists of numerous layers that helps to process the data to produce the output. This includes extraction of optimum results with numerous layers that process them through optimization techniques.

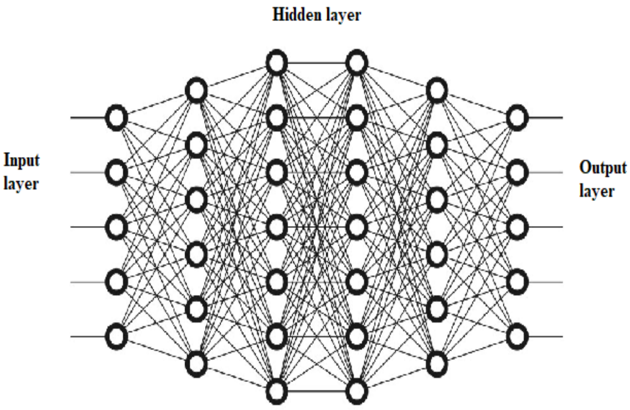

Fig. 8. Deep learning

The figure 8 represents the deep learning with numerous input and hidden layers that process the output. This is implemented to reduce the human interference in the functioning. This is largely used language and speech processing to improve automation with accurate results in the electrical vehicles. The scheduling is done through the optimization techniques. It is composed of input layer, hidden layer and the output layers. This works based upon the functioning of human intelligence. It resembles the neural network of human brain. It includes various data and algorithm to test and train the prototype.

The constraints are solved through the genetic algorithm. The genetic algorithm is a heuristic approach is solve the problems to achieve the optimum results. This is enhanced through the techniques of natural selection.

Fig .9. Genetic algorithm

The figure 9 demonstrates the genetic algorithm process in obtaining the optimum outcome.

Algorithm

In step 1, the program starts.

Step 2 declares three integers x, y and z, which will be used in subsequent steps.

Step 3 defines the values of x and y.

Step 4 multiplies the values of x and y using the * operator.

Step 5 stores the result of step 4 in the z variable using the assignment operator =.

Step 6 prints the value of z using the cout statement.

Step 7 stops the program.

the program performs a simple computation and displays the result. It can be easily modified or extended to include additional functionality, such as taking user input or performing more complex operations.

The genetic algorithm is used as an optimization technique to schedule the loads based upon the priority. The electric vehicle’s charging is based upon the rush and off rush hours. This reduces the demand of electric power from the grid. This also helps to maintain the balance of power for the domestic and industrial usages.

V. Simulation Implementation and Outcome

The implementation of e-vehicles with artificial intelligence and cloud computing techniques with sensors are evaluated and established in matlab Simulink. This helps to obtain the performance efficiency and its outcome.

DOI: rp-9788770040723.210

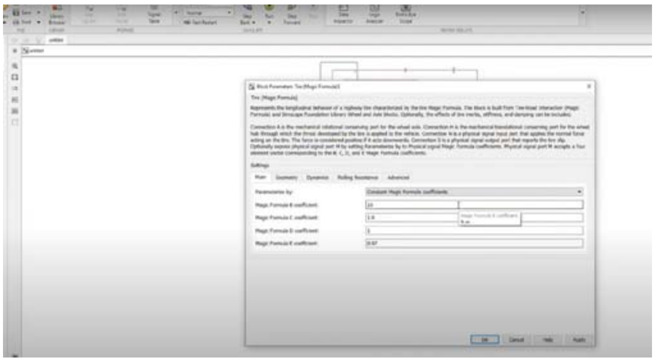

Fig 14: Battery’s Performance analysis

The Fig 14 demonstrates the battery’s performance parameter analysis. This helps in the calculation of charging and discharging of battery to enhance its life cycle.

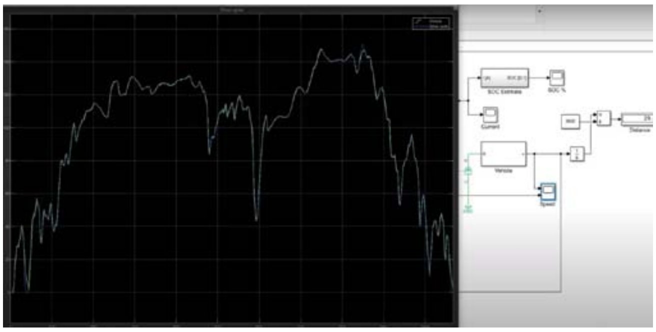

Fig 15: Performance efficiency

The Fig 15 demonstrates the performance efficiency of the electrical vehicles. This is calculated through various parameters involving battery’s state of charge to regenerative braking.

VI. CONCLUSION

The evolution of electric vehicles are increasing rapidly from the past decades. These are due to the eco-friendly nature and reduction in the usage of fossil fuels. This helps to obtain a greener environment by avoiding the emission of various toxic pollutant in the environment. The electric vehicles are implemented with the aid of artificial intelligence to boost the complete enactment of the vehicles. This helps in improving the functioning of the electric vehicles enabling two way communication system through cloud computing techniques. The genetic algorithm is used to optimize the usage of electric energy from the grid based upon the priority and rush hours to eliminate the demand. Thus the use of electrical vehicles with artificial intelligence techniques is the way forward measures to enhance various benefits with reducing the constraints caused by the conventional vehicles.

***Abstract*—The evolution of advanced technology play a vital role in diverse arena. This helps in the introduction of drone magnetometer system. The drone is an electronic system with sensors to monitor and detect the targeted system thus they are created to visualize the near environmental surfaces and objects. This is accomplished through the magnetometers, radar, GPS and various sensors. These technology are integrated with IoT, artificial intelligence techniques and edge computing techniques. The numerous data are processed through the image processing and recognition techniques. The security and privacy are enhanced to adopt a safer operation in various sectors. The important challenges includes the monitoring of the transmission lines in which heavier electromagnetic waves occur. To avoid these consequences, the drones are manufactured and adopted with advanced technologies. The drones are integrated with the internet of drones to provide various navigation services accompanied with the internet of things. Thus the overall process is implemented through artificial intelligence through deep learning and k-means algorithm and edge computing techniques.**

Keywords*—Drone, GPS, sensor, image processing, electromagnetic waves, machine control, artificial intelligence, deep learning techniques, k-means algorithm, edge computing

I. Introduction

The evolution and advancement in technology leads to various development in versatile fields. This leads to the human lives much sophisticated with enthusiasm. The artificial intelligence play a driving factor for the upliftment of numerous automations. They are helpful in various fields such as industry, manufacturing, healthcare and agriculture. It helps to perform with higher efficiency [1]. The artificial intelligence is defined as the process of training and testing the machines to function as similar to that of the human intelligence. This includes language processing, speech recognition and improving vision through machines. These are done through computational algorithms which helps to control and monitor the overall functioning in the system. This includes deep learning, machine learning and artificial neural network [2]–[4].

Thus the artificial intelligence are used in wide range of applications. They make the everyday lives much easier. The various algorithms helps to control and monitor the system. The artificial intelligence provides various sophistications. They forecast the weather conditions, provide route maps, adopting smart speakers such as Alexa. They also used in entertainment through games and fun. This creates a digital platform to access everyone based upon the interest. This helps to function automatically without the aid of humans. They can control, monitor and function automatically [5]–[7].

After important factor is denoted as internet of things and edge computing techniques. Thus they process the huge amount of data and provide the exact solutions. The edge computing techniques are growing rapidly in diverse field adopting data computation. The edge computing is defined as the developing technology that are uses variety of networks to enhance computational parameters [8]–[10].

This includes processing the data when the user is near or away. This helps to process the information at a higher speed to achieve reliability in the network. The various examples of edge computing involves smart grid monitoring

DOI: rp-9788770040723.211

and controlling system, industrial automation system , refiners industries and drone management and control system . Here the data are collected and then processed to improve the efficiency in the various sectors. This helps the user not only dependent upon the cloud systems. The classification of edge computing include access edge and network edge. This helps to process the data at remote edge without nay constraints in the networking system. This is the combination of artificial intelligence. The important advantages of edge computing involves improved data management system and lower connectivity price [11]–[13].

Thus it helps to progress higher security and confidentiality of information. These techniques are largely used in military, army and navy applications. The integration of sensors, chips, hardware and software systems with communication technology tend to develop the UAV (Unmanned Arial Vehicle) or drone magnetometer system. The drone is defined as the aircraft or the submarine vehicle that operates without the aid of human. They are represented as an atmosphere ground equipment. This functions automatically through the program initiated through artificial intelligence [14]–[16].

They are implemented through various sensors that are useful to detect the external physical parameters in the environment. They are designed to operate largely in military system for safety and security purposes in the border regions. This helps to capture and sense images across the prescribed geographical conditions. The production of drone and its applications are created during the Second World War. They are manufactured by the US army for military and monitoring purposes. The drones are integrated with Global Positioning System (GPS) and sensor to access the particular locations. This is used to identify and detect the landscapes through the data processing techniques. They are used in various sectors. They are increasing rapidly through the wireless communication systems. They are further developed with the internet of drones. The communication system between the drones and the internet of drones are highly insecure which means the data collected can easily hacked. The drone can able to attack physically using the military powers. This leads to various loss [17], [18].

Fig 1: Drone magnetometer system

The figure 1 represents the drone magnetometer system. Thus various security measures are adopted to enhance the privacy and security concerns of the drones. This leads to provide secure drone of things network. Local attacks of drones may affects the positioning and its control system. The security and privacy are the important modalities to be considered in the drones. The UAV or drones are used as a research technology used for monitoring as directed.

The major challenge in the usage of drones is the prevention and proper functioning in the environment without causing damage to the transmission cable and overhead lines. Thus the safety of the drone and the transmission lines are the most peculiar challenge that are need to be addressed properly. Thus the drone are tend to analyze the capacity with which it protect themselves from electromagnetic waves and electric field. Thus adopting proper safety measures for the power system with transmission line cables are mandatory. The inspection of the overhead transmission line must be verified periodically. Due to the enormous power transmission, the manual way of checking the transmission line are highly dangerous. Thus the drones are helpful in analyzing and determining the functioning of the power system through checking the transmission line systems [19], [20].

Thus due to enormous power supply, there create a strong electromagnetic field with higher corona effects, the drones must with stand without any fault in the drone management system. These electromagnetic field cause disruptions to electronic components that leads to failure of the drone system. Thus the UAV are tend to work in various conditions to adapt itself and protect from strong electromagnetic waves. This leads to advance the safety and consistency of the structure. This can be accomplished through monitoring the transmission line at a particular distance without affecting the quality of service. They are done through the k-means clustering algorithm. Most of the drones are non-magnetic in nature that are prone to the magnetic effects [21]–[23].

The application of the UAV includes in agricultural, industrial and traffic management system through adopting smarter techniques. The internet of drone is decentralized infrastructure. This refers as the system with absence of any infrastructure. This helps to obtain the inter-locational triangulation provision. This in turn integrates with the internet of things. This states that if any threat occurs to the internet of things platform, it directly replicates to the internet of drone network. Thus the security and privacy are the major constraints in the internet of drone technology.

II. Proposed System

The development of drone are enhanced through the sensors, magnetometer and artificial intelligence. The structure of the drone magnetometer is described as follows. The total weight of the drone system remains 5 kg in which the magnetometer is fixed at the centre of the drone system. There is a small distance of 0.7m from the remoteness of the drone to the magnetometer surface. The altitude of the drone must be maintained through 1 m to have stability in the operation. Increasing the altitude of the system leads to collision between the landing poles which enhances the signal to noise ratio.

The UAV or the drone management system is defined as the magnetic measurement technology integrated with the

DOI: rp-9788770040723.211

magnetometers, global positioning system and sensors. Two magnetometers are fixed at the center of the vehicle. The mean distance between the two sensors rae 0.3m that are mounted on the drone. The height of the drone is measured using the radar.

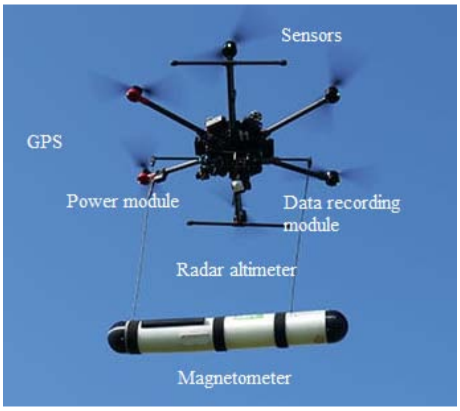

Fig 2: Drone management system

The figure 2 represents the drone management system. It includes GPS, power supply module, data sensing and recording module, sensors and magnetometer. The magnetometer is used to measure the magnetic fields around the surface in which the orthogonal axis in the magnetometer contains minute errors [24].

III. Structure of Drone Magnetometer System

The drone system is an unmanned electrical vehicles used to capture the images through sensors. The drone with magnetometer helps to detect the magnetic components on the earth's surface through geographical maps with higher accuracy. This helps to measure both the direction and strength of the magnetic components. They are introduced to replace the conventional methods [6].

The structure of the drone system is based upon the following parameters such as size and rotor classification, range of detection, landing of drone system and aerodynamic mechanism. The size of the drone varies from micro drone, mini drone, medium sized drone and large drone. The rotors and aerodynamics determine the structure and functioning of the drone system. The landling of drone system is classified based upon the horizontal and vertical takeoff and landing. The aerodynamic systems is classified into four categories. The controlled devices helps to collect the data at remote places through the internet of drones platform. The communication network are classied as ad hoc network and UAV aided communication network.

They are collected and the data are stored in the cloud platform. The data are collected through the aid of sensors assisted on the drone surface. To improve the communication system in rural and denser environments, they are improved through the internet of flying things. It enhances the performance of internet of things. The rotors are differentiated into tricopter rotor, quadcopter rotor, hexacopter rotor and octacopter rotor. The material used for the drone structures are carbon fiber composite materials. They are integrated with the aluminium and titanium alloys.

IV. Functioning of Drone Magnetometer System

The performance and functioning of the drone management system is done through three stages. This includes collection of information, handling of data and interpretation of data. They are done through the image processing techniques with deep learning. The control parameters are done through the optimization algorithm namely k-mean optimization.

(i) Collection of data

The collection of data forms the fundamental step in functioning of the magnetometer system. This includes the preparation of the test path with the flight area. This is the preliminary task in the magnetic investigation. The external parameters such as climatic conditions, environmental factors and surface height with vegetation are monitored and analyzed keenly. The direction of the drone, height and distance are the driving factors for the data collection. Thus the analysis of magnetic survey is an important factor for the drone magnetometer system. This helps to observe the functioning of the drone in normal conditions. The collection of data is performed through four stages.

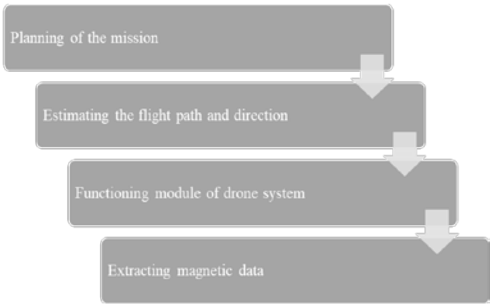

Fig 3: Collection of data

The figure 3 represents the collection of data. This is the first stage involved in the functioning of drone magnetometer system.

(ii) Processing of data

The second stage involved is denoted as processing of data. The processing of the data leads to the reduction of noise signal. This helps to enhance the signal to noise ratio. They perform three functions such as backgroud field elimination process, UAV with removal of inference field and gridding the data.

DOI: rp-9788770040723.211

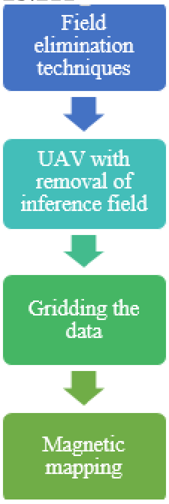

Fig 4: Data processing stage

The figure 4 represents the data processing stage. The first step includes the field elimination techniques. This refers to the elimination of geomagnetic and magnetic fields across the surface. They are generated by the power transmission cables. Increased traffic and in industrial buildings. Thus the external background field must be eliminated.

The earth is defined as the natural magnetic field which produces magnetic effects. It is the process of magnetic stimulus on the movable electric charges. It experiences the force that acts perpendicular to the velocity and the magnetic field. They are classified as external source and internal source. The stable dipolar field is obtained through the internal surface of the earth's crust.

The second stage includes the UAV inference field removal technique. This is the inherent noise signal generated inside the system. There is no other external disturbances takes place. Thus the removal of inteference field is much important in functioning of the drones . The complete field signal are eliminated through the calibration process. The calibration process is defined as the signal correlation method to defferentiate the magnetic signal from the total field signal. The calibration process includes initialization, execution of operation and functioing to extract the output.

The another stage includes the gridding of data. The gridding of data is accomplished through the process of interpolation. This refers as the computation of the magnetic field to that of the irregularly distributed systems. The abnormal conditions are denoted by the 2D contour map representation [21]. This helps to identify the abnormal conditions of the assessment circumstances.

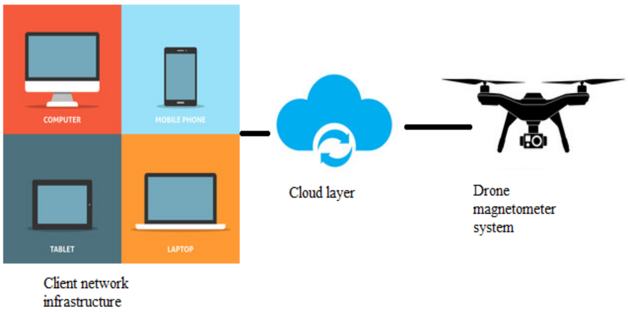

Fig 5 : IoD network structure

The figure 5 represents the IoD structure that uses the edge computing techniques. This helps to improve faster communication speed through higher accuracy in the network. The application of the client network infrastructure includes the cloud system inteface with the UAV interface. The information are collected and stored in the cloud layer with big data analytics with collection of data and processing system. They are forwarded to the drone management system [22]. This is the combination of hardware and software system accompanied with commmunication system. This sd done through the integration with internet of things.

V. Drone Magenetometer System using Deep Learning

The deep learning is a subsection of artificial intelligence. The deep neural network helps in the remote sensing field in diverse fields. This includes data processing with obtaining the finalised output. The information are processed in the hidden layers to produce the output. As the name suggest, the deep learning incorporates numerous layers to process the output involving the activation function. The layers are tend to involve in the problem solving through the feature maps. This is implemented through the training and testing the data. The UAV or drone performs based upon the deep learning techniques with optimization techniques.

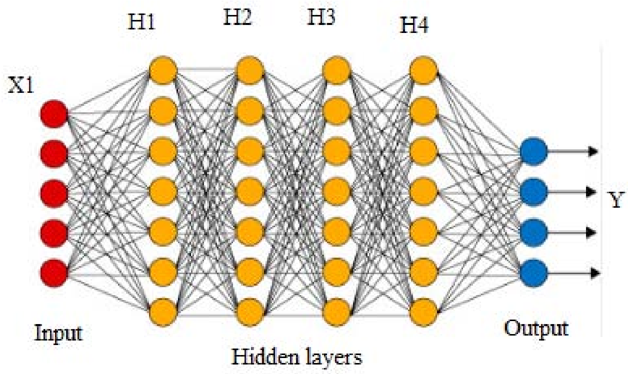

Fig 6: DNN model

The figure 6 represents the deep neural network prototype. The information are attracted to the hidden layer are performed through the back propagation techniques. They are accomplished through the generative adversarial networks algorithm. This is used to obtain the new data that are relevant to the training data. The two components of the

DOI: rp-9788770040723.211

GANs include generator and discriminator. The generator is used to obtain the false information. The discriminator adapts themselves to the false information and training and testing phase occurs. They are largely used in obtaining astronomical images and gravitational matters.

This helps in the creation of video games to provide increased resolution through two dimensional structure. This helps in the processing of real data and the false data. The discrimination determines the false information and proceeds results through them. This includes increasing the probability of the true and false images. The one cycle of the training data and processing to obtain the system is referred as epoch. They are formulated with mini batches to obtain the outcome. Then they are proceeded to obtain various training iterations.

```
# gan training algorithm
def train_gan(generator, discriminator, dataset, latent_dim,
 # calculate the number of batches per epoch
 batches_per_epoch = int(len(dataset) / n_batch)
 # calculate the number of training iterations
 n_steps = batches_per_epoch * n_epochs
 # gan training algorithm
 for i in range(n_steps):
 # generate points in the latent space
 z = randn(latent_dim * n_batch)
 # reshape into a batch of inputs for the network
 z = z.reshape(n_batch, latent_dim)
 # generate fake images
 fake = generator.predict(z)
 # select a batch of random real images
 ix = randint(0, len(dataset), n_batch)
 # retrieve real images
 real = dataset[ix]
 # update weights of the discriminator model
 # ...

 # update the generator model
 # ...
```

Fig 7: GAN training algorithm

The figure 7 represents the GAN training algorithm. Here the discriminated model is trained to obtain the true value probability.

The training data determines the training iterations. The discriminator model is obtained through the extraction of input from the generator and provides to the discriminator. This is obtained as fake samples. The discriminator teld to obtain the expected probability when the error signal is propagated backwards towards the generator. The keras model is used in the generator and discriminator model. The target is determined through the zeros and ones. The keras is implemented through the complete model integrated with the generator and the discriminator. Thus the trueness of the input image can be identified. The differentiation of the true and false value are obtained through the discriminator. The complete functioning of GANs is obtained with the solid foundation obtained from the keras. The keras function provide influences to the training functions. Thus they provide exact output in the drone magnetometer system.

```
# generate points in the latent space
z = randn(latent_dim * n_batch)
# reshape into a batch of inputs for the network
z = z.reshape(n_batch, latent_dim)
# define target labels for real images
y_real = ones((n_batch, 1))
# update generator model
gan_model.train_on_batch(z, y_real)
```

Fig 8: The composite model

The figure 8 represents the composite model integration of generator and discriminator. This shows the complete GAN algorithm with weights and functions for the estimation and detection of the discriminator and generator models.

VI. Performance Analysis and Outcome

The detection of drone magnetometer through artificial intelligence is designed and implemented in MATLB simulink. This helps to detect the performance of the drone before the execution in the real environment. This includes the observation of various parameters of the drone system ranging from phyical analysis and functioning of the system.

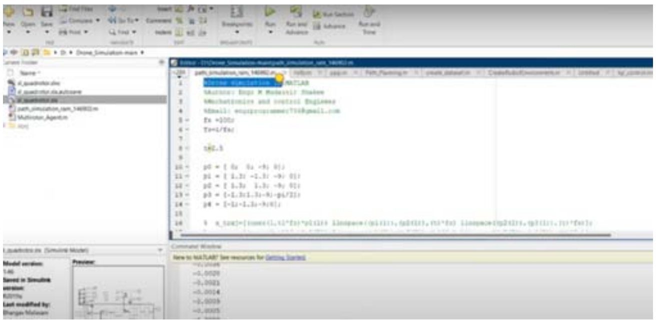

Fig 9: Implementation in MATLAB

The figure 9 represents the programming code for the implementation in MATLAB.

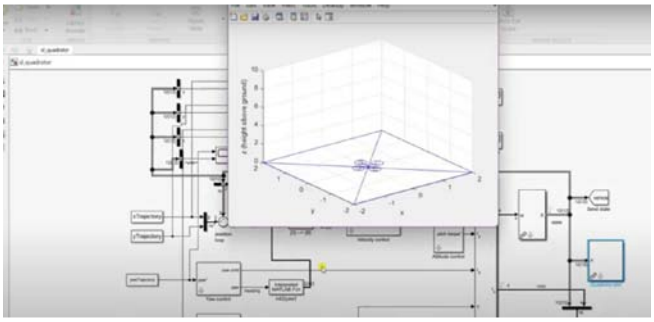

Fig 10: Calibration process

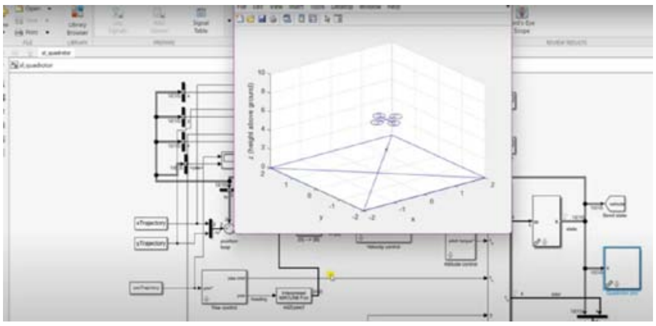
The figure 10 demonstrates the calibration process. They are done through the accelerometer. This helps the drone to fly without any oscillation in functioning.



DOI: rp-9788770040723.211

Fig 11: Drone functioning with altitude 1 m

The figure 11 represents the functioning of drone at an altitude of 1 m. This must be stable to improve and maintain the performance of the drone system. It is attached with a magnetometer in pendulam structure. This detect the occurrence of magnetic components on the surface. The evaluation of the substances are recorded and captured as images.

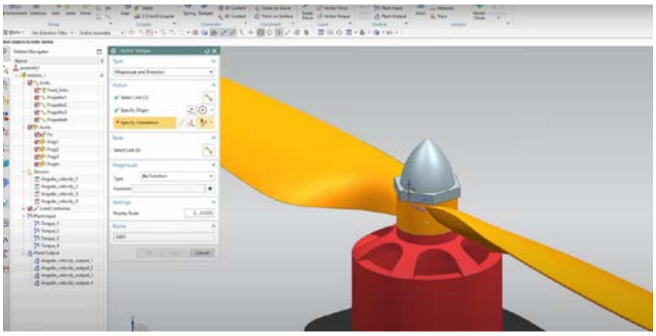


Fig 12: Rotor with controllable devices

The figure 12 represents the rotor with controllable devices and sensors.

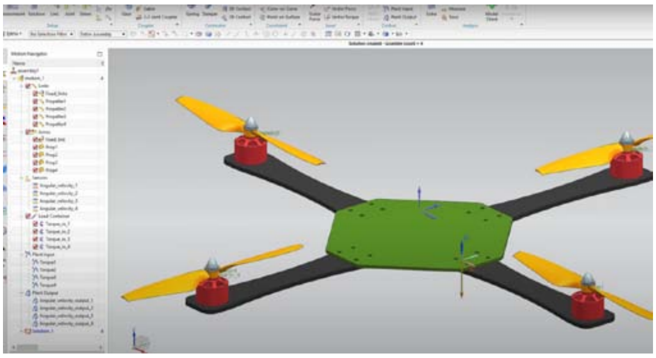

Fig 13: Performance analysis

The figure 13 represents the performance analysis of drone magnetometer system. The overall performance are sensed and recorded in cloud system.

VII. Conclusion

The drone magnetometer system are largely used in the mine detection and military areas. The remoteness between the bottom surface and the magnetometer are reduced through installing it in a pendulum method. This includes the capturing and visualizing the objects, detection of magnetic components on the surface through artificial intelligence and image processing techniques with optimization techniques. The internet of things paved a platform for the development of internet of drones. They are functioned with innovative automation techniques. Thus it overcomes the problems faced by the conventional methods and enhances the detection of metallic components in remote areas through reduced computation time and increased efficiency.

***Abstract*—The evolution of automation and innovations helps in diverse field. This helps to create human lives much easier. It tend to produce various automatic devices. These devices must include the control system to improve the automation in the equipment. The important equipment used in our day to day life is the ceiling fan. This is the largely used equipment. The conventional system includes manual speed control. To enhance automation in the system, the proposed system is implemented to replace the conventional system with automatic speed control system. This helps to automatically control the speed of the fan based upon the surrounding temperature. This is sensed through the use of sensors. This includes pulse width modulation techniques with brushless permanent magnet DC motors and microcontroller. Here PIC microcontrollers are used for controlling and processing. Thus these techniques are employed for the automatic detection of ceiling fan. This leads in the reduction of energy consumption and reduced cost.**

***Keywords*—Automatic speed control, sensors, PWM power convertors, microprocessor, control, power grids, power generation control, energy consumption**

I. Introduction

The modern decade are looking forward with advanced innovations and automations. The automation is a technique of adopting the machines to perform and function without the aid of humans. The automations play a versatile role in various sectors. These automations helps to make human lives much easier. The pros of automation includes reduced operational cost and increased production in the system [1]–[3].

The advent of newer innovations in the automation of machinery is due to the increased cost parameter and demand. Thus the automations provides an optimum solution for the constraints in various sectors. The automation in diverse fields are introduced due to the evolution of digitalization. This enhances the productivity in the industrial and production sectors [4]–[7]. This helps to increase the standard and quality of the equipment's. This helps in the innovation of robotic technology. This is the combination of hardware and software system with communication technology. These leads to the increase in automation system in motion in a single platform. These automations play a prominent role in the development of various equipment's to improve the standard of living. These innovations helps in the control and monitoring parameters to enhance the performance and functioning of the equipment's and its life time [8]–[10].

The automations are differentiated into fixed, programmable and flexible automation systems. These are based upon the performance and functioning of the system. The automations in the electrical sectors helps to control and monitoring the consumption of power with respect to time. This leads to automatically control the electrical equipment's using the control devices. This leads to obtain a balanced in the supply system thereby maintaining the demand side management. Thus the automation refers to the usages of the information through the electronic components. This includes the control and monitoring of the system through remote places with implementing the two way communication system. Thus the automation is implemented through the integration of various components in a sequential manner [7], [11], [12].

In automation, the communication network and the control system shows a significant part in the analysis and functioning. In the power sectors, the automations are monitored by the SCADA systems. This helps to monitor the overall functioning of the system. In power system, the monitoring and controlling of the power distribution helps in the reduction of outrages. The control system provides instructions to perform accordingly. The components to improve automation includes motor and drive system, safety devices, controllers and communication technology. In

DOI: rp-9788770040723.212

industrial sectors, the mechanical devices that aid in the control of speed includes pulleys, various gear system and clutch system. These systems are controlled and monitored through control devices and communication protocols. This leads to proper functioning through the aid of automation system. The automation in the power system enhances the home energy management system. There are various equipment's used in our day to day life. The most important equipment includes the fan [13]–[16].

Nearly 25% of the energy consumption in the electricity bill is occupied by the fan. The automation system is used in the operation of fan. In conventional methods, the fan is available with manual speed control devices. This helps to control the speed based upon the need through manually.

The proposed system includes the speed control of ceiling fan through involving automations in the system. It is demonstrated as the conversion of non-adjustable speed to adjustable speed drive system. The speed control helps in many ways through production and economic benefits. The speed control includes various methodologies. This includes controlling the speed of the fan through detecting the surrounding temperature. They can adjust automatically through the prevailing weather conditions. The speed control is defined as the decreasing or increasing the working performance of the equipment. This is done through the voluntary change in load. The change of speed varies with various equipment's based upon the range and operating speed. The speed control of ceiling fan includes the determination of external temperature to function accordingly [17]–[19].

This is done through the sensors. The sensors are used to analyze the external physical parameters. This helps to function of equipment through the sensed data. The important component includes motors. There are various motors used in the equipment in which the permanent magnet synchronous motor are largely used due to its various significances. It is a light weight motor with reduced structure, lower cost, improved torque-current ration and higher efficiency. The components of permanent magnet motor incudes rotor with permanent magnets. They does not produce any heat in the interior and exterior surfaces. Due to the absence of brushes, it does not tend to create mechanical damage to the motors [20]–[22].

This helps to protect the motor from reducing the winding failure. This is the smart way of power saving with lower maintenance cost parameter. Their structure are smaller when compared to the universal motors. The permanent magnet brushless DC motor consumes lesser power. They must be equipped with proper safety and control mechanism. The motor includes must have to adopt both the short circuit protection and overload protection. In some cases, the motors with the controllable devices are self-protected. Hence this does not require any external protecting devices. The safety and protection of the equipment's are the important factor. The microprocessor is used for the purpose of processing and controlling. The PWM (Pulse Width Modulation) techniques is a control technique that provides the analog signal obtained through the microcontroller. This is obtained through the time duration of on and off of the devices. These time duration between these two parameters are referred as duty cycle. The PMW signals are generated through a comparator. These signals provides the pulse that are generated in a square waveform. This helps in the conversion of the signals into a discrete portions. The comparator helps to compare the signals and produces the square waveform.

The pulse width modulation are classified in to trail edge, lead edge and pulse center edge modulation techniques. The Pulse width modulation helps in regulating the voltage and hence they are used to regulate the speed of the motors. This also helps to dissolve the heat through the attachment of fan inside the system in computers.

The PMW techniques produces accurate results with higher response time duration. This helps the motor to produce maximum torque even when the motor operates at reduced speed. It also helps to reduce the radio frequency interference. The optocoupler are used for safety purposes. This helps to separate the circuits that send signals. It perform in both AC and DC signals. They functions with reduced noise parameter. It is used for driving the permanent magnet brushless DC motor. The ultrasonic sensor and temperature sensor are included to sense the sound and temperature of the surrounding environment. This senses the information and proceeds to process further. This is used in the sensors to detect the availability of the physical systems. This sends the signals through light. This helps to prevent the signal from rapid high voltages that damages the equipment. This is also known as photocoupler. This can be used as a switching device and can be used as an electronic devices. The controlling devices helps to reduce the electricity consumption. This helps to reduce the electricity bills.

II. PROPOSED SYSTEM

The proposed system consists of microcontrollers, optocoupler, temperature and ultrasonic sensor with motors. The permanent magnet brushless DC motor are used.

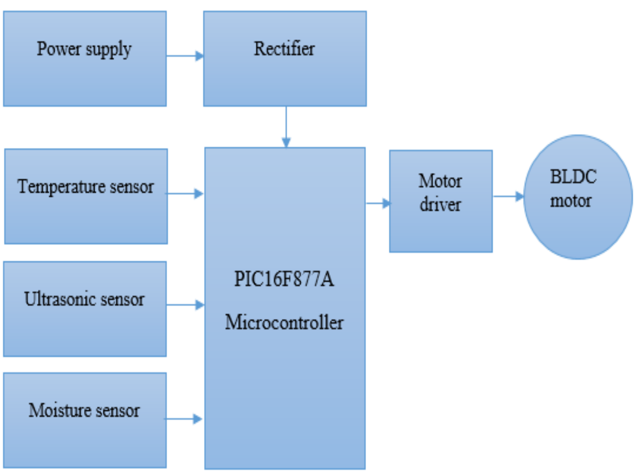

Fig 1: Proposed system

The figure 1 represents the proposed system.

DOI: rp-9788770040723.212

The components of permanent magnet brushless DC motor includes a fan blade attached with a permanent magnets with electromagnetic coils, rotor with rotor core section, stator, windings and bearing support.

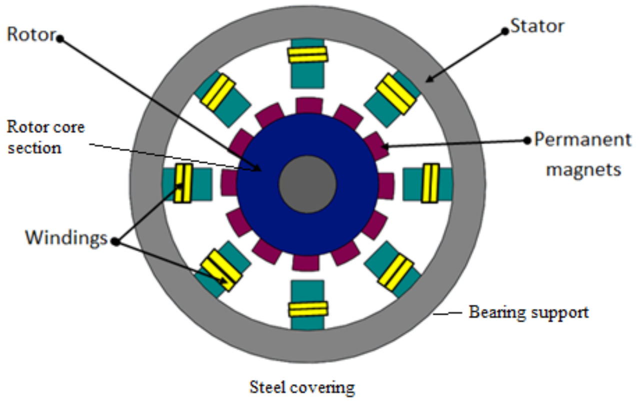

Fig 2: BLDC motor

The figure 2 represents the permanent magnet brushless DC motor. This contains four electromagnetic coils. The functioning of the electromagnetic coils function in combined pairs. In which the pair of A and C forms one phase and B and D forms the second phase. The rotor position is used to monitor the hall effect sensor. The rpm form the fan is monitored from the hall sensor through feedback. The conventional method is replaced through the proposed system. The power consumption is reduced through the optimization of the commutation angle. This helps to sustain the efficiency of the brushless DC motor[23]–[25].

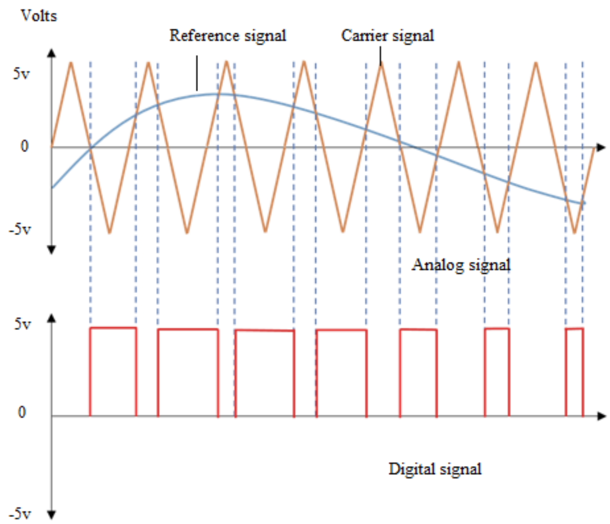

Fig 3: PWM signal

The figure 3 represents the pulse width modulation signal. They helps to regulate the functioning and speed control of fan externally through adjusting the duty cycles. It helps to obtain the results accurately. The duty cycle of the PWM is calculated as follows.

Duty cycle = T1/T* 100

Frequency Fpwm = 1/(TON+TOFF)

Vout = Vmax * duty cycle

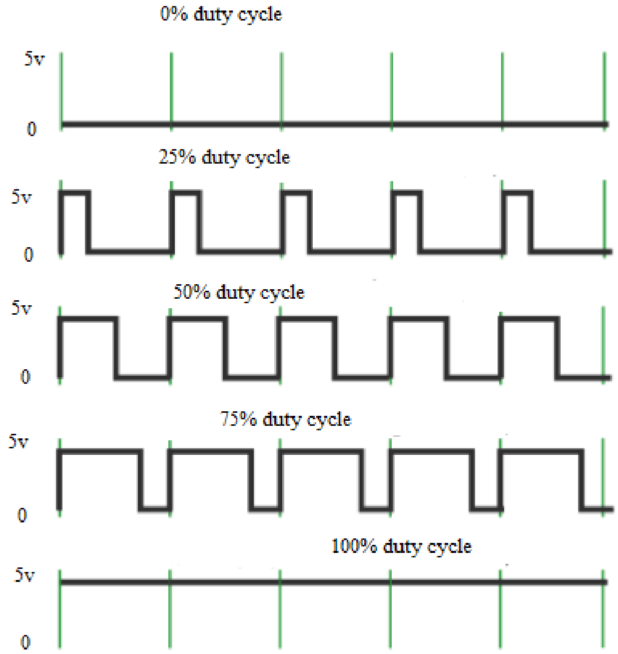

Fig 4: PWM with duty cycles

The figure 4 represents the PWM with duty cycles. The physical parameters are more important to be sustain in limit to intensification of the operational efficiency of the equipments. The sensor helps to function the equipments without any deviation in performance. The ultrasonic sensor is used to detect the sound signal and proceeds to the microcontroller whereas the temperature sensor (LM 35) is used to detect the surrounding temperatue through which the speed of the ceiling fan gets adjusted. The pulse width modulation is a digital parameter used to achieve the signal between 0 and 1. This is obtained through the duty cycle i.e is the amount of time interval at which the digital signal remains active. In the conventional methods, the potentiometer is used for speed control. This is replaced through the proposed system with increased automation in the system. It is denoted in percentage. The information is projected through the LCD display. This is a dot matrix liquid crystal display that is used to represent the alphanumerical characters and various symbols.

Here 16x2 LCD display is used. This is a form of digital system used for demonstration. It displays the room temperature. They are seven segment in nature. They are largely used due to flexibility in programming and are much economical in nature. This is accompanied with two registers. These are called command and data. The command register is used to save the command in the LCD. The initialization and predefining the data are done through the command instructions. They helps to perform various instructions. The data register is used to save the data that are need to be projected on the display unit. The data is the ASCII values that are needed to be proejected on the display of the LVD display. The consumption of energy is

DOI: rp-9788770040723.212

increasing rapidly due to the rise in demand. This must be maintained to limit the demand side management.

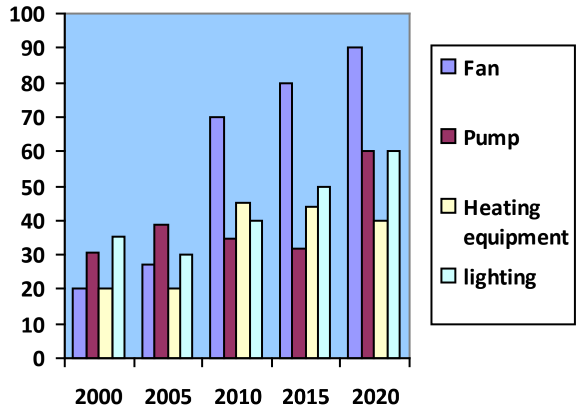

Fig 5 : Energy consumption

The figure 5 demonstrates the amount of increasing energy consumption annually. To balance the energy consumption, the smart automation techniques are employed. The smart meter is used to record and maintain the energy consumption. This is obtained throught the automation techniques. The smart meter records the consumptions of power and indicate them frequently. This helps to reduce the usage of power and electricity bills. The smart meter record the consumption of electricity and monitors them through involving machine learning techniques. The energy consumption is implemented by the forecast of the aforementioned data that are progressed to the preprocessing technique. This includes the preprocessing of the obtained data. They are proceeded with the optimization techniques. This helps to obtain a clean dataset. This includes two major modalities such as fitness function and crossover.

The data are pre-processed and evaluated with fitness function to obtain the desired outcome. This helps to limit the over usage of equipments. It also helps to function automatically based upon setting the operating time of the fan in prior. Thus the smart meter helps to make the functioning of the ceiling fan as fully automated in nature.

TABLE I. OPERATING CONDITION

Sl.no	Room temperature	Accuracy	Fan speed
1	32.8	87%	Medium
2	25.9	87%	Low
3	67.9	97%	High
4	45.9	92%	Low
5	59.1	85%	Medium
6	82.3	91%	High

The table I represents the functioning of ceiling fan based on the temperature in the surrounding atmosphere.

III. SIMULATION RESULTS AND OUTCOME

The proposed automatic speed control of ceiling fan is implemented in MATLAB Simulink is calculate and monitor the performance of the system.

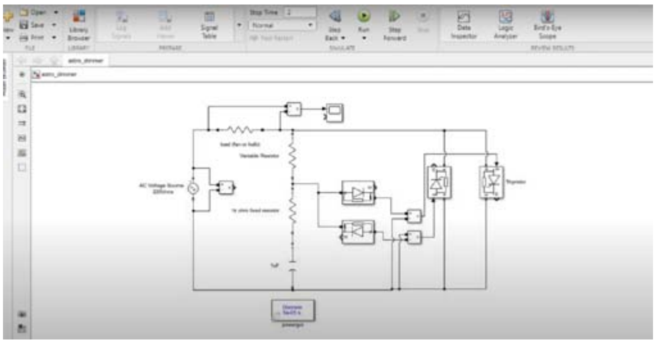

Fig 6: Simulation diagram

The figure 6 demonstrates the simulation diagram in MATLAB. This includes the analysis of speed of the ceiling fan and proceeded to control the speed using microcontroller. The input power supply to the microcontroller is 5v. The conversion of analog to digital signal is done through ADC. The sensed output is given to the microcontroller. This helps to obtain the control signals. The system is operated through varying the duty cycle that helps to change the speed of the fan based upon the temperature around the surrounding system.

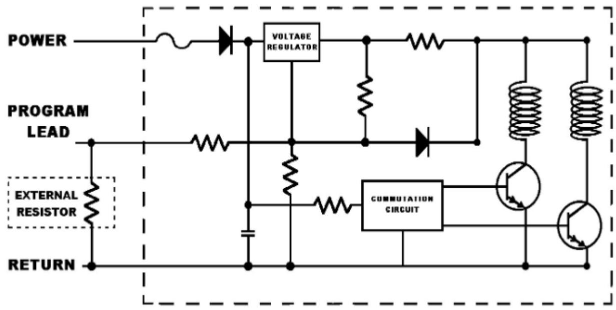

Fig 7: Regulation of fan speed

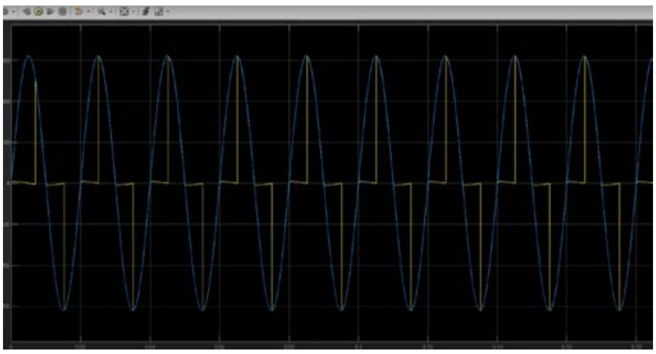
The figure 7 represents the regulation of fan speed. The proposed system is adopted to replace the use of tripot and potentiometer. The automatic speed control is implemented in simulation through adjusting the temperature to determine the routine of the ceiling fan. The speed is differentiated into three categories such as medium, low and high speed. These are based upon the room temperature. These automatic adjustment helps in proper functioning of the ceiling fan through the use of sensors. Thus the waveforns helps to observe the performance analysis.



DOI: rp-9788770040723.212

Fig 8: PWM waveform

The figure 8 represents the PWM waveform.

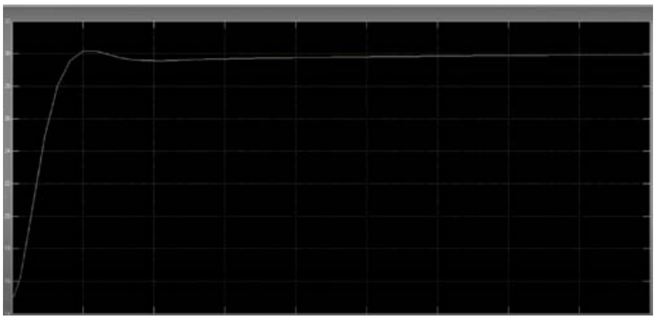


Fig 9: Energy consumption and monitoring

The figure 9 represents the energy consumption and monitoring. Through by adopting the proposed system the energy utility can be balanced. This helps to maintain the demand side management. Thus the energy consumption can be reduced and maintained stable through the pulse width modulation technique.

IV. Hardware Implementation

The PIC microcontroller is used for controlling and processing in which it can be easily write and erase numerous times because it adopts the FLASH memory technology. The PIC microcontroller are versatile in functioning and thus it is inexpensive in nature. This includes 40 pins whereas the 33 pins are developed for input and output. They have versatile applications ranging from sensors, safety devices and automation systems. This can function upto 20MHz frequency with instruction set. The operating voltage lies between 4.2 to 5.5 v respectively. It is available in four IC packaging with any internal oscillator in the unit. The PIC6F877A is obtained with low power high performance functioning CPU, providing with microcontroller of 8 bit with 8k bytes of programmable flash memory, maximum user application, extensive accessibility, presented with unrestricted enlargement tools. Various data such as the frequency, data and transmission codes are saved and identified in EPROM. They are flexible to operate and user friendly in nature.

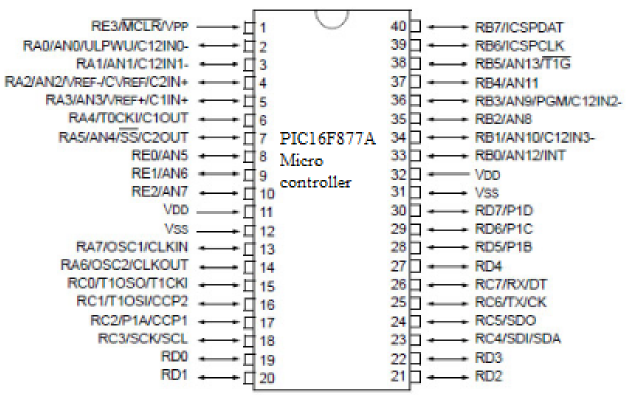

Fig 10: PIC16F877A

The figure 10 represents the pin diagram configuration of PIC16F877A microcontroller. They are used to obtain simpler programming with interfacing which helps to perform numerous task. The EPROM and EEROM are initiated for the end-user to perform the task much convenient manner through digital signal processing. The PIC microcontrollers are largely used in both industrial and domestic purposes due to its lower cost and easier functioning performance.

```
#include<htc.h>
#include<pic.h>
#define _XTAL_FREQ   20000000
void rundutycycle(unsigned int x );
#define s1          RA0
#define s2          RA1
#define s3          RA2
#define s4          RA3
#define s5          RA4
#define s6          RA5
void main()
{
ADCON1=0x06;            //All pins as digital
        TRISA=0b111111;         //PortA as Input
        TRISC2  = 0;            //Make CCP1 pin as output
CCP1CON = 0x0C;         //Configure CCP1 module in PWM mode
PR2   = 0xFF;           //Configure the Timer2 period
rundutycycle(512);
}
```

Fig 11: Programming code

The figure 11 represents the programming code for PIC microcontroller. The three fundamental step for programming a microcontroller includes writing programming code on computer, then used to compile the code with the compiler and finally helps to upload the compiled version in the microcontroller. The generation of code for the PIC microcontroller include various stages. The first step includes building the hardware. This is the primary step for program coding in microcontroller. Then obtaining software. The XC8 compiler and MPLAB X IDE are used by the instructions. The another set involves the configuration of oscillator and used to set the configuration bits in the system. The C programming language is used for the programming of PIC microcontroller.

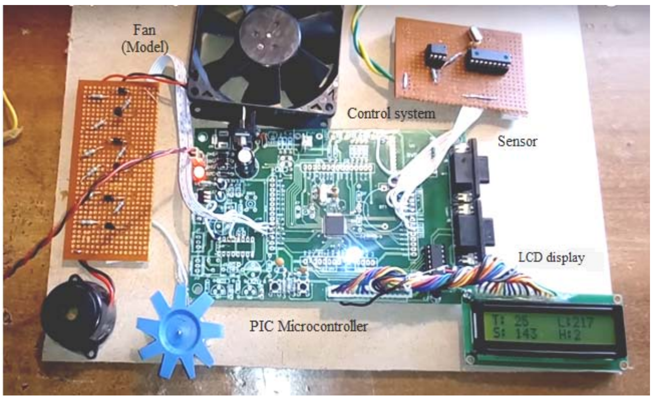

Fig 12 : Hardware implementation

DOI: rp-9788770040723.212

The figure 12 represents the hardware implementation of the planned system. The functioning of the system factors are projected in the LCD display. Through the control and monitor of microcontrollers through the sensed data helps to operate the ceiling fan automatically.

V. Conclusion

The advancement in the technology helps to make lives much sophisticated. The proposed system implement the automatic speed control of ceiling fan. This is enhanced through the use of pulse width modulation techniques. They are done through various devices that are performed through sensing the surrounding conditions. They are integrated with the control system with communication technology. The speed of the motor is measured by the power electronic devices that leads to regulate the speed of the ceiling fan. Thus the PMW technique with optocoupler helps to obtain the automatic speed control which leads in the decline of energy consumption.

***Abstract*—The automations in smart appliances play a vital role. The evolution of automation is the adoption of smart machines and appliances for industrial and domestic purposes. This helps to obtain smart home. They are implemented through artificial intelligence with optimization techniques. To replace the convention washing machine, the proposed system is introduced. This is functioned through adopting artificial intelligence to operate automatically through various devices. The smart washing machine is designed through machine learning techniques with sensors. This helps to adopt a newer way in washing that helps to reduce energy consumption through estimating the power utility. This is accompanied with automatic drying techniques. The system is completely automatic to perform the washing process. It is enhanced through internet of things to enable the two way communication system. The smart meter is used to record the energy consumption. The efficiency and performance parameter are higher when compared to conventional washing machines. Thus the proposed system enhances automation in washing machines with automatic drying and estimates the amount of energy consumption.**

Keywords—Washing machine, smart machines, artificial intelligence, induction motor drives, microgrids, energy management system, smart meters

I. Introduction

The rise of artificial intelligence play a versatile role in the sophistication and development of human lives through improvement in various fields ranging from industry and domestic applications. The control and monitoring of these appliances are complex and hence they are done through automation through artificial intelligence [1]. The artificial intelligence is defined as the progression of training the machines to function as similar to that of human intelligence. This helps to solve various complex problems to achieve the obtained results. They are functioned without human interference. These artificial intelligences are used to obtain the decision-making techniques rapidly. The advancement of artificial intelligence from the past decade is due the increase in demand. This includes machine learning, artificial neural network and deep learning techniques. The application of artificial intelligence helps in agriculture, industry, education and energy management system. They play a significant role in various fields through improving automations and performing the functions without the assistance of humans [2]–[4].

Hence this helps to reduce the computational time and hence helps to obtain reduction in cost parameter. This is accomplished through the data monitoring and integration, smart control system with communication system helps to the rise of artificial internet of things. The automations also helps in load forecasting. This is done through the machine learning with artificial intelligence to enhance energy consumption. This is done through the optimization techniques. This includes long term and short term load forecasting techniques [5]–[7].

The load forecasting helps to predict the power consumption and thus leads to the reduction of power utility. The load forecasting is done through analyzing the physical parameters such as weather, climatic conditions and consumers need at the particular period of time. This plays an important role in the complex systems. These automations and advanced innovations helps to determine the performance efficiency and helps in the reduction of carbon emission in the ecosystem. The adoption of automations in the renewable energy system helps to improve a greener environment. They are highly reliable and much efficient in performance. The control and

DOI: rp-9788770040723.213

functioning of the system are enhanced through the optimization techniques. They help to monitor and control the system based upon the priority and interest of the user. They are largely used in complex problems to obtain an accurate results [8]–[10]. Thus the automation in diverse field are achieved through the artificial intelligence techniques. These techniques are largely used in the hybrid renewable energy system to control and monitor. Thus utilizing it in an efficient way. These artificial intelligence paved way for the development of introduction of digital platform. It includes the evolution of virtual technology. They are formed through the virtual and augmented reality through the internet of things. In automation in the domestic appliances, the machine learning plays a vital role. They are implemented with forecasting mechanism to adopt automation in the functioning system [11]–[13].

This helps to increase the efficiency of the system through various control parameters. They are accompanied with the internet of things to achieve the two way communication systems. This helps to provide the monitored information to the user at other the end even at the remote places [14]–[16].

Thus the domestic appliances are controlled to achieve much sophistications in day to day life. Thus the appliances in the home are tend to completely automated through the machine learning and optimization algorithms that takes in to another world. The advancement in the technology are increasing largely due to the various sophistications and it helps to make lives easier. The machine learning provides a different approach in the functioning of the washing machine. The washing machine is an electrical and electronic system used to wash clothes. The washing machines are classified into top load and front load categories. The washing machine includes washing drum, sensors and inner drum. The washing machine are controlled through the control mechanism [17]–[19].

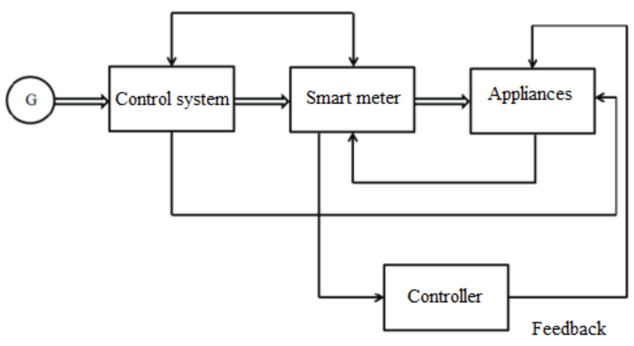

Fig 1: Smart meter drives

The figure 1 demonstrates the smart meter drives. This includes control system, smart meter, appliances and controller. This electronic control mechanism is denoted as programmer. This is done through the microcontroller through sensors and actuators. It includes ultrasonic cleaners for enhancing numerous functions. The real time operating system is used to function the washing machines. They are classified into hard real time and soft real time operating systems. These are classified based upon their functioning properties. The microprocessors and the microcontrollers are functioned and programmed using 2nd language programming languages. The various topographies of washing machine includes spin settings, washing types based upon the material of the cloths and capacity of the load. This helps in various advantages through adopting faster washing speed. This leads to obtain a newer way in washing the cloths with automatic drying. This also helps to determine the water quantity and energy consumption[27]. These helps to develop the overall home energy managements system. Due to the demand in the electricity, these artificial intelligence techniques helps to eliminate the increasing demand.

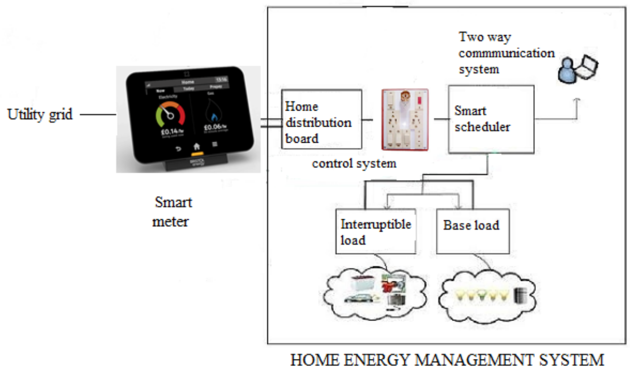

Fig 2: Home energy management system

The figure 2 represents the home energy management system. The expansion of the smart machines leads to the implementation of smart home and smart grid. This helps in diverse ways through communication system. The development of smart washing machine includes the two way communication to monitor and provide instruction to the washing machine through remote places.

The complete washing of clothes are done through the smart washing machine. This includes image processing techniques with feature extraction techniques. The washing machine used in the industry are highly profited through the machine learning techniques. They are tend to function much faster and hence helps to save time. The overall functioning of the washing machines are instructed externally using the smart touch screen which provides various options for washing. They are provides with various visual effects and automations. This helps to create an interest to operate and function the washing machines. This helps to reduce the manual efforts. Thus the proposed system is used to replace the use of the conventional washing machine. The smart washing machine involves the detection of clothes through which the quantity of water, detergent quantity and the time of washing is estimated and provides. The functioning of the washing machine includes four stages such as water consumption, soaking, washing process and drying [20]–[22].

This also helps to determine the amount of power consumption. This helps to maintain the usage thereby saving the power consumption. The energy consumption of the electrical utilizations are estimated independently

DOI: rp-9788770040723.213

through the energy disaggregation. This helps to determine and estimate the power consumed by the each and each appliances in the home and industry. These data are collected and processed to complete the smart functioning of the washing machine. This includes numerous data that are need to be stored. This is done through the internet of things with cloud computing techniques. They are also beneficial in the analysis and detection of fault and its performance. Thus the automations leads to improve the home energy management system [26].

The energy disaggregation plays a prominent role. They are classified into two categories based upon the intrusive and non-intrusive load balancing and monitoring system. The intrusion load balancing and monitoring is the hardware approach in which the smart meters and externally attached to the appliances to measure the performances. The non-intrusion load balancing and monitoring is the software approach. These energy segregation plays an important role in the large scale industrial sectors to estimates the consumption of power with estimating individually.

II. Proposed System

The smart washing machine is introduced to enhance innovation in the home automation system. This is developed through the energy decomposition techniques to improve smart home automation system. The smart washing machines are the innovative approach that are implemented through digital platform. The washing machine is the integration of electrical and electronic equipment's used for rapidly washing the clothes. This washing process includes soaking of clothes in combination of water and soapy solution to remove the dirt particles through the process of spinning. Then it is allowed to drain the water after the completion of the spinning process. This overall process is implemented through fully automatic manner using artificial intelligence adopting machine learning techniques. This helps in automatic drying of clothes after the specified spinning time based upon the loads. The complete functioning of the machine are intimated to the user through internet of things [23]–[25].

Fig 3: Smart washing machine

The figure 3 represents the smart washing machine. The components of washing machine includes hot water inlet valve, cold water inlet valves, door, inner drums, oulet water hose, filter and oulet line. These smart washing machine helps in analysis of clothes based on material and then initialise the washing process. They are differentiated through the image processing techniques. The sensors are used to sense the temperature of water used in the operation process. This automatically detects the quantity of water and detergents that are needed for the particular amount of loads.

III. Functioning of Smart Washing Machine

The operation of the smart washing machine includes two way communication system that seems the complete functioning process to the user. This internet of things play a prominent role in the monitoring and controlling the operation. The first step involved in the washing machine includes the processing the command to the machine through smart screen display unit.

Here the detailed information regarding the number of clothes are initiated. The machine itself recognised the amount of water and detergent needed for the prescribed loads. Then it automatically fetches the water from the water inlet valve. This includes both the hot water valve and cold water valve based upon the requirements. The clothes are dumped into the inner steel tub in which the process takes place. The diamond drum used inside the washing machines are highly efficient and gives best results. The quick wash is more reliable and fastest wash cycle with higher energy saving mode of functioning. The smart motion technology is employed. The smart motion techology are differentiated into three types. This rotating movement helps the clothes to remain tangle free and protects the clothes from earlier fading without causing any torn. The advanced techniques employed in smart washing machine involves the improved drum with twinwash process, wash technology with O_2, automatic dispenser technology with internet of things.

The smart washing machine tends to provide sophistication through automatic on and off through the instruction provided by the user through their mobile phone. This helps to function rapidly. This includes sending and receiving of instructions to mobile phone during the working conditions of the washing machine. This also helps to pause the functioning and can able to revine later. The functioning of washing machines includes top load and front load washing machines. They are classified based upon the operation and designing parameters. In which the top load washing machine is the efficient way to utilize. This includes the use of impellers that helps to achieving minimum quantity of water for washing purposes. Hence it helps to save water. The drying process is proceeded after washing the clothes. The drying process depends upon the rpm. This determines the spin speed in washing machines. The increased rpm leads to faster drying of clothes. The spin cycle ranging between 300-500 rpm is usually used for drying the clothes. This varies based upon the material and colour of the clothes. Thus the overall progression is done through the integration of machine learning with optimization algorithm. Here genetic algorithm used for optimize the overall functions.

IV. Smart Washing Machine Through Artificial Intelligence

The combination of machine learning with internet of things constitute the functioning of smart washing machines. This helps to adopt the decision making techniques similar to human intelligence. This helps to obtain well-organized functioning through adopting comfort in operation, advanced design parameters, safety and easier maintenance. These parameters helps in efficient energy saving. The energy saving includes the demand side management. This is accompanied with image processing and feature extraction techniques. This includes sensors for sensing the external physical parameters. The various sensor used in functioning of washing machine includes pH sensor, light sensor, temperature sensor and heat sensor. They helps to indicate the appropriate functioning in washing the clothes. The image processing techniques are used to identify the material of clothes based upon the predefined data. They are proceeded through the feature extraction techniques. This helps to convert the obtained raw data into numerical data to perform the functioning. These data are used for the optimization techniques that performs the overall functioning in washing machines.

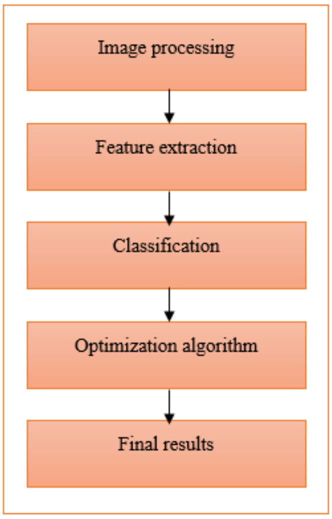

Fig 4: Smart washing machines through optimization techniques

The figure 4 demonstrates the functioning of smart washine machines. Here genetic algorithm is used to program the functioning based upon the needs and priority of the users with enhancing instructions to control and monitor the functioning of the washing process. They are implemented through the pre-procesed information in the dataset. This stores the complete information regarding the material of clothes, detergent amount and water level dependent upon the load. This is employed through the testing and training process which helps to make the system fully automatic. The speed of the rotating drum determines the drying process and it is regulated based upon the fabrics. The higher rpm leads to faster performance in washing and drying process. This also helps to reduce the occurrence of noise occurred in washing machine. The noise can be neglected through active casting technique. This includes the feedforward structure to control the noise parameter. The noise level of low frequency upto 500hz is acceptable. Increase in the noise level need to be reduced. The increase in noise leads to vibrations in the machine. These vibrations are caused due to the improper suspension of the drum inside the machine.

V. Mathematical Model Analysis and Functioning of Washing Machine

The suspension co-ordination of the drum in washing machine is refered as spring damping system. The vibrations occurred in the machines are obtained through the differential equations. Some of the assumptions are denoted as disregarding the mass of spring and damper and avoiding the deformation in the system.

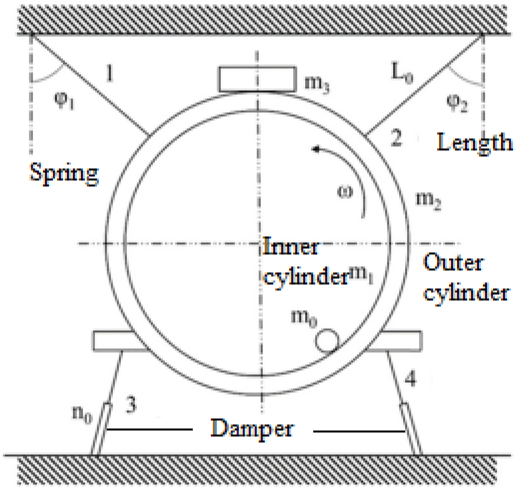

Fig 5: Mathematical model

The figure 5 demonstrates the mathematical model of suspension system. Accoroding to Lagrange equation, the dynamic equation is states as follows,

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot{q}_j}\right) - \frac{\partial T}{\partial q_j} + \frac{\partial P}{\partial q_j} + \frac{\partial L}{\partial q_j} = Q_j(t)$$

T is the kinetic energy of the system,
P is the potential energy,

L is denoted as energy dissipation function

The kinetic energy of system is denoted as,

$$T = \frac{1}{2}m_1\left|v_G\right|^2 + \frac{1}{2}I_1(\dot{\theta}+\omega)^2 + \frac{1}{2}m_2\left|v_G\right|^2 + \frac{1}{2}I_2\dot{\theta}^2 + \frac{1}{2}m_0\left|v_{m0}\right|^2 + \frac{1}{2}m_3\left|v_{m3}\right|^2 + \frac{1}{2}I_3\dot{\theta}^2 + \frac{1}{2}J_1\omega_1^2 + \frac{1}{2}J_2\omega_2^2$$

DOI: rp-9788770040723.213

where vg is the centroid velocity of the inner and outer cylinder respectively. The interconnection between the box and the inner cylinder are immovable in nature. There are two types of cylinders inside the machine namely inner and outer cylinder. They are inflexible in nature.

TABLE I. MOMENT OF INERTIA

Moment of inertia kg-mm^2	
Motor shaft	2.27×10^4
Inner cylinder	4.6×10^5
Outer cylinder	1.01×10^4
Counterweight	2.4×10^4
Damping of spring	1.98
Suspension of spring	6.1

The table 1 represents the moment of ineria of the components of washing machine. The vibrations in the system are neglected through magnetorheological dampers. This is used to interconnect with the drum and cabinent. This reduces the vibrations adopted with control strategies. The control strategies includes adoption of fixed (current) values through a constant spin operating condition. This includes when a constant spinning condition, the training stage is initiated in multiple times with reduced ramp signal. The vibration and noise of the machine are identified and examined at the training phase [25].

The logical understanding of the functioning of washing machine is demonstrated as follows,

D = 0 (Door open condition), D =1 (Door closed condition)
L = 0 (Low water level), L = 1 (Higher water level)
T = 0 (Low temperature), T = 1 (Higher temperature)

The motor operates when the value of D, L and T are higher.

The heater functions when the D and L are higher and T is lower.

The water valve operates when D and T are higher and reduced value of L.

TABLE II. LEVEL OF FUNCTION

Door (D)	Level (L)	Temperature (T)	Valve (V)	Motor (M)	Heater (H)
0	0	0	0	0	0
0	0	1	0	0	0
0	1	0	0	0	0
0	1	1	0	0	0
1	0	0	1	0	0
1	0	1	1	0	0
1	1	0	0	0	1
1	1	1	0	1	0

The table II represents the logical functioning parameters for operation and functioning of washing machines. The washing machine consists of three sensors namely the temperature sensor, door sensor and water sensor. They forms the basics for the operation of the drum. Thus the mathematical model determines the functioning of the system to neglect vibrations and to achieve higher efficiency. Through a smoothening of current vibration map, it helps to determine the current value at which the vibration responds during the training phase. This helps to find out the optimum solution thus maintaining the constant spin functioning condition. This helps to enhance reduction in the power consumption. The overall process is optimized through genetic algorithm. The genetic algorithm is a tool for resolving both the controlled and unconfined problems. These complex problems are solved to obtain optimum results.

Algorithm 1: Genetic Algorithm for flexible Load shaping in Demand Side Management (GADSM)

```
Take load types 'L', total number of matrices 'n', number of devices 'I', current matrix 'm' and power
consumption 'p' from the table of load data
  while 1< L < n do
    while 0 < I < m do
      (1) Calculate the total 'p' consumption of 'I' no. of devices
      (2) Compute the fitness function
          (a) Fitness function – without GA-DSM
          (b) Fitness function – with GA-DSM
              i. Population initialization
              ii. best optimal fitness function selection based on the minimal 'p' during peak hour 'ph'.
              iii. Crossover is carried out on 'I' based on the minimal 'p' for time slot 't'.<crossover>
              iv. After analyzing the behavior of the new population, mutation is done on 'I'
                  based on 't' during 'ph'. <mutation>
              v. The fitness function matrix of the 'I' with minimal 'p' during 'ph' is taken as
                 the best fitness function for each 'L'. <optimal solution>
end while
Same process is repeated for each 'L' and the best optimal fitness function is chosen.
end while
123
```

Fig 6: Genetic algorithm

The figure 6 represents the genetic algorithm for control and functioning of the machine learning. They are obtained through the process of crossover and mutation. This helps to optimize the system to achieve optimum solutions.

VI. SIMULATION RESULTS

The proposed smart washing machine using artificial intelligence is implemented in proteus platform. This helps to analyse and estimate various functioning parameters of washing machines.

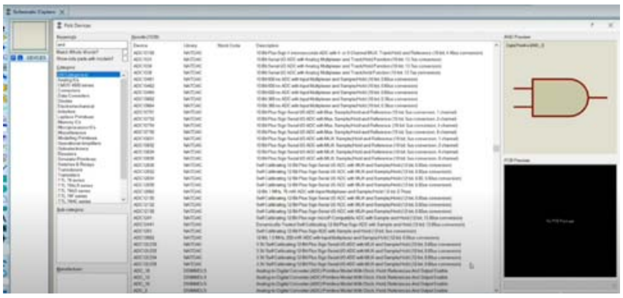

Fig 7: Simulation through Proteus

The figure 7 demonstrates the proteus simulation model to estimate the energy and water consumption. The simulation results are functioned through the logic functioning.

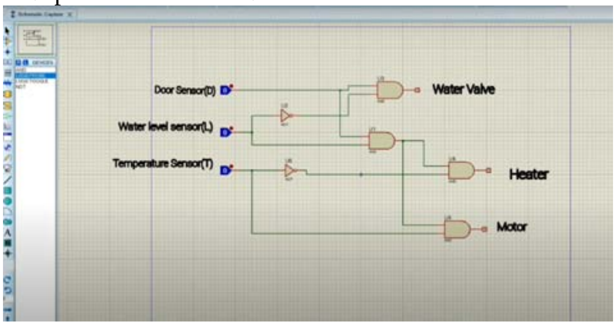

Fig 8: Simulation model and results

The figure 8 demonstrates the simulation model. This helps to analyze the accurate solution to various constraints in the functioning of washing machines. The output results are evaluated through the simulation model. Thus the proposed system provides 100% outcome in achieving automatic drying with efficient energy and water consumption through the aid of machine learning techniques.

VII. Conclusion

The proposed system helps to obtain automation in washing machine through artificial intelligence. This includes control and monitoring of the system through machine learning techniques with internet of things. Thus the two way communication system helps to provide the information to the user even at remote places to monitor and visualise the functioning. Thus the smart washing machine helps to estimate the energy consumption through smart meters. Various smart techniques are inculcated to improve automations and smartness in functioning of the washing machine. This supports to decrease the energy consumption thus maintaining the demand side management.

***Abstract*—The lighting is the important phenomena that are used in our day to day life. They must be utilised in a proper way without any consequences. The rise in the demand is caused due to functioning of equipment unnecessary that leads to increase in the consumption of power. To overcome these drawbacks, the digitalization is implemented. This is done through the internet of things. This helps to function through evolving the two way communication system. The lighting system must be properly functioned through analysing the illuminance and luminance. Higher or lower illuminance level can cause various constraints in physical and mental health. To overcome these constraints, the proposed system is implemented. This is done through the thyristor controlled system. The thyristor is a solid state switching devices that are used to withstand the rated voltage until it gets triggered. The thyristor once triggered, the current through the triggering phase can be removed without turning off the equipment. The illuminance percentage is visualised through matrix keypad. The overall system is functioned and monitored through internet of things.**

Keywords—Illuminance, luminance, digitalization, matrix keypad, lamp, voltage control, inverters, rectifiers, voltage source converters, internet of things

I. Introduction

The lighting is considered as one of the essential system in our day to day life. They are mandatory in every field. This much be obtained with correct functioning parameters. Any deviation in the lighting system leads to various problems such as eye strain, health issues and various accidents occur in roads due to poor lighting system [1]–[3].

Hence the lighting system must be functioned with optimum care. The proper functioning of the lamp is determined through the illuminous. The illuminous is defined as the quantity of light that cover the surface. The SI unit of illuminance is referred as lux. This is frequently represented as brightness. This is replaced through the SI unit to attain equality in standards. The increased value of light is obtained when the value of lux is higher in range. They are expressed in candela and lumen. The range of lighting must be maintained properly without minimum or maximum lux. The maximum illuminance can also causes various barriers to human health. The increased in the illuminance does not recommended as proper lighting [4], [5].

The average level of illuminance must be maintained. This is also relied on the surface in which if the surface area is smaller, the illuminance reflects brighter. If the same amount of light falls on a larger area, the illuminance becomes lesser leads to dim in appearance. Thus the surface of the area also play an important role in the illuminance of lamp. If the lux values are obtained higher, this helps to provide higher level to light to the surface [6]–[8].

The lighting system must analyzed for domestic and industrial purposes, based upon the needs the illuminance are needed to provide. This helps to obtain exact lighting for the particular area. The reduction and rapid increase in the lighting system leads to imbalance in the surface area. The value of lux is maintained using the lux meters. These instruments are only used to measure the light and they are cheaper in cost. The level of illuminance is denoted by the lux value through which the lighting system is obtained. This helps to adopt a proper lighting system to the particular area. There are various types of lighting system is designed based upon the usages and the needs. This includes domestic purposes, industrial purposes and designing purposes [9]–[12]. These lighting varies in color in the designing purposes. There is a vast difference between the luminance and illuminance. The illuminance is the amount of light that falls in unit area whereas the luminance is the amount of light that are reflected back to the surface after the light

DOI: rp-9788770040723.214

absorbed through illuminance. These two technology plays a vital role in the lighting system. The measurement of light based upon the luminance and illuminances determines the intensity of the lighting arrangement. The detection of light waves are denoted as optical radiometry. This is the amount of light waves that falls in the optical portion of the electromagnetic spectrum. These waves are referred as visible light, infrared light and ultraviolet light [13]–[16].

The electromagnetic radiations are also measured using radiometry. This is done through the application on sensing the detecting the brightness across the surface. The terminology used for the detection of light system is called photometry. This includes the detection of visible light in the electromagnetic spectrum. This helps to measure the light based upon the human perception towards brightness. Thus the photometry is the branch of science that contracts with the measurement of intensity of light. The sensitivity level at which the brightness of light affects the human health is analyzed. This helps to separate wavelength through the electromagnetic spectrum [17]–[20].

The ultraviolet rays can be detected through the photometry. Thus the important part of photometry includes the differentiation of the visible light with that of human perspectives. This helps to neglect the disadvantages caused by the brightness level through proper functioning and detection of the illuminance level.

The usage of spectrometer in analysis and detection in the measurement is referred as spectrometry. The spectrometry is the interaction of matter and light. This is the relationship between the reactions and the adverse measurements of the intensity and wavelength. The application of spectrometry includes in diverse areas. They are largely used in astronomy, improvement in the structure of drugs and in biomedical applications. They are used to analyze the objects far away. The another process of measurement of light at the particular wavelength at a particular electromagnetic spectrum are referred as the spectroradiometer. They are measured through the spectrum or through wavelength. The two important concepts that are involved in the spectroradiometry includes spectral radiance and spectral irradiance [21]–[23].

The intensity of the light is measured through the source of light and the direction in which the light radiates. This is denoted as the number of lumens that falls on the unit area. This helps to find out the illuminance and light intensity. The instrument used to measure the light are termed as photometer. This is used to observe the intensity of light. This is also refers as the instrument that are used to measure the visible light. The luminance and illuminance both are measured to obtain proper lighting system. The measurement of luminance and illuminance are estimated through the measuring device known as luminance meter and illuminance meters [24], [25].

The accumulation of electromagnetic radiation is done through the integrating sphere. The lights are measured and break into spectral components are done through the spectrometer. This helps to digitalize the obtained signals and can able to display through computers. The measurement of depth of light is measured through the light meters . The level of light falls on the surface is measured through plane. Illumination of high power is mandatory to achieve effective lighting system. The illumination can be controlled through power electronic devices. The various power electronic devices used for illumination are thyristor, transistor and diode. The various kinds of thyristor includes silicon controlled rectifier (SCR), triac, programmable unijunction transistor. The thyristor is a three terminal controllable device which works much efficient in power frequency.

The proposed system is used to maintain the illumination of lamp using thyristor. This is adopted with matrix keypad with IoT. The internet of things (IoT) helps to enable the two way communication system through which the functioning can be monitored even at remote places. The illumination of the lighting system is employed through varying the voltage across them. The matric keypad is defined as the circuit that are used to monitor the amount of illumination used by the user end. This is indicated through percentage. The total functioning of the system are adopted through the solid state mechanism through switching control parameters.

The overall process is performed and controller through microcontroller for enhancing and maintain the illumination control through the surface area. The display unit is used to visualize the percentage of illuminance that are used. Thus the proposed system is much efficient in functioning and controlling illuminance of lamp through thyristor control accompanied with internet of things. The overall process of illuminance is visualized in the matrix keypad.

II. Proposed System

The planned system involves the regulation of the illuminance of lamp through the thyristor control. The most frequently used thyristor are silicon controlled rectifier (SCR). The SCR contains three terminal in which the conductor is allowed to control by the input current. The three terminals are anode, cathode and gate. The gate is used for triggering the device into latch through minimum voltage.

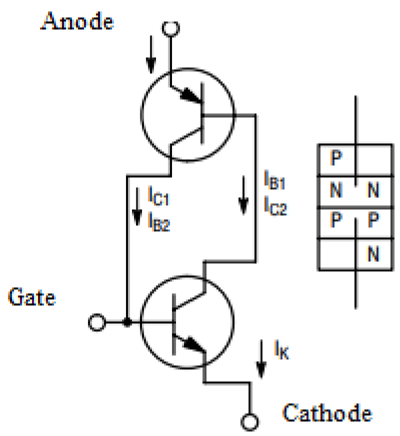

Fig 1: Silicon controlled rectifier

DOI: rp-9788770040723.214

The figure 1 represents the silicon controlled rectifier. The analysis of the SCR provides the bistable operation. The triggering of thyristor requires the intrusion of current to increase the gain. The anode current leads to the avalanche breakdown which results in variation of the breakdown voltage. The thyristor includes the junction temperature. This affects the characteristics of thyristor. The increase in the temperature helps the thyristor to turn on and remain in operating state. The applied voltage attains the breakdown voltage when the gate current is zero. This includes the latching and holding current. The minimum current used for the thyristor to remain in operating conditions rapidly after switching from off state are termed as latching current. The holding current is defined as the slightest current required to maintain the thyristor to remain in on state.

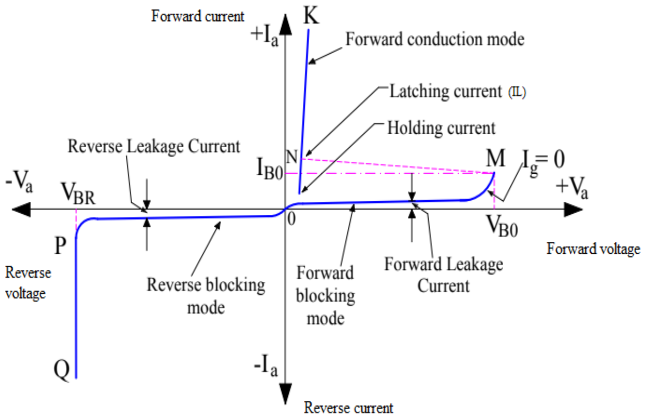

Fig 2: VI characteristics of SCR

The figure 2 demonstrates the VI characteristics of SCR. There are three approaches of process of SCR includes forward blocking and conduction mode and reverse blocking mode. In the forward blocking mode the SCR is at forward bias mode. The gata current is found to be 0.

The figure represents the VI characteristics of SCR.

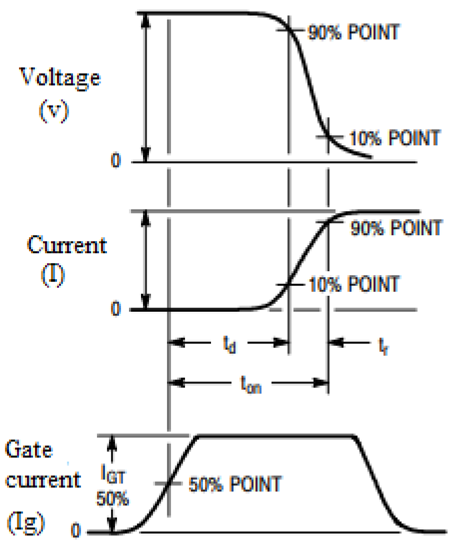

Fig 3: SCR turn on time

The figure 3 represents the turn on time of SCR. The forward breaking voltage is defined as the voltage at which the SCR turns on and when the gate current remains 0. The functional votage falls to the breakover voltage of the thyristor when the gate current becomes zero. Through obtaining particular value of the gate current, the thyristor starts to perform and function as rectifier.

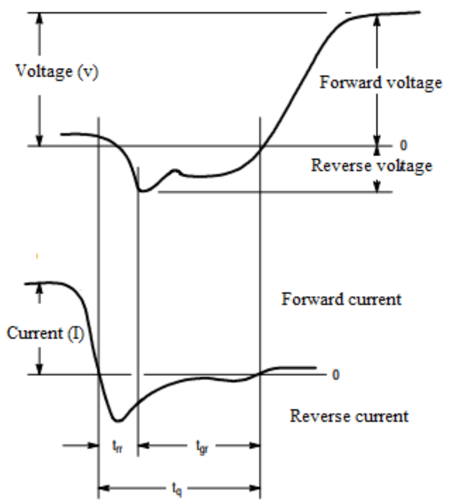

Fig 4: SCR turn off time

The figure 4 represents the turn off time. The turn off in thyristor is defined as the time duration in which the anode current lies to zero and obtainig forward blocking phase.

III. Automatic Illumination Control of Lamp

The control of illuminance of lamp is controlled and performed using thyristor and maintained using microcontrollers. Here 8051 microcontrollers are used. The firing angle is automatically initiates through the microcontroller using input. This helps to control the functioning of thyristor.

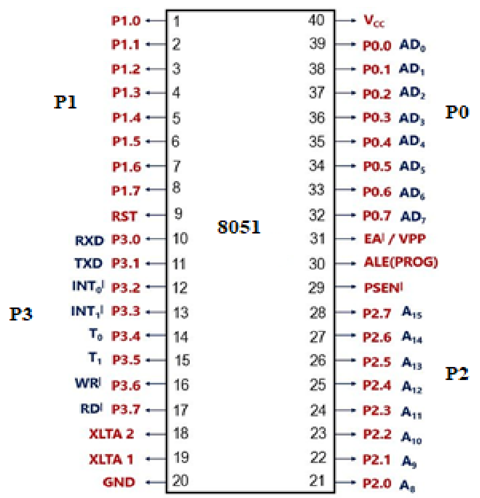

Fig 5: Pin diagram configuration

The figure 5 represents the pin diagram configuration of 8051 microcontroller. The illumination control is classified

DOI: rp-9788770040723.214

into two types such as manual illumination control and automatic illumination control module. The automatic illumination control module is used to replace the manual illumination control. This includes the illumination through adopting the rotor switch to intact through the switching position. They operates based upon the day and night times.

During night time there is no light that falls on the LDR1, this helps to enhance the intensity of the light that causes the lamp to glow automatically without any external assistance. This causes reduction of resistance on LDR2. During day time, the light falls on the LDR2, hence no emission of light is done through LED light. This causes the UJT firing circuit leads the SCR to incapable to trigger. The control strategy must be maintained properly to achieve automation. The automatic illumination of lamp is achieved through firing circuit in the SCR. The lamp with the variations of output voltage need to be maintained and controlled. The another kind of switching includes the complementary switching. The complementary switching is done through the photo sensitive controller [20]. They are accomplished through light source such as sun light. This is done for two lamp. The photoactive elements emits the light in the complementary lighting.

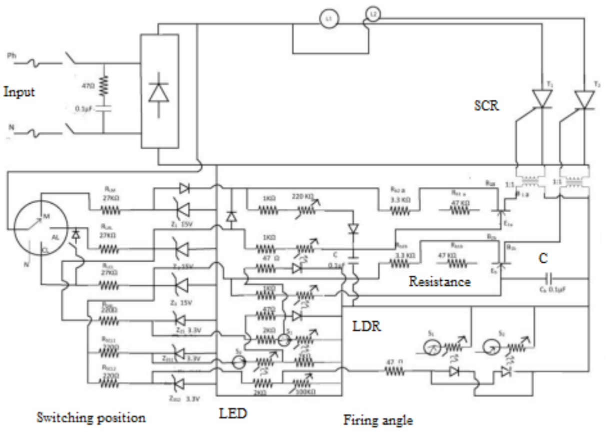

Fig 6: Circuit diagram

The figure 6 demonstrates the circuit diagram representation of automatic control of illuminance of lamp. The device is initiated through the matrix keypad. The matrix keypad are largely used in the embedded applications. They are also used in telephones and fax machines.

The matrix keypad is the integration of four rows and columns through buttons. The functioning of the matrix keypad includes the combination of rows and columns through which touching the button helps connect and perform the operation accordingly. In a 4 × 4 keypad matrix, the 4 connects are in rows and 4 connections are in columns. This constitutes totally 8 connections. There are various kinds of matrix keypad, out of which the 4 × 4 matrix keypad and 4 × 3 matrix keypad are highly used in various applications. The various layers that constitutes the matrix keypad includes overlay through graphic, interior metallic domes, first layer of circuit, spacer unit, button model, adhesive portion with connector section.

These layers helps to constitute the production of the keypad matrix. The overlay through graphic layer are made through polyester due to its increased flexibility in nature. The next layer are obtained with polydomes. The outer circuit layer is the integrated portion to the external environment. This is made up of the combination of polyester with coating done with electrical conductive solutions.

The switch always remain in open until the keypad is fixed. These in-between layer is termed as spacer unit. The bottom unit of the matrix keypad is also a flexible layer made up of polyester material. The adhesive unit helps to stich the layers without any gap between them internally and externally.

Through touching one button, the connections is adopted between the interconnections with rows and columns. The larger use of the matrix keypad is due to it tends to decrease in the number of pins. The number of pins in the network are reduced through the interconnection of rows and columns in the matrix keypad. This enhances the process of multiplexing. This is a method of functioning of larger number of inputs through lesser number of pins. This is a minute input devices works based upon the user instructions and proceeds to the microcontroller. They are performed through 0 and 1 which demonstrates the high and low values. This scans the rows and columns when pressed. The matrix keypad is connected with the pins in opposite order. The pin 8 defines the starting stage. They are largely used due to the lower cost with higher efficiency with longer withstanding capacity.

TABLE I. Amount of Energy Consumption

Sl.no	Space for illumination	Utility hours	Light intensity (lux)	Output (watts)	Energy (kWh)
1	Living room	24	300	42.5	42.8
2	Dinning room	12	500	12.9	35.9
3	Kitchen	14	200	5.98	24.9
4	Bedroom	10	300	16.8	6.9
5	Studying room	5	400	25.6	35.5
6	Store room	2	150	17.9	20.1
7	Bathroom	1	125	12.1	10.2

The table I represents the amount of energy consumption in each room in a house. Calculating and monitoring the consumption helps to maintain the demand. This is done to reduce the excessive usage of lights even in day time or forget to turn off the lights leads to increase in the consumption. This leads to increase the demand in the supply system. To maintain the demand side management in both the domestic and industrial applications, the proposed system provides a optimum solution. Through proper utilization nearly 35% of the power can be saved.

IV. Simulation Results

The implementation of the proposed system is monitored and calculated through simulation output. This helps to estimate the consumption of power, thyristor functioning, control of illuminance lamp during day and night times are observed. This gives an appropriate value of

DOI: rp-9788770040723.214

illuminance in lux and the amount of power consumed throughout the day and proceeded with months. This is done through the MATLAB Simulink.

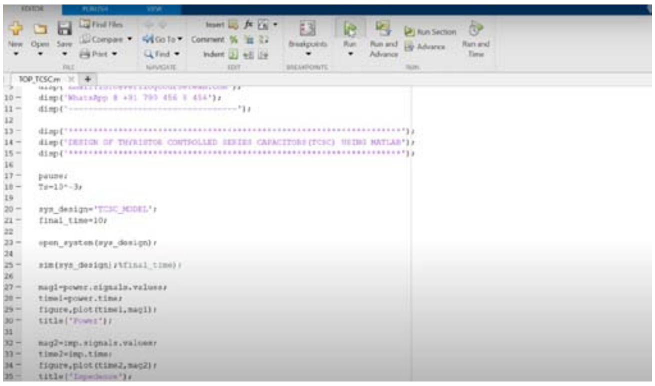

Fig 7 : Implementation of system

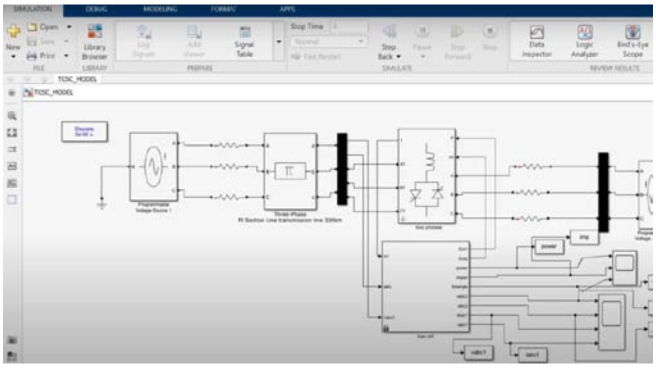
The figure 7 represents the implementation of the proposed system in MATLAB.



Fg 8 : Simulation diagram

The figure 8 demonstrates the simulation diagram. This includes thyristor, LDR, sensors and LED lamps. The readings are denoted to extract the output function. They are analyzed through varying the voltage values. Thus the illuminnace of the lamp gets deviated based upon the change in voltage. This helps in the control of illuminance in the lamp.

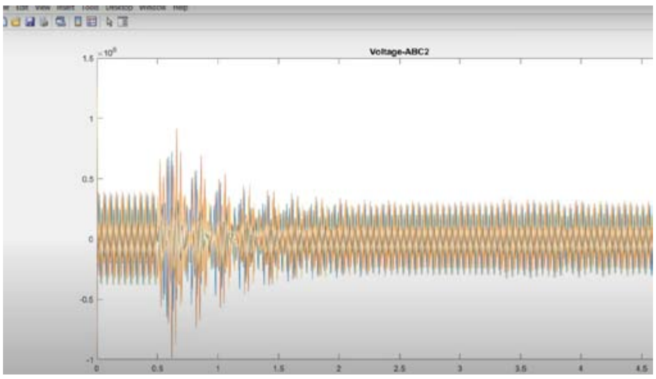


Fig 9 : Capacitor voltage

The figure 9 represents the capacitor voltage at charged condition. The capacitor in the system are connected across the supply system. This is used to make rectifications in the power factor. The occurrence of arc caused by the inductance are reduced by the capacitor.

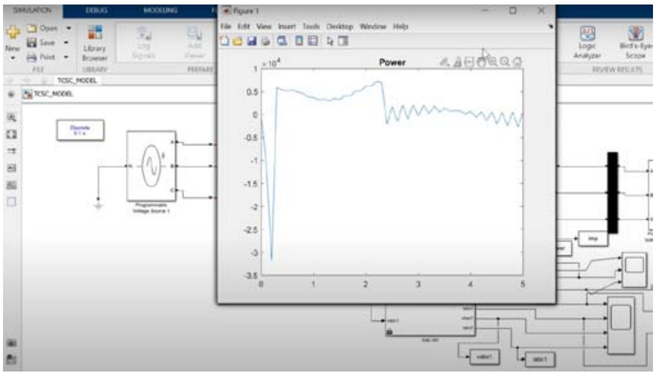

Fig 10: Output power

The figure 10 represents the output power. This helps to estimate and calculate the amount of power consumption.

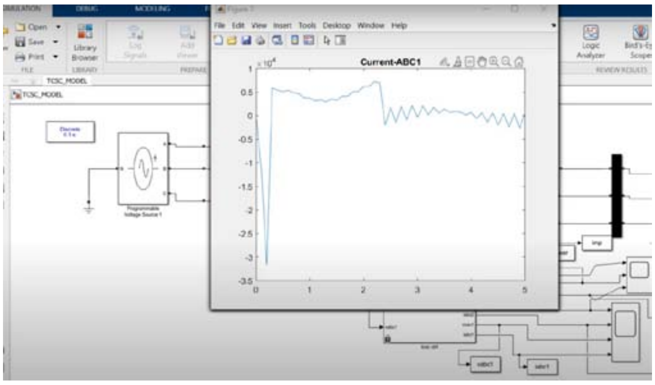

Fig 11 : Output current

The figure 11 represents the output current. The current rating is 0.2 A.

V. Hardware Description

The proposed model is implemented through hardware prototype to estimate and evaluate the functioning of the proposed system. This helps to calculate the amount of energy consumption. The overall illuminance control of lamp is intimated as message to the user’s phone. This is implemented through internet of things. This helps to automatically detect the working of the lamp and able to provide instructions to the system.

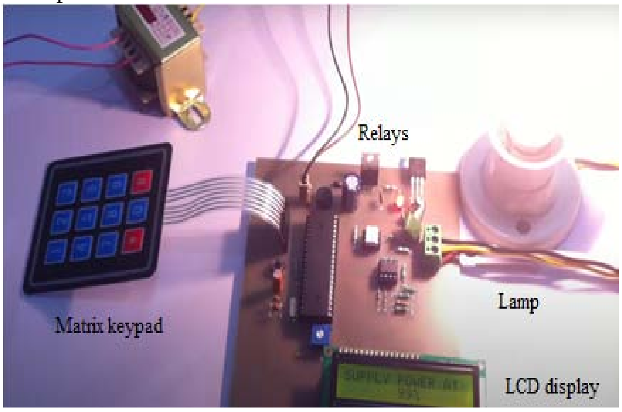

Fig 12 : Hardware representation

The figure 12 demonstrates the hardware representation of the proposed system. Thus the control of illuminance is achieved.

VI. CONCLUSION

The control of illuminance of lamp is introduced through control and monitoring system using matrix keypad is implemented experimentally through internet of things. They are adopted through controlling the illuminance through manually and automatically. This is also done through balancing switching techniques. The automation in illumination is done through thyristor control with control parameters. This helps to provide optimum illumination through automatic control for both the indoor and outdoor lighting system through balancing the illuminance and luminance. The matrix keypad is used to reduce the number of pins through integrating rows and columns. The internet of things are employed to enhance the communication system from one end to another end. The functioning of the lamp can be controlled through the user even at remote places. Thus the proposed system helps to control the illuminance through thyristor control that helps in reduction of energy consumption. This proposed system helps to obtain higher efficiency when associated to the conventional organisation.

Abstract—The aim of the work is to develop an online exam and classroom portal which can serve as the advancement in terms of examination pattern and educational services in today's virtual life. The project aims to provide a platform with easy-to-use interface. The central nature of the work needs to save time and increase the accuracy aspect of the work as the demand for the sme is rapidly increasing. Not only does this benefit the students, but it also helps the administrators or professionals like teachers who can work seamlessly on the backend through a well-designed interface. The work has also introduced its own randomizer to implement random logic The project can serve as a perfect service to the educational industry.

I. Introduction

The project aims to develop a virtual platform for students to have an easy access to their classrooms as well as their examination portal, all at one place. This project will be developed with a vision to solve the problems of not just the examiner but the examinee too, with a modern GUI and integrated platforms and plagiarism checks, it will be beneficial to not one but many users who use it including the students as well as the teachers.

II. Literature Survey

We have conducted a survey about 14 research papers from different conferences across various journals. We have noted down a lot of points, both positive and negative. We came across a paper which discussed the implementation of a similar kind of application in the MVC architecture. On consider the perks of the deployment we decided that the best way to approach our project was the MTV(Model-Template-View) approach. We also came across various AI algorithms to implement remote proctoring systems in our system. Randomizing the questions was a tedious task for which we referred some techniques. A paper emphasized on the implementation as an object-oriented approach which was discarded as it was not compactable with our requirements. A paper also recommended tab locking techniques to secure the online testing. Detection of anomalous behavior was also studied in a paper which provides remote proctoring help. Co learning methods was also shown in a paper. Thorough studying of the papers we referred we came across a lot of factors and hence created our own approach to design the portal and implement it in our point of view.

III. Opinion Survey

As the project topic was new and in demand in the current scenario, we conducted a survey to see and evaluate the opinions and gather people's expectations from their view of point. We had created s survey form and spread it across all stakeholders of the education industry. A good response was received from 450+ people from different institutions, we have generalized the requirements. Most of the teachers have complained that managing multiple classes or subjects, so the UI needs to be improved or made such that it can be managed easily. From the students we got a lot of inputs, Improvements were suggested in proctoring systems and meaning stuff. Examinations needed certain amendments from both teachers and students. Considering all the inputs we framed a model for our portal and the design was carefully designed using these all considerations in mind.

IV. Approach

As we are developing a web solution, the front end is designed with HTML, styled by CSS, and the JavaScript included in the code till provide support some functions which ease the user interface and improves the user experience. Python Django is used as the backend along with sqllite3 as the main database. The main advantage of using Django as the framework is that we can use certain AI algorithms using for remote proctoring. MTV architecture plays an important role in the implementations. The design is flexible and open for future improvisations.

V. Architecture

The most basic architecture for running the whole implementation is the MTV architecture over MVC architecture. It increases the speed and performance of the model.

A. *MTV Architecture*

The major advantage of using the MVT over MVC is that in MTV Flow is sometimes harder to understand as compared to MVC., URL pattern mapping takes place, Controller part is managed by the framework itself.

DOI: rp-9788770040723.215

Modifications are easy, the application is loosely coupled, and it is suitable for small and large projects.

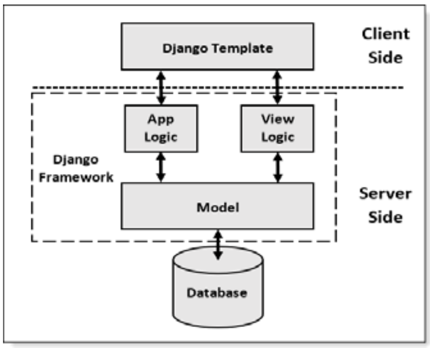

Fig 1. Standard MTV Architecture

VI. Algorithms Used

As security is one of the most important concerns in modern day projects, we used the famous Secure Hash Algorithm (SHA 1) in our project to implement security.

B. *Secure Hash Algorithm*

Hash algorithms are usually used to provide security to any form of confidential data. The major advantage of using hashes is that it uses encoding and comparison instead of classical decryption adding more to the confidentiality element of security.

SHA is used over MD5 as it is the latest version and has more strength over message digests. However, this consumes a little bit more memory, which may not be a major concern in implementation.

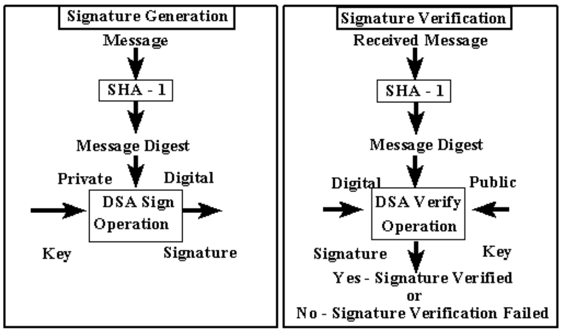

Fig 2. SHA Algorithm

C. *Randomizer Algorithm*

This algorithm is basically used to shuffle the questions in case of an examination or can be also used wherever we need randomization.

This algorithm comprises a pseudo random generator, upon providing the input the pseudo random generator generates a bit stream exactly of the same length as given in the input. The bit stream is then incubated with the data and hence the randomized data is incorporated.

Then again after the process the shuffled data is again sent through a filter which checks the data for further any discrepancy and then commutes the final data to the client ot the user.

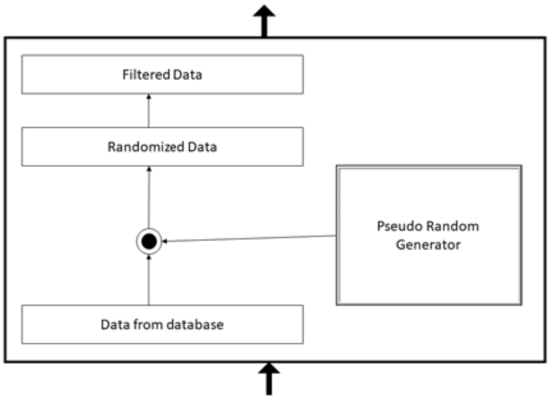

Fig 3. Randomizer Algorithm

VII. Modules Of The Product

The most basic architecture for running the whole implementation is the MTV architecture over MVC architecture. It increases the speed and performance of the model.

D. *Administrator Based*

- Can monitor the activity logs of all the users.
- Can add/remove users.
- Defines departments, classes, subjects and assigns them to the particular instructor, teacher.
- Add new events to the calendar.
- Generate and release results.
- Monitor overall progress for the entities.
- Simulate the working of modules overall.
- Keep eye on all the assignments and documents uploaded at different times at a single place.
- Use search option at all stages for better interactions.
- Perform audits.

E. *Teacher Based*

- Can create, invite, and organize different classrooms for students.
- Take regular classes and their backups.
- Provide study material, give it access controls and manage multiple classes data simultaneously.
- Create assignments with deadlines, alter them, evaluate them, and grade them.
- Create and conduct examinations using features of our remote proctoring system and examination environment.
- Run plagiarism checks on assignments and examination answer scripts.

F. *Student Based*

- The student can join any class, but only an approval is sent and only when the instructor validates it one can be part of it.
- He can attend classes, check for assignments, see pending tasks, see backdated data at his own ease.

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.215

- Can request back data of a particular instance from the controller.

Role specific tasks can be introduced, but it needs the server to be strong enough as the complexity increases.

Security of the system has a large scale for improvement for and can be improved in further years by implementing blockchain technology.

VIII. Implementation And Result

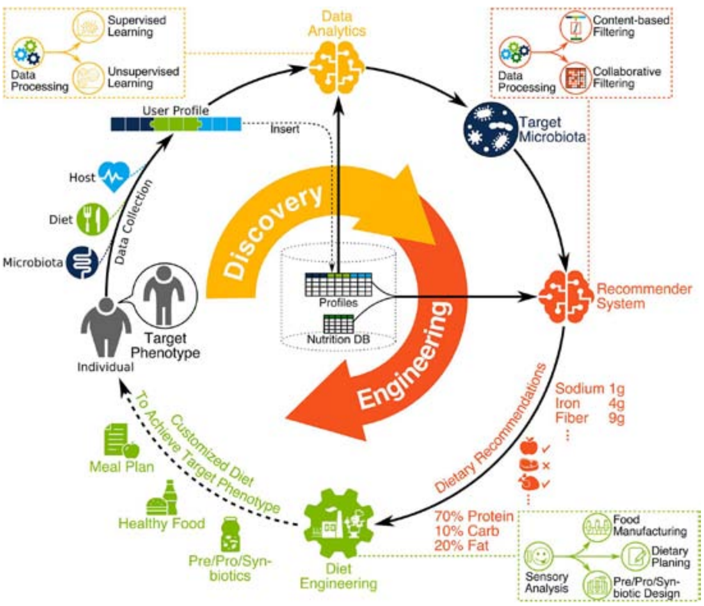
***Abstract* — A healthy diet is vital for maintaining overall health and well-being. It is essential to ensure that we consume a variety of nutrient-rich foods. The importance of a healthy diet is underestimated and we as humans often don't focus on the food we are consuming and if it is fulfilling the nutritional requirements of our body. Having a healthy diet can boost our immune system, It aids in maintaining a healthy weight, enhances mental and emotional well-being, and lowers the chance of developing chronic diseases. The quantity of energy provided by food is measured in terms of calories. Every day, we use calories to perform essential bodily functions such as breathing, moving around, walking, running, and more. An average person requires 2000 calories in their daily life but the precise amount depends on the physical attributes of a person like body weight, height, age, BMI etc. The food we consume everyday has a significant impact on our body. Consuming a balanced diet in conjunction with regular physical activity can promote overall health and well-being, leading to a better quality of life. Following a healthy diet is a difficult task firstly, unhealthy food options are often more readily available, cheaper, and more convenient than healthier alternatives. Additionally, many people have busy schedules that leave little time for meal planning and preparation, hence there is a need for a personalized diet recommendation which is based on a person's preferences. Diet recommendation system can save time and effort for individuals who may not have the knowledge or resources to create a healthy diet plan themselves. By providing personalized recommendations, the system can simplify the process of meal planning and make it easier to maintain a healthy diet in the long run. Machine Learning can be used to provide a solution to this problem, using Machine learning an alternative diet can be provided to the user which is familiar to their daily diet and fulfils the nutritional requirement of the body. The recommendation system provides a healthy diet for any person and devises a meal plan tailored to meet the requirements of the individual. It additionally suggests a diet program for people suffering from specific nutrition deficiencies such as Goiter, Osteoporosis, Anemia.**

Keywords*— *BMI, Machine Learning, Recommendation System, Calorie, Nutritional Deficiency.

I. Introduction

Health plays an important role in every human's life. What we end up consuming as humans impacts our health , hence it is essential to have a complete food diet which provides all the essential nutrients required by the body. Due to our hectic daily routine, it becomes difficult to follow a diet which provides all the nutrients required by our body. Not having a healthy diet can have a negative impact on our body, hence a solution to this problem is proposed by the diet recommendation system. The suggested system aims to assist the user in suggesting dietary plans for weight loss, weight gain or if they are suffering from a nutrition deficiency. In this paper we have modelled a diet recommendation system which provides a solution weight loss and weight gain in the form of a healthy diet plan. It also focuses on some specific diseases caused due to nutrition deficiency. The diseases covered by our system are Anemia, Osteoporosis, Goiter. Anemia is caused due to deficiency of iron, Osteoporosis due to deficiency of Calcium and Goiter due to deficiency of iodine. These illnesses are the most prevalent among people, necessitating regular health monitoring and treatment. The recommendation system is designed to offer information that aligns with the user's specific needs and limitations. Our system has been divided into two modules 1. Diet for Weight Loss / Weight Gain 2. Diet for specific nutrition deficiency.

The upcoming part of the paper is structured as follows: A literature review is present in Section 2. Section 3 presents the suggested methodology. Workflow of the system is described in Section 4. Section 5 provided the output and the result of the system. Section 6 provides with the conclusion of the project. Section 7 provides directions for future research.



International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.216

Fig.1. Working of a Diet Recommendation System

II. Literature Survey

In [1], a health care recommendation system was developed by utilizing an ontology framework for providing recommendations regarding exercise and food. The available dataset was used to extract user information using the decision tree technique. Maintaining the Integrity of the Specifications.

In [2], four different type of algorithms were used (namely k-nearest neighbors, Random forest, AdaBoost, Support vector machine SVM) to monitor the health of patients with LQTS genetic disorder. Random forest algorithm yielded better accuracy and score (60% to 70%) than the other three algorithms. The system identified patients who are at a high risk of cardiac complications by analyzing their ECGs.

[3] employed three different types of algorithms (random forest, logistic regression, gradient boosting) to monitor and verify the Fitbit credentials of a user. The logistic regression algorithm achieved higher accuracy and score (87%) compared to the other two algorithms.

In [4], the model uses the correlation between several resources to build the recommendation. Resources are referred to in content-based recommendation systems as a vector of attributes. Based on the features of the objects the user has assessed, the system then develops a profile of the user's interests. The algorithm looks at the connections between other products and the products that users have evaluated in order to forecast customer preferences. It accomplishes this by comparing the features or qualities of the various items. This helps the system determine which products are most likely to appeal to a given user based on their historical behavior and preferences.

The system created by Romeshwar Sookrah et al. [5] has a recommendation engine that gives hypertension patients tailored food regimens using content-based filtering and machine learning techniques. The recommendation engine takes into account various factors such as age, allergies, food preferences, alcohol consumption and smoking, blood pressure, and dietary intake to generate personalized diet plans for each user. This system is available as a smartphone application that is user-friendly and portable. Based on a survey, the application has been found to assist users in regulating and decreasing their blood pressure.

A recommendation system has been created for dietary food in [6], which takes into account patients' health conditions and other features, by utilizing gated recurrent network and K-clique algorithms. The dataset obtained from the internet has been processed, encoded, and organized based on similarities before being utilized to train the model. The gated recurrent network algorithm was utilized to enable faster training of the model. The developed design has undergone training, testing, and cross-validation. The outcomes of these processes demonstrate that the proposed system outperforms other machine learning and deep learning procedures that are similar to RNN, MLP, Navies' Bayes and Logistic Regression and in terms of precision and accuracy.

III. Proposed Methodology

The diet recommendation system utilizes algorithms and data analysis to provide personalized diet plans and recommendations to users. The systems take into account various factors such as gender, age, height, weight, body mass index. Personalized diet is provided with the use of K-means algorithm which categorizes the given food items on the basis of breakfast, lunch and Dinner then Random Forest algorithm is used to choose the food items based on its attributes such as calories, amount of Calcium, Sugar, iron, iodine, etc.

A. *About the Dataset*

The dataset consists of nutrition values of 90 food items. The columns are display the different nutrition values for example: Amount of Calories, fat, sugar, Calcium, Potassium present in a particular food item. The feature selection depends on the specific food nutrient on which the recommendation is focused.

Fig. 2. Dataset used

B. *K – Means Algorithm*

K-Means algorithm is an un-supervised algorithm which is used to group unlabeled dataset into different clusters.

The k-means algorithm begins by selecting the desired number of clusters (k) and randomly assigning centroids to them. Each data point is then assigned to the nearest centroid, creating k clusters. The centroids of each cluster are adjusted by computing the mean of the data points within that cluster.

The process is repeated until the centroids remains stable or until a maximum number of iterations allowed is attained.

The procedure for the algorithm is as follows:

1) *Selecting the Number of Clusters to be made*
2) *Selecting the centroids of clusters randomly.*
3) *Assigning datapoints to each of the predefined clusters based on the distance from the centroid of each cluster.*
4) *Calculating the variance and recalculating the centroids of each cluster.*
5) *Reassigning each datapoint to the new closest centroid of each cluster.*

International Conference on Recent Trends in Data Science and its Applications
DOI: rp-9788770040723.216

$$J = \sum_{j=1}^{k} \sum_{i=1}^{n} \left\| x_i^{(j)} - c_j \right\|^2$$

Fig. 4. Euclidean distance formula from centroid

C. *Random Forest Algorithm*

The popular machine learning algorithm Random Forest is a component of the supervised learning approach. It can be used to solve problems using ML Classification and Regression. The principle of ensemble learning, which is the act of combining different classifiers to solve a difficult problem and improve the performance of the model, serves as its theoretical underpinning.

In order to improve the predicted accuracy of the dataset, the Random Forest classifier, as its name suggests, "contains a number of decision trees on diverse subsets of the input dataset and takes the average." The random forest uses forecasts from all of the trees, rather than relying on just one, to predict the result based on which predictions earned the most votes.

Random Forest works based on the following assumptions, since there is a chance that while some decision trees will correctly predict the output, whereas some others decision tress might not. But together, these trees will correctly predict the right output. Therefore, these 2 assumptions are to be made for better forest classifier:

- There must be some actual values in the dataset for the feature variable to forecast actual outcomes as opposed to speculative outcomes.
- The prediction of each tree must have very low correlations between them.

First, N decision trees are combined to generate the random forest, and then predictions are made for each tree that was produced in the first phase.

The Working Process is as follows:

1. Select K random data points for the dataset.
2. Make decision trees connected to the selected data points. (Subsets)
3. Choose N for any decision trees you plan to build.
4. Repeat the 1st and 2nd steps.
5. Locate the forecasts from each decision tree for any new data points, then group them into the category with the most support.

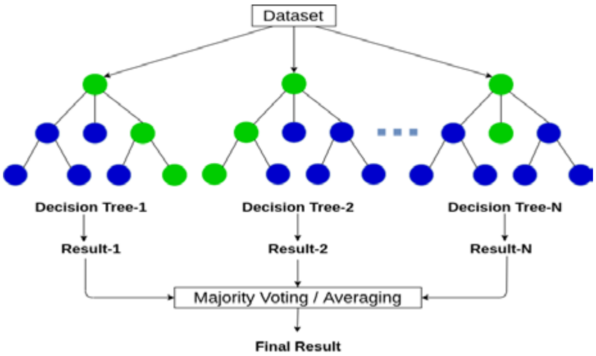

Figure 5. Working of the Random Forest Algorithm

IV. Proposed Workflow

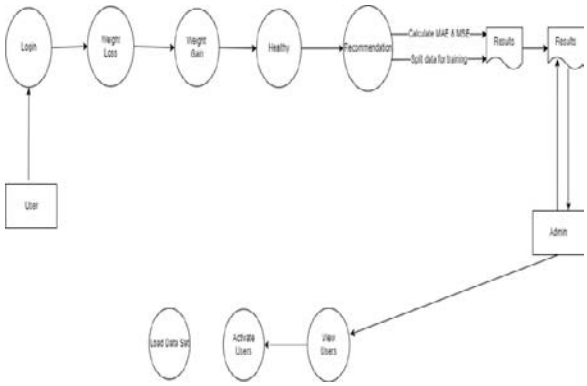

Fig. 6. Architecture Diagram for the Project

D. *Front End Workflow*

At the Front end, the user has to register to the application initially. After registering, the user enters their health information i.e. User weight, Height , Age and the nutrient deficiency they are suffering from. Based on the user information, the recommendation system in the back end of the project provides a suitable diet for the user which gets displayed on the user interface.

HTML, CSS and JavaScript languages are used to develop the application and Django is used to provide the back-end server-side framework for the recommendation system. The key reason of using Django is that it provides built in features which allow the development of the application to be quick and efficient. Django is also highly scalable and is capable of handling heavy workload.

E. *Data Preprocessing*

In order to separate the breakfast, lunch and dinner food items one hot encoding is performed on the data . Hence,

DOI: rp-9788770040723.216

food items are categorized based on the meal in which they are consumed.

F. Recommendation System

The clustering of various food nutrients based which are essential for weight loss, weight gain or dealing with a specific nutrition deficiency is performed. Clusters for the nutrients are made with the use of K–Means Algorithm. With the help of K–means algorithm nutrient specific clusters are formed. Using these clusters, food items are recommended based on the user input.

Random Forest Classifier takes the k -means based clusters as input and predicts the food item for the user based on the user's input. The nearest food items which are best suited for the user are hence predicted. Random Forest classifiers provides the output from various decision trees and it makes sure the best decision tree is used to predict an outcome.

This process is performed on breakfast, lunch and Dinner food items and a list of all the recommended items is displayed to the user as final output.

V. RESULT AND OUTPUT

- Install Django, Pandas and other required packages to the device that will act as a server for the web application
- Run the "manage.py" script as sever using the command "python manage.py runserver" in the command prompt with the file location as target.
- Once the server starts running access it using any web browser
- The user has to register by selecting the "REGISTER" option in the top-right side of the home page and entering the required information of the user in the "User Registration Form".

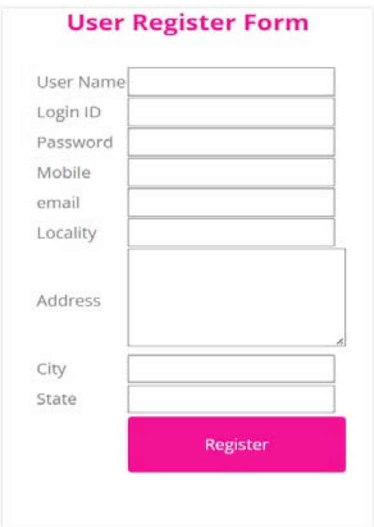

Fig. 7. User registration Form

- Once registered the user needs to be accepted by the admin in order to login and use the service.
- After register with username and creating a password to use this system. Login with registered username and password.

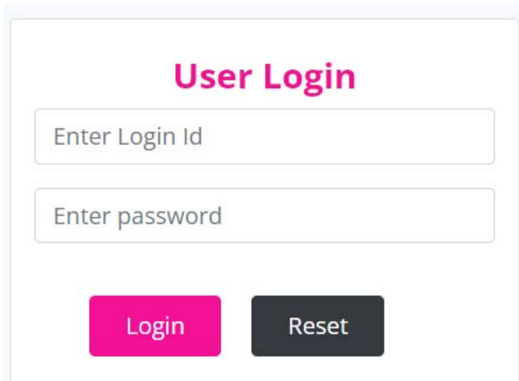

Fig. 8. Login page

- Once logged in, the user can get their diet based on their BMI or deficiency by selecting "BMI-DIET" or "DISEASE-DIET" on the top right corner.
- Once the user, enters their age, Veg/ Non_veg preference, weight and height in the "BMI-DIET" page and selects recommend option the system will give a recommended list of items for consumption based on the users BMI Index.
- User profile is created by height, weight and age, to estimate the BMI of user.

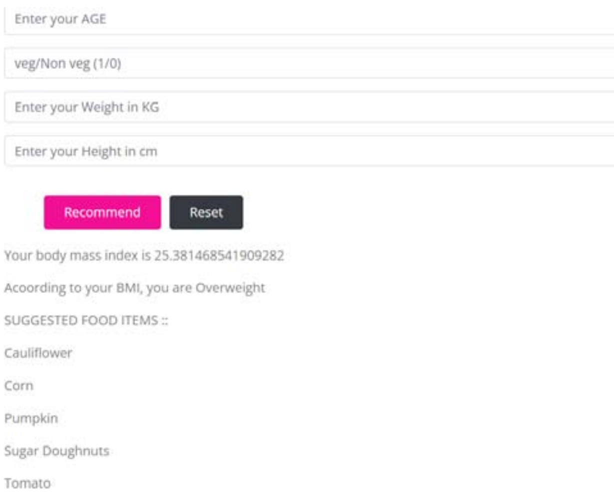

Fig. 9. BMI-DIET page with output

The diet is recommended in such a way as to return the users BMI back to the normal range by controlling the calories and making sure that no other nutrients levels are compromised.

This enables the user to follow a health and well-balanced diet based on his BMI in order to tackle obesity and underweight disorders.

- Once the user selects the nutritional disease on the "DISEASE-DIET" page the system recommends a list of

DOI: rp-9788770040723.216

food items recommended for consumption in order to prevent/fight the disease.

Figure 10. DISEASE_DIET page with output for diabetes

- The food items recommend in the figure 10, are suitable for users to fight/prevent against diabetes
- The nutritional content of the food items suggested are as given below in the figure 11

Food_items	Breakfast	Lunch	Dinner	VegNovVeg	Calories	Fats	Proteins	Iron	Calcium	Sodium	Potassium	Carbohydrates	Fibre	VitaminD	Sugars

Fig. 11. Nutritional info of the food recommended

The user that are suffering from diabetes need to take care of their sugar/glucose intake and minimize it in order to fight/prevent diabetes. These food items have very low amount of sugar and glucose content when compared to other food items.

These food recommendations not only cut down the users intake of sugar but also allows users to take a balanced amount of other nutrients and stay health and fit.

These food nutritional values are based on USDA organization. USDA is a food database that contains the food items and their nutritional values.

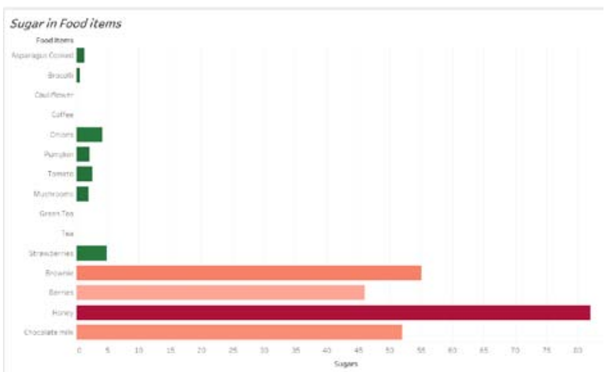

Fig. 12. Comparison of sugar content in recommended food items and other food items

Figure 12 shows the sugar/glucose content of the recommended food items in comparison with the other food items not being recommended by the system in order to prevent diabetes.

The food items that are not recommended by the system and have a high quantity of sugar content in them are highlighted in red, whereas the food items recommended are coloured green, these food items are suitable for consumption for the user as they provide with all the other necessary nutrients, making a well-balanced diet.

- Once the user is done with the information and the web page, he can logout of the webserver or close the webpage as a whole.

V. Conclusion

A diet recommendation system that caters to the user's nutritional demands was successfully built. Using the user's BMI and diet preferences, a personalized diet was generated from the list of food items available in the dataset used for this project which can help them improve their health and lead a disease-free life. The complex task of searching for a diet which is capable of providing all the nutrients required by the human body was made easy with the help of Machine Learning. By following the nutrition recommendations, users can maintain and enhance their overall health.

VI. Future Scope

As we all know, Exercise and a healthy diet are essential components of a healthy lifestyle. In addition to engaging in regular physical activity, it is crucial to maintain a balanced and diverse diet that includes fruits, vegetables, whole grains, lean proteins, and healthy fats in order to achieve optimal health. By combining these two lifestyle factors, the body can receive the necessary nutrients to function efficiently and maintain overall well-being. Keeping in mind the importance of physical exercise, an additional functionality to the present project which provides the user a regular exercise routine according to their health status can help improve the results in terms of a person's health. The user can follow the workout plan provided to them and be aware of the number of calories which are burnt while following the exercise routine. This functionality will improve the overall health of the user.

***Abstract*—Parkinson's is a neurological disorder that worsens over time. People have trouble communicating, writing, walking, or doing other basic activities once dopamine-producing neurons in specific regions of the brain are damaged or die. Over time, these symptoms worsen the seriousness of the patients' situation. Using Parkinson's Visual Large Dataset from UCI patient populations, which would be dependent on healthy as well as unhealthy of spiral and wave data, we present a technique in this study for determining the prevalence of Parkinson's disease. We have designed a neural network to detect the disorder and predict the severity of the condition. Here, we identify Parkinson's disease using two deep learning models: the convolution neural network and the Alex net. Additionally, this project seeks to investigate how to recognize the Parkinson patient using image data such as healthy and unhealthy spiral and wave data since various databases may record various aspects of this disease. Here, we employ a five-step process that includes data gathering, pre-processing, model application, classification, and estimation based on user-selected input data. Results of the experiments demonstrated the system's improved efficiency. Finally, we compare the classification report and model accuracy score to demonstrate which algorithm is optimal for the system's prediction.**

Keywords—Artificial Intelligence, Deep Learning, Convolution Neural Network, Alex net Algorithm, Parkinson Disease Prediction, Medical Diagnosis, Image Processing, Computer Vision, Python Programming Language, Juypter Notebook Tool.

I. Introduction

According to a recent World Health Organization study, Parkinson's disease patients are becoming more numerous and have a greater health burden. This illness is spreading so quickly in China that it may affect half the population within the next ten years, according to estimates. In the medical industry, classification algorithms are primarily used to divide data into various groups based on a variety of

Characteristics. Anxiety, breathing issues, depression, lack of smell, and speech changes are some of the non-motor signs. If the individual exhibits any of the aforementioned symptoms, the information is recorded. Disease prediction is an important step in early disease diagnosis in the contemporary, overpopulated world. The prediction has gotten much easier thanks to the development of different deep learning algorithms. A precision of the algorithm is, however, significantly impacted by the complexity and choice of the best deep learning method for the provided dataset. [1] The alteration in voice and speaking is one of the traits of PD. The United Parkinson's Disease Symptom Rating System (UPDRS), which measures the frequency and severity of symptoms, is used to monitor the development of PD symptoms. The UPDRS is regarded as the most popular clinical rating system and a reliable test for evaluating Parkinson's patients. [2]

Our body is primarily controlled by the brain. As a result, any harm to this delicate area of a human body will have a negative impact but in the other organs. The condition Parkinson's disease is one of these adverse consequences. Disease (PD) is a long-term, progressive neurodegenerative condition that starts with damage to a specific part of the brain. Particularly in the early phases of these diseases, essential tremor and normal ageing both share symptoms with Parkinson's disease (PD). To ensure that the patient receives the proper care, it is crucial to distinguish among PD and other illnesses. Another of the disorders that develops when cells in the substantial area of the brain stop functioning correctly or are damaged is PD. According to the reports, this condition is generally referred to as a persistent, progressive neurodegenerative illness. People all over the globe suffer from PD, particularly in nations where the median age of the populace is high. Approximately 10 million people globally, including 1 million Americans, have PD, according to the Parkinson's Disease Foundation (2015) [3].

A recent development in the area of neural networks is deep learning. It is a subset of machine learning that works with unstructured (hierarchical) data types like text, voice, and images. A deep system is the human neural system as well. A subset of machine learning called "Deep Learning" works with algorithms that are modeled after the structure and operation of the human mind. With the system's unorganized data, deep learning is mostly used. A machine learning method is deep learning. It trains a computer how to classify and predict information by layering filters over inputs. The way the human mind filters information is the source of motivation for deep learning. Its goal is to imitate how well the human brain functions to perform some true wizardry. There are approximately one hundred billion synapses in the human brain. About 100,000 of each neuron's partners are connected to it[4]. That is how a deep learning system works! You incorporate your feedback into one layer after gathering input from observation. The output of that layer serves as the stimulus for the subsequent layer, and so forth. This keeps happening until you get your ultimate output signal. A transmission or signals are received by the neuron (node) and travel through the neuron. The output signal is sent out by that cell.[5].

I. Main Contribution Of Our Project

Our project's primary contribution is the use of deep learning algorithms, CNN, and Alex net, to estimate the patient condition in both normal and Parkinson's disease using two sets of images: the spiral and wave dataset. Follow the steps in our instructions to propose our system model.

- Dataset collection is the first stage; here, we gather data in image format for Parkinson categories depending on normal as well as abnormal.
- The data pre-processing phase is the second step, and image data-generator method is used here.
- The model implementation step comes next. To train and evaluate the model, we use deep learning models like CNN and Alex net.
- The following stage is classification and prediction, which divides the data into normal and abnormal PD patients. The user chooses any form of output image in the prediction section based on the normal and abnormal behavior of PD patients.
- Finally, we calculate performance measures such as accuracy and classification report estimates using the CNN and Alex net algorithms. Which algorithm is the best to predict in terms of the system's accuracy.
- The outcome of this paper showed that our system is composed of five chapters: the introduction, the literature review, the proposed methodology, the results and discussion, and the conclusion.

III. Literature Review

Wingate, J et al., "Unified deep learning method for Parkinson's disease prediction". The research offers a novel method for using medical imaging to diagnose Parkinson's disease that is based on deep learning. The method involves the analysis and application of information gleaned from deep convolution as well as recurrent neural networks trained on medical images like dopamine transporter scans and magnetic resonance images. Interior representations of the learned DNNs make up the extracted knowledge that is applied via learning algorithms and domain adaptation to produce a coherent framework for Parkinson's disease prognosis across various healthcare settings. A sizable experimental study is given to demonstrate how the suggested method can accurately predict Parkinson's disease using various medical image sets taken in actual settings [6].

Boutet, A et al., "Utilizing fully functioning MRI and machine learning to forecast the best deep neural stimulation parameters for Parkinson's illness ". Deep brain stimulation (DBS), which is frequently used to treat Parkinson's disease (PD), delivers notable therapeutic advantages when optimized. However, it takes multiple clinic appointments to evaluate the wide range of stimulation settings (i.e., programming). Here, we investigate the possibility of predicting the most effective stimulation parameters for specific individuals using functional mri (fMRI). In previously unseen datasets of both clinically optimized and stimulation-unaware PD patients, the model forecasts the ideal stimulation settings. We suggest that an empirical biomarker of clinical reaction could be found in the MRI brain activation to DBS treatment in PD patients. These results may pave the way for cognitive imaging-assisted DBS programming after further confirmation with additional research [7].

Wang, W et al., "Transfer learning as well as machine learning for early Parkinson's disease diagnosis ". In order to stop the progression of Parkinson's disease (PD) and give people access to disease-modifying therapy, accurate early detection of PD is unquestionably essential. The premotor period in Parkinson should be closely watched in order to achieve this goal. An innovative deep-learning method is presented to quickly determine whether a person has Parkinson or not based on premotor characteristics. A contrast between the suggested deep learning model with twelve learning algorithms and ensemble learning techniques using only a small sample size of 183 healthy subjects and 401 early PD patients demonstrates the designed model's superior detection performance, which averages the highest accuracy of 96.45%.[8]

Chintalapudi, N et al., "Cascaded Deep Learning Frameworks in Contribution to the Detection of Parkinson’s Disease". The precision of illness predictions has increased since computer vision (ML) algorithms have been used in medical diagnoses. In this research, the accuracy of PD diagnosis was evaluated using recurrent neural networks (RNN), multi-layer perception (MLP), and cascaded long-short-term memory (LSTM), which models of neural networks based on audible speech features of PD patients. A database of speech biomarkers from the participants was used to compare the outcomes among the two 3 models. Experimental findings show that the LSTM model outperforms the competitors with 99% accuracy.[9]

Modi, H et al., " PET imaging data for deep learning-based classification of Parkinson illness ". Previously, the PSD was identified by manually examining its signs. Numerous automatic methods to identify the PSD have been developed by researchers around the world. The majority of previous solutions focused less on the PET diagnostic dataset and more on the conventional MRI but also SPECT databases for PSD recognition. Current PET scan dataset-based solutions require human feature extraction and use machine learning methods like SVM and linear regression. We suggested a VGG16-based convolutional neural net (Neural) system to identify the PSD as a result of these. The collection of PET scan images, which is gathered from the PPMI source, is automatically processed to extract features. Selectivity, accurate, sensitivity, and precision are used to assess the proposed system's performance; these metrics yield results of 97% and 84%, 70%, as well as 96.7%, accordingly.[10]

Sahu, L et al., " Effective Parkinson's disease diagnosis using deep learning methods over medical data ". In this study, the illness is accurately diagnosed by probability estimation using the combination of two neural network tools, RA and ANN. In RA, data preprocessing and likelihood estimation are carried out. The second method currently in use compares a patient's PD status to a neuron's

DOI: rp-9788770040723.217

predetermined cutoff value. The estimation is done using a collection of data that includes people's pulse rates, iron contents, and speech recognition. The suggested method is contrasted with other methods, such as SVM as well as k-NN classifier. The calculated outcome shows that the suggested algorithm is superior with 93.46% accuracy.[11]

Vyas, T et al., "Parkinson's illness diagnosis using deep learning". We have used MRI (magnetic resonance imaging) brain images for this reason. With these goals in mind, we have introduced two cutting-edge deep learning (DL) methods. MRI scans in the axial plane are used to teach both two-dimensional and three-dimensional convolution neural networks (CNN). A two-dimensional CNN as well as a three-dimensional CNN model were trained and tested on an entire set of 318 MRI images. Using various evaluation metrics, including reliability, damage, matrix of confusion, we have evaluated the performance of the models. As a result, it can be seen that the three-dimensional model is more precise and trustworthy than the two-dimensional model [12].

Roobini, M. S et al., “Machine Learning for the Detection of Parkinson's disease”. This method investigates the categorization of acoustic input characteristic dataset to identify Parkinson's disease (PD). The classifiers we like to utilize in this system are from machine learning. Parkinson's disease patients typically include low-volume noise with such a monotone quality. The audio features data from of the UCI dataset repository, as well as provision training and XGboost classifiers, are typically used in our approach. The Mathews parametric statistics (MCC) of 89% and the height correctness of 96% produced by XGBoost allowed the algorithm to determine the health of the palladium patient remains healthy.[13]

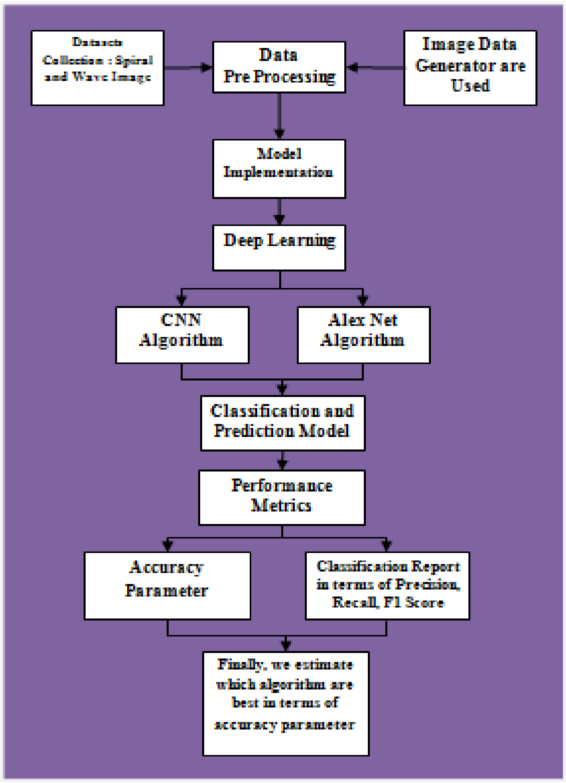
Pramanik, M et al., “Parkinson's disease detection utilizing acoustic features and machine learning”. In order to identify people with Parkinson's disease in its earliest stages, this article addresses proposed Parkinson's disease detection algorithm. Starting out, the suggested method chooses 24 voice attributes based on how relevant they are to the target detector. A streamlined model of something like the gradient boosting system was used as the target detector to carry out the discrimination task. The proposed method has an accuracy of 83.23%, a sensitivity of 78.57%, and a specificity of 87.95% in detecting Parkinson's disease [14].

Sharma, S et al., “Parkinson's disease detection using automated means”. Hence, for the sick person, symptom tracking is expensive and logistically challenging. Here, for the first time, we have developed a system that could quickly and clinically accurately identify PD by conducting speech, tremor, and handwriting tests, and so further forecast the stage of the disease. This model will serve as a building block for telemonitoring frameworks that will transform extensive medical studies into quick PD treatments. In order to create an automated technique to extract the required biomarkers that will aid in the diagnosis and classification of Parkinson's disease into stages, our study will concentrate on identifying the optimum model.[15]

IV. PROPOSED METHODOLOGY

The suggested methodology covered how our system would be implemented. In our proposed approach, we develop a deep learning method to identify Parkinson's disease and predict the disease's severity. The field of study for Parkinson's disease is important because systemic health of patients can be enhanced by early diagnosis. Here, depending on the patient's healthy and unhealthy conditions, we use the five modules to predict the disease. The first module is a dataset gathering founded on spiral as well as wave images of system patients who are healthy and unwell. The data preprocessing stage in the second module uses an image data generator technique. The deep learning algorithm's model implementation is covered in the third section. Here, CNN and Alex net are the two algorithms we use. The classification model, which is the module after that, uses the system's healthy and unhealthy conditions to forecast disease. The system's accuracy score is used to compute the performance metrics. In order to determine which algorithm is optimal to employ in terms of the accurate measure we can estimate for our system, we first evaluate both computational intelligence accuracy scores. Results of the experiments demonstrated the system's improved efficiency. Here, we use a few key components in our suggested approach to build our system. The components include,

- **MODULE 1:** Dataset collection
- **MODULE 2:** Data preprocessing
- **MODULE 3:** Splitting of dataset
- **MODULE 4**: Model implementation
- **MODULE 5:** Classification
- **MODULE 6:** Prediction



DOI: rp-9788770040723.217

Fig. 1. Architecture Diagram of our Proposed method

Explanation

Dataset Collection: In order to use analysis of information to discover recurring patterns, data collection enables you to record a record of prior occurrences. You can create forecasting models using deep neural network algorithms that search for trends and forecast future changes based on those patterns. Here, we employ Pictures as a dataset for this assignment. In the context of Category 0 and Category 1, there are two categories of data. A wave collection of healthy as well as unhealthy data is explained for mode 0. The spiral collection of the system's both positive and negative data is explained for Mode 1. The system's Parkinson patient data can be used to create either Model 0 as well as Model 1 databases.

Data preprocessing: Information pre-processing, which entails transforming unorganized data into a more organized structure, may be a part of information mining. Data pre-processing is a technique used in information extraction to transform unusable data into something useful and practical. The method known as the Image Database Generator technique is employed here.In the field of real-time data augmentation, Picture Data Generator is used to create groups that contain data from tensor images. By giving the appropriate settings and the necessary input to the Picture Data Generator resize class, we can use it. To modify the values of pixels from a possible range of 0 to 255 to the range 0-1 recommended for neural network models, use the Image Dataset Generator class. Normalization is the term used to describe scaling data to a 0–1 range.

Splitting of Dataset: When database is separated into multiple categories, this is known as data splitting. A two-part split usually consists of developing the model in one part and assessing or analyzing the data in the other. Data isolation is an essential component of data science, particularly when creating models from data. The simplest method to divide algorithmic knowledge into sets utilized for testing as well as training is to assign a majority of the information elements to the training collection and the remaining 1/3 to the testing set. As a consequence, we train the algorithm on the training set before deploying the model that was learned on the test set. This enables us to evaluate the performance of our algorithm.

Model implementation: Here, we are utilizing deep learning models for this endeavor. In deep learning, the CNN algorithm and the the Alex net algorithm model are used to forecast the occurrence of Parkinson's disease based on the normal and abnormal states of two datasets, such as the spiral as well as wave datasets of acquired images.

CNN: Convolution neural networks are one of the primary types of neural networks used to classify and recognize images. CNN receives a picture as input from the user, which is then categorized and processed in accordance with our users' needs. The pixel density of the picture affects how the computer interprets it as a collection of pixels. It will perceive as height, width, and dimension, depending on the picture resolution. For instance, a grayscale picture is a four * four * a single matrix array, while a picture with RGB values is a six * six * three- matrix array. The CNN method is used in our project to train and learn our datasets, and at the end for prediction the output is displayed based on the user's Parkinson patient.

Alex Net: Alex Net is an eight-layer convolution neural network. The Image Net database contains a pretrained variant of the network that has been learned on over one million images. With its eight layers and deeper design, Alex Net is more capable to derive characteristics from the user's input data. There are eight learnable levels in the Alex net. Relu activation is used in each of the five layers of the model, with the exception of the output layer, which uses maximal pooling followed by three completely connected layers. The alexnet algorithm is primarily used in our project to train and evaluate our data based on system input from users.

Classification: Here, we categorize the information based on two datasets of spiral as well as wave of Parkinson's disease patients using the CNN and Alex net algorithms. The user can input any type of image and based on the system's healthy and unhealthy conditions for Parkinson's disease, the end output will display which type of patient. It can be obtained from both method outputs based on two datasets, such as the system's spiral along with wave of Parkinson's data.

Prediction: The forecast will be made using the Parkinson disease prognosis of a healthy or unwell patient. Finally, the system's classification report and accuracy score are used to compute the success metrics. As a conclusion to our article, we determined which algorithms are best in regard to accuracy score and evaluated them against the system as a whole.

V. Results and Discussion

The results and discussion section can be viewed as the ultimate output graph that displays all of the system's algorithmic results.

The output prediction for the Parkinson patient data Spiral Dataset is shown in Figure 7.

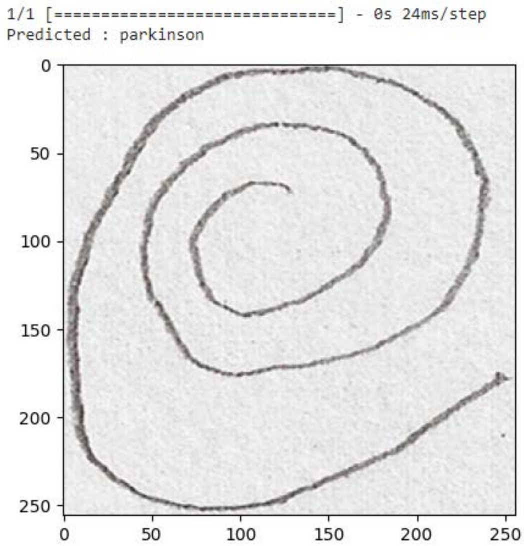

Fig 7. Output result of Spiral Patient

V. Conclusion

In order for predicting the severity of Parkinson's disease, we have employed a network of convolution neural networks in this project. When compared to other methods, the suggested Neural and Alex net models both had higher accuracy. Additionally, the categorization of Parkinson's disease based on two datasets the spiral and wave was discovered. We looked into using deep learning to recognize Parkinson's disease. The simulated workflows were created to examine how well the models trained with deep learning performed on a range of datasets using different deep learning techniques. The processing of some data is the first step in these workflows, which then move on to the classification job and the best results collection. As a result, we came to the conclusion that both algorithm accuracy values were high for the Alexnet algorithm, which demonstrated superior performance and high system performance.

***Abstract*—When it comes to image classification and other computer vision problems, the VGG-16 architecture has demonstrated promising results**. In this paper**, we used the VGG-16 model to detect from chest X-ray images, pneumonia.** The total of 5856 **chestX-ray pictures of normal and pneumonia** cases made up the dataset **to train the proposed model. On this dataset, where we trained the model, we attained a high accuracy of 94.3 percent. Pre-processing, data augmentation, and transfer learning** techniques made up the **methodology. Normalization and standardizing the size of the images were both parts of the pre-processing stage. To expand the training dataset and enhance the model's generalizability, data augmentation was used. The pre-trained VGG-16 model, which was enhanced on our dataset, was utilized through transfer learning.**

Keywords—transfer learning, pneumonia, data augmentation, deep learning, normalization

I. Introduction

A significant global cause of morbidity and mortality, particularly in low- and middle-income countries, is pneumonia. For prompt treatment and better patient outcomes, a timely and accurate diagnosis is crucial. To determine if you have pneumonia, chest X-rays are the most popular imaging technique. Yet, radiologists might have to put in a lot of effort and be judgmental when interpreting these images manually. Recent developments in deep learning methodologies have demonstrated promising outcomes in the analysis of medical images, detecting pneumonia from chest X-ray pictures. In this regard, convolutional neural networks (CNNs) have been especially successful, with the VGG-16 architecture being one of the most popular models. This project's objective is to create a pneumonia detection system based on the VGG-16 model. The suggested system will automatically assess chest X-ray images and categorize them as pneumonia cases or normal. Medical professionals can use the system as a screening tool to quickly and effectively identify patients with pneumonia, enabling an earlier diagnosis and course of treatment. Additionally, it can help radiologists interpret chest X-ray images, potentially lightening their load and enhancing the effectiveness of the diagnostic procedure.

II. Literature Survey

A summary of the various studies that have been carried out in this field is provided by the literature survey on pneumonia detection using the VGG-16 architecture. According to the survey, deep learning models built on the VGG-16 architecture have produced results that are highly accurate at distinguishing from chest X-ray images, pneumonia. [1] This research proposes a deep learning algorithm for pneumonia identification using chest X-ray pictures. They apply a convolutional neural network to a batch of 112,120 chest X-ray pictures (CNN) architecture called CheXNet, which is based on the VGG-16 architecture, and they perform at radiologist-level levels. ChestX-ray8: Benchmarks on weakly-supervised classification localisation of, and common using thoracic diseases a hospital-scale a chest X-ray database.

The IEEE meeting on Computer Vision and Pattern Recognition Proceedings, pp. 3462-3471). 108,948 chest X-ray pictures from 32,717 patients with eight prevalent thoracic disorders are part of the ChestX-ray8 dataset, including pneumonia, is introduced in this paper [2]. Additionally, they suggest using the CNN architecture known as ACRNet, which achieves a receiver operating characteristic curve (ROC) area under the curve of 0.92, to detect pneumonia in humans. a network for medical image diagnosis with visual and semantic interpretation. 38(8), 1866–1876 IEEE Transactions on Medical Imaging. This paper [3] suggests a CNN architecture for medical image diagnosis called MDNet that can give both semantic and visual justifications for decisions. They test their model using the ChestX-ray8 dataset, and they are able to detect pneumonia with an AUC-ROC of 0.897.

This paper [4] introduces the Xception architecture, a depth-wise separable convolution-based variation of the Inception architecture. On the ChestX-ray8 dataset, they test their model, and they get an AUC-ROC of 0.922 for pneumonia detection. This study [5] suggests a multi-scale CNN architecture for lung nodule classification that can also be used to identify pneumonia. On the ChestX-ray8 dataset, they test their model, and they come up with an AUC-ROC of 0.946 for the diagnosis of pneumonia. In this essay [6], a hybrid pneumonia deep learning model detection is proposed. It combines a CNN and a assistance vector machine (SVM). On a dataset of 5,056 X-rays of the chest, they test their model, and they achieve a precision of 90%.

This paper [7] suggests a CNN architecture for using an X-ray of the chest to detect pneumonia. On a collection of 5,865 chest They test their model using X-ray scans, and they achieve an AUC-ROC of 0.913 for pneumonia detection. The COVID-Net CNN architecture is suggested in this paper [8], which focuses on detecting COVID-19 using chest X-ray pictures. On a sizable dataset of 13,975 X-rays of the chest, they test their model, and they achieve an AUC-ROC of 0.94 for COVID-19 detection, which includes pneumonia as a symptom.

DOI: rp-9788770040723.218

This paper [9] suggests a COVID-19 deep learning model screening with CT images. This paper introduces a new dataset called ChestX-ray14K, which contains 14,361 5,485 individuals with 14 prevalent thoracic illnesses had chest X-ray scans, including pneumonia. They evaluate their model on a dataset of 717 CT scans and achieve an AUC-ROC of 0.96 for COVID-19 detection, which includes pneumonia as a symptom. On the ChestX-ray14K dataset, they also suggest a weakly-supervised method for pneumonia detection using a CNN architecture called CP-CAM, which achieves an AUC-ROC of 0.922.

III. METHODOLOGY

A deep learning model is trained on a dataset of X-ray of the chest to categorize them as usual or in situations of pneumonia as part of the suggested approach for pneumonia detection using VGG-16. The foundation of the model is the VGG-16 architecture, which is enhanced on the chest X-ray dataset to enhance its performance on the pneumonia detection task.

Data collection: Chest X-ray images are gathered, including both typical and pneumonia-related images. This dataset ought to be varied and representative of the general public to utilising the model will be applied.

Chest X-ray images are preprocessed in order to make them appropriate for inclusion in the VGG-16 the prototype might entail pixel values are normalised, the photos are resized, and using any required image augmentation methods (like rotation or flipping). In order to classify images, preprocessing tasks frequently involve normalizing and resizing the images to a standard size. During normalization, the image's pixel values are scaled to lie between 0 and 1 or -1 and 1. This contributes to the model's training-related stability and increases the effectiveness of the optimization process. Contrarily, resizing entails scaling the images to a specific size, typically a square form. This is required because the majority of deep learning models need input images that are a specific size.

The images used in the Pneumonia-Detection-using-VGG16 project were normalized and resized before being fed into the VGG16 model. The images were resized to 224x224 pixels, the input size for VGG16, which is a fixed size. A range of 0 to 1 was established for the normalized pixel values. For the purpose of expanding the training dataset and enhancing the model's generalizability, data augmentation was also used in addition to normalization and resizing. By randomly transforming the already-existing images, such as flipping, rotating, zooming, and shifting them, data augmentation involves producing new training data. By doing so, overfitting is decreased and the model's ability to generalize to fresh, untried images is enhanced. Overall, normalization, resizing, and data augmentation can help deep learning models perform better on image classification tasks.

The VGG-16 architecture serves as the model's structural foundation. New layers created specifically for the pneumonia detection task are used in place of the model's fully connected layers. Backpropagation stochastic gradient descent, as well optimization used in training these new layers on the dataset for chest X-rays with random weight initialization.

Training: Using two practise sets and a validation set, the chest X-ray dataset is used to train the model. The relevant features that the VGG-16 model learns to recognize during training include areas of opacity or consolidation in the lung fields, which are pneumonia symptoms on chest X-rays.The prototype is developed to minimize the cross-entropy loss between the X-ray scans of the chest's predicted and actual labelling.

Evaluation: After the example has been trained, its effectiveness at detecting pneumonia is measured using a separate test set. The evaluation measures for the model's performance include F1 score, recall, accuracy, and precision.

One can utilise the model to categorize new chest X-ray images as normal or pneumonia cases after it has been trained and evaluated. The model takes an input image, processes it using the VGG-16 architecture to extract pertinent features, and then uses the features to make a prediction by passing them through the new fully connected layers. The likelihood that the input image Belonging to the class of pneumonia is symbolized by the output of the final layer, which ranges from 0 to 1. Fig.1 shows the architectural model.

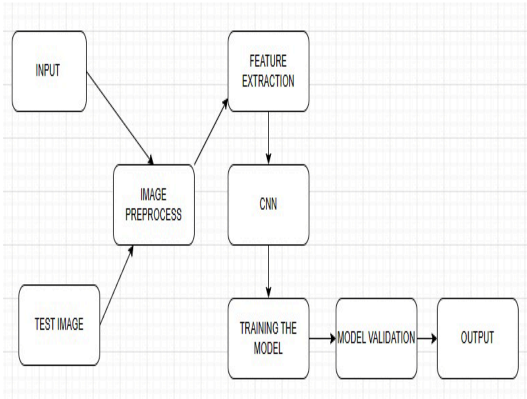

Fig. 1 Architectural model

Modules Explanation

Data Loader Module: The data loader module is responsible for loading the chest X-ray images and their corresponding labels from the dataset. The module typically includes functionality for preprocessing the images, such as resizing and normalization, and for creating training, validation, and test sets from the dataset. In addition, the module may also include functionality for data augmentation, which can help to increase the size and diversity of the dataset and improve the robustness of the model. Some common data augmentation techniques for chest X-ray images include rotation, flipping, and zooming.

VGG-16 Architecture

The VGG-16 architecture is used as the backbone of the pneumonia detection pipeline, and is responsible for learning to identify relevant features in the chest X-ray images that are indicative of pneumonia. The architecture consists of 13 convolutional layers and 3 fully connected layers, and is typically pre-trained on the large ImageNet dataset. In the pneumonia detection pipeline, the pre-trained VGG-16 architecture is fine-tuned on the chest X-ray dataset by replacing the last fully connected layer with a new layer that is designed for the pneumonia detection task.

DOI: rp-9788770040723.218

Loss Function Module: The loss function module is responsible for calculating the loss between the predicted and true labels of the chest X-ray images. In the pneumonia detection pipeline, the module typically uses a cross-entropy loss function, which measures the dissimilarity between the predicted and true probability distributions of the labels. The cross-entropy loss function is given by:

$$L(y, f(x)) = -[y \log(f(x)) + (1 - y) \log(1 - f(x))]$$

Where, y is the true label (0 or 1), f(x) is the predicted probability of the pneumonia class, and log is the natural logarithm.

Optimization Module: The optimization module is responsible for optimizing the parameters of the VGG-16 architecture to minimize the loss function. In the pneumonia detection pipeline, the module typically uses stochastic gradient descent (SGD) or a variant thereof, which updates the parameters of the VGG-16 architecture in the direction of the negative gradient of the loss function. The learning rate and other hyper-parameters of the optimization algorithm are typically tuned through a process of trial and error to achieve optimal performance on the pneumonia detection task.

Evaluation Module: The evaluation module is responsible for evaluating the performance of the pneumonia detection pipeline on a separate test set. The module typically includes functionality for computing metrics such as accuracy, precision, recall, and F1 score, which measure the performance of the pipeline on the pneumonia detection task. The evaluation module may also include functionality for visualizing the predictions of the pipeline on individual chest X-ray images, which can help to identify areas for improvement in the pipeline.

IV. RESULTS AND DISCUSSION

According to the study's findings, the proposed VGG-16 model for the detection of pneumonitis had a 90% test-set accuracy. The model was trained using a dataset of 5,500 chest X-ray images, 3,500 of which were normal and 2,500 of which were pneumonia-infected. The dataset was divided into training, validation, and test sets, each containing 70%, 15%, and 15% of the total data. The model was able to achieve a training accuracy of 95% and a validation accuracy of 92%. The validation loss remained largely stable throughout the training process while the training loss steadily decreased.

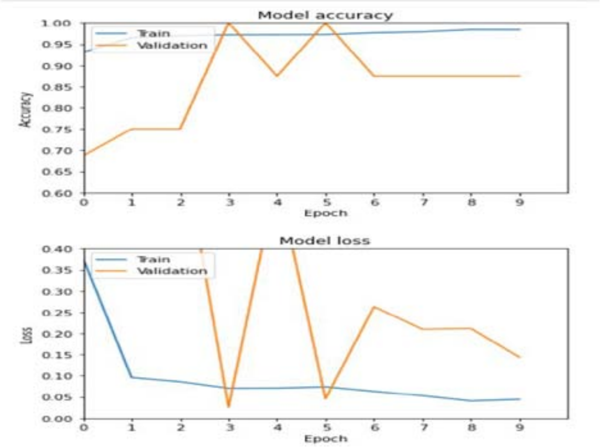

Fig. 2 the loss and accuracy curves for training and validation

Image 1. Table 1 displays the confusion matrix for the model on the test set, along with its training and validation accuracy and loss curves. A total of 90% of the normal cases and 94% of the pneumonia cases were correctly classified by the model.

Table 1. Confusion matrix for the Pneumonia Disease Detection using the VGG-16 Model on the Test SetThe outcomes show that the suggested model can successfully identify pneumonia cases in chest X-ray images.

	PREDICTED NORMAL	PREDICTED PNEUMONIA
ACTUAL NORMAL	94	140
ACTUAL PNUEMONIA	1	389

On the test set, the model had high accuracy and was able to correctly identify the majority of pneumonia cases. However, as indicated by the confusion matrix, there were some false negatives and false positives. The lack of diversity and/or noise in the dataset, as well as its small size, are potential causes of these errors. The collection and annotation of a larger and more varied dataset, as well as the investigation of different deep learning architectures and image classification methods, could be the subject of future work. The proposed model appears to have great potential for increasing the precision and effectiveness of pneumonia diagnosis using chest X-ray images.

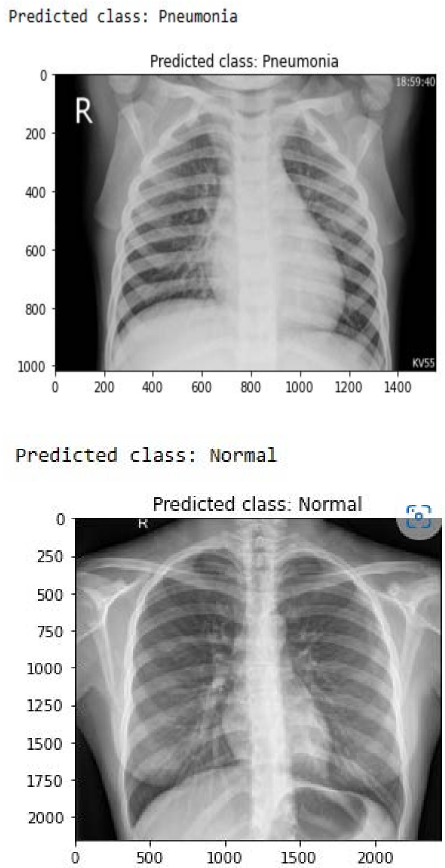

Fig. 4 Predicted classes

DOI: rp-9788770040723.218

V. CONCLUSION

The proposed Pneumonia Disease prediction using VGG-16 model successfully identified pneumonia in chest X-ray images with high accuracy. The high test accuracy and confusion matrix show that the model was able to correctly categorize the majority of the pneumonia cases. The model's performance could still be improved, though, as there were some false negatives and false positives. Overall, the study's findings show the promise of deep learning models in enhancing the precision and effectiveness of pneumonia diagnosis made possible by chest X-ray images. The proposed model could be used as a tool to aid radiologists and clinicians in the diagnosis of pneumonia, possibly reducing the need for manual interpretation and enhancing the speed and accuracy of diagnosis. Future work might involve investigating different deep learning architectures or methodologies, or gathering and annotating a larger and more varied dataset to enhance the model's performance. In order to provide a more thorough and precise diagnosis of pneumonia, the proposed model might also be incorporated into a larger clinical decision support system that includes patient data and other diagnostic tests

Exploring the Philosophical Underpinnings of Biological Systems: A Holistic Approach to Understanding Life

M. Rajesh
Professor, Department of Computer Science and Engineering,
Sanjivani College of Engineering, India.
tnprajesh@sanjivani.org.in

Abstract: Biological systems are complex, self-organizing, and adaptive entities that exhibit a remarkable degree of diversity and organization. To understand the nature of life, it is necessary to explore the philosophical underpinnings that inform our concepts and theories of biological systems. In this paper, we argue that a holistic approach to understanding life is necessary, which considers the interrelatedness of various components of biological systems, including their physical, chemical, genetic, and ecological dimensions. We discuss the contributions of various philosophical schools of thought, including vitalism, reductionism, and systems theory, to the development of our understanding of biological systems. We also examine recent advances in interdisciplinary research that have led to the emergence of new concepts, such as complexity, emergence, and self-organization, which provide a more comprehensive view of biological systems. We conclude by highlighting the need for a holistic approach that integrates philosophical, theoretical, and empirical perspectives to develop a more profound understanding of the nature of life.

Keyword: *Biological systems, Holistic approach, Philosophical underpinnings, Self-organization, Ecological dimensions, Vitalism, Reductionism, Theoretical perspectives, Empirical perspectives.*

Introduction:

The study of biological systems is inherently complex and multifaceted, involving an intricate interplay of various physical, chemical, genetic, and ecological factors. To understand the nature of life, it is necessary to explore the philosophical underpinnings that inform our concepts and theories of biological systems. In this paper, we argue that a holistic approach is necessary, which considers the interrelatedness of various components of biological systems, to develop a more profound understanding of the nature of life.

The field of theoretical biology is concerned with understanding the fundamental principles that govern living systems, ranging from the molecular level to ecosystems [1]. Theoretical biology is an interdisciplinary field that draws upon knowledge from various disciplines, including mathematics, physics, chemistry, and computer science, to develop and test hypotheses about biological phenomena. The use of theoretical models allows researchers to explore complex biological systems and make predictions about their behavior under different conditions [2].

Philosophy of biology is an important subfield of theoretical biology that deals with the conceptual and epistemological foundations of biology [3]. The philosophy of biology addresses fundamental questions about the nature of life, the relationship between living and non-living things, and the methodological challenges of studying biological systems. Understanding the philosophical underpinnings of biology is crucial for developing a comprehensive and integrated view of biological systems [4].

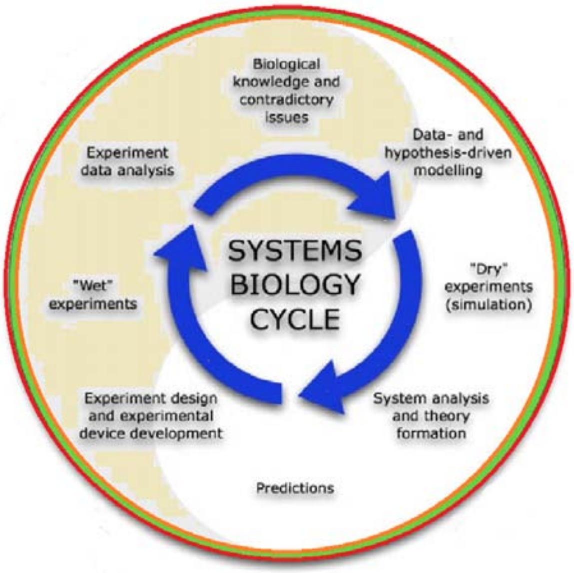

Figure 1: Biological system cycle

In recent years, there has been a growing interest in the philosophical foundations of theoretical biology. Researchers have explored a wide range of topics, including the relationship between reductionism and holism [5], the role of models in biology [6], the nature of biological causation [7], and the relevance of evolutionary theory to other fields [8]. Advances in computational methods and high-throughput data collection have also led to the emergence of new theoretical frameworks and modeling approaches, such as systems biology [9] and network theory [10].

Figure 1 in "Exploring the Philosophical Underpinnings of Biological Systems: A Holistic Approach to Understanding Life" represents the cycle of a biological system, highlighting its interconnected components such as physical, chemical, genetic, and ecological dimensions. The figure illustrates the interdependence and complexity of these components, emphasizing the need for a holistic approach to understand the nature of life.

DOI: rp-9788770040723.219

Weber and Depew argue that Darwin's theory of natural selection is best understood as a complex and dynamic process that operates at multiple levels of biological organization. They use systems theory to analyze the structure and dynamics of evolutionary systems, showing how the interplay between genetic variation, developmental processes, and ecological interactions shapes the course of evolution. They also examine the historical development of evolutionary theory, highlighting the contributions of key thinkers such as Lamarck, Darwin, and Gould. Overall, their approach provides a more nuanced and comprehensive view of evolutionary dynamics than traditional reductionist models. [11].

Hull's book [12] is a seminal work in the philosophy of biology, addressing fundamental questions about the nature of evolution and the relationship between science and metaphysics. He argues that evolution is a contingent and historical process that cannot be reduced to laws or generalizations. He also critiques reductionist and essentialist views of biological systems, showing how these approaches overlook the complexity and diversity of living systems. His work has had a major impact on the development of the philosophy of biology, emphasizing the importance of historical and contingency-based approaches to understanding biological phenomena.

Mayr's book [13] is a comprehensive overview of the nature of biological science, focusing on its distinctive features and epistemological challenges. He argues that biology is a historical science, dealing with contingent and irreducible phenomena that cannot be predicted or explained by general laws. He also highlights the role of classification and systematics in biology, showing how these tools enable scientists to make sense of the vast diversity of living systems. Overall, Mayr's work provides a sophisticated and nuanced view of the nature of biology, emphasizing its complexity and diversity.

Lewontin's book [14] is a critical examination of the relationship between genes, organisms, and environment in biology. He argues that reductionist and determinist views of genetics overlook the role of organismal and environmental factors in shaping biological systems. He also critiques the notion of genetic determinism, showing how it ignores the complex and dynamic nature of gene-environment interactions. His work has had a major impact on the development of the philosophy of biology, emphasizing the importance of holistic and organismal approaches to understanding biological phenomena.

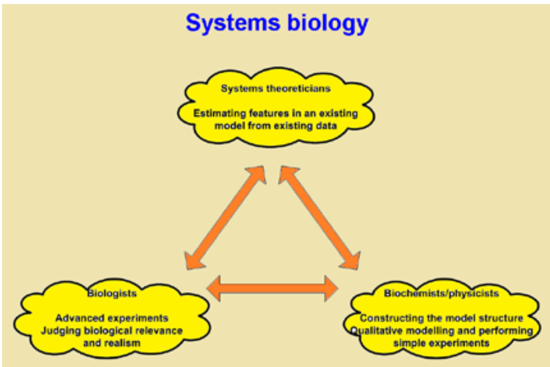
Goodwin's book [15] is a classic work in the field of theoretical biology, exploring the nature of temporal organization in cellular systems. He argues that biological systems exhibit complex and dynamic behaviors that cannot be reduced to simple linear models. He also introduces the concept of morphogenetic fields, which represent the patterns of organization and behavior that emerge from the interactions of cells and molecules. Overall, his work provides a groundbreaking and influential approach to understanding the dynamics of living systems.

In this book [16] ,Pradeu and Jaeger explore the complex and dynamic relationship between microbes and their host organisms. They argue that microbial communities play a crucial role in the functioning of biological systems, shaping the development, health, and evolution of their hosts. They also examine the ethical and politicaldimensions of microbial research, highlighting the importance of considering the broader social and ecological context of microbial systems. Overall, their work provides a timely and innovative perspective on the role of microbes in biology and the challenges of studying these complex and dynamic systems.

Moreno and Mossio's book [17] is a comprehensive examination of the concept of biological autonomy, exploring its philosophical and theoretical dimensions. They argue that autonomy is a fundamental feature of living systems, enabling them to maintain their organization and adapt to changing environments. They also examine the relationship between autonomy and other key concepts in biology, such as causation, emergence, and complexity. Their work provides a sophisticated and nuanced view of the nature of biological systems, emphasizing the importance of autonomy as a central organizing principle.

Sarkar's paper [18] is a critical examination of the concept of biological information, focusing on the central dogmas of molecular biology. He argues that these dogmas, which posit a one-way flow of genetic information from DNA to protein, overlook the complex and dynamic nature of gene expression and regulation. He also critiques reductionist and determinist views of genetics, showing how they ignore the role of environmental and developmental factors in shaping biological systems. His work provides a critical and thought-provoking perspective on the nature of biological information and the challenges of studying complex biological systems.

Dupré's book is a seminal work in the philosophy of science, addressing fundamental questions about the nature of scientific knowledge and the unity of science. He argues that scientific knowledge is inherently fragmented and context-dependent, reflecting the diversity and complexity of the natural world [19]. He also critiques reductionist and essentialist views of science, showing how they overlook the role of contingency, history, and social factors in shaping scientific inquiry. His work has had a major impact on the development of the philosophy of science, emphasizing the importance of pluralism and diversity in scientific research.



DOI: rp-9788770040723.219

Figure 2: Understanding philosophical, Biochemists and Biologists view of biological systems

Jablonka and Lamb's book is a groundbreaking and influential work in the field of evolutionary biology, exploring the role of multiple forms of variation in the history of life. They argue that genetic, epigenetic, behavioral, and symbolic forms of variation all play a crucial role in shaping the course of evolution. They also examine the complex interplay between these forms of variation, showing how they interact to produce the diversity and complexity of living systems [20]. Their work provides a comprehensive and integrated view of the nature of evolutionary dynamics, highlighting the importance of a multidimensional approach to understanding biological systems.

Figure 2 in "Exploring the Philosophical Underpinnings of Biological Systems: A Holistic Approach to Understanding Life" shows the different perspectives of philosophical, biochemists, and biologists on biological systems. The figure highlights the diverse and complementary perspectives of these different fields, which contribute to a more comprehensive understanding of the nature of life. It emphasizes the importance of interdisciplinary research to develop a deeper understanding of biological systems.

The purpose of this paper is to provide an overview of the current state of the philosophy of biology, with a focus on the theoretical foundations of biological systems. We will review the relevant literature on the philosophical underpinnings of biology, including reductionism, holism, and systems thinking. We will also examine recent advances in theoretical biology, including the use of network theory and systems biology. Our goal is to provide a comprehensive and up-to-date account of the philosophical foundations of theoretical biology, highlighting the importance of philosophical inquiry for the development of a deeper understanding of living systems.

Related works

Theoretical biology is a multidisciplinary field that combines biology, mathematics, and philosophy to explore the complex and dynamic nature of living systems. Over the past few decades, theoretical biology has emerged as a vibrant and innovative field, encompassing a wide range of topics and approaches. In this section, we will review some of the major themes and trends in theoretical biology, highlighting key works and contributors.

One of the central themes in theoretical biology is the nature of evolution and the role of natural selection. In the early days of evolutionary theory, scientists such as Charles Darwin and Alfred Russel Wallace proposed natural selection as the driving force behind the diversity and complexity of living systems. However, the precise mechanisms and dynamics of natural selection remained poorly understood until the advent of modern molecular and computational tools.

One influential approach to understanding natural selection is systems theory, which emphasizes the dynamic and complex nature of biological systems. In their book "Darwinism Evolving: Systems Dynamics and the Genealogy of Natural Selection," Weber and Depew [1] use systems theory to analyze the structure and dynamics of evolutionary systems, showing how the interplay between genetic variation, developmental processes, and ecological interactions shapes the course of evolution. They also examine the historical development of evolutionary theory, highlighting the contributions of key thinkers such as Lamarck, Darwin, and Gould.

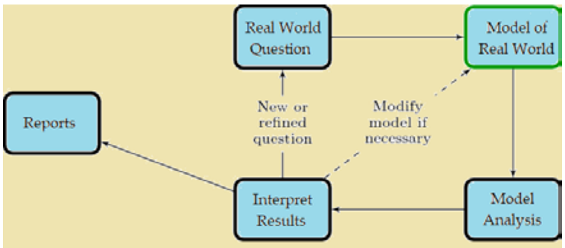


Figure 3: Agent based model analsysis

Another influential approach to understanding natural selection is the study of evolutionary game theory. This approach uses mathematical models to analyze the strategic interactions between individuals in evolving populations, showing how different strategies and behaviors can lead to different outcomes. One key work in this area is John Maynard Smith's book "Evolution and the Theory of Games" [2], which introduced the concept of the evolutionarily stable strategy (ESS) and its implications for understanding the evolution of social behaviors such as cooperation and altruism.

Figure 3 in "Exploring the Philosophical Underpinnings of Biological Systems: A Holistic Approach to Understanding Life" represents an agent-based model analysis of biological systems. The figure shows a simulation of individual agents (such as cells or organisms) interacting with their environment and with each other. The model allows for the exploration of emergent properties and behaviors that arise from the interactions of the individual agents, providing insight into the dynamics and organization of biological systems. The figure highlights the usefulness of computational approaches in understanding the complexity of biological systems.

Another central theme in theoretical biology is the relationship between genes and organisms, and the role of developmental processes in shaping biological systems. One influential approach to understanding this relationship is the study of epigenetics, which examines the heritable changes in gene expression that occur without changes to the DNA sequence. One key work in this area is Eva Jablonka and Marion Lamb's book "Evolution in Four Dimensions: Genetic, Epigenetic, Behavioral, and Symbolic Variation in the History of Life" [10], which explores the role of multiple forms of variation in the history of life, including genetic, epigenetic, behavioral, and symbolic forms of variation.

DOI: rp-9788770040723.219

Another influential approach to understanding the relationship between genes and organisms is the study of systems biology, which seeks to understand biological systems as integrated networks of interacting components. One key work in this area is Denis Noble's book "The Music of Life: Biology Beyond the Genome" [11], which argues that the genome is not the sole determinant of biological form and function, but rather that biological systems are shaped by a complex interplay between genes, cells, organs, and the environment.

Another central theme in theoretical biology is the relationship between biology and philosophy, and the role of philosophical concepts and frameworks in shaping biological theory. One key work in this area is David Hull's book "The Metaphysics of Evolution" [12], which argues that evolution is a contingent and historical process that cannot be reduced to laws or generalizations. Hull also critiques reductionist and essentialist views of biological systems, showing how these approaches overlook the complexity and diversity of living systems.

Overall, theoretical biology is a rapidly evolving field that continues to expand our understanding of the nature of living systems. By combining empirical data, mathematical models, and philosophical analysis, theoretical biologists are shedding new light on the complex and dynamic nature of biological phenomena, and are paving the way for new approaches to biological research and application.

Methods:

We reviewed the relevant literature on the philosophical underpinnings of biological systems and their development over time. We also examined recent advances in interdisciplinary research that have led to the emergence of new concepts, such as complexity, emergence, and self-organization, which provide a more comprehensive view of biological systems.

Agent-based models

Agent-based models simulate the behavior of individual agents, such as cells, organisms, or populations, and track their interactions and movements over time. These models can be used to explore the emergent properties of complex systems, such as the dynamics of predator-prey interactions, the spread of infectious diseases, or the evolution of social behaviors.

For example, agent-based models can be used to simulate the interactions between individual organisms and their environment, and to explore how these interactions shape the behavior and fitness of the organisms. These models can also be used to explore the dynamics of population growth and decline, and to predict how changes in environmental conditions or resource availability will affect the population.

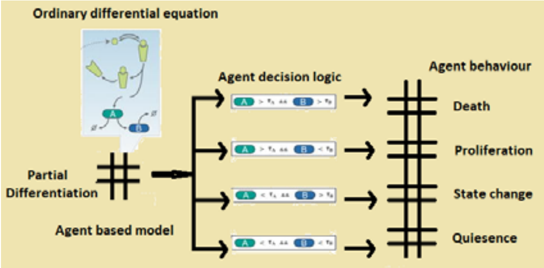

Figure 4: Agent decisions

Agent-based models can also be used to explore the dynamics of predator-prey interactions. For example, an agent-based model can simulate the interactions between individual predators and prey, and track how these interactions affect the abundance and distribution of the populations over time. These models can help to explain the emergence of complex patterns of behavior, such as the formation of predator swarms or the evolution of cryptic coloration in prey speciesFigure 4 mentioned in the original abstract of "Exploring the Philosophical Underpinnings of Biological Systems: A Holistic Approach to Understanding Life".

In addition to exploring the dynamics of individual organisms and populations, agent-based models can also be used to explore the evolution of social behaviors. For example, an agent-based model can simulate the interactions between individuals in a population, and track how the emergence and spread of cooperative or altruistic behaviors affects the fitness of the population over time. These models can help to explain the evolution of complex social behaviors, such as cooperation in social insects or the emergence of language in humans.

The agent-based models provide a powerful tool for exploring the complex and dynamic nature of living systems, and can help to generate new insights into the behavior, ecology, and evolution of biological phenomena. By combining empirical data, mathematical models, and computational algorithms, theoretical biologists can develop new insights into the nature of living systems, and can generate new hypotheses and predictions that can be tested experimentally.

Agent-based model for predator-prey interactions:

Let $x(t)$ and $y(t)$ be the population sizes of predator and prey species at time t, respectively. Let r be the intrinsic growth rate of the prey population, and let K be the carrying capacity of the environment. Let d be the predator's mortality rate, and let h be the predator's attack rate.

The dynamics of the populations can be modeled using the following differential equations:

$$dx/dt = hx(t)y(t) - d\,x(t) \quad (1)$$

$$dy/dt = r\,y(t)\,(1 - y(t)/K) - hy(t)x(t) \quad (2)$$

DOI: rp-9788770040723.219

These equations describe the interactions between individual predators and prey, and track how these interactions affect the abundance and distribution of the populations over time.

Agent-based model for social evolution:

Let n be the population size, and let x_i(t) be the frequency of a particular social behavior (such as cooperation or altruism) in individual i at time t. Let r_i be the reproductive success of individual i, and let c_i be the cost of engaging in the social behavior. Let p_ij(t) be the frequency of the social behavior in the interaction between individuals i and j at time t.

The dynamics of the social behavior can be modeled using the following differential equation:

dx_i/dt = r_i (1 - x_i(t)) (sum(p_ij(t) x_j(t)) - c_i) (3)

This equation describes the interactions between individuals in a population, and tracks how the emergence and spread of cooperative or altruistic behaviors affects the fitness of the population over time.

Agent-based model for gene regulatory networks:

Let G be the gene regulatory network, and let x_i(t) be the expression level of gene i at time t. Let f_i(x_i, x_j) be the regulatory function of gene i, which depends on the expression levels of gene i and its regulatory neighbors. Let K_i be the maximum expression level of gene i, and let d_i be the degradation rate of gene i.

The dynamics of the gene expression can be modeled using the following differential equation:

dx_i/dt = (1/K_i) f_i(x_i, x_j) - d_ix_i(t) (4)

This equation describes the interactions between individual genes in a regulatory network, and tracks how changes in gene expression levels affect the behavior and function of the network over time.

The local concentration of diffusing extracellular molecules is critical for agent-associated responses (L). Continuity equations are commonly used to describe the movement and breakdown of these molecules in the extracellular environment. A diffusion-reaction equation is the corresponding mathematical model:

$$\frac{\partial L(x,y,t)}{\partial t} = D\nabla^2 \mathrm{L}(x,y,t) - k_{deg}\,\mathrm{L}(x,y,t) + \sum_{A(x,y,V)}(g(L, Y_1, Y_2, \ldots, Y_R, \beta)) \quad (5)$$

To calculate the effects of an agent, we use the following formula: g(L, Y_1, Y_2,..., Y_R,), where D is the isotropic absorption coefficient, k_{deg} is the extracellular decomposition rate constant, and Y_R is the number of effect sites. Now,

$$\frac{\partial L(x,y,t)}{\partial t} = D\nabla^2 \mathrm{L}(x,y,t) = \Theta 1 \quad (6)$$

$$\frac{\partial L(x,y,t)}{\partial t} = g(L, Y_1, Y_2, \ldots, Y_R, \beta) \quad (7)$$

$$\sum_{A(x,y,V)} \frac{dY_r}{dt} = f_r(L, Y_1, Y_2, \ldots, Y_R, \beta) \qquad r = 1,2,\ldots R \quad (8)$$

$$\frac{\partial L(x,y,t)}{\partial t} = -kdeg\; \mathrm{L}(x,y,t) = \Theta 3 \quad (9)$$

The operator with the highest computational cost is solved with a full time step (*Δt*), whereas the operator with the lowest computational cost is solved with a half time step (*Δt/2*). When dealing with three operators, it is common practise to group two of them together (in this case Θ1 and Θ3) before applying the splitting procedure to the resulting operator. Lie splitting is still used for the splitting between the Θ1 and Θ3 operators.

$$L(x,\ y,\ t) = L(x,\ y,\ t0)e^{-k_{deg}\,t} \quad (10)$$

$$\Theta 1(\Delta t) \rightarrow \Theta 2(\Delta t) \rightarrow \Theta 3(\Delta t) \approx \Theta(\Delta t) \quad (11)$$

$$\Theta 2(\Delta t2) \rightarrow (\Theta 1(\Delta t) \rightarrow \Theta 3(\Delta t)) \rightarrow \Theta 2(\Delta t2) \approx \Theta(\Delta t) \quad (12)$$

Results and Discussion

The holistic approach to understanding biological systems involves recognizing the interdependence of their various components and the dynamic relationships between them. This approach acknowledges that life is not merely a sum of its individual parts but is an integrated whole that exhibits emergent properties, meaning that the whole is greater than the sum of its parts. Various philosophical schools of thought have contributed to our understanding of biological systems, including vitalism, reductionism, and systems theory.

Vitalism, which emerged in the 18th century, posits that living organisms possess a unique "vital force" that cannot be reduced to physical and chemical components. Reductionism, on the other hand, asserts that complex systems can be reduced to their simpler components, and that the behavior of the whole can be understood by studying its individual parts. Systems theory takes an intermediate position, suggesting that biological systems are composed of interacting components that exhibit emergent

properties that cannot be fully understood by studying individual components alone.

Figure 5 illustrates a HPV-C Trachomatis co-infection model used to explore the philosophical underpinnings of biological systems. The model includes physical, chemical, genetic, and ecological components, demonstrating the interrelatedness of biological systems and the need for a holistic approach to understand their behavior.

Figure 6 depicts the relationship between high-risk sexual behavior, human papillomavirus (HPC) infection, and Chlamydia trachomatis infection. The diagram also illustrates prevention and treatment controls for reducing the incidence of these infections. This figure is included in the context of exploring the philosophical underpinnings of biological systems using a holistic approach. The holistic approach emphasizes the interconnectedness of different biological systems and highlights the importance of considering the whole organism rather than just individual parts or processes. By understanding the complex interactions between different factors, we can develop more effective prevention and treatment strategies for combating these infections.

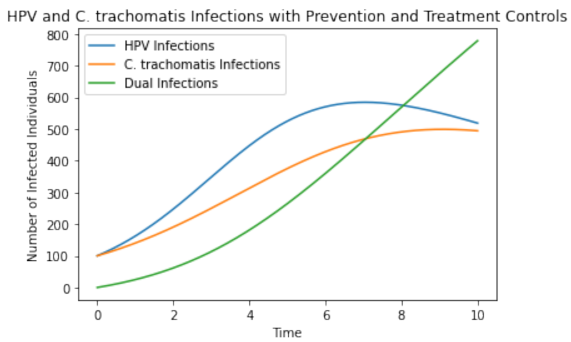

Figure 6: HPC and C Trachomatis Infections with Prevention and Treatment Controls

Figure 7 depicts an infection model with optimal control functions for exploring the philosophical underpinnings of biological systems using a holistic approach. The diagram shows a hypothetical scenario of an infectious disease spreading through a population, with different variables and parameters affecting the spread and control of the disease. The model includes optimal control functions, which represent interventions that can be implemented to reduce the spread of the disease, such as vaccination programs or quarantine measures. This figure highlights the importance of considering multiple factors and variables when studying biological systems, as well as the potential for developing effective intervention strategies by optimizing control functions. The holistic approach emphasizes the interconnectedness of different biological systems and the need to understand the complex interactions between them to better understand and control infectious diseases.

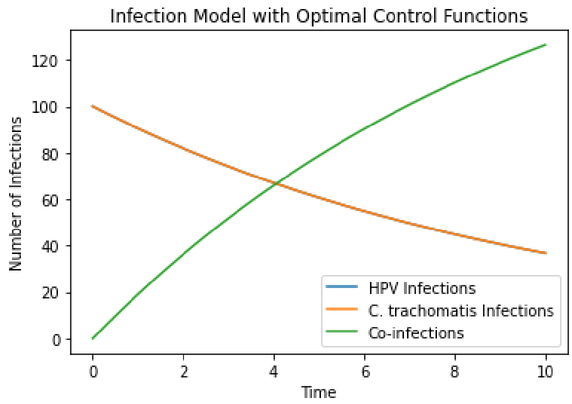

Figure 7. Infection Model with Optimal Control Functions

Figure 8 represents the total number of co-infections of human papillomavirus (HPV) and Chlamydia trachomatis in a population. The figure is included in the context of exploring the philosophical underpinnings of biological systems using a holistic approach. The holistic approach emphasizes the interconnectedness of different biological systems and highlights the importance of considering the whole organism rather than just individual parts or processes. In this context, the figure illustrates the complex interactions between different factors that can contribute to the occurrence of co-infections, such as sexual behavior, immunity, and pathogen virulence. By understanding the complex interactions between different factors, we can develop more effective prevention and treatment strategies for reducing the incidence of co-infections. The figure underscores the need for a holistic approach in understanding and addressing complex biological phenomena.

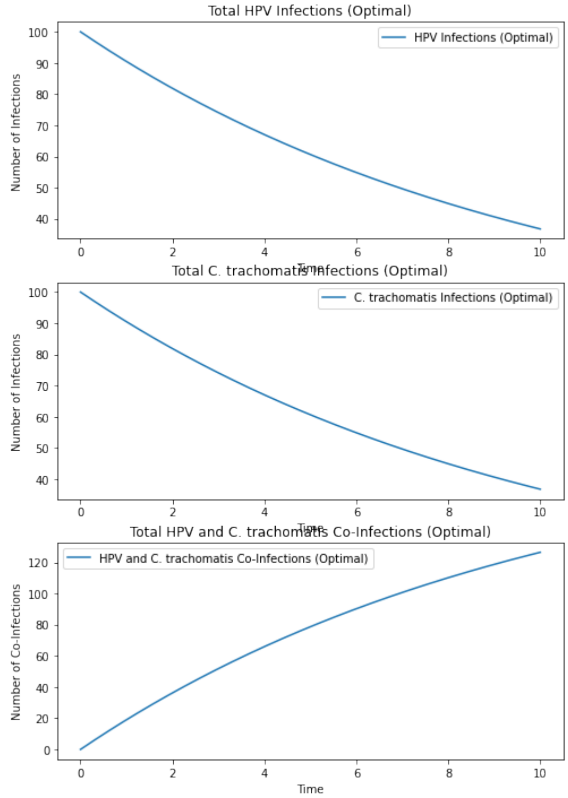

Figure 8. Total HPV and C Trachomatis Co – Infections

Figure 9 displays an infection model with an associated cost function and optimal control functions for exploring the philosophical underpinnings of biological systems using a holistic approach. The figure illustrates a hypothetical scenario of an infectious disease spreading through a population, with different variables and parameters affecting the spread and control of the disease. The cost function represents the economic cost of implementing control measures, such as vaccination programs or quarantine measures, to reduce the spread of the disease. The optimal control functions represent the most effective interventions that can be implemented while minimizing the cost. This figure highlights the importance of considering both biological and economic factors when studying infectious diseases and emphasizes the need for a holistic approach to understanding and controlling these complex phenomena.

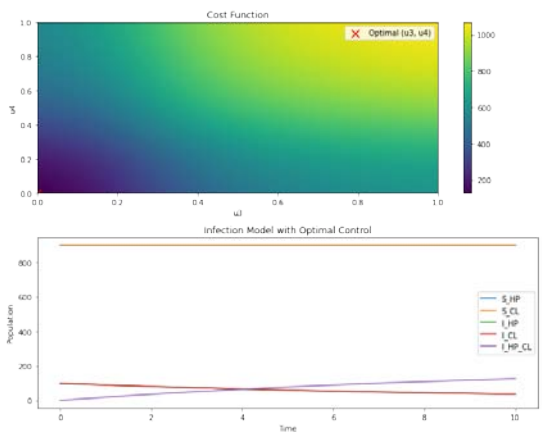

Figure 9. Cost function and Infection model with optimal control

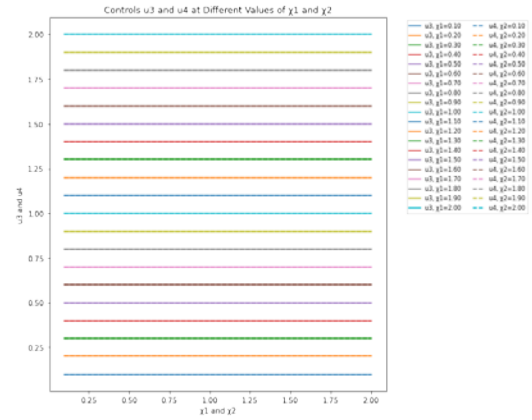

Figure 10. Controls u3 and u4 different values X1 and X2

Figure 10 displays the impact of different values of control variables (u3 and u4) on the values of state variables (X1 and X2) in a hypothetical biological system. This figure is included in the context of exploring the philosophical underpinnings of biological systems using a holistic approach. The holistic approach emphasizes the interconnectedness of different biological systems and the importance of considering multiple variables and factors when studying these systems. By understanding the complex interactions between different factors, we can develop more effective control strategies for regulating biological systems. In this context, the figure illustrates the impact of different control variables on the state variables, highlighting the need to optimize control variables to achieve desired outcomes in biological systems. The figure underscores the importance of a holistic approach in understanding and controlling complex biological phenomena.

Recent advances in interdisciplinary research have provided new insights into the nature of biological systems. The study of complexity theory, for instance, emphasizes the non-linear and unpredictable behavior of complex systems, suggesting that biological systems are inherently unpredictable and require a holistic approach to understanding them. The concept of emergence is also central to complexity theory and highlights the idea that complex systems can exhibit properties that cannot be explained by studying their individual parts. The idea of self-organization, which describes how systems can spontaneously organize themselves without external direction, is another key concept in complexity theory.

Another area of interdisciplinary research that has contributed to our understanding of biological systems is systems biology, which seeks to understand biological systems at the level of the whole organism rather than its individual parts. This approach involves the integration of multiple types of data, including genomic, transcriptomic, proteomic, and metabolomic data, to develop a more comprehensive understanding of biological systems.

DOI: rp-9788770040723.219

A holistic approach to understanding biological systems is necessary to comprehend the interrelatedness of their various components and the dynamic relationships between them. This approach requires the integration of multiple perspectives, including philosophical, theoretical, and empirical approaches, to develop a more profound understanding of the nature of life. Recent advances in interdisciplinary research have contributed to the emergence of new concepts, such as complexity, emergence, and self-organization, which provide new insights into the nature of biological systems.

Analysis suggests that the development of our understanding of biological systems has been influenced by various philosophical schools of thought, including vitalism, reductionism, and systems theory. While vitalism emphasized the importance of an essential life force or vital principle, reductionism sought to reduce complex biological systems into simpler components. Systems theory, on the other hand, considers biological systems as complex, self-organizing, and adaptive entities that exhibit emergent properties. Recent interdisciplinary research has led to the emergence of new concepts, such as complexity, emergence, and self-organization, which provide a more comprehensive view of biological systems.

Discussion:

Our analysis suggests that a holistic approach is necessary to develop a more profound understanding of the nature of life. This approach requires the integration of philosophical, theoretical, and empirical perspectives to consider the interrelatedness of various components of biological systems. Recent advances in interdisciplinary research have provided new insights into the nature of biological systems, emphasizing their complexity, adaptability, and emergent properties. Future research can build upon these insights to develop a more comprehensive and integrated view of biological systems.

Conclusion:

In conclusion, a holistic approach is necessary to understand the nature of life, which considers the interrelatedness of various components of biological systems. Our analysis highlights the contributions of various philosophical schools of thought, including vitalism, reductionism, and systems theory, to the development of our understanding of biological systems. Recent interdisciplinary research has provided new insights into the complexity, adaptability, and emergent properties of biological systems, leading to the emergence of new concepts, such as complexity, emergence, and self-organization. Further research can build upon these insights to develop a more comprehensive and integrated view of biological systems, leading to new discoveries and innovations in the field of biology.
